
Kinetis K27F MCU Sub-Family Reference Manual

Supports: MK27FN2M0VMI15, MK27FN2M0AVMI15

Document Number: K27P169M150SF5RM
Rev. 2, 08/2017

Contents

Section number	Title	Page
Chapter 1		
About This Manual		
1.1	Audience.....	23
1.2	Organization.....	23
1.3	Module descriptions.....	23
1.4	Register descriptions.....	26
1.5	Conventions.....	27
Chapter 2		
Introduction		
2.1	Overview.....	29
2.2	Block Diagram.....	29
2.3	Module Functional Categories.....	30
2.4	Orderable part numbers.....	39
Chapter 3		
Core Overview		
3.1	Introduction.....	41
3.2	Interrupt priority levels.....	43
3.3	Non-maskable interrupt.....	43
3.4	Interrupt channel assignments.....	44
3.5	AWIC overview.....	48
3.6	Wake-up sources.....	48
Chapter 4		
Memories and Memory Interfaces		
4.1	Flash memory types.....	49
4.2	Flash Memory Sizes.....	49
4.3	Flash Security.....	49
4.4	Flash Modes.....	49
4.5	Erase All Flash Contents.....	50

Section number	Title	Page
4.6	FTFE_FOPT Register.....	50
4.7	SRAM sizes.....	50
4.8	SRAM accesses.....	51
4.9	SRAM retention in low power modes.....	52
4.10	QuadSPI memory interface.....	52
4.11	System Register file.....	52
4.12	VBAT register file.....	53

Chapter 5 Memory Map

5.1	Introduction.....	55
5.2	System memory map.....	55
5.3	Flash Memory Map.....	57
5.4	Flash Access Control Introduction.....	58
5.5	SRAM memory map.....	59
5.6	Peripheral bridge (AIPS-Lite0 and AIPS-Lite1) memory maps.....	59
5.7	Private Peripheral Bus (PPB) memory map.....	67

Chapter 6 Clock Distribution using MCG

6.1	Introduction.....	69
6.2	Programming model.....	69
6.3	High-Level device clocking diagram.....	70
6.4	Clock definitions.....	71
6.5	Internal clocking requirements.....	74
6.6	Clock Gating.....	76
6.7	Module clocks.....	76

Chapter 7 Reset and Boot

7.1	Introduction.....	87
7.2	Reset.....	87
7.3	Boot.....	95

Section number	Title	Page
Chapter 8		
Power Management		
8.1	Introduction.....	99
8.2	Clocking modes.....	99
8.3	Power Modes Description.....	103
8.4	Entering and exiting power modes.....	105
8.5	Power mode transitions.....	106
8.6	Power modes shutdown sequencing.....	107
8.7	Flash Program Restrictions.....	108
8.8	Module Operation in Low Power Modes.....	108
Chapter 9		
Flash Security Measures and Module Interactions		
9.1	Introduction.....	113
9.2	Flash Security.....	113
9.3	Security Interactions with other Modules.....	114
Chapter 10		
Debug		
10.1	Introduction.....	115
10.2	Cortex-M4 Debug Topology with CAU.....	116
10.3	Debug Components.....	116
10.4	The Debug Port.....	117
10.5	Debug Port Pin Descriptions.....	119
10.6	System TAP connection.....	119
10.7	JTAG status and control registers.....	120
10.8	Debug Resets.....	124
10.9	AHB-AP.....	125
10.10	ITM.....	125
10.11	Core Trace Connectivity with ETM.....	126
10.12	Embedded Trace Macrocell v3.5 (ETM).....	127
10.13	TPIU.....	127

Section number	Title	Page
10.14	DWT.....	127
10.15	Debug in Low Power Modes.....	128
10.16	Debug and Security.....	129

Chapter 11 Signal Multiplexing and Signal Descriptions

11.1	Signal Multiplexing Introduction.....	131
11.2	Signal Multiplexing Integration.....	131
11.3	Pinout.....	133
11.4	Module Signal Description Tables.....	134

Chapter 12 Port Control and Interrupts (PORT)

12.1	Introduction.....	151
12.2	Overview.....	151
12.3	External signal description.....	153
12.4	Detailed signal description.....	153
12.5	Memory map and register definition.....	153
12.6	Functional description.....	166

Chapter 13 System Integration Module (SIM)

13.1	Introduction.....	171
13.2	Memory map and register definition.....	172
13.3	Functional description.....	217

Chapter 14 Kinetis ROM Bootloader

14.1	Chip-Specific Kinetis ROM Bootloader information.....	219
14.2	Introduction.....	221
14.3	Functional Description.....	223
14.4	Peripherals Supported.....	268
14.5	Get/SetProperty Command Properties.....	288
14.6	Verifying the application in flash using CRC-32.....	292

Section number	Title	Page
14.7	Kinetis Bootloader Status Error Codes.....	293
Chapter 15 Reset Control Module (RCM)		
15.1	Introduction.....	297
15.2	Reset memory map and register descriptions.....	297
Chapter 16 System Mode Controller (SMC)		
16.1	Introduction.....	309
16.2	Modes of operation.....	309
16.3	Memory map and register descriptions.....	311
16.4	Functional description.....	317
Chapter 17 Power Management Controller (PMC)		
17.1	Chip-specific PMC information.....	331
17.2	Introduction.....	331
17.3	Features.....	331
17.4	Low-voltage detect (LVD) system.....	332
17.5	High-voltage detect (HVD) system.....	333
17.6	I/O retention.....	334
17.7	Memory map and register descriptions.....	335
Chapter 18 Low-Leakage Wakeup Unit (LLWU)		
18.1	Chip-specific LLWU information.....	343
18.2	Introduction.....	344
18.3	LLWU signal descriptions.....	347
18.4	Memory map/register definition.....	348
18.5	Functional description.....	372
Chapter 19 Miscellaneous Control Module (MCM)		
19.1	Introduction.....	375

Section number	Title	Page
19.2	Memory map/register descriptions.....	375
19.3	Functional description.....	388
Chapter 20		
Crossbar Switch (AXBS)		
20.1	Chip-specific AXBS information.....	389
20.2	Introduction.....	390
20.3	Memory Map / Register Definition.....	391
20.4	Functional Description.....	397
20.5	Initialization/application information.....	401
Chapter 21		
Peripheral Bridge (AIPS-Lite)		
21.1	Chip-specific AIPS-Lite information.....	403
21.2	Introduction.....	404
21.3	Memory map/register definition.....	405
21.4	Functional description.....	419
Chapter 22		
Memory Protection Unit (MPU)		
22.1	Chip-specific MPU information.....	421
22.2	Introduction.....	423
22.3	Overview.....	423
22.4	Memory map/register definition.....	425
22.5	Functional description.....	438
22.6	Initialization information.....	441
22.7	Application information.....	441
Chapter 23		
Bit Manipulation Engine2 (BME2)		
23.1	Introduction.....	445
23.2	Memory map and register definition.....	446
23.3	Functional description.....	447
23.4	Application information.....	460

Section number	Title	Page
Chapter 24		
Direct Memory Access Multiplexer (DMAMUX)		
24.1	Chip-specific DMAMUX information.....	463
24.2	Introduction.....	467
24.3	External signal description.....	469
24.4	Memory map/register definition.....	469
24.5	Functional description.....	471
24.6	Initialization/application information.....	475
Chapter 25		
Enhanced Direct Memory Access (eDMA)		
25.1	Introduction.....	479
25.2	Modes of operation.....	482
25.3	Memory map/register definition.....	483
25.4	Functional description.....	558
25.5	Initialization/application information.....	568
Chapter 26		
External Watchdog Monitor (EWM)		
26.1	Chip-specific EWM information.....	585
26.2	Introduction.....	586
26.3	EWM Signal Descriptions.....	588
26.4	Memory Map/Register Definition.....	589
26.5	Functional Description.....	593
Chapter 27		
Watchdog Timer (WDOG)		
27.1	Chip-specific WDOG information.....	597
27.2	Introduction.....	598
27.3	Features.....	598
27.4	Functional overview.....	599
27.5	Testing the watchdog.....	604
27.6	Backup reset generator.....	607

Section number	Title	Page
27.7	Generated resets and interrupts.....	607
27.8	Memory map and register definition.....	608
27.9	Watchdog operation with 8-bit access.....	615
27.10	Restrictions on watchdog operation.....	616

Chapter 28 Multipurpose Clock Generator (MCG)

28.1	Chip-specific MCG information.....	619
28.2	Introduction.....	620
28.3	External Signal Description.....	624
28.4	Memory Map/Register Definition.....	624
28.5	Functional description.....	640
28.6	Initialization / Application information.....	647

Chapter 29 Oscillator (OSC)

29.1	Chip-specific OSC information.....	659
29.2	Introduction.....	659
29.3	Features and Modes.....	659
29.4	Block Diagram.....	660
29.5	OSC Signal Descriptions.....	661
29.6	External Crystal / Resonator Connections.....	661
29.7	External Clock Connections.....	662
29.8	Memory Map/Register Definitions.....	663
29.9	Functional Description.....	665
29.10	Reset.....	669
29.11	Low power modes operation.....	670
29.12	Interrupts.....	670

Chapter 30 RTC Oscillator (OSC32K)

30.1	Introduction.....	671
30.2	RTC Signal Descriptions.....	672

Section number	Title	Page
30.3	External Crystal Connections.....	673
30.4	Memory Map/Register Descriptions.....	673
30.5	Functional Description.....	673
30.6	Reset Overview.....	674
30.7	Interrupts.....	674

Chapter 31 Local Memory Controller

31.1	Chip-specific LMEM information.....	675
31.2	Introduction.....	676
31.3	Memory Map/Register Definition.....	679
31.4	Functional Description.....	697

Chapter 32 Flash Memory Controller (FMC)

32.1	Chip-specific FMC information.....	707
32.2	Introduction.....	707
32.3	Modes of operation.....	709
32.4	External signal descriptions.....	709
32.5	Memory map and register descriptions.....	709
32.6	Functional description.....	735
32.7	Initialization and application information.....	736

Chapter 33 Flash Memory Module (FTFE)

33.1	Introduction.....	737
33.2	External signal description.....	740
33.3	Memory map and registers.....	741
33.4	Functional Description.....	756
33.5	Reset Sequence.....	797

Chapter 34 Synchronous DRAM Controller Module (SDRAM)

34.1	Chip-specific SDRAM information.....	799

Section number	Title	Page
34.2	Introduction.....	800
34.3	Overview.....	800
34.4	SDRAM Controller Operation.....	802
34.5	General Synchronous Operation Guidelines.....	810
34.6	Initialization Sequence.....	817
34.7	SDRAM Example.....	819

Chapter 35 Quad Serial Peripheral Interface (QuadSPI)

35.1	Chip-specific QuadSPI information.....	825
35.2	Introduction.....	831
35.3	External Signal Description.....	836
35.4	Memory Map and Register Definition.....	839
35.5	Flash memory mapped AMBA bus.....	888
35.6	Interrupt Signals.....	894
35.7	Functional Description.....	895
35.8	Initialization/Application Information.....	918
35.9	Byte Ordering - Endianness.....	929
35.10	Driving Flash Control Signals in Single and Dual Mode.....	932
35.11	Serial Flash Devices.....	933
35.12	Sampling of Serial Flash Input Data.....	941
35.13	Data Input Hold Requirement of Flash.....	954

Chapter 36 External Bus Interface (FlexBus)

36.1	Chip-specific Flexbus information.....	957
36.2	Introduction.....	959
36.3	Signal descriptions.....	960
36.4	Memory Map/Register Definition.....	962
36.5	Functional description.....	969
36.6	Initialization/Application Information.....	1005

Section number	Title	Page
Chapter 37		
Cyclic Redundancy Check (CRC)		
37.1	Introduction.....	1007
37.2	Memory map and register descriptions.....	1008
37.3	Functional description.....	1011
Chapter 38		
Memory-Mapped Cryptographic Acceleration Unit (MMCAU)		
38.1	Overview.....	1017
38.2	Features.....	1017
38.3	Register definition.....	1018
38.4	Functional description.....	1021
38.5	Application/initialization information.....	1029
Chapter 39		
True Random Number Generator		
39.1	Standalone True Random Number Generator (SA-TRNG).....	1031
Chapter 40		
Analog-to-Digital Converter (ADC)		
40.1	Chip-specific ADC information.....	1085
40.2	Introduction.....	1089
40.3	ADC signal descriptions.....	1092
40.4	Memory map and register definitions.....	1094
40.5	Functional description.....	1116
40.6	Initialization information.....	1134
40.7	Application information.....	1136
Chapter 41		
Comparator (CMP)		
41.1	Chip-specific Comparator information.....	1143
41.2	Introduction.....	1144
41.3	Memory map/register definitions.....	1149
41.4	Functional description.....	1155

Section number	Title	Page
41.5	CMP interrupts.....	1168
41.6	DMA support.....	1168
41.7	CMP Asynchronous DMA support.....	1169
41.8	Digital-to-analog converter.....	1170
41.9	DAC functional description.....	1170
41.10	DAC resets.....	1171
41.11	DAC clocks.....	1171
41.12	DAC interrupts.....	1171

Chapter 42 Voltage Reference (VREFV1)

42.1	Chip-specific VREF information.....	1173
42.2	Introduction.....	1173
42.3	Memory Map and Register Definition.....	1176
42.4	Functional Description.....	1178
42.5	Initialization/Application Information.....	1181

Chapter 43 12-bit Digital-to-Analog Converter (DAC)

43.1	Chip-specific DAC information.....	1183
43.2	Introduction.....	1184
43.3	Features.....	1184
43.4	Block diagram.....	1184
43.5	Memory map/register definition.....	1185
43.6	Functional description.....	1191

Chapter 44 FlexTimer Module (FTM)

44.1	Chip-specific FTM information.....	1195
44.2	Introduction.....	1201
44.3	FTM signal descriptions.....	1206
44.4	Memory map and register definition.....	1206
44.5	Functional description.....	1256

Section number	Title	Page
44.6	Reset overview.....	1334
44.7	FTM Interrupts.....	1335
44.8	Initialization Procedure.....	1336

Chapter 45 Timer/PWM Module (TPM)

45.1	Chip-specific TPM information.....	1339
45.2	Introduction.....	1341
45.3	TPM Signal Descriptions.....	1343
45.4	Memory Map and Register Definition.....	1344
45.5	Functional description.....	1359

Chapter 46 Low-Power Timer (LPTMR)

46.1	Chip-specific LPTMR information.....	1383
46.2	Introduction.....	1384
46.3	LPTMR signal descriptions.....	1385
46.4	Memory map and register definition.....	1386
46.5	Functional description.....	1390

Chapter 47 Carrier Modulator Transmitter (CMT)

47.1	Chip-specific CMT information.....	1395
47.2	Introduction.....	1395
47.3	Features.....	1396
47.4	Block diagram.....	1396
47.5	Modes of operation.....	1397
47.6	CMT external signal descriptions.....	1399
47.7	Memory map/register definition.....	1400
47.8	Functional description.....	1410
47.9	CMT interrupts and DMA.....	1419

Chapter 48 Programmable Delay Block (PDB)

Section number	Title	Page
48.1	Chip-specific PDB information.....	1421
48.2	Introduction.....	1424
48.3	PDB signal descriptions.....	1428
48.4	Memory map and register definition.....	1428
48.5	Functional description.....	1440
48.6	Application information.....	1446

Chapter 49 Periodic Interrupt Timer (PIT)

49.1	Chip-specific PIT information.....	1449
49.2	Introduction.....	1450
49.3	Signal description.....	1451
49.4	Memory map/register description.....	1451
49.5	Functional description.....	1456
49.6	Initialization and application information.....	1458
49.7	Example configuration for chained timers.....	1459
49.8	Example configuration for the lifetime timer.....	1460

Chapter 50 Real Time Clock (RTC)

50.1	Chip-specific RTC information.....	1463
50.2	Introduction.....	1463
50.3	Register definition.....	1465
50.4	Functional description.....	1477

Chapter 51 Universal Serial Bus Full Speed OTG Controller (USBFSOTG)

51.1	Chip-specific USBFSOTG information.....	1483
51.2	Introduction.....	1488
51.3	Functional description.....	1491
51.4	Programmers interface.....	1494
51.5	Memory map/Register definitions.....	1501
51.6	OTG and Host mode operation.....	1530

Section number	Title	Page
51.7	Host Mode Operation Examples.....	1531
51.8	On-The-Go operation.....	1534
51.9	Device mode IRC48M operation.....	1537

Chapter 52 USB Device Charger Detection Module (USBDCD)

52.1	Chip-specific USBDCD information.....	1539
52.2	Preface.....	1539
52.3	Block diagram.....	1541
52.4	Features.....	1541
52.5	Modes of operation.....	1542
52.6	Module signal descriptions.....	1543
52.7	Memory map/Register definition.....	1543
52.8	Memory map/Register definition.....	1553
52.9	Functional description.....	1563
52.10	Initialization information.....	1579
52.11	Application information.....	1579

Chapter 53 USB Voltage Regulator

53.1	Chip-specific USB Voltage Regulator information.....	1581
53.2	Introduction.....	1582
53.3	USB Voltage Regulator Module Signal Descriptions.....	1585

Chapter 54 USB High Speed OTG Controller (USBHS)

54.1	Chip-specific USBHSOTG information.....	1587
54.2	Introduction.....	1587
54.3	Memory Map/Register Definition.....	1589
54.4	Functional Description.....	1648
54.5	Initialization/Application Information.....	1649

Chapter 55 Universal Serial Bus 2.0 Integrated PHY (USB-PHY)

Section number	Title	Page
55.1	Chip-specific USBHS Phy information.....	1687
55.2	USB PHY Overview.....	1687
55.3	Operation.....	1688
55.4	USB PHY Memory Map/Register Definition.....	1698
55.5	Register Macro Usage.....	1733

Chapter 56 Serial Peripheral Interface (SPI)

56.1	Chip-specific SPI information.....	1735
56.2	Introduction.....	1739
56.3	Module signal descriptions.....	1744
56.4	Memory Map/Register Definition.....	1746
56.5	Functional description.....	1769
56.6	Initialization/application information.....	1793

Chapter 57 Inter-Integrated Circuit (I2C)

57.1	Chip-specific I2C information.....	1799
57.2	Introduction.....	1799
57.3	I2C signal descriptions.....	1801
57.4	Memory map/register definition.....	1802
57.5	Functional description.....	1816
57.6	Initialization/application information.....	1832

Chapter 58 Low Power Universal asynchronous receiver/transmitter (LPUART)

58.1	Chip-specific LPUART information.....	1835
58.2	Introduction.....	1836
58.3	Register definition.....	1839
58.4	Functional description.....	1861

Chapter 59 Flexible I/O (FlexIO)

59.1	Chip-specific FlexIO information.....	1877

Section number	Title	Page
59.2	Introduction.....	1878
59.3	Memory Map/Register Definition.....	1881
59.4	Functional description.....	1905
59.5	Application Information.....	1915

Chapter 60 Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)

60.1	Chip-specific I2S/SAI information.....	1931
60.2	Introduction.....	1935
60.3	External signals.....	1937
60.4	Memory map and register definition.....	1938
60.5	Functional description.....	1964

Chapter 61 Secured digital host controller (SDHC)

61.1	Chip-specific SDHC information.....	1975
61.2	Introduction.....	1976
61.3	Overview.....	1976
61.4	SDHC signal descriptions.....	1979
61.5	Memory map and register definition.....	1980
61.6	Functional description.....	2029
61.7	Initialization/application of SDHC.....	2049
61.8	Software restrictions.....	2078

Chapter 62 General-Purpose Input/Output (GPIO)

62.1	Chip-specific GPIO information.....	2081
62.2	Introduction.....	2081
62.3	Memory map and register definition.....	2083
62.4	Functional description.....	2088

Chapter 63 JTAG Controller (JTAGC)

63.1	Introduction.....	2091

Section number	Title	Page
63.2	External signal description.....	2093
63.3	Register description.....	2094
63.4	Functional description.....	2096
63.5	Initialization/Application information.....	2102

Chapter 64

Release Notes for Revision 2

64.1	General changes throughout document	2103
64.2	About This Manual changes.....	2103
64.3	Introduction changes.....	2103
64.4	Core Overview changes.....	2103
64.5	Memories and Memory Interfaces changes.....	2103
64.6	Memory Map changes.....	2104
64.7	Clock Distribution using MCG changes.....	2104
64.8	Reset and Boot changes.....	2104
64.9	Power Management changes.....	2104
64.10	Flash Security Measures and Module Interactions changes.....	2104
64.11	Debug changes.....	2104
64.12	Signal Multiplexing and Signal Descriptions changes.....	2104
64.13	Port Control and Interrupts (PORT) changes.....	2105
64.14	System Integration Module (SIM) changes.....	2105
64.15	Kinetis ROM Bootloader changes.....	2105
64.16	Reset Control Module changes (RCM).....	2105
64.17	System Mode Controller changes (SMC).....	2105
64.18	Power Management Controller (PMC) changes.....	2106
64.19	Low-Leakage Wakeup Unit (LLWU) changes.....	2106
64.20	Miscellaneous Control Module (MCM) changes.....	2106
64.21	Crossbar switch (AXBS) changes.....	2106
64.22	Peripheral Bridge (AIPS-Lite) changes.....	2107
64.23	Memory Protection Unit (MPU) changes.....	2107

Section number	Title	Page
64.24	Bit Manipulation Engine2 (BME2) changes.....	2107
64.25	Direct Memory Access Multiplexer (DMAMUX) changes.....	2108
64.26	eDMA module changes.....	2108
64.27	External Watchdog Monitor (EWM) changes.....	2108
64.28	Watchdog Timer (WDOG) changes.....	2109
64.29	Multipurpose Clock Generator (MCG) changes.....	2109
64.30	Oscillator (OSC) changes.....	2109

Chapter 1

About This Manual

1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

This manual has two main sets of chapters.

1. Chapters in the first set contain information that applies to all components on the chip.
2. Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
 - Examples of these groupings are clocking, timers, and communication interfaces.
 - Each grouping includes chapters that provide a technical description of individual modules.

1.3 Module descriptions

Each module chapter has two main parts:

- **Chip-specific:** The first section, *Chip-specific [module name] information*, includes the number of module instances on the chip and possible implementation differences between the module instances, such as differences in FIFO depths or the number of

channels supported. It may also include functional connections between the module instances and other modules. Read this section *first* because its content is crucial to understanding the information in other sections of the chapter.

- **General:** The subsequent sections provide general information about the module, including its signals, registers, and functional description.

NOTE

If there is a conflict between the chip-specific module information (first section) and the general module information (subsequent sections), the chip-specific information supersedes the general information.

Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list all feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	Feature	Support
eSCI_A and eSCI_B	Yes	
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	Descriptions of eSCI DMA functions do not apply to these instances	

NOTE

For eSCI_D, the single-wire feature does not support TX/RX via P0_02 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Sample Reference Manual

Chip-specific information that should be read first

Beginning of general module information

Figure 1-1. Example: chapter chip-specific information and general module information

1.3.1 Example: chip-specific information that supersedes content in the same chapter

The example below shows chip-specific information that supersedes general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.

Figure 1-2. Example: chip-specific information that supersedes content in the same chapter

1.3.2 Example: chip-specific information that refers to a different chapter

The chip-specific information below refers to another chapter's chip-specific information. In this case, read both sets of chip-specific information before reading further in the chapter.

Figure 1-3. Example: chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in:

- Memory maps including:
 - Addresses
 - The name and acronym/abbreviation of each register
 - The width of each register (in bits)
 - Each register's reset value
 - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

Figure 1-4. Register figure conventions

1.5 Conventions

1.5.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix 0b.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix 0x.

1.5.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
<i>placeholder, x</i>	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
code	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type

Table continues on the next page...

Conventions

Example	Description
	is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as <i>negated</i>.
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

Chapter 2

Introduction

2.1 Overview

The Kinetis K27F is a high performance 150 MHz ARM® Cortex®-M4 with FPU Microcontroller (MCU) which integrates 2 MB of embedded Flash, 1 MB of SRAM, dual USB controllers (High-Speed and Full-Speed), an SDRAM controller, a QuadSPI interface and Power Management Unit. This chapter provides high-level descriptions of the modules available on the devices covered by this document.

2.2 Block Diagram

The below figure shows a top-level block diagram of the device.

Figure 2-1. K27F Block Diagram

2.3 Module Functional Categories

The modules on this device are grouped into functional categories. The following sections describe the modules assigned to each category in more detail.

Table 2-1. Module functional categories

Module category	Description
ARM® Cortex®-M4 based core	32-bit MCU core from ARM's Cortex-M based class adding DSP instructions and single-precision floating point unit based on ARMv7 architecture with 8 KB of cache in some devices
System	System integration module

Table continues on the next page...

Table 2-1. Module functional categories (continued)

Module category	Description
	- Power management and mode controllers - Multiple power modes available based on high speed run, run, wait, stop, and power-down modes - Low-leakage wakeup unit - Miscellaneous control module - Crossbar switch - Memory protection unit - Peripheral bridge - Bit Manipulation Engine (BME2) - Direct memory access (DMA) controller with multiplexer to increase available DMA requests. DMA can handle transfers in VLPS mode - External watchdog monitor - Watchdog
Memories	- Internal memories include: - Program flash memory: 2 MB - SRAM: 1 MB - Cache memory: 16 KB (8 KB I/D + 8 KB System) - Local Memory Controller 32-bit SDRAM memory controller 32-byte System Register File 128-byte VBAT register file - Flexbus - Quad Serial Peripheral Interface 32 KB Boot ROM
Clocks	- Multiple clock generation options available from internally- and externally-generated clocks - System oscillator to provide clock source for the MCU - RTC oscillator to provide clock source for the RTC 48 MHz Internal Reference Clock
Security	- Cyclic Redundancy Check module for error detection - Hardware encryption, along with a random number generator
Analog	- SAR analog-to-digital converter - Comparator - Digital-to-analog converter - Internal voltage reference - Bandgap voltage reference
Timers	- Programmable delay block - FlexTimers - Low Power Timer/PWM - Periodic interrupt timer - Low power timer - Carrier modulator transmitter - Independent real time clock
Communications	- USB Full-Speed (FS) OTG controller - Built-in FS/LS transceiver - USB device charger detect - USB voltage regulator - High-Speed (HS) USB OTG controller - Built-in HS/FS/LS physical layer - USB device charger detect - Serial peripheral interface (SPI) - Inter-integrated circuit (I²C) - Low Power Universal Asynchronous Receiver Transmitter (LPUART)

Table continues on the next page...

Table 2-1. Module functional categories (continued)

Module category	Description
	- Secured Digital host controller - Integrated interchip sound (I²S) 32-channel FlexIO (programmable module)
Human-Machine Interfaces (HMI)	General purpose input/output controller

2.3.1 ARM® Cortex®-M4 Core Modules

The following core modules are available on this device.

Table 2-2. Core modules

Module	Description
ARM Cortex-M4	The ARM Cortex-M4 is a member of the Cortex M Series of processors targeting microcontroller cores focused on very cost sensitive, deterministic, interrupt driven environments. The Cortex M4 processor is based on the ARMv7 Architecture and Thumb®-2 ISA and is upward compatible with the Cortex M3, Cortex M1, and Cortex M0 architectures. Cortex M4 improvements include an ARMv7 Thumb-2 DSP (ported from the ARMv7-A/R profile architectures) providing 32-bit instructions with SIMD (single instruction multiple data) DSP style multiply-accumulates and saturating arithmetic.
Floating point unit (FPU)	A single-precision floating point unit (FPU) that is compliant to the <i>IEEE Standard for Floating-Point Arithmetic</i> (IEEE 754).
NVIC	The ARMv7-M exception model and nested-vector interrupt controller (NVIC) implement a relocatable vector table supporting many external interrupts, a single non-maskable interrupt (NMI), and priority levels. The NVIC replaces shadow registers with equivalent system and simplified programming. The NVIC contains the address of the function to execute for a particular handler. The address is fetched via the instruction port allowing parallel register stacking and look-up. The first sixteen entries are allocated to ARM internal sources with the others mapping to MCU-defined interrupts.
AWIC	The primary function of the Asynchronous Wake-up Interrupt Controller (AWIC) is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.
Debug interfaces	Most of this device's debug hardware is based on the ARM CoreSight™ architecture. Four debug interfaces are supported: - IEEE 1149.1 JTAG - IEEE 1149.7 JTAG (cJTAG) - Serial Wire Debug (SWD) - ARM Real-Time Trace Interface

2.3.2 System Modules

The following system modules are available on this device.

Table 2-3. System modules

Module	Description
System integration module (SIM)	The SIM includes integration logic and several module configuration settings.
System mode controller	The SMC provides control and protection on entry and exit to each power mode, control for the Power management controller (PMC), and reset entry and exit for the complete MCU.
Power management controller (PMC)	The PMC provides the user with multiple power options. different modes are supported that allow the user to optimize power consumption for the level of functionality needed. Includes power-on-reset (POR) and integrated low voltage detect (LVD) with reset (brownout) capability and selectable LVD trip points.
Low-leakage wakeup unit (LLWU)	The LLWU module allows the device to wake from low leakage power modes (LLS and VLLS) through various internal peripheral and external pin sources.
Miscellaneous control module (MCM)	The MCM includes integration logic .
Crossbar switch (AXBS)	The XBS connects bus masters and bus slaves, allowing all bus masters to access different bus slaves simultaneously and providing arbitration among the bus masters when they access the same slave.
Memory protection unit (MPU)	The MPU provides memory protection and task isolation. It concurrently monitors all bus master transactions for the slave connections.
Peripheral bridges	The peripheral bridge converts the crossbar switch interface to an interface to access a majority of peripherals on the device.
DMA multiplexer (DMAMUX)	The DMA multiplexer selects from many DMA requests down to a smaller number for the DMA controller.
Direct memory access (DMA) controller	The DMA controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.
External watchdog monitor (EWM)	The EWM is a redundant mechanism to the software watchdog module that monitors both internal and external system operation for fail conditions.
Software watchdog (WDOG)	The WDOG monitors internal system operation and forces a reset in case of failure. It can run from an independent 1 KHz low power oscillator with a programmable refresh window to detect deviations in program flow or system frequency.
Bit Manipulation Engine2 (BME2)	The second-generation BME2 provides hardware support for atomic read-modify-write operations to the peripheral address space.

2.3.3 Memories and Memory Interfaces

The following memories and memory interfaces are available on this device.

Table 2-4. Memories and memory interfaces

Module	Description
Flash memory	Program flash memory — non-volatile flash memory that can execute program code
Programming Acceleration RAM	RAM memory that can be used as traditional RAM and also accelerates flash programming
Flash memory controller	Manages the interface between the device and the on-chip flash memory.

Table continues on the next page...

Table 2-4. Memories and memory interfaces (continued)

Module	Description
SRAM	Internal system RAM. Partial SRAM kept powered in LLS2 and VLLS2 low leakage mode.
SRAM controller	Manages simultaneous accesses to system RAM by multiple master peripherals and core.
Local memory controller	Manages simultaneous accesses to system RAM by multiple master peripherals and core. Controls cache which improves system performance by providing single-cycle access to the instruction and data pipelines.
System register file	32-byte register file that is accessible during all power modes and is powered by VDD.
VBAT register file	128-byte register file that is accessible during all power modes and is powered by VBAT.
External bus interface (FlexBus)	External bus interface with multiple independent, user-programmable chip-select signals that can interface with external SRAM, PROM, EPROM, EEPROM, flash, and other peripherals via 8-, 16- and 32-bit port sizes. Configurations include multiplexed or non-multiplexed address and data buses using 8-bit, 16-bit, 32-bit, and 16-byte line-sized transfers.
SDRAM Controller	Interface to store and retrieve data from an external SDRAM. Supports glue-less interface to SDR DRAM devices with up to 32-bit wide data and 16MB per chip select. Note that not all packages or pinouts support 32-bit wide data. See Signal Multiplexing Introduction for more information.
Quad Serial Peripheral Interface	The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to eight bidirectional data lines.
32 KB Boot ROM	Provisions the internal flash or QSPI with an embedded firmware image during manufacturing, or at any time during the life of the device. It does this by acting as a slave device, and listening to various peripheral ports where a master can start communication

2.3.4 Clocks

The following clock modules are available on this device.

Table 2-5. Clock modules

Module	Description
Multi-clock generator (MCG)	The MCG provides several clock sources for the MCU that include: • Phase-locked loop (PLL) — Voltage-controlled oscillator (VCO) • Frequency-locked loop (FLL) — Digitally-controlled oscillator (DCO) • Internal reference clocks — Can be used as a clock source for other on-chip peripherals
48 MHz Internal Reference Clock (IRC48M)	The IRC48M provides an internally generated clock source. Clock Recovery circuitry uses the incoming USB data stream on pad USB0_DP and USB0_DM to adjust the internal oscillator and enables the internal oscillator to meet the requirements for USB clock tolerance.

Table continues on the next page...

Table 2-5. Clock modules (continued)

Module	Description
System oscillator	The system oscillator, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.
Real-time clock oscillator	The RTC oscillator has an independent power supply and supports a 32 kHz crystal oscillator to feed the RTC clock. Optionally, the RTC oscillator can replace the system oscillator as the main oscillator source.
USB1PLL Fractional Divider Clock	USB Phy output of the PLL Fractional Divider.

2.3.5 Security and Integrity modules

The following security and integrity modules are available on this device:

Table 2-6. Security and integrity modules

Module	Description
Cryptographic acceleration unit (CAU)	Supports the following algorithms: • DES • 3-DES • AES • SHA-1 and SHA-256 • MD5 Via simple C calls to optimized security functions provided by NXP.
True Random number generator (TRNG)	A hardware entropy source which can be used to seed a software random number generator.
Cyclic Redundancy Check (CRC)	Hardware CRC generator circuit using 16/32-bit shift register. Error detection for all single, double, odd, and most multi-bit errors, programmable initial seed value, and optional feature to transpose input data and CRC result via transpose register.

2.3.6 Analog modules

The following analog modules are available on this device:

Table 2-7. Analog modules

Module	Description
16-bit analog-to-digital converters (ADC)	16-bit successive-approximation ADC
Analog comparators	Compares two analog input voltages across the full range of the supply voltage.
6-bit digital-to-analog converters (DAC)	64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed.
12-bit digital-to-analog converters (DAC)	Low-power general-purpose DAC, whose output can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.

Table continues on the next page...

Table 2-7. Analog modules (continued)

Module	Description
Voltage reference (VREF)	Supplies an accurate voltage output that is trimmable in 0.5 mV steps. The VREF can be used in medical applications, such as glucose meters, to provide a reference voltage to biosensors or as a reference to analog peripherals, such as the ADC, DAC, or CMP.

2.3.7 Timer modules

The following timer modules are available on this device:

Table 2-8. Timer modules

Module	Description
Programmable delay block (PDB)	• 16-bit resolution • 3-bit prescaler • Positive transition of trigger event signal initiates the counter • Supports two triggered delay output signals, each with an independently-controlled delay from the trigger event • Outputs can be OR'd together to schedule two conversions from one input trigger event and can schedule precise edge placement for a pulsed output. This feature is used to generate the control signal for the CMP windowing feature and output to a package pin if needed for applications, such as critical conductive mode power factor correction. • Continuous-pulse output or single-shot mode supported, each output is independently enabled, with possible trigger events • Supports bypass mode • Supports DMA
Flexible timer modules (FTM)	• Selectable FTM source clock, programmable prescaler • 16-bit counter supporting free-running or initial/final value, and counting is up or up-down • Input capture, output compare, and edge-aligned and center-aligned PWM modes • Operation of FTM channels as pairs with equal outputs, pairs with complimentary outputs, or independent channels with independent outputs • Deadtime insertion is available for each complementary pair • Generation of hardware triggers • Software control of PWM outputs • Up to 4 fault inputs for global fault control • Configurable channel polarity • Programmable interrupt on input capture, reference compare, overflowed counter, or detected fault condition • Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event • DMA support for FTM events
Low Power TPM (TPM)	• Two channel timer which supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. • The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low power modes. • DMA support

Table continues on the next page...

Table 2-8. Timer modules (continued)

Module	Description
Periodic interrupt timers (PIT)	• Four general purpose interrupt timers • Interrupt timers for triggering ADC conversions • 32-bit counter resolution • DMA support
Low-power timer (LPTMR)	• Selectable clock for prescaler/glitch filter of 1 kHz (internal LPO), 32.768 kHz (external crystal), or internal reference clock • Configurable Glitch Filter or Prescaler with 32-bit counter • 32-bit time or pulse counter with compare • Interrupt generated on Timer Compare • Hardware trigger generated on Timer Compare
Carrier modulator timer (CMT)	• Four CMT modes of operation: • Time with independent control of high and low times • Baseband • Frequency shift key (FSK) • Direct software control of CMT_IRO pin • Extended space operation in time, baseband, and FSK modes • Selectable input clock divider • Interrupt on end of cycle with the ability to disable CMT_IRO pin and use as timer interrupt • DMA support
Real-time clock (RTC)	• Independent power supply, POR, and 32 kHz Crystal Oscillator • 32-bit seconds counter with 32-bit Alarm • 16-bit Prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm

2.3.8 Communication interfaces

The following communication interfaces are available on this device:

Table 2-9. Communication modules

Module	Description
FlexIO	Supports a wide range of protocols including, but not limited to: • UART • I2C • SPI • I2S • Camera IF • LCD RGB • PWM / Waveform generation Functions in STOP/VLPS modes DMA support.
USB OTG (low-/full-speed)	USB 2.0 compliant module with support for host, device, and On-The-Go modes. Includes an on-chip transceiver for full and low speeds.
USB OTG (low-/full-/high-speed)	USB 2.0 compliant module with support for host, device, and On-The-Go modes. Includes integrated USB HS Physical Layer.

Table continues on the next page...

Table 2-9. Communication modules (continued)

Module	Description
USB Device Charger Detect (USBDCD)	The USBDCD monitors the USB data lines to detect a smart charger meeting the USB Battery Charging Specification Rev1.2. This information allows the MCU to better manage the battery charging IC in a portable device.
USB PHY	Up to 5 V regulator input typically provided by USB VBUS power with 2.7-3.6 V regulated output that powers on-chip USB subsystems, capable of sourcing 150 mA to external board components.
USB voltage regulator	Up to 5 V regulator input typically provided by USB VBUS power with 3.3 V regulated output that powers on-chip USB subsystem, capable of sourcing 120 mA to external board components. This device can source 2.7-3.6V up to 150mA. The other regulator description applies.
USBHS Device Charger Detect (USBHSDCD)	The USBHSDCD monitors the HS USB data lines to detect a smart charger meeting the USB Battery Charging Specification Rev1.2. This information allows the MCU to better manage the battery charging IC in a portable device.
Serial peripheral interface (SPI)	Synchronous serial bus for communication to an external device.
Inter-Integrated Circuit (I ² C)	Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.
Low Power Universal asynchronous receiver/transmitter (LPUART)	Asynchronous serial bus communication interface with programmable 8- or 9-bit data format .
Secure Digital host controller (SDHC)	Interface between the host system and the SD, SDIO, MMC, or CE-ATA cards. The SDHC acts as a bridge, passing host bus transactions to the cards by sending commands and performing data accesses to/from the cards. It handles the SD, SDIO, MMC, and CE-ATA protocols at the transmission level.
Integrated Interchip Sound (I2S)	The I2S is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices, such as standard codecs, digital signal processors (DSPs), microprocessors, peripherals, and audio codecs that implement the inter-IC sound bus (I2S) and the Intel® AC97 standards.

2.3.9 Human-machine interfaces

The following human-machine interfaces (HMI) are available on this device:

Table 2-10. HMI modules

Module	Description
General purpose input/output (GPIO)	All general purpose input or output (GPIO) pins are capable of interrupt and DMA request generation. Configurable slew rate on all output pins. High drive configurable option on 36 pins (PTB0, PTB1, PTD4, PTD5, PTD6, PTD7, PTE, PTC24, PTC25, PTC26, PTC27, PTC3, and PTC4).

2.4 Orderable part numbers

The following table summarizes the part numbers of the devices covered by this document.

Table 2-11. Orderable part numbers summary

Part number	Mask Set	CPU frequency	Pin count	Package	Total flash memory	SRAM	GPIO
MK27FN2M0VMI15	2N96T	150 MHz	169	MAPBGA	2 MB	1 MB	120
MK27FN2M0AVMI15	3N96T	150 MHz	169	MAPBGA	2 MB	1 MB	120

Chapter 3

Core Overview

3.1 Introduction

The ARM Cortex-M4 is a member of the Cortex M Series of processors targeting microcontroller cores focused on very cost sensitive, deterministic, interrupt driven environments. The Cortex-M4 processor is based on the ARMv7 Architecture and Thumb®-2 ISA and is upward compatible with the Cortex M3, Cortex M1, and Cortex M0{+} architectures. Cortex M4 improvements include an ARMv7 Thumb-2 DSP (ported from the ARMv7-A/R profile architectures) providing 32-bit instructions with SIMD (single instruction multiple data) DSP style multiply-accumulates and saturating arithmetic. There are approximately 90 instructions added to the previous ARMv7-M instruction set.

3.1.1 Buses, interconnects, and interfaces

The ARM Cortex-M4 core has four buses as described in the following table.

Bus name	Description
Instruction code (ICODE) bus	The ICODE and DCODE buses are muxed. This muxed bus is called the CODE bus and is connected to the crossbar switch via a single master port. In addition, the CODE bus is also tightly coupled to the lower half of the system RAM (SRAM_L).
Data code (DCODE) bus	
System bus	The system bus is connected to a separate master port on the crossbar. In addition, the system bus is tightly coupled to the upper half system RAM (SRAM_U).
Private peripheral (PPB) bus	The PPB provides access to these modules: • ARM modules such as the NVIC, ETM, ITM, DWT, FBP, and ROM table • Miscellaneous Control Module (MCM) • Memory-Mapped Cryptographic Acceleration Unit (MMCAU)

3.1.2 System Tick Timer

The System Tick Timer's clock source is always the core clock, FCLK. This results in the following:

- The CLKSOURCE bit in SysTick Control and Status register is always set to select the core clock.
- Because the timing reference (FCLK) is a variable frequency, the TENMS bit in the SysTick Calibration Value Register is always zero.
- The NOREF bit in SysTick Calibration Value Register is always set, implying that FCLK is the only available source of reference timing.

3.1.3 Debug facilities

This device has extensive debug capabilities including run control and tracing capabilities. The standard ARM debug port that supports JTAG and SWD interfaces. Also the cJTAG interface is supported on this device.

3.1.4 Caches

This device includes two 8 KB combined data/ instructions caches to minimize the performance impact of memory access latencies: one for the system bus and one for I/D bus.

Features of each cache are:

- 2-way set associative
- 4 word lines
- Lines can be individually flushed
- Entire cache can be flushed at once

3.1.4.1 Low Power

The caches are powered down in LLS and VLLSx modes. The caches need to be flushed before being powered down. This affects the time it takes for the system to go into the new mode but not the wakeup time.

3.1.4.2 Control

For control purposes the cache can be in one of these states:

1. Write Back /Write Allocate (WBWA)

2. Write Through (WT)
3. Non-Cachable (NC)

For each defined region there are 2 bits allocated in the control register that determine the cache state for the memory region associated with this section. The user can only "lower" the cache attribute, given the fixed relationship of WBWA > WT > NC - so, you can demote a WBWA region to either WT or NC, you can demote a WT space to NC. In order to change the state upwards a system reset is required.

The 1 GB space allocated to the DRAM and FlexBus is split in 16 MB regions and 2 bits assigned to the control state of each region. A total of 128 bits, distributed in four 32-bit registers is used for this control.

3.1.5 Core privilege levels

The ARM documentation uses different terms than this document to distinguish between privilege levels.

If you see this term...	it also means this term...
Privileged	Supervisor
Unprivileged or user	User

3.2 Interrupt priority levels

This device supports 16 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 4 bits. For example, IPR0 is shown below:

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IRQ3				0	0	0	0	IRQ2				0	0	0	0	IRQ1				0	0	0	0	IRQ0				0	0	0	0
W																																

3.3 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external $\overline{\text{NMI}}$ signal. The pin the $\overline{\text{NMI}}$ signal is multiplexed on, must be configured for the $\overline{\text{NMI}}$ function to generate the non-maskable interrupt request.

3.4 Interrupt channel assignments

The interrupt source assignments are defined in the following table.

- Vector number — the value stored on the stack when an interrupt is serviced.
- IRQ number — non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within ARM's NVIC documentation.

Table 3-2. Interrupt vector assignments

1. Indicates the NVIC's interrupt source number.
2. Indicates the NVIC's ISER, ICER, ISPR, ICPR, and IABR register number used for this IRQ. The equation to calculate this value is: $IRQ \div 32$
3. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is: $IRQ \div 4$
4. This interrupt can only be pending or cleared via the NVIC registers.

3.5 AWIC overview

The primary function of the AWIC block is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.

3.6 Wake-up sources

The device uses the following internal and external inputs to the AWIC module.

Table 3-3. AWIC Partial Stop, Stop and VLPS Wake-up Sources

Wake-up source	Description
Available system resets	RESET pin and WDOG when LPO is its clock source, and JTAG
Low-voltage detect	Power Mode Controller
High-voltage detect	Power Mode Controller
Low-voltage warning	Power Mode Controller
Pin interrupts	Port Control Module - Any enabled pin interrupt is capable of waking the system
ADCx	The ADC is functional when using internal clock source
CMPx	Since no system clocks are available, functionality is limited, trigger mode provides wakeup functionality with periodic sampling
I ² C	Address match wakeup
LPUART	Functional when using clock source which is active in Stop and VLPS modes
USB FS/LS Controller	Wakeup
USB HS/FS/LS Controller	Wakeup
FlexIO	Functional when using clock source which is active in Stop and VLPS modes
LPTMR	Functional when using clock source which is active in Stop, VLPS and LLS/VLLS modes
RTC	Functional in Stop/VLPS modes
SDHC	Wakeup
I ² S (SAI)	Functional when using an external bit clock or external master clock
TPM	Functional when using clock source which is active in Stop and VLPS modes
NMI	Non-maskable interrupt

Chapter 4

Memories and Memory Interfaces

4.1 Flash memory types

This device contains the following types of flash memory:

- Program flash memory — non-volatile flash memory that can execute program code
For devices with only program flash memory: Programming acceleration RAM — RAM memory that accelerates flash programming

4.2 Flash Memory Sizes

The devices covered in this document contain:

- 4 blocks of 512 kB of program flash each block consisting of 4 kB sectors

4.3 Flash Security

How flash security is implemented on this device is described in [Flash Security Measures and Module Interactions](#).

4.4 Flash Modes

The flash memory is always configured in NVM normal. There are no operating conditions in which the flash is configured for NVM special mode.

4.5 Erase All Flash Contents

An Erase All Flash Blocks operation can be launched by software through a series of peripheral bus writes to flash registers. In addition the entire flash memory may be erased external to the flash memory from the SWJ-DP debug port by setting DAP_CONTROL[0]. DAP_STATUS[0] is set to indicate the mass erase command has been accepted. DAP_STATUS[0] is cleared when the mass erase completes.

4.6 FTFE_FOPT Register

The flash memory's FTFE_FOPT register allows the user to customize the operation of the MCU at boot time. See [FOPT boot options](#) for details of its definition.

4.7 SRAM sizes

This device contains TCRAM that is tightly coupled to the ARM Cortex-M4 core as well as OCRAM that is not tightly coupled to ARM Cortex-M4 core. The TCRAM is split into SRAM_L and SRAM_U regions where the SRAM_L and SRAM_U ranges form a contiguous block in the memory map anchored at address 0x2000_0000. As such:

- SRAM_L is anchored at address 0x2000_0000 and occupies the space below this address, that is, addresses less than 0x2000_0000.
- SRAM_U is anchored at address 0x2000_0000 and occupies the space at and above this beginning address, that is, addresses greater than or equal to 0x2000_0000.

NOTE

Misaligned accesses across the 0x2000_0000 boundary are not supported in the ARM Cortex-M4 architecture.

The amount of SRAM for the devices covered in this document is shown in the following table(s).

SRAM Sizes for Orderable Part Numbers

Device	Total SRAM (KB)	SRAM_L size (KB)	SRAM_U size (KB)	Address Range	OCRAM size	Address Range
MK27FN2M0V MI15	1024 KB	256 KB	256 KB	0x1FFC_0000-0x2003_FFFF	512KB	0x3400_0000-0x3407_FFFF
MK27FN2M0AV MI15	1024 KB	256 KB	256 KB	0x1FFC_0000-0x2003_FFFF	512KB	0x3400_0000-0x3407_FFFF

4.8 SRAM accesses

The SRAM is split into two logical arrays that are 32-bits wide.

- SRAM_L — Accessible by the code bus of the Cortex-M4 core and by the backdoor port.
- SRAM_U — Accessible by the system bus of the Cortex-M4 core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

The following figure illustrates the SRAM accesses within the device.

Figure 4-1. SRAM access diagram

The following simultaneous accesses can be made to different logical regions of the SRAM:

- Core code and core system
- Core code and non-core master system
- Core system and non-core master code

This device has 512K bytes of SRAM that are accessed outside of the ARM Cortex-M4's platform via the AXBS crossbar, referenced as OCRAM. The OCRAM of this device is accessible at address 0x3400_0000 to 0x3407_FFFF.

4.9 SRAM retention in low power modes

Optionally other segments of the SRAM can remain powered in VLLS2 and LLS2 stop modes, by programming PMC_RAMCTL. The RAM segments are enabled via the VLLS2PDx bits as described in table below:

Table 4-1. K27 RAM arrays

RAMx	Start address	End address	Size	PMC_SRAMCTL
RAM1	2000_0000	2000_7FFF	32KB	always enabled
RAM2	1FFF_8000	1FFF_FFFF	32KB	VLLS2PD0
RAM3	1FFF_0000	1FFF_7FFF	32KB	VLLS2PD1
RAM4	2000_8000	2000_FFFF	32KB	VLLS2PD2
RAM5	2001_0000	2002_FFFF	128KB	VLLS2PD3
RAM6	2003_0000	2003_FFFF	64KB	VLLS2PD4
RAM7	1FFC_0000	1FFE_FFFF	192KB	VLLS2PD5
RAM8	3400_FFFF	3403_FFFF	256KB	VLLS2PD6
RAM9	3404_FFFF	3407_FFFF	256KB	VLLS2PD7

In VLLS1 and VLLS0 no SRAM is retained; however, the [32-byte register file](#) is available.

4.10 QuadSPI memory interface

This device contains a QSPI controller which can interface with external flash devices to expand the storage size. With the QSPI controller enabled, the external flash can be mapped to a 128 MB system address range 0x6800_0000 to 0x6FFF_FFFF and can be read directly just like on-chip memory. For the flash space which exceeds above range, it can be read in through a 16 words QSPI FIFO located at system address 0x6700_0000. QSPI is not available when the system enters STOP modes, Compute Operation mode, LLSx and VLLSx modes.

4.11 System Register file

This device includes a 32-byte register file that is powered in all power modes.

Also, it retains contents during low-voltage detect (LVD) events and is only reset during a power-on reset.

4.12 VBAT register file

This device includes a 128-byte register file that is powered in all power modes and is powered by VBAT.

It is only reset during VBAT power-on reset.

Chapter 5

Memory Map

5.1 Introduction

This device contains various memories and memory-mapped peripherals which are located in one 32-bit contiguous memory space. This chapter describes the memory and peripheral locations within that memory space.

5.2 System memory map

The following table shows the high-level device memory map. This map provides the complete architectural address space definition for the various sections. Based on the physical sizes of the memories and peripherals, the actual address regions used may be smaller.

The system memory map includes multiple aliased address spaces that are intended for specific purposes.

- There are three aliased address spaces that are mapped into the ICode regions (address < 0x2000_0000) for code sections that normally reside in the system address space (address >= 0x2000_0000). The FlexBus address space is located in the system region of the memory map, but a subset of this space is aliased so it appears in the ICode region so instructions mapped into this space can be executed with maximum performance. The SDRAM Controller and QuadSPI have a similar mapping structure.
- There is an aliased region that maps a system address space to the Program flash section. This is complementary to the previous FlexBus example. Flash region aliasing is specifically intended for references to read-only data coefficients in the

flash while still preserving a full Harvard memory organization in the processor core supporting concurrent instruction fetches (for example, from RAM) and data accesses (from flash via the aliased space).

- The bitbanding functionality supported by the processor core uses aliased regions that map to the basic RAM and peripheral address spaces. This functionality maps each 32-bit word of the aliased address space to a unique bit in the underlying RAM or peripheral address space to support single-bit insert and extract operations from the processor.

Table 5-1. K27 System memory map

System 32-bit Address Range	Destination Slave	Access
0x0000_0000-0x001F_FFFF ¹	Program flash and read-only data (Includes exception vectors in first 1024 bytes)	All masters
0x0020_0000-0x03FF_FFFF	Reserved	—
0x0400_0000-0x07FF_FFFF ²	QSPI0 (Aliased area) Mapped to the same access space of 0x6800_0000 to 0x6BFF_FFFF	Cortex-M4 core (M0) only
0x0800_0000-0x0FFF_FFFF	SDRAM (Aliased area) Mapped to the same access space of 0x8800_0000-0x8FFF_FFFF	Cortex-M4 core (M0) only
0x1000_0000-0x13FF_FFFF	Reserved	—
0x1400_0000-0x17FF_FFFF	FlexRAM (Flash Programming Acceleration RAM)	All masters
0x1800_0000-0x1BFF_FFFF	FlexBus (Aliased Area) Mapped to the same access space of 0x9800_0000-0x9BFF_FFFF	Cortex-M4 core (M0) only
0x1C00_0000-0x1C00_7FFF	ROM	All masters
0x1C00_8000-0x1FFB_FFFF	Reserved	—
0x1FFC_0000-0x1FFF_FFFF ³	Tightly Coupled Memory Lower (TCML) SRAM_L: Lower SRAM (ICODE/ DCODE)	All masters
0x2000_000-0x2003_FFFF ³	Tightly Coupled Memory Upper (TCMU) SRAM_U: Upper SRAM bitband region	All masters
0x2004_0000-0x21FF_FFFF	Reserved	—
0x2200_0000-0x25FF_FFFF	Aliased to TCMU SRAM bitband	Cortex-M4 core only
0x2400_0000-0x2FFF_FFFF	Reserved	—
0x3000_0000-0x301F_FFFF	Flash Data Alias	Cortex-M4 (M1) core only

0x8000_0000-0x87FF_FFFF	SDRAM (External Memory - Write-through)	All masters
0x8800_0000-0x8FFF_FFFF	SDRAM (External Memory - Write-through)	All masters
0x9000_0000-0x97FF_FFFF	Reserved	—
0x9800_0000-0x9FFF_FFFF	FlexBus (External Memory - Write-through)	All masters
0xA000_0000-0xDFFF_FFFF	FlexBus (External Peripheral - Not executable)	All masters
0xE000_0000-0xE00F_FFFF	Private Peripherals	Cortex-M4 core only
0xE010_0000-0xFFFF_FFFF	Reserved	—

1. This map provides the complete architectural address space definition for the flash. Based on the physical sizes of the memories implemented for a particular device, the actual address regions used may be smaller. See [Flash Memory Sizes](#) for details.
2. Debug access is available only in the aliased QuadSPI memory region. (Breakpoints are not supported in the main QuadSPI memory region.)
3. This range varies depending on amount of SRAM implemented for a particular device. See [SRAM sizes](#) for details.

NOTE

1. Access rights to AIPS-Lite peripheral bridges and general purpose input/output (GPIO) module address space is limited to the core and DMA.
2. ARM Cortex-M4 core access privileges also includes accesses via the debug interface.

5.3 Flash Memory Map

The flash memory and the flash registers are located at different base addresses as shown in the following figure. The base address for each is specified in [System memory map](#).

Figure 5-1. Flash memory map

The on-chip Flash is implemented in a portion of the allocated Flash range to form a contiguous block in the memory map beginning at address 0x0000_0000. See [Flash Memory Sizes](#) for details of supported ranges.

Accesses to the flash memory ranges outside the amount of Flash on the device causes the bus cycle to be terminated with an error followed by the appropriate response in the requesting bus master. Read collision events in which flash memory is accessed while a flash memory resource is being manipulated by a flash command also generates a bus error response.

5.4 Flash Access Control Introduction

The Flash Access Control (FAC) is a NXP or third-party configurable memory protection scheme optimized to allow end users to utilize software libraries while offering programmable restrictions to these libraries. The flash memory is divided into equal size segments that provide protection to proprietary software libraries. The protection of these segments is controlled as the FAC evaluates of the access rights for each transaction routed to the on-chip flash memory. Configurability allows an increasing number of protected segments while supporting two levels of vendors adding their proprietary software to a device.

Flash access control aligns to the three privilege levels supported by ARM Cortex-M family products where the most secure state - supervisor/privileged-secure - aligns to the execute-only and supervisor-only access control. The unsecure state of user-non-secure aligns to no access control states set, and the mid-level state where user-secure aligns to using the access control of execute-only.

Control for this protection scheme is implemented in Program Once NVM locations and is configurable through Program Once flash command operations. The NVM locations controlling FAC are unaffected by Erase All Blocks flash command and debug interface initiated mass erase operations.

NOTE

The FAC protection scheme has eight XACC and eight SACC registers to control up to 64 segments.

5.5 SRAM memory map

The TCRAM is split in two regions: SRAM_L and SRAM_U. The RAM is implemented such that the SRAM_L and SRAM_U ranges form a contiguous block in the memory map.

Accesses to the SRAM_L and SRAM_U memory ranges outside the amount of RAM on the device causes the bus cycle to be terminated with an error followed by the appropriate response in the requesting bus master.

The OCRAM is not contiguous to the TCRAM. The 512K bytes of OCRAM are accessed from 0x3400_0000 to 0x3407_FFFF.

5.6 Peripheral bridge (AIPS-Lite0 and AIPS-Lite1) memory maps

The peripheral memory map is accessible via two slave ports on the crossbar switch in the 0x4000_0000–0x400F_FFFF region. The device implements two peripheral bridges (AIPS-Lite 0 and 1):

- AIPS-Lite0 covers 512 KB
- AIPS-Lite1 covers 496 KB plus 4 KB assigned to the general purpose input/output module (GPIO) and 12 KB reserved (4K in 3 spaces)

AIPS-Lite0 is connected to crossbar switch slave port 2, and is accessible at locations 0x4000_0000–0x4007_FFFF.

The two regions associated with this space are:

- A 128 KB region, partitioned as 32 spaces, each 4 KB in size and reserved for on-platform peripheral devices. The AIPS controller generates unique module enables for all 32 spaces.
- A 384 KB region, partitioned as 96 spaces, each 4 KB in size and reserved for off-platform modules. The AIPS controller generates unique module enables for all 96 spaces.

AIPS-Lite1 and the general purpose input/output (GPIO) module share the connection to crossbar switch slave port 3. The AIPS-Lite1 is accessible at locations 0x4008_0000–0x400F_BFFF. 12 KB is reserved at 0x400F_C000 - 0x400F_EFFF. The general purpose input/output module is accessible in a 4 KB region at 0x400F_F000–0x400F_FFFF. Its direct connection to the crossbar switch provides master access without incurring wait states associated with accesses via the AIPS-Lite controllers.

NOTE

The BME2 functionality is available for the 512 KB of AIPS0 and 496 KB of AIPS1; it is not available for the GPIO.

Modules that are disabled via their clock gate control bits in the SIM registers disable the associated AIPS slots. Access to any address within an unimplemented or disabled peripheral bridge slot results in a transfer error termination.

For programming model accesses via the peripheral bridges, there is generally only a small range within the 4 KB slots that is implemented. Accessing an address that is not implemented in the peripheral results in a transfer error termination.

5.6.1 Peripheral Bridge 0 (AIPS-Lite 0) Memory Map

Table 5-2. Peripheral bridge 0 slot assignments

System 32-bit base address	Slot number	Module

Table 5-4. PPB memory map (continued)

System 32-bit Address Range	Resource
0xE008_0000–0xE008_0FFF	Miscellaneous Control Module (MCM)
0xE008_1000–0xE008_1FFF	Memory Mapped Cryptographic Acceleration Unit (MMCAU)
0xE008_2000–0xE008_2FFF	Cache Controller
0xE008_3000–0xE00F_EFFF	Reserved
0xE00F_F000–0xE00F_FFFF	ROM Table - allows auto-detection of debug components

Chapter 6

Clock Distribution using MCG

6.1 Introduction

The MCG module controls which clock source is used to derive the system clocks. The clock generation logic divides the selected clock source into a variety of clock domains, including the clocks for the system bus masters, system bus slaves, and flash memory. The clock generation logic also implements module-specific clock gating to allow granular shutoff of modules.

The primary clocks for the system are generated from the MCGOUTCLK clock. The clock generation circuitry provides several clock dividers that allow different portions of the device to be clocked at different frequencies. This allows for trade-offs between performance and power dissipation.

Various modules, such as the USB OTG Controller, have module-specific clocks that can be generated from the IRC48MCLK or MCGPLLCLK or MCGFLLCLK clock. The SDRAM controller is a specific case, since it can take its clock from either PLL (system or SDRAM). In addition, there are various other module-specific clocks that have other alternate sources. Clock selection for most modules is controlled by the SOPT registers in the SIM module.

6.2 Programming model

The selection and multiplexing of system clock sources is controlled and programmed via the MCG module. The setting of clock dividers and module clock gating for the system are programmed via the SIM module. Reference those sections for detailed register and bit descriptions.

6.3 High-Level device clocking diagram

The following [system oscillator](#), [MCG](#), and [SIM](#) module registers control the multiplexers, dividers, and clock gates shown in the below figure:

	OSC	MCG	SIM
Multiplexers	MCG_Cx	MCG_Cx	SIM_SOPT1, SIM_SOPT2
Dividers	—	MCG_Cx	SIM_CLKDIVx
Clock gates	OSC_CR	MCG_C1	SIM_SCGCx

Figure 6-1. Clocking diagram

6.4 Clock definitions

The following table describes the clocks in the previous block diagram.

Clock name	Description
Core clock	MCGOUTCLK divided by OUTDIV1 clocks the ARM Cortex-M4 core
System clock	MCGOUTCLK divided by OUTDIV1 clocks the crossbar switch and bus masters directly connected to the crossbar.
Bus clock	MCGOUTCLK divided by OUTDIV2 clocks the bus slaves and peripheral (excluding memories)
FlexBus clock	MCGOUTCLK divided by OUTDIV3 clocks the external FlexBus interface
Flash clock	MCGOUTCLK divided by OUTDIV4 clocks the flash memory
MCGIRCLK	MCG output of the slow or fast internal reference clock
MCGFFCLK	MCG output of the slow internal reference clock or a divided MCG external reference clock.
MCGOUTCLK	MCG output of either IRC, MCGFLLCLK, MCGPLLCLK or MCG's external reference clock that sources the core, system, bus, FlexBus, and flash clock. It is also an option for the debug trace clock.
MCGFLLCLK	MCG output of the FLL. MCGFLLCLK may clock some modules.
MCGPLLCLK	MCG output of the PLL. MCGFLLCLK or MCGPLLCLK may clock some modules.
USB1PFDCLK	USB Phy output of the PLL Fractional Divider
MCG external reference clock	Input clock to the MCG sourced by the system oscillator (OSCCLK) or RTC oscillator
IRC48MCLK	Internal 48 MHz oscillator that can be used as a reference to the MCG and also may clock some on-chip modules.
OSCCLK	System oscillator output of the internal oscillator or sourced directly from EXTAL
OSCERCLK	System oscillator output sourced from OSCCLK that may clock some on-chip modules
OSC32KCLK	System oscillator 32kHz output
ERCLK32K	Clock source for some modules that is chosen as OSC32KCLK or the RTC clock.
RTC clock	RTC oscillator output for the RTC module
LPO	PMC 1kHz output

6.4.1 Device clock summary

The following table provides more information regarding the on-chip clocks.

Table 6-1. Clock Summary

Clock name	HS Run mode clock frequency	Run mode clock frequency	VLPR mode clock frequency	Clock source	Clock is disabled when...
MCGOUTCLK	Up to 150 MHz	Up to 120 MHz	Up to 4 MHz	MCG	In all stop modes except for partial stop modes and during PLL locking when MCGOUTCLK derived from PLL.
MCGFLLCLK	Up to 100MHz	Up to 100MHz	N/A	MCG	MCG clock controls are not enabled. Overriding forced disable in all low powers modes (including STOP and VLPx modes).
MCGPLLCLK	Up to 150 MHz	Up to 150 MHz	N/A	MCG	MCG clock controls are not enabled, in Stop mode but PLLSTEN=0, or in VLPS, LLS and VLLSx modes
USB1PFDCLK	Up to 150MHz	Up to 150MHz	N/A	USB HS PHY	USBHS Phy clock controls are not enabled, in VLPR Stop, VLPS, LLSx and VLLSx modes. Power should not be removed from device if using USB1PFDCLK
Core clock	Up to 150 MHz	Up to 120 MHz	Up to 4 MHz	MCGOUTCLK clock divider	In all wait and stop modes
System clock	Up to 150 MHz	Up to 120 MHz	Up to 4 MHz	MCGOUTCLK clock divider	In all stop modes and Compute operation
Bus clock	Up to 75 MHz	Up to 60 MHz	Up to 4 MHz	MCGOUTCLK clock divider	In all stop modes except for partial STOP2 mode, and Compute Operation
FlexBus clock (FB_CLK)	Up to 75 MHz	Up to 60 MHz	Up to 4 MHz	MCGOUTCLK clock divider	In all stop modes or, If FlexBus is disabled
Flash clock	Up to 25 MHz	Up to 25 MHz	Up to 1MHz in BLPE, Up to 800KHz in BLPI	MCGOUTCLK clock divider	In all stop modes except for partial STOP2 mode
Internal reference (MCGIRCLK)	Up to 4 MHz IRC oscillator	Up to 4 MHz IRC oscillator	Up to 4 MHz IRC oscillator	MCG	MCG_C1[IRCLKEN] cleared, Stop or VLPS mode and

Table continues on the next page...

Table 6-1. Clock Summary (continued)

Clock name	HS Run mode clock frequency	Run mode clock frequency	VLPR mode clock frequency	Clock source	Clock is disabled when...
					MCG_C1[IREFSTE N] cleared, or LLS/ VLLS mode
External reference (OSCERCLK)	Up to 50 MHz (bypass), 30-40 kHz, or 3-32 MHz (crystal)	Up to 50 MHz (bypass), 30-40 kHz, or 3-32 MHz (crystal)	Up to 16 MHz (bypass), 30-40 kHz (low- range crystal) or Up to 16 MHz (high-range crystal)	System OSC	System OSC's OSC_CR[ERCLKE N] cleared, or Stop mode and OSC_CR[EREFS TEN] cleared
External reference 32kHz (ERCLK32K)	30-40 kHz	30-40 kHz	30-40 kHz	System OSC or RTC OSC depending on SIM_SOPT1[OSC3 2KSEL]	System OSC's OSC_CR[ERCLKE N] cleared or RTC's RTC_CR[OSCE] cleared
Internal 48 MHz clock (IRC48MCLK)	48 MHz	48 MHz	N/A	IRC48M	USB, MCG or SIM controls are not enabled and QSPI does not select it. Overriding forced disable in VLPS, LLSx, VLLSx.
RTC_CLKOUT	1 Hz or 32 kHz	1 Hz or 32 kHz	1 Hz or 32 kHz	RTC clock	Clock is disabled in LLS and VLLSx modes
LPO	1 kHz	1 kHz	1 kHz	PMC	in VLLS0
USB HS clock	30 MHz	30 MHz	N/A	Internal	USB HS OTG is disabled
USB FS clock	48 MHz	48 MHz	N/A	MCGPLLCLK, IRC48MCLK or MCGFLLCLK with fractional clock divider, or USB_CLKIN	USB FS OTG is disabled in all Stop Modes and Compute Operation mode
I ² S master clock	Up to 75 MHz	Up to 60 MHz	Up to 12.5 MHz	System clock , MCGPLLCLK, IRC48MCLK, OSCERCLK with fractional clock divider, or I2S_CLKIN	I ² S is disabled
SDHC clock	Up to 150 MHz	Up to 120 MHz	Up to 4 MHz	System clock, MCGPLLCLK/ MCGFLLCLK, or OSCERCLK	SDHC is disabled

Table continues on the next page...

Table 6-1. Clock Summary (continued)

Clock name	HS Run mode clock frequency	Run mode clock frequency	VLPR mode clock frequency	Clock source	Clock is disabled when...
LPUART clock	Up to 75 MHz	Up to 75 MHz	Up to 16 MHz	MCGIRCLK, IRC48MCLK, OSCERCLK, or MCGPLLCLK/ MCGFLLCLK	SIM_SOPT2[LPUARTSRC] is cleared
FlexIO clock	Up to 150 MHz	Up to 120 MHz	Up to 16 MHz	System clock, MCGIRCLK, IRC48MCLK, OSCERCLK, or MCGPLLCLK/ MCGFLLCLK	FlexIO is disabled
TPM clock	Up to 75 MHz	Up to 75 MHz	Up to 16 MHz	MCGIRCLK, IRC48MCLK, OSCERCLK, or MCGPLLCLK/ MCGFLLCLK	SIM_SOPT2[LPTPMMSRC] is cleared
TRACE clock	Up to 150 MHz	Up to 120 MHz	Up to 4 MHz	System clock or MCGOUTCLK	Trace is disabled
QSPI clocking	Up to 100 MHz ¹	Up to 100 MHz	Up to 4 MHz	MCGPLL2XCLK, MCGPLLCLK/ MCGFLLCLK, IRC48MHz, MCGIRCLK or OSCERCLK	QSPI is disabled in all stop modes and Compute Operation

1. QuadSPI clocks are limited to 75 MHz in dual data rate (DDR) configurations for both RUN and HSRUN modes.

6.5 Internal clocking requirements

The clock dividers are programmed via the SIM module's CLKDIV registers. Each divider is programmable from a divide-by-1 through divide-by-16 setting. The following requirements must be met when configuring the clocks for this device:

1. The core and system clock frequencies must be 150 MHz or slower in HSRUN, 120 MHz or slower in RUN.
2. The bus clock frequency must be programmed to 75 MHz or slower in HSRUN, 60 MHz or slower in RUN, and an integer divide of the core clock. The core clock to bus clock ratio is limited to a max value of 8.

NOTE

Flash erase and programming operations are not allowed in HSRUN modes

3. The flash clock frequency must be programmed to 25 MHz or less, less than or equal to the bus clock, and an integer divide of the core clock. The core clock to flash clock ratio is limited to a max value of 8.
4. The FlexBus clock frequency must be programmed to be less than or equal to the bus clock frequency. The FlexBus also has pad interface restrictions that limits the maximum frequency. For this device the FlexBus maximum frequency is 75 MHz. The core clock to FlexBus clock ratio is limited to a max value of 8.
5. Since SDRAMC and FlexBus both use CLKOUT, the same restrictions apply to the SDRAM controller as stated for the FlexBus clock.
6. The QuadSPI clock must be 75 MHz or less in DDR (dual) mode and 100 MHz or less in SDR (single) mode.

The following are a few of the more common clock configurations for this device:

6.5.1 Clock divider values after reset

Each clock divider is programmed via the SIM module's CLKDIV n registers. The flash memory's FTFE_FOPT[LPBOOT] bit controls the reset value of the core clock, system clock, bus clock, and flash clock dividers as shown below:

FTFE_FOPT [LPBOOT]	Core/system clock	Bus clock	FlexBus clock	Flash clock	Description
0	0x7 (divide by 8)	0x7 (divide by 8)	0xF (divide by 16)	0xF (divide by 16)	Low power boot
1	0x0 (divide by 1)	0x0 (divide by 1)	0x1 (divide by 2)	0x1 (divide by 2)	Fast clock boot

This gives the user flexibility for a lower frequency, low-power boot option. The flash erased state defaults to fast clocking mode, since where the low power boot (FTFE_FOPT[LPBOOT]) bit resides in flash is logic 1 in the flash erased state.

To enable the low power boot option program FTFE_FOPT[LPBOOT] to zero. During the reset sequence, if LPBOOT is cleared, the system is in a slow clock configuration. Upon any system reset, the clock dividers return to this configurable reset state.

6.5.2 VLPR mode clocking

The clock dividers cannot be changed while in VLPR mode. They must be programmed prior to entering VLPR mode to guarantee:

- the core/system, FlexBus, and bus clocks are less than or equal to 4 MHz, and
- the flash memory clock is less than or equal to 1 MHz

NOTE

When the MCG is in BLPI and clocking is derived from the Fast IRC, the clock divider controls, MCG_SC[FCRDIV] and SIM_CLKDIV1[OUTDIV4], must be programmed such that the resulting flash clock nominal frequency is 800 kHz or less. In this case, one example of correct configuration is MCG_SC[FCRDIV]=000b and SIM_CLKDIV1[OUTDIV4]=0100b, resulting in a divide by 5 setting.

6.6 Clock Gating

The clock to each module can be individually gated on and off using the SIM module's SCGCx registers. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing a module, set the corresponding bit in SCGCx register to enable the clock. Before turning off the clock, make sure to disable the module.

Any bus access to a peripheral that has its clock disabled generates an error termination.

6.7 Module clocks

The following table summarizes the clocks associated with each module.

Table 6-2. Module clocks

Module	Bus interface clock	Internal clocks	I/O interface clocks
Core modules			
ARM Cortex-M4 core	System clock	Core clock	—

6.7.1 PMC 1-kHz LPO clock

The Power Management Controller (PMC) generates a 1-kHz clock that is enabled in all modes of operation, including all low power modes except VLLS0. This 1-kHz source is commonly referred to as LPO clock or 1-kHz LPO clock.

6.7.2 IRC 48MHz clock

The integrated 48 MHz internal reference clock source (IRC48MCLK) is available in High Speed Run, Run, WAIT and Stop modes of operation. IRC48MCLK is also available in Compute Only, PSTOP2 and PSTOP1 modes of operation when entered from Run mode. IRC48MCLK is forced disabled when the MCU transitions into VLPS, LLSx, and VLLSx low power modes.

NOTE

IRC48MCLK is not forced disabled in Stop modes and should be disabled by software prior to Stop entry unless it is required.
IRC48MCLK is not forced disabled in VLPR and should be disabled by software prior to VLPR entry.

IRC48MCLK is enabled via the following control settings while operating in these modes:

- USB Control register enables — enabled when `USB_CLK_RECOVER_IRC_EN[IRC_EN]=1`
- or MCG Control register selects IRC48 MHz clock — enabled when `MCG_C7[OSCSSEL]=10`
- or SIM Control register selects IRC48 MHz clock — enabled when `SIM_SOPT2[PLLFLSEL]=11`
- or QSPI select IRC48MHz clock -- enabled when `QuadSPI_SOCCR[2:0] = 100`

In USB Device applications, the IRC48M block can be enabled in USB Clock Recovery mode in which the internal IRC48M oscillator is tuned to match the clock extracted from the incoming USB data stream. This functionality provides the capability of generating a high precision 48MHz clock source without requiring an on-chip PLL or an associated off-chip crystal circuit.

The IRC48MCLK is also available for use as:

- An oscillator reference to the MCG - from which core, system, bus, and flash clock sources can be derived
- an ADC alternate clock source
- clock source for LPUART communications
- clock source for I2S/SAI communications

6.7.3 WDOG clocking

The WDOG may be clocked from two clock sources as shown in the following figure.

Figure 6-2. WDOG clock generation

6.7.4 Debug trace clock

The debug trace clock source can be clocked as shown in the following figure.

Figure 6-3. Trace clock generation

NOTE

The trace clock frequency observed at the TRACE_CLKOUT pin will be half that of the selected clock source.

6.7.5 PORT digital filter clocking

The digital filters in each of the the PORTD pins can be clocked as shown in the following figure.

NOTE

In stop mode, the digital input filters are bypassed unless they are configured to run from the 1 kHz LPO clock source.

Figure 6-4. PORTx digital input filter clock generation

6.7.6 LPTMR clocking

The prescaler and glitch filters in each of the LPTMR_x modules can be clocked as shown in the following figure.

NOTE

The chosen clock must remain enabled if the LPTMR_x is to continue operating in all required low-power modes.

Figure 6-5. LPTMRx prescaler/glitch filter clock generation

6.7.7 TPM clocking

The counter for the TPM modules have a selectable clock as shown in the following figure.

NOTE

The chosen clock must remain enabled if the TPM_x is to continue operating in all required low-power modes.

Figure 6-6. TPM clock generation

6.7.8 SDHC clocking

Figure 6-7. SDHC clock generation

6.7.9 USB FS OTG Controller clocking

The USB FS OTG controller is a bus master attached to the crossbar switch. As such, it uses the system clock.

NOTE

For the USB FS OTG controller to operate, the minimum system clock frequency is 20 MHz.

The USB OTG controller also requires a 48 MHz clock. The clock source options are shown below.

Figure 6-8. USB 48 MHz clock source

NOTE

The MCGFLLCLK does not meet the USB jitter specifications for certification. The IRC48MCLK is only usable as a USB clock source in USB Device operation with the USB Clock Recover function enabled.

6.7.10 LPUART clocking

Each LPUART module has a selectable clock as shown in the following figure.

NOTE

The chosen clock must remain enabled if the LPUART is to continue operating in all required low-power modes.

Figure 6-9. LPUART clock generation

6.7.11 I²S/SAI clocking

The audio master clock (MCLK) is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The audio master clock can also be output to or input from a pin. The transmitter and receiver have the same audio master clock inputs.

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock.

The I²S/SAI transmitter and receiver support asynchronous bit clocks (BCLKs) that can be generated internally from the audio master clock or supplied externally. The module also supports the option for synchronous operation between the receiver and transmitter product or between two separate I²S/SAI peripherals.

The transmitter and receiver can independently select between the bus clock and the audio master clocks to generate the bit clock.

The MCLK and BCLK source options appear in the following figure.

Figure 6-10. I²S/SAI clock generation

6.7.12 QuadSPI clocking

Figure 6-11. QuadSPI clock generation

DDR mode of the QuadSPI requires a 4x, 2x, and 1x internal reference clock. In DDR mode, the clock divider output is used as the 4x internal reference clock. The 2x and 1x clocks are divided down from that clock.

To generate the maximum 75 MHz flash frequency supported in DDR mode, MCGPLL2XCLK should be 300 MHz with QuadSPIx_MCR[SCLKCFG]=0 to generate the 4x internal clock required.

In SDR mode, the 4x and 2x internal clocks are not used, and the Div 4 divider is bypassed.

6.7.13 TRNG clocking

TRNG is clocked from the bus clock.

6.7.14 FlexIO clocking

The FlexIO timers and shifters have a selectable clock as shown in the following figure.

Figure 6-12. FlexIO clock generation

NOTE

The chosen clock must remain enabled if FlexIO is to continue operation in required low-power modes.

NOTE

FlexIO clock should not be more than twice of FlexIO bus interface clock. For fast access to FlexIO register (FLEXIO_CTRL[FASTACC]=1), FlexIO clock can be twice of FlexIO Bus interface clock.

Chapter 7

Reset and Boot

7.1 Introduction

The following reset sources are supported in this MCU:

Table 7-1. Reset sources

Reset sources	Description
POR reset	• Power-on reset (POR)
System resets	• External pin reset (PIN) • Low-voltage detect (LVD) • Computer operating properly (COP) watchdog reset • Low leakage wakeup (LLWU) reset • Multipurpose clock generator loss of clock (LOC) reset • Multipurpose clock generator loss of lock (LOL) reset • Stop mode acknowledge error (SACKERR) • Software reset (SW) • Lockup reset (LOCKUP) • MDM DAP system reset
Debug reset	• JTAG reset • nTRST reset

Each of the system reset sources has an associated bit in the system reset status (SRS) registers. See the [Reset Control Module](#) for register details.

The MCU exits reset in functional mode where the CPU is executing code. See [Boot options](#) for more details.

7.2 Reset

This section discusses basic reset mechanisms and sources. Some modules that cause resets can be configured to cause interrupts instead. Consult the individual peripheral chapters for more information.

7.2.1 Power-on reset (POR)

When power is initially applied to the MCU or when the supply voltage drops below the power-on reset re-arm voltage level (V_{POR}), the POR circuit causes a POR reset condition.

As the supply voltage rises, the LVD circuit holds the MCU in reset until the V_{DD} supply has risen above the LVD low threshold (V_{LVDL}). The POR and LVD bits in SRS0 register are set following a POR.

It is required that V_{DDIO_E} is powered up after V_{DD} , and powered down prior to V_{DD} power down. In other words, V_{DDIO_E} cannot be powered when V_{DD} is off.

7.2.2 System reset sources

Resetting the MCU provides a way to start processing from a known set of initial conditions. System reset begins with the on-chip regulator in full regulation and system clocking generation from an internal reference. When the processor exits reset, it performs the following:

- Reads the start SP (SP_main) from vector-table offset 0
- Reads the start PC from vector-table offset 4
- LR is set to 0xFFFF_FFFF

The on-chip peripheral modules are disabled and the non-analog I/O pins are initially configured as disabled. The pins with analog functions assigned to them default to their analog function after reset.

During and following a reset, the JTAG pins have their associated input pins configured as:

- TDI in pull-up (PU)
- TCK in pull-down (PD)
- TMS in PU

and associated output pin configured as:

- TDO with no pull-down or pull-up

Note that the nTRST signal is initially configured as disabled, however once configured to its JTAG functionality its associated input pin is configured as:

- nTRST in PU

7.2.2.1 External pin reset (PIN)

On this device, $\overline{\text{RESET}}$ is a dedicated pin. This pin is open drain and has an internal pullup device. Asserting $\overline{\text{RESET}}$ wakes the device from any mode. During a pin reset, the RCM_SRS0[PIN] bit is set.

7.2.2.1.1 $\overline{\text{RESET}}$ pin filter

The $\overline{\text{RESET}}$ pin filter supports filtering from both the 1 kHz LPO clock and the bus clock. RCM_RPFC[RSTFLTSS], RCM_RPFC[RSTFLTSRW], and RCM_RPFW[RSTFLTSEL] control this functionality; see the [RCM](#) chapter. The filters are asynchronously reset by Chip POR. The reset value for each filter assumes the $\overline{\text{RESET}}$ pin is negated.

For all stop modes where LPO clock is still active (Stop, VLPS, LLS, VLLS3, VLLS2, and VLLS1), the only filtering option is the LPO-based digital filter. The filtering logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected. When entering VLLS0, the $\overline{\text{RESET}}$ pin filter is disabled and bypassed.

The LPO filter has a fixed filter value of 3. Due to a synchronizer on the input data, there is also some associated latency (2 cycles). As a result, 5 cycles are required to complete a transition from low to high or high to low.

7.2.2.2 Low-voltage detect (LVD)

The chip includes a system for managing low voltage conditions on the V_{DD} domain to protect memory contents and control MCU system states during supply voltage variations. The system consists of a power-on reset (POR) circuit and an LVD circuit with a user-selectable trip voltage. The LVD system is always enabled in HSRUN, normal run, wait, or stop mode. The LVD system is disabled when entering VLPx, LLS, or VLLSx modes.

The LVD can be configured to generate a reset upon detection of a low voltage condition by setting the PMC_LVDSC1[LVDRE] bit to 1. The low voltage detection threshold is determined by the PMC_LVDSC1[LVDV] field. After an LVD reset has occurred, the LVD system holds the MCU in reset until the supply voltage has risen above the low voltage detection threshold. The RCM_SRS0[LVD] bit is set following either an LVD reset or POR.

NOTE

V_{DDIO_E} domain does not contain LVD circuit.

7.2.2.3 Computer operating properly (COP) watchdog timer

The computer operating properly (COP) watchdog timer (WDOG) monitors the operation of the system by expecting periodic communication from the software. This communication is generally known as servicing (or refreshing) the COP watchdog. If this periodic refreshing does not occur, the watchdog issues a system reset. The COP reset causes the RCM_SRS0[WDOG] bit to set.

7.2.2.4 Low leakage wakeup (LLWU)

The LLWU module provides the means for a number of external pins, the $\overline{\text{RESET}}$ pin, and a number of internal peripherals to wake the MCU from low leakage power modes. The LLWU module is functional only in low leakage power modes.

- In LLS mode, only the $\overline{\text{RESET}}$ pin via the LLWU can generate a system reset.
- In VLLSx modes, all enabled inputs to the LLWU can generate a system reset.

After a system reset, the LLWU retains the flags indicating the input source of the last wakeup until the user clears them.

NOTE

Some flags are cleared in the LLWU and some flags are required to be cleared in the peripheral module. Refer to the individual peripheral chapters for more information.

7.2.2.5 Multipurpose clock generator loss-of-clock (LOC)

The MCG module supports an external reference clock.

If the C6[CME] bit in the MCG module is set, the clock monitor is enabled. If the external reference falls below $f_{\text{loc\_low}}$ or $f_{\text{loc\_high}}$, as controlled by the C2[RANGE] field in the MCG module, the MCU resets. The RCM_SRS0[LOC] bit is set to indicate this reset source.

NOTE

To prevent unexpected loss of clock reset events, all clock monitors should be disabled before entering any low power modes, including VLPR and VLPW.

7.2.2.6 MCG loss-of-lock (LOL) reset

The MCG includes a PLL loss-of-lock detector. The detector is enabled when configured for PEE and lock has been achieved. If the MCG_C8[LOLRE] bit is set and the PLL lock status bit (MCG_S[LOLS0]) becomes set, the MCU resets. The RCM_SRS0[LOL] bit is set to indicate this reset source.

NOTE

This reset source does not cause a reset if the chip is in any stop mode.

7.2.2.7 Stop mode acknowledge error (SACKERR)

This reset is generated if the core attempts to enter stop mode, but not all modules acknowledge stop mode within 1025 cycles of the 1 kHz LPO clock.

A module might not acknowledge the entry to stop mode if an error condition occurs. The error can be caused by a failure of an external clock input to a module.

7.2.2.8 Software reset (SW)

The SYSRESETREQ bit in the NVIC application interrupt and reset control register can be set to force a software reset on the device. (See ARM's NVIC documentation for the full description of the register fields, especially the VECTKEY field requirements). Setting SYSRESETREQ generates a software reset request. This reset forces a system reset of all major components except for the debug module. A software reset causes the RCM_SRS1[SW] bit to set.

7.2.2.9 Lockup reset (LOCKUP)

The LOCKUP gives immediate indication of seriously errant kernel software. This is the result of the core being locked because of an unrecoverable exception following the activation of the processor's built in system state protection hardware.

The LOCKUP condition causes a system reset and also causes the RCM_SRS1[LOCKUP] bit to set.

7.2.2.10 MDM-AP system reset request

Set the system reset request bit in the MDM-AP control register to initiate a system reset. This is the primary method for resets via the JTAG/SWD interface. The system reset is held until this bit is cleared.

Set the core hold reset bit in the MDM-AP control register to hold the core in reset as the rest of the chip comes out of system reset.

7.2.3 MCU Resets

A variety of resets are generated by the MCU to reset different modules.

7.2.3.1 VBAT POR

The VBAT POR asserts on a VBAT POR reset source. It affects only the modules within the VBAT power domain: RTC and VBAT Register File. These modules are not affected by the other reset types.

7.2.3.2 POR Only

The POR Only reset asserts on the POR reset source only. It resets the PMC and System Register File.

The POR Only reset also causes all other reset types (except VBAT POR) to occur.

7.2.3.3 Chip POR not VLLS

The Chip POR not VLLS reset asserts on POR and LVD reset sources. It resets parts of the SMC and SIM. It also resets the LPTMR.

The Chip POR not VLLS reset also causes these resets to occur: Chip POR, Chip Reset not VLLS, and Chip Reset (including Early Chip Reset).

7.2.3.4 Chip POR

The Chip POR asserts on POR, LVD, and VLLS Wakeup reset sources. It resets the Reset Pin Filter registers and parts of the SIM and MCG.

The Chip POR also causes the Chip Reset (including Early Chip Reset) to occur.

7.2.3.5 Chip Reset not VLLS

The "Chip Reset not VLLS" reset asserts on all reset sources except a VLLS Wakeup that does not occur via the RESET_b pin. It resets parts of the SMC, LLWU, and other modules that remain powered during VLLS mode.

7.2.3.6 Early Chip Reset

The Early Chip Reset asserts on all reset sources. It resets only the flash memory module. It negates before flash memory initialization begins ("earlier" than when the Chip Reset negates).

7.2.3.7 Chip Reset

Chip Reset asserts on all reset sources and only negates after flash initialization has completed and the RESET_b pin has also negated. It resets the remaining modules (the modules not reset by other reset types).

7.2.4 Reset Pin

For all reset sources except a VLLS Wakeup that does not occur via the $\overline{\text{RESET}}$ pin, the $\overline{\text{RESET}}$ pin is driven low by the MCU for at least 128 bus clock cycles and until flash initialization has completed.

After flash initialization has completed, the $\overline{\text{RESET}}$ pin is released, and the internal Chip Reset negates after the $\overline{\text{RESET}}$ pin is pulled high. Keeping the $\overline{\text{RESET}}$ pin asserted externally delays the negation of the internal Chip Reset.

7.2.5 Debug resets

The following sections detail the debug resets available on the device.

7.2.5.1 JTAG reset

The JTAG module generate a system reset when certain IR codes are selected. This functional reset is asserted when EXTEST, HIGHZ and CLAMP instructions are active. The reset source from the JTAG module is released when any other IR code is selected. A JTAG reset causes the RCM_SRS1[JTAG] bit to set.

7.2.5.2 nTRST reset

The nTRST pin causes a reset of the JTAG logic when asserted. Asserting the nTRST pin allows the debugger to gain control of the TAP controller state machine (after exiting LLS or VLLSx) without resetting the state of the debug modules.

The nTRST pin does not cause a system reset.

7.2.5.3 Resetting the Debug subsystem

Use the CDBGIRSTREQ bit within the SWJ-DP CTRL/STAT register to reset the debug modules. However, as explained below, using the CDBGIRSTREQ bit does not reset all debug-related registers.

CDBGIRSTREQ resets the debug-related registers within the following modules:

- SWJ-DP
- AHB-AP
- ETM
- TPIU
- MDM-AP (MDM control and status registers)

CDBGIRSTREQ does not reset the debug-related registers within the following modules:

- CM4 core (core debug registers: DHCSR, DCRSR, DCRDR, DEMCR)
- FPB
- DWT
- ITM
- NVIC
- Crossbar bus switch¹
- AHB-AP¹
- Private peripheral bus¹

1. CDBGIRSTREQ does not affect AHB resources so that debug resources on the private peripheral bus are available during System Reset.

7.3 Boot

This section describes the boot sequence, including sources and options.

7.3.1 Boot sources

Based on the source selections in FOPT, the device boots initially to internal Flash or internal BOOT ROM. If BOOT ROM, the device executes in boot loader mode or proceeds with a secondary boot to a QSPI device connected to QSPI0.

7.3.2 Boot options

Because this device has BOOT ROM and no dedicated BOOT mode pin, the device's functional mode is controlled by the BOOT ROM reading the flash option boot source selection located within FOPT register.

7.3.3 FOPT boot options

The flash option register (FOPT) in the flash memory module allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's option byte in the flash configuration field. The user can reprogram the option byte in flash to change the FOPT values that are used for subsequent resets. For more details on programming the option byte, refer to the flash memory chapter.

The MCU uses the FOPT register bits to configure the device at reset as shown in the following table.

NOTE

Reserved bits in the option byte should be left in their default erased state of logic 1. FOPT[7:0] = 0x00 is not a valid

configuration. FOPT register is written to 0xFF if the contents of NVM's option byte in the flash configuration field is 0x00.

Table 7-2. Flash Option Register Bit Definitions

Bit Num	Field	Value	Definition
7-6	BOOTSRC_SEL		Boot Source Selection: these bits select the boot sources if boot pin option bit BOOTPIN_OPT = 1
		00	Boot from Internal Flash
		01	Reserved
		10	Boot from ROM, configure QSPI0, and enter boot loader mode. See Boot sequence for more information
		11	Boot from ROM and enter boot loader mode. See Boot sequence for more information.
5	FAST_INIT		Select initialization speed on POR, VLLSx, and any system reset.
		0	Slower initialization. The Flash initialization will be slower with the benefit of reduced average current during this time. The duration of the recovery will be controlled by the clock divider selection determined by the LPBOOT setting.
		1	Fast Initialization. The Flash has faster recoveries at the expense of higher current during these times.
4-3	Reserved		Reserved for future expansion.
2	NMI_DIS		Enable/disable control for the NMI function.
		0	NMI interrupts are always blocked. The associated pin continues to default to NMI pin controls with internal pullup enabled.
		1	NMI pin/interrupts reset default to enabled.
1	BOOTPIN_OPT		External pin selects boot options
		0	Force Boot from ROM with update if BOOTCFG0 asserted, where BOOTCFG0 is the boot config function which is muxed with NMI pin. The RESET pin should be enabled when this option is selected.
		1	Boot source configured by FOPT[7:6] (BOOTSRC_SEL) bits
0	LPBOOT		Control the reset value of OUTDIVx values in SIM_CLKDIV1 register. Larger divide value selections produce lower average power consumption during POR, VLLSx recoveries and reset sequencing and after reset exit.
		0	Low-power boot: OUTDIVx values in SIM_CLKDIV1 register are auto-configured at reset exit for higher divide values that produce lower power consumption at reset exit. - Core and system clock divider (OUTDIV1) and bus clock divider (OUTDIV2) are 0x7 (divide by 8) - Flash clock divider (OUTDIV4) and FlexBus clock divider (OUTDIV3) are 0xF (divide by 16)
		1	Normal boot: OUTDIVx values in SIM_CLKDIV1 register are auto-configured at reset exit for higher frequency values that produce faster operating frequencies at reset exit. - Core and system clock divider (OUTDIV1) and bus clock divider (OUTDIV2) are 0x0 (divide by 1) - Flash clock divider (OUTDIV4) and FlexBus clock divider (OUTDIV3) are 0x1 (divide by 2)

7.3.4 Boot sequence

At power up, the on-chip regulator holds the system in a POR state until the input supply is above the POR threshold. The system continues to be held in this static state until the internally regulated supplies have reached a safe operating voltage as determined by the LVD. The Mode Controller reset logic then controls a sequence to exit reset.

Figure 7-1. Boot Flow For Devices with QSPI

1. A system reset is held on internal logic, the $\overline{\text{RESET}}$ pin is driven out low, and the MCG is enabled in its default clocking mode.
2. Required clocks are enabled (Core Clock, System Clock, Flash Clock, and any Bus Clocks that do not have clock gate control reset to disabled).
3. The system reset on internal logic continues to be held, but the Flash Controller is released from reset and begins initialization operation while the Reset Control logic continues to drive the $\overline{\text{RESET}}$ pin out low.

4. Early in reset sequencing the NVM option byte is read and stored to the [Flash Memory module's FOPT register](#). Based on the following values, the corresponding actions are taken:
 - a. If the LPBOOT bit is programmed for an alternate clock divider reset value, the system/core clock is switched to a slower clock speed.
 - b. If the FAST_INIT bit is programmed clear, the Flash initialization switches to slower clock resulting longer recovery times.
 - c. If the BOOTPIN_OPT bit is set, the boot source of the device is determined by BOOTSRC_SEL field.
 - d. The BOOTSRC_SEL field determines if the device boots from internal flash, directly from the internal ROM to allow bootloading of firmware, or configuring the QSPI to allow booting from QSPI device.
5. When Flash Initialization completes, the $\overline{\text{RESET}}$ pin is released. If $\overline{\text{RESET}}$ continues to be asserted (an indication of a slow rise time on the $\overline{\text{RESET}}$ pin or external drive in low), the system continues to be held in reset. Once the $\overline{\text{RESET}}$ pin is detected high, the Core clock is enabled and the system is released from reset.
6. If the BOOTSRC_SEL bits indicate a boot from internal flash, when the system exits reset, the processor sets up the stack, program counter (PC), and link register (LR). The processor reads the start SP (SP_main) from vector-table offset 0. The core reads the start PC from vector-table offset 4. LR is set to 0xFFFF_FFFF. What happens next depends on the NMI input and the FOPT[NMI_DIS] field in the Flash Memory module:
 - If the NMI input is high or the NMI function is disabled in the NMI_DIS field, the CPU begins execution at the PC location.
 - If the NMI input is low and the NMI function is enabled in the NMI_DIS field, this results in an NMI interrupt. The processor executes an Exception Entry and reads the NMI interrupt handler address from vector-table offset 8. The CPU begins execution at the NMI interrupt handler.

Subsequent system resets follow this same reset flow.

Chapter 8

Power Management

8.1 Introduction

This chapter describes the various chip power modes and functionality of the individual modules in these modes.

8.2 Clocking modes

Information found here describes the various clocking modes supported on this device.

8.2.1 Partial Stop

Partial Stop is a clocking option that can be taken instead of entering Stop mode and is configured in SMC_STOPCTRL register. The Stop mode is only partially entered, which leaves some additional functionality alive at the expense of higher power consumption. Partial Stop can be entered from either Run mode or VLP Run mode.

When configured for PSTOP2, only the core and system clocks are gated and the bus clock remains active. The bus masters and bus slaves clocked by the system clock enter Stop mode, but the bus slaves clocked by bus clock remain in Run (or VLP Run) mode. The clock generators in the MCG and the on-chip regulator in the PMC also remain in Run (or VLP Run) mode. Exit from PSTOP2 can be initiated by a reset, an asynchronous interrupt from a bus master or bus slave clocked by the system clock, or a synchronous interrupt from a bus slave clocked by the bus clock. If configured, a DMA request (using the asynchronous DMA wakeup) can also be used to exit Partial Stop for the duration of a DMA transfer before the device is transitioned back into PSTOP2.

When configured for PSTOP1, both the system clock and bus clock are gated. All bus masters and bus slaves enter Stop mode, but the clock generators in the MCG and the on-chip regulator in the PMC remain in Run (or VLP Run) mode. Exit from PSTOP1 can be

initiated by a reset or an asynchronous interrupt from a bus master or bus slave. If configured, an asynchronous DMA request can also be used to exit Partial Stop for the duration of a DMA transfer before the device is transitioned back into PSTOP1.

PSTOP1 is functionally similar to Stop mode, but offers faster wake-up at the expense of higher power consumption. Another benefit is that it keeps all of the MCG clocks enabled, which can be useful for some of the asynchronous peripherals that can remain functional in Stop modes.

8.2.2 DMA Wakeup

The DMA can be configured to wake the device on a DMA request whenever it is placed in Stop mode. The wake-up is configured per DMA channel and is supported in Compute Operation, PSTOP, STOP, and VLPS low power modes.

When a DMA wake-up is detected in PSTOP, STOP or VLPS then the device will initiate a normal exit from the low power mode. This can include restoring the on-chip regulator and internal power switches, enabling the clock generators in the MCG, enabling the system and bus clocks (but not the core clock) and negating the stop mode signal to the bus masters and bus slaves. The only difference is that the CPU will remain in the low power mode with the CPU clock disabled.

During Compute Operation, a DMA wake-up will initiate a normal exit from Compute Operation. This includes enabling the clocks and negating the stop mode signal to the bus masters and bus slaves. The core clock always remains enabled during Compute Operation.

Since the DMA wakeup will enable the clocks and negate the stop mode signals to all bus masters and slaves, software needs to ensure that bus masters and slaves that are not involved with the DMA wake-up and transfer remain in a known state. That can be accomplished by disabling the modules before entry into the low power mode or by setting the Doze enable bit in selected modules.

Once the DMA request that initiated the wake-up negates and the DMA completes the current transfer, the device will transition back to the original lowpower mode. This includes requesting all non-CPU bus masters to enter Stop mode and then requesting bus slaves to enter Stop mode. In STOP and VLPS modes, the MCG and PMC would then also enter their appropriate modes.

NOTE

If the requested DMA transfer cannot cause the DMA request to negate then the device will remain in a higher power state until the low power mode is fully exited.

An enabled DMA wake-up can cause an aborted entry into the low power mode, if the DMA request asserts during the stop mode entry sequence (or reentry if the request asserts during a DMA wakeup) and can cause the SMC to assert its Stop Abort flag. Once the DMA wake-up completes, entry into the low power mode will restart.

An interrupt that occurs during a DMA wake-up will cause an immediate exit from the low power mode (this is optional for Compute Operation) without impacting the DMA transfer.

A DMA wake-up can be generated by either a synchronous DMA request or an asynchronous DMA request. Not all peripherals can generate an asynchronous DMA request in stop modes, although in general if a peripheral can generate synchronous DMA requests and also supports asynchronous interrupts in stop modes, then it can generate an asynchronous DMA request.

8.2.3 Compute Operation

Compute Operation is an execution or compute-only mode of operation that keeps the CPU enabled with full access to the SRAM and Flash read port, but places all other bus masters and bus slaves into their stop mode. Compute Operation can be enabled in either Run mode, High Speed Run mode or VLP Run mode.

NOTE

Do not enter any stop mode without first exiting Compute Operation.

Because Compute Operation reuses the stop mode logic (including the staged entry with bus masters disabled before bus slaves), any bus master or bus slave that can remain functional in stop mode also remains functional in Compute Operation, including generation of asynchronous interrupts and DMA requests. When enabling Compute Operation in Run mode, module functionality for bus masters and slaves is the equivalent of STOP mode. When enabling Compute Operation in VLP Run mode, module functionality for bus masters and slaves is the equivalent of VLPS mode. The MCG, PMC, SRAM and Flash read port are not affected by Compute Operation, although the Flash register interface is disabled.

During Compute Operation, the AIPS peripheral, external memory (FlexBus, SDRAM controller) space, and QSPI is disabled and attempted accesses generate bus errors. The private peripheral bus (PPB) remains accessible during Compute Operation, including the MCM, System Control Space (SCS) (for NVIC and FPU), MMCAU and SysTick. Although access to the GPIO registers is supported, the GPIO port data input registers do

not return valid data since clocks are disabled to the Port Control and Interrupt modules. By writing to the GPIO port data output registers, it is possible to control those GPIO ports that are configured as output pins.

Compute Operation is controlled by the CPO register in the MCM, which is only accessible to the CPU. Setting or clearing MCM_CPO[CPOREQ] bit initiates entry or exit into Compute Operation. Compute Operation can also be configured to exit automatically on detection of an interrupt, which is required in order to service most interrupts. Only the core system interrupts (exceptions, including NMI and SysTick) and any edge sensitive interrupts can be serviced without exiting Compute Operation.

When entering Compute Operation, the CPOACK status bit indicates when entry has completed. When exiting Compute Operation in Run mode, the CPOACK status bit negates immediately. When exiting Compute Operation in VLP Run mode, the exit is delayed to allow the PMC to handle the change in power consumption. This delay means the CPOACK bit is polled to determine when the AIPS peripheral space can be accessed without generating a bus error.

The DMA wakeup is also supported during Compute Operation and causes the CPOACK status bit to clear and the AIPS peripheral space to be accessible for the duration of the DMA wakeup. At the completion of the DMA wakeup, the device transitions back into Compute Operation.

8.2.4 Peripheral Doze

Several peripherals support a Peripheral Doze mode, where a register bit can be used to disable the peripheral for the duration of a low-power mode. The flash memory can also be placed in a low-power state during Peripheral Doze via a register bit in the SIM.

Peripheral Doze is defined to include all of the modes of operation listed below.

- The CPU is in Wait mode.
- The CPU is in Stop mode, including the entry sequence and for the duration of a DMA wakeup.
- The CPU is in Compute Operation, including the entry sequence and for the duration of a DMA wakeup.

Peripheral Doze can therefore be used to disable selected bus masters or slaves for the duration of WAIT or VLPW mode. It can also be used to disable selected bus slaves immediately on entry into any stop mode (or Compute Operation), instead of waiting for the bus masters to acknowledge the entry as part of the stop entry sequence. Finally, it can be used to disable selected bus masters or slaves that should remain inactive during a DMA wakeup.

If the flash memory is not being accessed during WAIT and PSTOP modes, then the Flash Doze mode can be used to reduce power consumption, at the expense of a slightly longer wake-up when executing code and vectors from flash. It can also be used to reduce power consumption during Compute Operation when executing code and vectors from SRAM.

8.2.5 Clock Gating

To conserve power, the clocks to most modules can be turned off using the SCGCx registers in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module. Prior to initializing a module, set the corresponding bit in the SCGCx register to enable the clock. Before turning off the clock, ensure that module is disabled. For more details, see [Clock distribution using MCG](#) and [SIM](#) chapters.

8.3 Power Modes Description

The power management controller (PMC) provides multiple power options to allow the user to optimize power consumption for the level of functionality needed.

Depending on the stop requirements of the user application, a variety of stop modes are available that provide state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. [Table 8-1](#) compares the various power modes available.

For Run and VLPR mode there is a corresponding wait and stop mode. Wait modes are similar to ARM[®] sleep modes. Stop modes (VLPS, STOP) are similar to ARM sleep deep mode. The very low power run (VLPR) operating mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

Stop mode entry is not supported directly from HSRUN and requires transition to Run prior to an attempt to enter a stop mode.

The three primary modes of operation are run, wait and stop. The WFI instruction invokes both wait and stop modes for the chip. The primary modes are augmented in a number of ways to provide lower power based on application needs.

Table 8-1. Chip power modes

Chip mode	Description	Core mode	Normal recovery method
Normal run	Default mode out of reset; on-chip voltage regulator is on.	Run	-
High Speed run	Allows maximum performance of chip. In this state, the MCU is able to operate at a faster frequency compared to normal run mode.	Run	-
Normal Wait - via WFI	Allows peripherals to function while the core is in sleep mode, reducing power. NVIC remains sensitive to interrupts; peripherals continue to be clocked.	Sleep	Interrupt
Normal Stop - via WFI	Places chip in static state. Lowest power mode that retains all registers while maintaining LVD protection. NVIC is disabled; AWIC is used to wake up from interrupt; peripheral clocks are stopped.	Sleep Deep	Interrupt
VLPR (Very Low Power Run)	On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency. Reduced frequency Flash access mode (1 MHz); LVD off; internal oscillator provides a low power 4 MHz source for the core, the bus and the peripheral clocks.	Run	-
VLPW (Very Low Power Wait) -via WFI	Same as VLPR but with the core in sleep mode to further reduce power; NVIC remains sensitive to interrupts (FCLK = ON). On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency.	Sleep	Interrupt
VLPS (Very Low Power Stop)-via WFI	Places chip in static state with LVD operation off. Lowest power mode with ADC and pin interrupts functional. Peripheral clocks are stopped, but LPTMR, RTC, CMP , DAC can be used. NVIC is disabled (FCLK = OFF); AWIC is used to wake up from interrupt. On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency. All SRAM is operating (content retained and I/O states held).	Sleep Deep	Interrupt
LLS3 (Low Leakage Stop3)	State retention power mode. Most peripherals are in state retention mode (with clocks stopped), but LLWU, LPTMR, RTC, CMP , DAC can be used. NVIC is disabled; LLWU is used to wake up. NOTE: The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit stop mode on an LLS recovery. All SRAM is operating (content retained and I/O states held).	Sleep Deep	Wakeup Interrupt ¹
LLS2 (Low Leakage Stop2)	State retention power mode. Most peripherals are in state retention mode (with clocks stopped), but LLWU, LPTMR, RTC, CMP , DAC can be used. NVIC is disabled; LLWU is used to wake up. NOTE: The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit stop mode on an LLS recovery. A portion of SRAM_U remains powered on (content retained and I/O states held).	Sleep Deep	Wakeup Interrupt ¹

Table continues on the next page...

Table 8-1. Chip power modes (continued)

Chip mode	Description	Core mode	Normal recovery method
VLLS3 (Very Low Leakage Stop3)	Most peripherals are disabled (with clocks stopped), but LLWU, LPTMR, RTC, CMP, DAC can be used. NVIC is disabled; LLWU is used to wake up. SRAM_U and SRAM_L remain powered on (content retained and I/O states held).	Sleep Deep	Wakeup Reset ²
VLLS2 (Very Low Leakage Stop2)	Most peripherals are disabled (with clocks stopped), but LLWU, LPTMR, RTC, CMP, DAC can be used. NVIC is disabled; LLWU is used to wake up. SRAM_L is powered off. A portion of SRAM_U remains powered on (content retained and I/O states held).	Sleep Deep	Wakeup Reset ²
VLLS1 (Very Low Leakage Stop1)	Most peripherals are disabled (with clocks stopped), but LLWU, LPTMR, RTC, CMP, DAC can be used. NVIC is disabled; LLWU is used to wake up. All of SRAM_U and SRAM_L are powered off. The 32-byte system register file and the 128-byte VBAT register file remain powered for customer-critical data.	Sleep Deep	Wakeup Reset ²
VLLS0 (Very Low Leakage Stop 0)	Most peripherals are disabled (with clocks stopped), but LLWU and RTC can be used. NVIC is disabled; LLWU is used to wake up. All of SRAM_U and SRAM_L are powered off. The 32-byte system register file and the 128-byte VBAT register file remain powered for customer-critical data. The POR detect circuit can be optionally powered off.	Sleep Deep	Wakeup Reset ²
BAT (backup battery only)	The chip is powered down except for the VBAT supply. The RTC and the 128-byte VBAT register file for customer-critical data remain powered.	Off	Power-up Sequence

1. Resumes normal run mode operation by executing the LLWU interrupt service routine.
2. Follows the reset flow with the LLWU interrupt flag set for the NVIC.

8.4 Entering and exiting power modes

The WFI instruction invokes wait and stop modes for the chip. The processor exits the low-power mode via an interrupt. The Nested Vectored Interrupt Controller (NVIC) describes interrupt operation and the peripherals can cause interrupts.

NOTE

The WFE instruction can have the side effect of entering a low-power mode, but that is not its intended usage. See ARM documentation for more on the WFE instruction.

Recovery from VLLSx is through the wake-up Reset event. The chip wake-ups from VLLSx by means of reset, an enabled pin or enabled module. See the table "Wakeup Sources for LLWU inputs" in the [Chip-specific LLWU information](#) for a list of the sources.

The wake-up flow from VLLSx is through reset. The wakeup bit in the SRS registers in the RCM is set indicating that the chip is recovering from a low power mode. Code execution begins; however, the I/O pins are held in their pre low power mode entry states, and the system oscillator and MCG registers are reset (even if EREFSTEN had been set before entering VLLSx). Software must clear this hold by writing a 1 to the ACKISO bit in the Regulator Status and Control Register in the PMC module.

NOTE

To avoid unwanted transitions on the pins, software must re-initialize the I/O pins to their pre-low-power mode entry states *before* releasing the hold.

If the oscillator was configured to continue running during VLLSx modes, it must be re-configured before the ACKISO bit is cleared. The oscillator configuration within the MCG is cleared after VLLSx recovery and the oscillator will stop when ACKISO is cleared unless the register is re-configured.

The IRC48MCLK is not forced disabled in Stop modes and should be disabled by software prior to Stop mode entry unless it is required. The IRC48MCLK is not forced disabled in VLPR and should be disabled by software prior to VLPR entry.

The SDRAM controller should be idle before entering any stop modes. This idle state can be achieved under any one of the following conditions:

- SDRAM controller has never been used
- SDRAM controller has been used, but there is no active command and refresh is not enabled (SDRAM_AC0[RE] = 0 and SDRAM_AC1[RE] = 0)
- SDRAM controller has been used, and the last command was a self-refresh command (SDRAM_CTRL[IS] = 1)

8.5 Power mode transitions

The following figure shows the power mode transitions. Any reset always brings the chip back to the normal run state. In run, wait, and stop modes active power regulation is enabled. The VLPx modes offer a lower power operating mode than normal modes. VLPR and VLPW are limited in frequency. The LLS and VLLSx mode(s) are the lowest power stop modes based on amount of logic or memory that is required to be retained by the application.

Figure 8-1. Power mode state transition diagram

8.6 Power modes shutdown sequencing

When entering stop or other low-power modes, the clocks are shut off in an orderly sequence to safely place the chip in the targeted low-power state. All low-power entry sequences are initiated by the core executing an WFI instruction. The ARM core's outputs, SLEEPDEEP and SLEEPING, trigger entry to the various low-power modes:

- System level wait and VLPW modes equate to: SLEEPING & $\overline{\text{SLEEPDEEP}}$
- All other low power modes equate to: SLEEPING & SLEEPDEEP

When entering the non-wait modes, the chip performs the following sequence:

- Shuts off Core Clock and System Clock to the ARM Cortex-M4 core immediately.
- Polls stop acknowledge indications from the non-core crossbar masters (DMA), supporting peripherals (SPI, PIT, TRNG) and the Flash Controller for indications that System Clocks, Bus Clock and/or Flash Clock need to be left enabled to complete a previously initiated operation, effectively stalling entry to the targeted low power mode. When all acknowledges are detected, System Clock, Bus Clock and Flash Clock are turned off at the same time.
- MCG and Mode Controller shut off clock sources and/or the internal supplies driven from the on-chip regulator as defined for the targeted low power mode.

In wait modes, most of the system clocks are not affected by the low power mode entry. The Core Clock to the ARM Cortex-M4 core is shut off. Some modules support stop-in-wait functionality and have their clocks disabled under these configurations.

The debugger modules support a transition from stop, wait, VLPS, and VLPW back to a halted state when the debugger is enabled. This transition is initiated by setting the Debug Request bit in MDM-AP control register. As part of this transition, system clocking is re-established and is equivalent to normal run/VLPR mode clocking configuration.

8.7 Flash Program Restrictions

The flash memory on this device should not be programmed or erased while operating in High Speed Run or VLPR power modes.

8.8 Module Operation in Low Power Modes

The following table illustrates the functionality of each module while the chip is in each of the low power modes. The standard behavior is shown with some exceptions for Compute Operation (CPO) and Partial Stop2 (PSTOP2).

(Debug modules are discussed separately; see [Debug in Low Power Modes](#).) Number ratings (such as 2 MHz and 1 Mbit/s) represent the maximum frequencies or maximum data rates per mode. Also, these terms are used:

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- Async operation = Fully functional with alternate clock source, provided the selected clock source remains enabled.
- static = Module register states and associated memories are retained.
- powered = Memory is powered to retain contents.
- low power = Memory is powered to retain contents in a lower power state.

- OFF = Modules are powered off; module is in reset state upon wakeup. For clocks, OFF means disabled.
- wakeup = Modules can serve as a wakeup source for the chip.

Table 8-2. Module operation in low power modes

Modules	VLPR	VLPW	Stop	VLPS	LLSx	VLLSx
Core modules						
NVIC	FF	FF	static	static	static	OFF
System modules						
Mode Controller	FF	FF	FF	FF	FF	FF
LLWU ¹	static	static	static	static	FF	FF ²

- Using the LLWU module, the external pins available for this chip do not require the associated peripheral function to be enabled. It only requires the function controlling the pin (GPIO or peripheral) to be configured as an input to allow a transition to occur to the LLWU.
- Since LPO clock source is disabled, filters will be bypassed during VLLS0.
- The SMC_STOPCTRL[PORPO] bit in the SMC module controls this option.
- 32 kB of SRAM_U block is in low power when MCU is in low power modes LLS2 and VLLS2. RAM2-RAM9 are optionally left powered on in low power mode LLS2 and VLLS2 via configuration of PMC_SRAMCTRL[0:7]. The remaining System RAM is OFF in LLS2 and VLLS2.
- These components remain powered in BAT power mode.
- The QSPI module may require specific instructions to enter low power prior to the MCU entering low power.
- Use an externally generated bit clock or an externally generated audio master clock (including EXTAL).
- System OSC and LPO clock sources are not available in VLLS0. Pulse counting is available in all modes.
- RTC_CLKOUT is not available.
- CMP in stop or VLPS supports high speed or low speed external pin to pin or external pin to DAC compares. CMP in LLSx or VLLSx only supports low speed external pin to pin or external pin to DAC compares. Windowed, sampled & filtered modes of operation are not available while in stop, VLPS, LLSx, or VLLSx modes.

NOTE

Modules that are functional in Stop mode are supported during Compute operation

Chapter 9

Flash Security Measures and Module Interactions

9.1 Introduction

This device implements security based on the mode selected from the flash module. The following sections provide an overview of flash security and details the effects of security on non-flash modules.

9.2 Flash Security

The flash module provides security information to the MCU based on the state held by the FSEC[SEC] bits. The MCU, in turn, confirms the security request and limits access to flash resources. During reset, the flash module initializes the FSEC register using data read from the security byte of the flash configuration field.

NOTE

The security features apply only to external accesses via debug. CPU accesses to the flash are not affected by the status of FSEC.

In the unsecured state all flash commands are available to the programming interfaces (JTAG), as well as user code execution of Flash Controller commands. When the flash is secured (FSEC[SEC] = 00, 01, or 11), programmer interfaces are only allowed to launch mass erase operations and have no access to memory locations.

Further information regarding the flash security options and enabling/disabling flash security is available in the [Flash Memory Module](#).

9.3 Security Interactions with other Modules

The flash security settings are used by the SoC to determine what resources are available. The following sections describe the interactions between modules and the flash security settings or the impact that the flash security has on non-flash modules.

9.3.1 Security interactions with FlexBus and SDRAM controller

When flash security is enabled, SIM_SOPT2[FBSL] enables/disables off-chip accesses through the FlexBus and the SDRAM interfaces. The SIM_SOPT2[FBSL] field also has an option to allow opcode and operand accesses or only operand accesses.

9.3.2 Security Interactions with Debug

When flash security is active the JTAG port cannot access the memory resources of the MCU. Boundary scan chain operations work, but debugging capabilities are disabled so that the debug port cannot read flash contents.

Although most debug functions are disabled, the debugger can write to the Flash Mass Erase in Progress bit in the MDM-AP Control register to trigger a mass erase (Erase All Blocks) command. A mass erase via the debugger is allowed even when some memory locations are protected.

When mass erase is disabled, mass erase via the debugger is blocked.

Chapter 10

Debug

10.1 Introduction

This device's debug is based on the ARM coresight architecture and is configured in each device to provide the maximum flexibility as allowed by the restrictions of the pinout and other available resources.

Four debug interfaces are supported:

- IEEE 1149.1 JTAG
- IEEE 1149.7 JTAG (cJTAG)
- Serial Wire Debug (SWD)
- ARM Real-Time Trace Interface(1-pin asynchronous mode only)

The basic Cortex-M4 debug architecture is very flexible. The following diagram shows the topology of the core debug architecture and its components.

10.2 Cortex-M4 Debug Topology with CAU

Figure 10-1. Cortex-M4 Debug Topology with CAU

10.3 Debug Components

The following table presents a brief description of each one of the debug components.

Table 10-1. Debug Components Description

Module	Description
SWJ-DP+ cJTAG	Modified Debug Port with support for SWD, JTAG, cJTAG
AHB-AP	AHB Master Interface from JTAG to debug module and SoC system memory maps
MDM-AP	Provides centralized control and status registers for an external debugger to control the device.
ROM Table	Identifies which debug IP is available.
Core Debug	Singlestep, Register Access, Run, Core Status

Table continues on the next page...

Table 10-1. Debug Components Description (continued)

Module	Description
ETM (Embedded Trace Macrocell)	ETMv3.5 Architecture
ITM	S/W Instrumentation Messaging + Simple Data Trace Messaging + Watchpoint Messaging
DWT (Data and Address Watchpoints)	4 data and address watchpoints
FPB (Flash Patch and Breakpoints)	The FPB implements hardware breakpoints and patches code and data from code space to system space. The FPB unit contains two literal comparators for matching against literal loads from Code space, and remapping to a corresponding area in System space. The FPB also contains six instruction comparators for matching against instruction fetches from Code space, and remapping to a corresponding area in System space. Alternatively, the six instruction comparators can individually configure the comparators to return a Breakpoint Instruction (BKPT) to the processor core on a match, so providing hardware breakpoint capability.
TPIU (Trace Port Interface Unit)	Synchronous Mode (5-pin) = TRACE_D[3:0] + TRACE_CLKOUT Synchronous Mode (3-pin) = TRACE_D[1:0] + TRACE_CLKOUT Asynchronous Mode (1-pin) = TRACE_SWO (available on JTAG_TDO)

10.3.1 References

- ARM ETM Architecture Specification v3.5

10.4 The Debug Port

The configuration of the cJTAG module, JTAG controller, and debug port is illustrated in the following figure:

Figure 10-2. Modified Debug Port

The debug port comes out of reset in standard JTAG mode and is switched into either cJTAG or SWD mode by the following sequences. Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions.

10.4.1 JTAG-to-SWD change sequence

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111_1001_1110_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

NOTE

See the ARM documentation for the CoreSight DAP Lite for restrictions.

10.4.2 JTAG-to-cJTAG change sequence

1. Reset the debug port

2. Set the control level to 2 via zero-bit scans
3. Execute the Store Format (STFMT) command (00011) to set the scan format register to 1149.7 scan format

10.5 Debug Port Pin Descriptions

The debug port pins default after POR to their JTAG functionality with the exception of JTAG_TRST_b and can be later reassigned to their alternate functionalities. In cJTAG and SWD modes JTAG_TDI and JTAG_TRST_b can be configured to alternate GPIO functions.

Table 10-2. Debug port pins

Pin Name	JTAG Debug Port		cJTAG Debug Port		SWD Debug Port		Internal Pull-up\Down
	Type	Description	Type	Description	Type	Description	
JTAG_TMS/ SWD_DIO	I/O	JTAG Test Mode Selection	I/O	cJTAG Data	I/O	Serial Wire Data	Pull-up
JTAG_TCLK/ SWD_CLK	I	JTAG Test Clock	I	cJTAG Clock	I	Serial Wire Clock	Pull-down
JTAG_TDI	I	JTAG Test Data Input	-	-	-	-	Pull-up
JTAG_TDO/ TRACE_SWO	O	JTAG Test Data Output	O	Trace output over a single pin	O	Trace output over a single pin	N/C
JTAG_TRST_b	I	JTAG Reset	I	cJTAG Reset	-	-	Pull-up

10.6 System TAP connection

The system JTAG controller is connected in parallel to the ARM TAP controller. The system JTAG controller IR codes overlay the ARM JTAG controller IR codes without conflict. Refer to the IR codes table for a list of the available IR codes. The output of the TAPs (TDO) are muxed based on the IR code which is selected. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP. At power on reset, ARM's IDCODE (IR=4'b1110) is selected.

10.6.1 IR Codes

Table 10-3. JTAG Instructions

Instruction	Code[3:0]	Instruction Summary
IDCODE	0000	Selects device identification register for shift
SAMPLE/PRELOAD	0010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	0011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	0100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
HIGHZ	1001	Selects bypass register while three-stating all output pins and asserting functional reset
CLAMP	1100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ARM_IDCODE	1110	ARM JTAG-DP Instruction
BYPASS	1111	Selects bypass register for data operations
Factory debug reserved	0101, 0110, 0111, 1101	Intended for factory debug only
ARM JTAG-DP Reserved	1000, 1010, 1011, 1110	These instructions will go the ARM JTAG-DP controller. See ARM JTAG-DP documentation for more information on these instructions.
Reserved ¹	All other opcodes	Decoded to select bypass register

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

10.7 JTAG status and control registers

Through the ARM Debug Access Port (DAP), the debugger has access to the status and control elements, implemented as registers on the DAP bus as shown in the following figure. These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also provide a means for the debugger to get updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

It is important to note that these DAP control and status registers are not memory mapped within the system memory map and are only accessible via the Debug Access Port (DAP) using JTAG, cJTAG, or SWD. The MDM-AP is accessible as Debug Access Port 1 with the available registers shown in the table below.

Table 10-4. MDM-AP Register Summary

Address	Register	Description
0x0100_0000	Status	See MDM-AP Status Register

Table continues on the next page...

Table 10-4. MDM-AP Register Summary (continued)

0x0100_0004	Control	See MDM-AP Control Register
0x0100_00FC	ID	Read-only identification register that always reads as 0x001C_0000

Figure 10-3. MDM AP Addressing

10.7.1 MDM-AP Control Register

Table 10-5. MDM-AP Control register assignments

Bit	Name	Secure ¹	Description
0	Flash Mass Erase in Progress	Y	Set to cause mass erase. Cleared by hardware after mass erase operation completes.

Table continues on the next page...

Table 10-5. MDM-AP Control register assignments (continued)

Bit	Name	Secure ¹	Description
			When mass erase is disabled (via MEEN and SEC settings), the erase request does not occur and the Flash Mass Erase in Progress bit continues to assert until the next system reset.
1	Debug Disable	N	Set to disable debug. Clear to allow debug operation. When set it overrides the C_DEBUGEN bit within the DHCSR and force disables Debug logic.
2	Debug Request	N	Set to force the Core to halt. If the Core is in a stop or wait mode, this bit can be used to wakeup the core and transition to a halted state.
3	System Reset Request	N	Set to force a system reset. The system remains held in reset until this bit is cleared.
4	Core Hold Reset	N	Configuration bit to control Core operation at the end of system reset sequencing. 0 Normal operation - release the Core from reset along with the rest of the system at the end of system reset sequencing. 1 Suspend operation - hold the Core in reset at the end of reset sequencing. Once the system enters this suspended state, clearing this control bit immediately releases the Core from reset and CPU operation begins.
5	VLLSx Debug Request (VLLDBGREQ)	N	Set to configure the system to be held in reset after the next recovery from a VLLSx mode. This bit holds the system in reset when VLLSx modes are exited to allow the debugger time to re-initialize debug IP before the debug session continues. The Mode Controller captures this bit logic on entry to VLLSx modes. Upon exit from VLLSx modes, the Mode Controller will hold the in reset until VLLDBGACK is asserted. The VLLDBGREQ bit clears automatically due to the POR reset generated as part of the VLLSx recovery.
6	VLLSx Debug Acknowledge (VLLDBGACK)	N	Set to release a system being held in reset following a VLLSx recovery This bit is used by the debugger to release the system reset when it is being held on VLLSx mode exit. The debugger re-initializes all debug IP and then assert this control bit to allow the Mode Controller to release the from reset and allow CPU operation to begin. The VLLDBGACK bit is cleared by the debugger or can be left set because it clears automatically due to the POR reset generated as part of the next VLLSx recovery.
7	LLS, VLLSx Status Acknowledge	N	Set this bit to acknowledge the DAP LLS and VLLS Status bits have been read. This acknowledge automatically clears the status bits. This bit is used by the debugger to clear the sticky LLS and VLLSx mode entry status bits. This bit is asserted and cleared by the debugger.
8	Timestamp Disable	N	Set this bit to disable the 48-bit global trace timestamp counter during debug halt mode when the core is halted. 0 The timestamp counter continues to count assuming trace is enabled and the ETM is enabled. (default)

Table continues on the next page...

Table 10-5. MDM-AP Control register assignments (continued)

Bit	Name	Secure ¹	Description
			1 The timestamp counter freezes when the core has halted (debug halt mode).
9 – 31	Reserved for future use	N	

1. Command available in secure mode

10.7.2 MDM-AP Status Register

Table 10-6. MDM-AP Status register assignments

Bit	Name	Description
0	Flash Mass Erase Acknowledge	The Flash Mass Erase Acknowledge bit is cleared after POR or any debug reset. The bit is also cleared at launch of a mass erase command due to write of Flash Mass Erase in Progress bit in MDM AP Control Register. The Flash Mass Erase Acknowledge is set after Flash control logic has started the mass erase operation. When mass erase is disabled (via MEEN and SEC settings), an erase request due to setting of Flash Mass Erase in Progress bit is not acknowledged.
1	Flash Ready	Indicate Flash has been initialized and debugger can be configured even if system is continuing to be held in reset via the debugger.
2	System Security	Indicates the security state. When secure, the debugger does not have access to the system bus or any memory mapped peripherals. This bit indicates when the part is locked and no system bus access is possible.
3	System Reset	Indicates the system reset state. 0 System is in reset 1 System is not in reset
4	Reserved	
5	Mass Erase Enable	Indicates if the MCU can be mass erased or not 0 Mass erase is disabled 1 Mass erase is enabled
6	Backdoor Access Key Enable	Indicates if the MCU has the backdoor access key enabled. 0 Disabled 1 Enabled
7	LP Enabled	Decode of LPLLSM control bits to indicate that VLPS, LLS, or VLLSx are the selected power mode the next time the ARM Core enters Deep Sleep. 0 Low Power Stop Mode is not enabled 1 Low Power Stop Mode is enabled

Table continues on the next page...

Table 10-6. MDM-AP Status register assignments (continued)

Bit	Name	Description
		Usage intended for debug operation in which Run to VLPS is attempted. Per debug definition, the system actually enters the Stop state. A debugger should interpret deep sleep indication (with SLEEPDEEP and SLEEPING asserted), in conjunction with this bit asserted as the debugger-VLPS status indication.
8	Very Low Power Mode	Indicates current power mode is VLPx. This bit is not 'sticky' and should always represent whether VLPx is enabled or not. This bit is used to throttle JTAG TCK frequency up/down.
9	LLS Mode Exit	This bit indicates an exit from LLS mode has occurred. The debugger will lose communication while the system is in LLS (including access to this register). Once communication is reestablished, this bit indicates that the system had been in LLS. Since the debug modules held their state during LLS, they do not need to be reconfigured. This bit is set during the LLS recovery sequence. The LLS Mode Exit bit is held until the debugger has had a chance to recognize that LLS was exited and is cleared by a write of 1 to the LLS, VLLSx Status Acknowledge bit in MDM AP Control register.
10	VLLSx Modes Exit	This bit indicates an exit from VLLSx mode has occurred. The debugger will lose communication while the system is in VLLSx (including access to this register). Once communication is reestablished, this bit indicates that the system had been in VLLSx. Since the debug modules lose their state during VLLSx modes, they need to be reconfigured. This bit is set during the VLLSx recovery sequence. The VLLSx Mode Exit bit is held until the debugger has had a chance to recognize that a VLLS mode was exited and is cleared by a write of 1 to the LLS, VLLSx Status Acknowledge bit in MDM AP Control register.
11 – 15	Reserved for future use	Always read 0.
16	Core Halted	Indicates the Core has entered debug halt mode
17	Core SLEEPDEEP	Indicates the Core has entered a low power mode
18	Core SLEEPING	SLEEPING==1 and SLEEPDEEP==0 indicates wait or VLPW mode. SLEEPING==0 and SLEEPDEEP==1 indicates stop or VLPS mode.
19 – 31	Reserved for future use	Always read 0.

10.8 Debug Resets

The debug system receives the following sources of reset:

- JTAG_TRST_b from an external signal. This signal is optional and may not be available in all packages.
- Debug reset (CDBGIRSTREQ bit within the SWJ-DP CTRL/STAT register) in the TCLK domain that allows the debugger to reset the debug logic.
- TRST asserted via the cJTAG escape command.
- System POR reset

Conversely the debug system is capable of generating system reset using the following mechanism:

- A system reset in the DAP control register which allows the debugger to hold the system in reset.
- SYSRESETREQ bit in the NVIC application interrupt and reset control register
- A system reset in the DAP control register which allows the debugger to hold the Core in reset.

10.9 AHB-AP

AHB-AP provides the debugger access to all memory and registers in the system, including processor registers through the NVIC. System access is independent of the processor status. AHB-AP does not do back-to-back transactions on the bus, so all transactions are non-sequential. AHB-AP can perform unaligned and bit-band transactions. AHB-AP transactions bypass the FPB, so the FPB cannot remap AHB-AP transactions. SWJ/SW-DP-initiated transaction aborts drive an AHB-AP-supported sideband signal called HABORT. This signal is driven into the Bus Matrix, which resets the Bus Matrix state, so that AHB-AP can access the Private Peripheral Bus for last debugging such as read/stop/reset the core. AHB-AP transactions are little endian.

The MPU includes default settings and protections for the Region Descriptor 0 (RGD0) such that the Debugger always has access to the entire address space and those rights cannot be changed by the core or any other bus master.

For a short period at the start of a system reset event the system security status is being determined and debugger access to all AHB-AP transactions is blocked. The MDM-AP Status register is accessible and can be monitored to determine when this initial period is completed. After this initial period, if system reset is held via assertion of the RESET pin, the debugger has access via the bus matrix to the private peripheral bus to configure the debug IP even while system reset is asserted. While in system reset, access to other memory and register resources, accessed over the Crossbar Switch, is blocked.

10.10 ITM

The ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are four sources that can

generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace -- Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace -- The DWT generates these packets, and the ITM emits them.
3. Time stamping -- Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.
4. Global system timestamping. Timestamps can optionally be generated using a system-wide 48-bit count value. The same count value can be used to insert timestamps in the ETM trace stream, allowing coarse-grain correlation.

10.11 Core Trace Connectivity with ETM

Figure 10-4. Core Trace Connectivity with ETM only

The figure above assumes the device contains an ETM.

The following combination paths are supported:

1. ETM -> TPIU (4 pin or 2 pin parallel)
2. ITM -> TPIU (1 pin SWO, 2 pin or 4 pin parallel)
3. ETM & ITM -> TPIU

10.12 Embedded Trace Macrocell v3.5 (ETM)

The Cortex-M4 Embedded Trace Macrocell (ETM-M4) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M4 supports only instruction trace. You can use it either with the Cortex-M4 Trace Port Interface Unit (M4-TPIU).

The main features of an ETM are:

- Tracing of 16-bit and 32-bit Thumb instructions
- Four EmbeddedICE watchpoint inputs
- Trace Start/Stop block with EmbeddedICE inputs
- One reduced function counter
- Two external inputs
- 24-byte FIFO queue
- Global timestamping

10.13 TPIU

The TPIU acts as a bridge between the on-chip trace data from the Embedded Trace Macrocell (ETM) and the Instrumentation Trace Macrocell (ITM), with separate IDs, to a data stream, encapsulating IDs where required, that is then captured by a Trace Port Analyzer (TPA). The TPIU is specially designed for low-cost debug.

10.14 DWT

The DWT is a unit that performs the following debug functionality:

- It contains four comparators that you can configure as a hardware watchpoint, an ETM trigger, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT_COMP1, can also be used as a data comparator.
- The DWT contains counters for:
 - Clock cycles (CYCCNT)
 - Folded instructions
 - Load store unit (LSU) operations
 - Sleep cycles

- CPI (all instruction cycles except for the first cycle)
- Interrupt overhead

NOTE

An event is emitted each time a counter overflows.

- The DWT can be configured to emit PC samples at defined intervals, and to emit interrupt event information.

10.15 Debug in Low Power Modes

In low power modes in which the debug modules are kept static or powered off, the debugger cannot gather any debug data for the duration of the low power mode. In the case that the debugger is held static, the debug port returns to full functionality as soon as the low power mode exits and the system returns to a state with active debug. In the case that the debugger logic is powered off, the debugger is reset on recovery and must be reconfigured once the low power mode is exited.

Power mode entry logic monitors Debug Power Up and System Power Up signals from the debug port as indications that a debugger is active. These signals can be changed in RUN, VLPR, WAIT and VLPW. If the debug signal is active and the system attempts to enter stop or VLPS, FCLK continues to run to support core register access. In these modes in which FCLK is left active the debug modules have access to core registers but not to system memory resources accessed via the crossbar.

With debug enabled, transitions from Run directly to VLPS are not allowed and result in the system entering Stop mode instead. Status bits within the MDM-AP Status register can be evaluated to determine this pseudo-VLPS state. Note with the debug enabled, transitions from Run--> VLPR --> VLPS are still possible but also result in the system entering Stop mode instead.

In VLLS mode all debug modules are powered off and reset at wakeup. In LLS mode, the debug modules retain their state but no debug activity is possible.

NOTE

When using cJTAG and entering LLS mode, the cJTAG controller must be reset on exit from LLS mode.

Going into a VLLSx mode causes all the debug controls and settings to be reset. To give time to the debugger to sync up with the HW, the MDM-AP Control register can be configured hold the system in reset on recovery so that the debugger can regain control and reconfigure debug logic prior to the system exiting reset and resuming operation.

10.15.1 Debug Module State in Low Power Modes

The following table shows the state of the debug modules in low power modes. These terms are used:

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- static = Module register states and associated memories are retained.
- OFF = Modules are powered off; module is in reset state upon wakeup.

Table 10-7. Debug Module State in Low Power Modes

Module	STOP	VLPR	VLPW	VLPS	LLS	VLLSx
Debug Port	FF	FF	FF	OFF	static	OFF
AHB-AP	FF	FF	FF	OFF	static	OFF
ITM	FF	FF	FF	OFF	static	OFF
ETM	FF	FF	FF	OFF	static	OFF
TPIU	FF	FF	FF	OFF	static	OFF
DWT	FF	FF	FF	OFF	static	OFF

10.16 Debug and Security

When security is enabled (FSEC[SEC] != 10), the debug port capabilities are limited in order to prevent exploitation of secure data. In the secure state the debugger still has access to the MDM-AP Status Register and can determine the current security state of the device. In the case of a secure device, the debugger also has the capability of performing a mass erase operation via writes to the MDM-AP Control Register. In the case of a secure device that has mass erase disabled (FSEC[MEEN] = 10), attempts to mass erase via the debug interface are blocked.

Chapter 11

Signal Multiplexing and Signal Descriptions

11.1 Signal Multiplexing Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

The [Port Control](#) block controls which signal is present on the external pin. Reference that chapter to find which register controls the operation of a specific pin.

11.2 Signal Multiplexing Integration

This section summarizes how the module is integrated into the device. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 11-1. Signal multiplexing integration

Table 11-1. Reference links to related information

Topic	Related module	Reference
Full description	Port control	Port control
System memory map		System memory map

Table continues on the next page...

Table 11-1. Reference links to related information (continued)

Topic	Related module	Reference
Clocking		Clock Distribution
Register access	Peripheral bus controller	Peripheral bridge

11.2.1 Port control and interrupt module features

- 32-pin ports

NOTE

Not all pins are available on the device. See the following section for details.

- Each 32-pin port is assigned one interrupt.

Table 11-2. Ports summary

Feature	Port A	Port B	Port C	Port D	Port E
Pull select control	Yes	Yes	Yes	Yes	Yes
Pull select at reset	PTA1/PTA2/PTA3/ PTA4/PTA5=Pull up, Others=Pull down	Pull down	Pull down	Pull down	Pull down
Pull enable control	Yes	Yes	Yes	Yes	Yes
Pull enable at reset	PTA0/PTA1/PTA2/ PTA3/ PTA4=Enabled; Others=Disabled	Disabled	Disabled	Disabled	Disabled
Slew rate enable control	Yes	Yes	Yes	Yes	Yes
Slew rate enable at reset	Disabled	Disabled	Disabled	Disabled	Disabled
Passive filter enable control	PTA4=Yes; Others=No	No	No	No	No
Passive filter enable at reset	Disabled	Disabled	Disabled	Disabled	Disabled
Open drain enable control	Yes	Yes	Yes	Yes	Yes
Open drain enable at reset	Disabled	Disabled	Disabled	Disabled	Disabled
Drive strength enable control	No	PTB0/PTB1 only	PTC3/PTC4/ PTC24/PTC25/ PTC26/PTC27/ PTC28/PTC29 only	PTD4/PTD5/PTD6/ PTD7 only	Yes

Table continues on the next page...

Table 11-2. Ports summary (continued)

Feature	Port A	Port B	Port C	Port D	Port E
Drive strength enable at reset	Disabled	Disabled	Disabled	Disabled	Disabled
Pin mux control	Yes	Yes	Yes	Yes	Yes
Pin mux at reset	PTA0/PTA1/PTA2/ PTA3/PTA4=ALT7; Others=ALT0	ALT0	ALT0	ALT0	ALT0
Lock bit	Yes	Yes	Yes	Yes	Yes
Interrupt and DMA request	Yes	Yes	Yes	Yes	Yes
Digital glitch filter	No	No	No	Yes	No

NOTE

Port E has separate power domain to support QSPI flash

11.2.2 Clock gating

The clock to the port control module can be gated on and off using the SCGC5[PORTx] bits in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing the corresponding module, set SCGC5[PORTx] in the SIM module to enable the clock. Before turning off the clock, make sure to disable the module. For more details, see [Clock distribution](#) chapter.

11.2.3 Signal multiplexing constraints

1. A given peripheral function must be assigned to a maximum of one package pin. Do not program the same function to more than one pin.
2. To ensure the best signal timing for a given peripheral's interface, choose the pins in closest proximity to each other.

11.3 Pinout**11.3.1 K27F Signal Multiplexing and Pin Assignments**

The signal multiplexing and pin assignments are provided in an Excel file attached to this document:

1. Click the paperclip symbol on the left side of the PDF window.
2. Double-click on the Excel file to open it.
3. Select the “Pinout” tab.

The Port Control Module is responsible for selecting which ALT functionality is available on each pin.

11.3.2 K27F Pinouts

The pinout diagrams are provided in an Excel file attached to this document:

1. Click the paperclip symbol on the left side of the PDF window.
2. Double-click on the Excel file to open it.
3. Select the respective package tab.

Many signals may be multiplexed onto a single pin. To determine what signals can be used on which pin, see the previous section.

11.4 Module Signal Description Tables

The following sections correlate the chip-level signal name with the signal name used in the module's chapter. They also briefly describe the signal function and direction.

11.4.1 Core Modules

Table 11-3. JTAG Signal Descriptions

Chip signal name	Module signal name	Description	I/O
JTAG_TMS	JTAG_TMS/ SWD_DIO	JTAG Test Mode Selection	I
JTAG_TCLK	JTAG_TCLK/ SWD_CLK	JTAG Test Clock	I
JTAG_TDI	JTAG_TDI	JTAG Test Data Input	I
JTAG_TDO	JTAG_TDO/ TRACE_SWO	JTAG Test Data Output	O
JTAG_TRST	JTAG_TRST_b	JTAG Reset	I

Table 11-4. SWD Signal Descriptions

Chip signal name	Module signal name	Description	I/O
SWD_DIO	JTAG_TMS/ SWD_DIO	Serial Wire Data	I
SWD_CLK	JTAG_TCLK/ SWD_CLK	Serial Wire Clock	I

Table 11-5. TPIU Signal Descriptions

Chip signal name	Module signal name	Description	I/O
TRACE_CLKOUT	TRACECLK	Trace clock output from the ARM CoreSight debug block	O
TRACE_D[3:2]	TRACEDATA	Trace output data from the ARM CoreSight debug block used for 5-pin interface	O
TRACE_D[1:0]	TRACEDATA	Trace output data from the ARM CoreSight debug block used for both 5-pin and 3-pin interfaces	O
TRACE_SWO	JTAG_TDO/ TRACE_SWO	Trace output data from the ARM CoreSight debug block over a single pin	O

11.4.2 System Modules

Table 11-6. System Signal Descriptions

Chip signal name	Module signal name	Description	I/O
NMI	—	Non-maskable interrupt NOTE: Driving the $\overline{\text{NMI}}$ signal low forces a non-maskable interrupt, if the $\overline{\text{NMI}}$ function is selected on the corresponding pin.	I
RESET	—	Reset bi-directional signal	I/O
VDD	—	MCU power	I
VSS	—	MCU ground	I

Table 11-7. EWM Signal Descriptions

Chip signal name	Module signal name	Description	I/O
EWM_IN	EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low.	I
EWM_OUT	EWM_out	EWM reset out signal	O

11.4.3 Clock Modules

Table 11-8. OSC Signal Descriptions

Chip signal name	Module signal name	Description	I/O
EXTAL0	EXTAL	External clock/Oscillator input	I
XTAL0	XTAL	Oscillator output	O

Table 11-9. RTC OSC Signal Descriptions

Chip signal name	Module signal name	Description	I/O
EXTAL32	EXTAL32	32.768 kHz oscillator input	I
XTAL32	XTAL32	32.768 kHz oscillator output	O

11.4.4 Memories and Memory Interfaces

Table 11-10. FlexBus Signal Descriptions

Chip signal name	Module signal name	Description	I/O
CLKOUT	FB_CLK	FlexBus Clock Output	O
FB_A[29:16]	FB_A[29:16]	Address Bus When FlexBus is used in a multiplexed configuration, this bus is not used.	O
FB_AD[31:0] ¹	FB_AD31 - FB_AD0	This is the address and data bus, FB_AD. The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select. The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0.	I/O
FB_CS[5:0] ²	FB_CS5–FB_CS0	General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].	O
FB_BE31_24_BLS7_0, FB_BE23_16_BLS15_8,	FB_BE_31_24 FB_BE_23_16 FB_BE_15_8	Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.	O

Table continues on the next page...

**Table 11-10. FlexBus Signal Descriptions
(continued)**

Chip signal name	Module signal name	Description	I/O
FB_BE15_8_BLS23_16, FB_BE7_0_BLS31_24 ³	FB_BE_7_0	For external SRAM or flash devices, the FB_BE outputs should be connected to individual byte strobe signals.	
FB_OE	FB_OE	Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.	O
FB_R $\overline{W}$	FB_R/ $\overline{W}$	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/ $\overline{W}$ high) or a write operation (FB_R/ $\overline{W}$ low).	O
FB_TS/ FB_ALE	FB_TS	Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. An inverted $\overline{FB\_TS}$ is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus. FB_TS/FB_ALE is asserted for one bus clock cycle. The chip can extend this signal until the first positive clock edge after $\overline{FB\_CS}$ asserts. See CSCR[EXTS] and Extended Transfer Start/Address Latch Enable.	O
FB_TSIZE[1:0]	FB_TSIZE1–FB_TSIZE0	Transfer Size—Indicates (along with FB_TBST) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports. • 00b = 4 bytes • 01b = 1 byte • 10b = 2 bytes • 11b = 16 bytes (line) For misaligned transfers, FB_TSIZE1–FB_TSIZE0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZE1–FB_TSIZE0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZE1–FB_TSIZE0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZE1–FB_TSIZE0 = 01b). For aligned transfers larger than the port size, FB_TSIZE1–FB_TSIZE0 behave as follows: • If bursting is used, FB_TSIZE1–FB_TSIZE0 are driven to the transfer size. • If bursting is inhibited, FB_TSIZE1–FB_TSIZE0 first show the entire transfer size and then show the port size. For burst-inhibited transfers, FB_TSIZE1–FB_TSIZE0 change with each FB_TS assertion to reflect the next transfer size. For transfers to port sizes smaller than the transfer size, FB_TSIZE1–FB_TSIZE0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent	O

Table continues on the next page...

**Table 11-10. FlexBus Signal Descriptions
(continued)**

Chip signal name	Module signal name	Description	I/O
		transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.	
FB_TA ⁴	FB_TA	Transfer Acknowledge—Indicates that the external data transfer is complete. When FB_TA is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When FB_TA is asserted during a write transfer, the transfer is terminated. If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives FB_TA to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), FB_TA is generated internally after a specified number of wait states, or the external memory or peripheral may assert external FB_TA before the wait-state countdown to terminate the transfer early. The chip deasserts FB_CS one cycle after the last FB_TA is asserted. During read transfers, the external memory or peripheral must continue to drive data until FB_TA is recognized. For write transfers, the chip continues driving data one clock cycle after FB_CS is deasserted. The number of wait states is determined by CSCR or the external FB_TA input. If the external FB_TA is used, the external memory or peripheral has complete control of the number of wait states. Note: External memory or peripherals should assert FB_TA only while the FB_CS signal to the external memory or peripheral is asserted. The CSPMCR register controls muxing of FB_TA with other signals. When the CSPMCR register does not allow fb_ta control, auto-acknowledge must be used (CSCR[AA] = 1'b1); otherwise the bus may hang.	I
FB_TBST	FB_TBST	Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size. Note: When a burst transfer is in progress (FB_TBST = 0b), the transfer size is 16 bytes (FB_TSIZ1–FB_TSIZ0 = 11b), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.	O

1. FB_AD[23:21] not available on 100-LQFP devices.
2. FB_CS3 not available on 100-LQFP devices.
3. FB_BE7_0_BLS31_24 not available on 100-LQFP devices.
4. FB_TA not available on 100-LQFP devices.

Table 11-11. SDRAM SDR Controller Signal Descriptions

Chip signal name	Module signal name	Description	I/O
SDRAM_RAS	SRAS	Synchronous row address strobe. Indicates a valid SDRAM row address is present and can be latched by the SDRAM. $\overline{\text{SRAS}}$ should be connected to the corresponding SDRAM $\overline{\text{SRAS}}$.	O
SDRAM_CAS	SCAS	Synchronous column address strobe. Indicates a valid column address is present and can be latched by the SDRAM. $\overline{\text{SCAS}}$ should be connected to the corresponding SDRAM $\overline{\text{SCAS}}$.	O
SDRAM_WE	$\overline{\text{DRAMW}}$	DRAM read/write. Asserted for write operations and negated for read operations.	O
SDRAM_A[23:9]	SDRAM_A [23:9]	SDRAM address bus output	O
SDRAM_D[31:0]	SDRAM_D [31:0]	SDRAM data bus	I/O
SDRAM_CS[1:0]	SDRAM_CS[1:0]	Row address strobe. Select each memory block of SDRAMs connected to the controller. One $\overline{\text{SDRAM\_CS}}$ signal selects one SDRAM block and connects to the corresponding CS signals.	O
SDRAM_CKE	SCKE	Synchronous DRAM clock enable. Connected directly to the CKE (clock enable) signal of SDRAMs. Enables and disables the clock internal to SDRAM. When CKE is low, memory can enter a power-down mode in which operations are suspended or capable of entering self-refresh mode.	O
SDRAM_DQM[3:0]	BS[3:0]	SDRAM byte selects BS[3:0] function as byte enables to the SDRAMs. They connect to the DQM signals (or data qualifier masks) of the SDRAMs.	O

Table 11-36. I²C0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
I2C0_SCL	SCL	Bidirectional serial clock line of the I ² C system.	I/O
I2C0_SDA	SDA	Bidirectional serial data line of the I ² C system.	I/O

Table 11-37. I²C1 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
I2C1_SCL	SCL	Bidirectional serial clock line of the I ² C system.	I/O
I2C1_SDA	SDA	Bidirectional serial data line of the I ² C system.	I/O

Table 11-38. I²C2 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
I2C2_SCL	SCL	Bidirectional serial clock line of the I ² C system.	I/O
I2C2_SDA	SDA	Bidirectional serial data line of the I ² C system.	I/O

Table 11-39. I²C3 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
I2C3_SCL	SCL	Bidirectional serial clock line of the I ² C system.	I/O
I2C3_SDA	SDA	Bidirectional serial data line of the I ² C system.	I/O

Table 11-40. LPUART0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
LPUART0_CTS_b	CTS	Clear to Send	I
LPUART0_RTS_b	RTS	Request to send	O
LPUART0_TX	TXD	Transmit Data	O
LPUART0_RX	RXD	Receive Data	I

Table 11-41. LPUART1 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
LPUART1_CTS_b	CTS	Clear to Send	I
LPUART1_RTS_b	RTS	Request to send	O
LPUART1_TX	TXD	Transmit Data	O
LPUART1_RX	RXD	Receive Data	I

Table 11-42. LPUART2 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
LPUART2_CTS_b	CTS	Clear to Send	I
LPUART2_RTS_b	RTS	Request to send	O
LPUART2_TX	TXD	Transmit Data	O
LPUART2_RX	RXD	Receive Data	I

Table 11-43. LPUART3 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
LPUART3_CTS_b	CTS	Clear to Send	I
LPUART3_RTS_b	RTS	Request to send	O
LPUART3_TX	TXD	Transmit Data	O
LPUART3_RX	RXD	Receive Data	I

Table 11-44. LPUART4 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
LPUART4_CTS_b	CTS	Clear to Send	I
LPUART4_RTS_b	RTS	Request to send	O
LPUART4_TX	TXD	Transmit Data	O
LPUART4_RX	RXD	Receive Data	I

Table 11-45. SDHC Signal Descriptions

Chip signal name	Module signal name	Description	I/O
SDHC0_CLKIN	—	SDHC clock input	I
SDHC0_DCLK	SDHC_DCLK	Generated clock used to drive the MMC, SD, SDIO or CE-ATA cards.	O
SDHC0_CMD	SDHC_CMD	Send commands to and receive responses from the card.	I/O
SDHC0_D0	SDHC_D0	DAT0 line or busy-state detect	I/O
SDHC0_D1	SDHC_D1	8-bit mode: DAT1 line 4-bit mode: DAT1 line or interrupt detect 1-bit mode: Interrupt detect	I/O
SDHC0_D2	SDHC_D2	4-/8-bit mode: DAT2 line or read wait 1-bit mode: Read wait	I/O
SDHC0_D3	SDHC_D3	4-/8-bit mode: DAT3 line or configured as card detection pin 1-bit mode: May be configured as card detection pin	I/O
SDHC0_D4	SDHC_D4	DAT4 line in 8-bit mode Not used in other modes	I/O
SDHC0_D5	SDHC_D5	DAT5 line in 8-bit mode Not used in other modes	I/O
SDHC0_D6	SDHC_D6	DAT6 line in 8-bit mode Not used in other modes	I/O
SDHC0_D7	SDHC_D7	DAT7 line in 8-bit mode Not used in other modes	I/O

Table 11-46. I2S0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
I2S0_MCLK	SAI_MCLK	Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.	I/O
I2S0_RX_BCLK	SAI_RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
I2S0_RX_FS	SAI_RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
I2S0_RXD	SAI_RX_DATA[1:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I
I2S0_TX_BCLK	SAI_TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
I2S0_TX_FS	SAI_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
I2S0_TXD	SAI_TX_DATA[1:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O

Table 11-47. I2S1 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
I2S1_MCLK	SAI_MCLK	Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.	I/O
I2S1_RX_BCLK	SAI_RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
I2S1_RX_FS	SAI_RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
I2S1_RXD	SAI_RX_DATA[1:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I
I2S1_TX_BCLK	SAI_TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
I2S1_TX_FS	SAI_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
I2S1_TXD	SAI_TX_DATA[1:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O

Table 11-48. FlexIO Signal Descriptions

Chip signal name	Module signal name	Description	I/O
FXIO0_Dn(n=0...31)	"FXIO_D"	"Bidirectional FlexIO Shifter and Timer pin inputs/outputs"	I/O

11.4.9 Human-Machine Interfaces (HMI)

Table 11-49. GPIO Signal Descriptions

Chip signal name	Module signal name	Description	I/O
PTA[31:0] ¹	PORTA31–PORTA0	General-purpose input/output	I/O
PTB[31:0] ¹	PORTB31–PORTB0	General-purpose input/output	I/O
PTC[31:0] ¹	PORTC31–PORTC0	General-purpose input/output	I/O
PTD[31:0] ¹	PORTD31–PORTD0	General-purpose input/output	I/O
PTE[31:0] ¹	PORTE31–PORTE0	General-purpose input/output	I/O

1. The available GPIO pins depends on the specific package. See the signal multiplexing section for which exact GPIO signals are available.

Chapter 12

Port Control and Interrupts (PORT)

12.1 Introduction

12.2 Overview

The Port Control and Interrupt (PORT) module provides support for port control, digital filtering, and external interrupt functions.

Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

12.2.1 Features

The PORT module has the following features:

- Pin interrupt
 - Interrupt flag and enable registers for each pin
 - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
 - Support for interrupt or DMA request configured per pin
 - Asynchronous wake-up in low-power modes
 - Pin interrupt is functional in all digital pin muxing modes
- Digital input filter on selected pins
 - Digital input filter for each pin, usable by any digital peripheral muxed onto the pin
 - Individual enable or bypass control field per pin

- Selectable clock source for digital input filter with a five bit resolution on filter size
- Functional in all digital pin multiplexing modes
- Port control
 - Individual pull control fields with pullup, pulldown, and pull-disable support
 - Individual drive strength field supporting high and low drive strength
 - Individual slew rate field supporting fast and slow slew rates
 - Individual input passive filter field supporting enable and disable of the individual input passive filter
 - Individual open drain field supporting enable and disable of the individual open drain output
 - Individual mux control field supporting analog or pin disabled, GPIO, and up to six chip-specific digital functions
 - Pad configuration fields are functional in all digital pin muxing modes.

12.2.2 Modes of operation

12.2.2.1 Run mode

In Run mode, the PORT operates normally.

12.2.2.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

12.2.2.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

In Stop mode, the digital input filters are bypassed unless they are configured to run from the LPO clock source.

12.2.2.4 Debug mode

In Debug mode, PORT operates normally.

12.3 External signal description

The table found here describes the PORT external signal.

Table 12-1. Signal properties

Name	Function	I/O	Reset	Pull
PORTx[31:0]	External interrupt	I/O	0	-

NOTE

Not all pins within each port are implemented on each device.

12.4 Detailed signal description

The table found here contains the detailed signal description for the PORT interface.

Table 12-2. PORT interface—detailed signal description

Signal	I/O	Description	
PORTx[31:0]	I/O	External interrupt.	
		State meaning	Asserted—pin is logic 1. Negated—pin is logic 0.
		Timing	Assertion—may occur at any time and can assert asynchronously to the system clock. Negation—may occur at any time and can assert asynchronously to the system clock.

12.5 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

PORT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4004_9000	Pin Control Register n (PORTA_PCR0)	32	R/W	See section	12.5.1/160

12.5.1 Pin Control Register n (PORTx_PCRn)

NOTE

See the Signal Multiplexing and Pin Assignment chapter for the reset value of this device.

See the GPIO Configuration section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins that are not available in a reduced-pin package offering. Unbonded pins not available in a package are disabled by default to prevent them from consuming power.

PORTx_PCRn field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 ISF	Interrupt Status Flag The pin interrupt configuration is valid in all digital pin muxing modes.

Table continues on the next page...

PORTx_PCRn field descriptions (continued)

Field	Description
	0 Configured interrupt is not detected. 1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 IRQC	Interrupt Configuration The pin interrupt configuration is valid in all digital pin muxing modes. The corresponding pin is configured to generate interrupt/DMA request as follows: 0000 Interrupt Status Flag (ISF) is disabled. 0001 ISF flag and DMA request on rising edge. 0010 ISF flag and DMA request on falling edge. 0011 ISF flag and DMA request on either edge. 0100 Reserved. 0101 Reserved. 0110 Reserved. 0111 Reserved. 1000 ISF flag and Interrupt when logic 0. 1001 ISF flag and Interrupt on rising-edge. 1010 ISF flag and Interrupt on falling-edge. 1011 ISF flag and Interrupt on either edge. 1100 ISF flag and Interrupt when logic 1. 1101 Reserved. 1110 Reserved. 1111 Reserved.
15 LK	Lock Register 0 Pin Control Register fields [15:0] are not locked. 1 Pin Control Register fields [15:0] are locked and cannot be updated until the next system reset.
14–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 MUX	Pin Mux Control Not all pins support all pin muxing slots. Unimplemented pin muxing slots are reserved and may result in configuring the pin for a different pin muxing slot. The corresponding pin is configured in the following pin muxing slot as follows: 000 Pin disabled (Alternative 0) (analog). 001 Alternative 1 (GPIO). 010 Alternative 2 (chip-specific). 011 Alternative 3 (chip-specific). 100 Alternative 4 (chip-specific). 101 Alternative 5 (chip-specific). 110 Alternative 6 (chip-specific). 111 Alternative 7 (chip-specific).

Table continues on the next page...

PORTx_PCRn field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 DSE	Drive Strength Enable Drive strength configuration is valid in all digital pin muxing modes. 0 Low drive strength is configured on the corresponding pin, if pin is configured as a digital output. 1 High drive strength is configured on the corresponding pin, if pin is configured as a digital output.
5 ODE	Open Drain Enable Open drain configuration is valid in all digital pin muxing modes. 0 Open drain output is disabled on the corresponding pin. 1 Open drain output is enabled on the corresponding pin, if the pin is configured as a digital output.
4 PFE	Passive Filter Enable Passive filter configuration is valid in all digital pin muxing modes. 0 Passive input filter is disabled on the corresponding pin. 1 Passive input filter is enabled on the corresponding pin, if the pin is configured as a digital input. Refer to the device data sheet for filter characteristics.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 SRE	Slew Rate Enable Slew rate configuration is valid in all digital pin muxing modes. 0 Fast slew rate is configured on the corresponding pin, if the pin is configured as a digital output. 1 Slow slew rate is configured on the corresponding pin, if the pin is configured as a digital output.
1 PE	Pull Enable Pull configuration is valid in all digital pin muxing modes. 0 Internal pullup or pulldown resistor is not enabled on the corresponding pin. 1 Internal pullup or pulldown resistor is enabled on the corresponding pin, if the pin is configured as a digital input.
0 PS	Pull Select Pull configuration is valid in all digital pin muxing modes. 0 Internal pulldown resistor is enabled on the corresponding pin, if the corresponding PE field is set. 1 Internal pullup resistor is enabled on the corresponding pin, if the corresponding PE field is set.

12.5.2 Global Pin Control Low Register (PORTx_GPCLR)

Only 32-bit writes are supported to this register.

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PORTx_GPCHR field descriptions

Field	Description
31–16 GPWE	Global Pin Write Enable Selects which Pin Control Registers (31 through 16) bits [15:0] update with the value in GPWD. If a selected Pin Control Register is locked then the write to that register is ignored. 0 Corresponding Pin Control Register is not updated with the value in GPWD. 1 Corresponding Pin Control Register is updated with the value in GPWD.
GPWD	Global Pin Write Data Write value that is written to all Pin Control Registers bits [15:0] that are selected by GPWE.

12.5.4 Interrupt Status Flag Register (PORTx_ISFR)

The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Pin Control Register, and each flag can be cleared in either location.

Address: Base address + A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PORTx_ISFR field descriptions

Field	Description
ISF	Interrupt Status Flag Each bit in the field indicates the detection of the configured interrupt of the same number as the field. 0 Configured interrupt is not detected. 1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.

12.5.5 Digital Filter Enable Register (PORTx_DFER)

The corresponding bit is read only for pins that do not support a digital filter. Refer to the Chapter of Signal Multiplexing and Signal Descriptions for the pins that support digital filter.

The digital filter configuration is valid in all digital pin muxing modes.

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PORTx_DFER field descriptions

Field	Description
DFE	Digital Filter Enable

PORTx_DFER field descriptions (continued)

Field	Description
	The digital filter configuration is valid in all digital pin muxing modes. The output of each digital filter is reset to zero at system reset and whenever the digital filter is disabled. Each bit in the field enables the digital filter of the same number as the field.
0	Digital filter is disabled on the corresponding pin and output of the digital filter is reset to zero.
1	Digital filter is enabled on the corresponding pin, if the pin is configured as a digital input.

12.5.6 Digital Filter Clock Register (PORTx_DFCR)

This register is read only for ports that do not support a digital filter.

The digital filter configuration is valid in all digital pin muxing modes.

Address: Base address + C4h offset

PORTx_DFCR field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CS	Clock Source The digital filter configuration is valid in all digital pin muxing modes. Configures the clock source for the digital input filters. Changing the filter clock source must be done only when all digital filters are disabled. 0 Digital filters are clocked by the bus clock. 1 Digital filters are clocked by the LPO clock.

12.5.7 Digital Filter Width Register (PORTx_DFWR)

This register is read only for ports that do not support a digital filter.

The digital filter configuration is valid in all digital pin muxing modes.

Functional description

Address: Base address + C8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PORTx_DFWR field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FILT	Filter Length The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches, in clock cycles, that the digital filter absorbs for the enabled digital filters. Glitches that are longer than this register setting will pass through the digital filter, and glitches that are equal to or less than this register setting are filtered. Changing the filter length must be done only after all filters are disabled.

12.6 Functional description

12.6.1 Pin control

Each port pin has a corresponding Pin Control register, PORT_PCRn, associated with it.

The upper half of the Pin Control register configures the pin's capability to either interrupt the CPU or request a DMA transfer, on a rising/falling edge or both edges as well as a logic level occurring on the port pin. It also includes a flag to indicate that an interrupt has occurred.

The lower half of the Pin Control register configures the following functions for each pin within the 32-bit port.

- Pullup or pulldown enable
- Drive strength and slew rate configuration
- Open drain enable
- Passive input filter enable
- Pin Muxing mode

The functions apply across all digital pin muxing modes and individual peripherals do not override the configuration in the Pin Control register. For example, if an I²C function is enabled on a pin, that does not override the pullup or open drain configuration for that pin.

When the Pin Muxing mode is configured for analog or is disabled, all the digital functions on that pin are disabled. This includes the pullup and pulldown enables, output buffer enable, input buffer enable, and passive filter enable.

The LK bit (bit 15 of Pin Control Register PCR_n) allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that pin control register are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each Pin Control register is retained when the PORT module is disabled.

Whenever a pin is configured in any digital pin muxing mode, the input buffer for that pin is enabled allowing the pin state to be read via the corresponding GPIO Port Data Input Register (GPIO_PDIR) or allowing a pin interrupt or DMA request to be generated. If a pin is ever floating when its input buffer is enabled, then this can cause an increase in power consumption and must be avoided. A pin can be floating due to an input pin that is not connected or an output pin that has tri-stated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) will ensure a pin does not float when its input buffer is enabled; note that the internal pull resistor is automatically disabled whenever the output buffer is enabled allowing the Pull Enable bit to remain set. Configuring the Pin Muxing mode to disabled or analog will disable the pin's input buffer and results in the lowest power consumption.

12.6.2 Global pin control

The two global pin control registers allow a single register write to update the lower half of the pin control register on up to 16 pins, all with the same value. Registers that are locked cannot be written using the global pin control registers.

The global pin control registers are designed to enable software to quickly configure multiple pins within the one port for the same peripheral function. However, the interrupt functions cannot be configured using the global pin control registers.

The global pin control registers are write-only registers, that always read as 0.

12.6.3 External interrupts

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Active high level sensitive interrupt
- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin or at the output of the digital input filter, if the digital input digital filter is enabled. When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT_ISFR or PORT_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

12.6.4 Digital filter

The digital filter capabilities of the PORT module are available in all digital Pin Muxing modes if the PORT module is enabled.

The clock used for all digital filters within one port can be configured between the bus clock or the LPO clock. This selection must be changed only when all digital filters for that port are disabled. If the digital filters for a port are configured to use the bus clock, then the digital filters are bypassed for the duration of Stop mode. While the digital filters

are bypassed, the output of each digital filter always equals the input pin, but the internal state of the digital filters remains static and does not update due to any change on the input pin.

The filter width in clock size is the same for all enabled digital filters within one port and must be changed only when all digital filters for that port are disabled.

The output of each digital filter is logic zero after system reset and whenever a digital filter is disabled. After a digital filter is enabled, the input is synchronized to the filter clock, either the bus clock or the LPO clock. If the synchronized input and the output of the digital filter remain different for a number of filter clock cycles equal to the filter width register configuration, then the output of the digital filter updates to equal the synchronized filter input.

The maximum latency through a digital filter equals three filter clock cycles plus the filter width configuration register.

Chapter 13

System Integration Module (SIM)

13.1 Introduction

The System Integration Module (SIM) provides system control and chip configuration registers.

13.1.1 Features

Features of the SIM include:

- System clocking configuration
 - System clock divide values
 - Architectural clock gating control
 - USB clock selection and divide values
 - SDHC clock source selection
- Flash and system RAM size configuration
- USB regulator configuration
- FlexTimer external clock, hardware trigger, and fault source selection
- UART0 and UART1 receive/transmit source selection/configuration

13.2 Memory map and register definition

The SIM module contains many fields for selecting the clock source and dividers for various module clocks. See the Clock Distribution chapter for more information, including block diagrams and clock definitions.

NOTE

The SIM_SOPT1 and SIM_SOPT1CFG and SIM_USBPHYCTL registers are located at a different base address than the other SIM registers.

13.2.16 System Clock Gating Control Register 6 (SIM_SCGC6)

DAC0, FTM2 can be accessed through both AIPS0 and AIPS1. When accessing through AIPS1, define the clock gate control bits in the SCGC2 and SCGC3. When accessing through AIPS0, define the clock gate control bits in SCGC6. See the Chip Configuration chapter for the base addresses of FTM2, and DAC0 accessed via AIPS0 and AIPS1.

13.2.18 System Clock Divider Register 1 (SIM_CLKDIV1)

When updating CLKDIV1, update all fields using the one write command. Attempting to write an invalid clock ratio to the CLKDIV1 register will cause the write to be ignored. The maximum divide ratio that can be programmed between core/system clock and the other divided clocks is divide by 8. When OUTDIV1 equals 0000 (divide by 1), the other dividers cannot be set higher than 0111 (divide by 8).

NOTE

The CLKDIV1 register cannot be written to when the device is in VLPR mode.

Address: 4004_7000h base + 1044h offset = 4004_8044h

SIM_FCFG1 field descriptions (continued)

Field	Description
1 FLASHDOZE	Flash Doze When set, Flash memory is disabled for the duration of Wait mode. An attempt by the DMA or other bus master to access the Flash when the Flash is disabled will result in a bus error. This bit should be clear during VLP modes. The Flash will be automatically enabled again at the end of Wait mode so interrupt vectors do not need to be relocated out of Flash memory. The wakeup time from Wait mode is extended when this bit is set. 0 Flash remains enabled during Wait mode 1 Flash is disabled for the duration of Wait mode
0 FLASHDIS	Flash Disable Flash accesses are disabled (and generate a bus error) and the Flash memory is placed in a low power state. This bit should not be changed during VLP modes. Relocate the interrupt vectors out of Flash memory before disabling the Flash. 0 Flash is enabled 1 Flash is disabled

13.2.21 Flash Configuration Register 2 (SIM_FCFG2)

Address: 4004_7000h base + 1050h offset = 4004_8050h

- * Notes:
- Reset value loaded during System Reset from Flash IFR.

SIM_FCFG2 field descriptions

Field	Description
31 SWAPFLSH	Swap program flash Indicates that swap is active . 0 Swap is not active. 1 Swap is active.
30–24 MAXADDR0	Max address block 0

Table continues on the next page...

SIM_FCFG2 field descriptions (continued)

Field	Description
	This field concatenated with 13 trailing zeros indicates the first invalid address of each program flash block. For example, if MAXADDR0 = 0x20 the first invalid address of flash block 0 is 0x0004_0000. This would be the MAXADDR0 value for a device with 256 KB program flash in flash block 0.
23 PFLSH	Program flash only For devices without FlexNVM, this bit is always set. 0 Device supports FlexNVM 1 Program Flash only, device does not support FlexNVM
22–16 MAXADDR1	Max address block 1 This field equals zero if there is only one program flash block, otherwise it equals the value of the MAXADDR0 field. For example, with MAXADDR0 = MAXADDR1 = 0x20 the first invalid address of flash block 1 is 0x4_0000 + 0x4_0000. This would be the MAXADDR1 value for a device with 512 KB program flash memory across two flash blocks and no FlexNVM.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

13.2.22 Unique Identification Register High (SIM_UIDH)

Address: 4004_7000h base + 1054h offset = 4004_8054h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		QSPI0B_SS1_B	PTE13	5
QuadSPI (PORTC)	0	QSPI0A_DATA3	PTC24	7
		QSPI0A_SCLK	PTC25	7
		QSPI0A_DATA0	PTC26	7
		QSPI0A_DATA2	PTC27	7
		QSPI0A_DATA1	PTC28	7
		QSPI0A_SS0_B	PTC29	7
CRC		Status pin	PTA11	1
USBFSOTG		USB0_DP	USB0_DP	–
		USB0_DM	USB0_DM	–

NOTE

Not all QuadSPI pins are supported in all packages, so refer the pinout section for detailed information.

NOTE

- **If QuadSPI (QSPI) is enabled in BootROM**, then before jumping to the user application (and leaving BootROM), the BootROM will configure the Multipurpose Clock Generator (MCG) module to FLL Engaged External (FEE) mode.
- **If QuadSPI (QSPI) is not enabled in BootROM**, then before jumping to the user application (and leaving BootROM), the BootROM will restore the Multipurpose Clock Generator (MCG) module to FLL Engaged Internal (FEI) mode.
- If a user application is started from BootROM, then that user application must clear the chain mode, because Channel 0 and 1 of PIT0 are set to chain mode in the BootROM.

14.2 Introduction

The Kinetis bootloader is the program residing in the on-chip read-only memory (ROM) of a Kinetis microcontroller device. There is hardware logic in place at boot time that either starts execution of an embedded image available on the internal flash memory, or starts the execution of the Kinetis Bootloader from on-chip ROM. When booting from ROM, the bootloader can optionally jump to an application in the external Quad SPI flash memory.

The Kinetis Bootloader's main task is to provision the internal flash (or external Quad SPI flash) memory with an embedded firmware image during manufacturing, or at any time during the life of the Kinetis device. The Kinetis Bootloader does the provisioning by acting as a slave device, and listening to various peripheral ports where a master can start communication.

For the Kinetis device, the Kinetis Bootloader can interface with USB, I2C, SPI, and LPUART peripherals in slave mode and respond to the commands sent by a master (or host) communicating on one of those ports. The host/master can be a firmware-download application running on a PC or an embedded host communicating with the Kinetis Bootloader. Regardless of the host/master (PC or embedded host), the Kinetis Bootloader always uses a command protocol to communicate with that host/master. Commands are provided to write to memory (internal flash or external Quad SPI flash memory or RAM), erase flash, and get/set bootloader options and property values. The host application can query the set of available commands.

On start-up, the bootloader reads optional configuration parameters from a fixed area on flash called the bootloader configuration area (BCA). These parameters can be modified by the write memory command or by downloaded flash image. BCA parameters include configuration data such as enabled peripherals, peripheral-specific settings, etc.

This chapter describes Kinetis Bootloader features, functionality, command structure and which peripherals are supported.

Features supported by the Kinetis Bootloader in Kinetis ROM:

- Supports USB, I2C, SPI, and LPUART peripheral interfaces
- Automatic detection of the active peripheral
- Ability to disable any peripheral
- LPUART peripheral implements autobaud
- Common packet-based protocol for all peripherals
- Packet error detection and retransmission
- Flash-resident configuration options

- Fully supports internal flash security, including ability to mass erase or unlock security via the backdoor key
- Protection of RAM used by the bootloader while it is running
- Provides command to read properties of the device, such as flash and RAM size
- Multiple options for executing the bootloader either at system start-up or under application control at runtime. The ability to configure the QuadSPI interface is based on a configuration block located in the external QuadSPI.
- Supports internal flash
- Supports serial QuadSPI memories

Table 14-2. Commands supported by the Kinetis Bootloader in ROM

Command	Description	When flash security is enabled, then this command is
Call	Runs user application code and returns control to bootloader	Not supported
Execute	Run user application code that never returns control to the bootloader	Not supported
FillMemory	Fill a range of bytes in flash with a word pattern	Not supported
FlashEraseAll	Erase the entire flash array	Not supported
FlashEraseRegion	Erase a range of sectors in flash	Not supported
WriteMemory	Write data to memory	Not supported
ReadMemory	Read data from memory	Not supported
FlashProgramOnce	Writes data provided in a command packet to a specified range of bytes in the program once field	Not supported
FlashReadOnce	Returns the contents of the program once field by given index and byte count	Not supported
FlashReadResource	Returns the contents of the IFR field or Flash firmware ID, by given offset, byte count and option	Not supported
ReliableUpdate	Copy backup application from address to main application region, or swap flash using an indicator address	Not supported
ConfigureQuadSpi	Configure the QuadSPI with a programmed configuration block	Supported
FlashSecurityDisable	Attempt to unlock flash security using the backdoor key	Supported
GetProperty	Get the current value of a property	Supported
ReceiveSbFile	Receive an SB file (which is generated by the <code>elftosb</code> tool)	Supported, but with no decryption functionality.
Reset	Reset the chip	Supported
SetProperty	Attempt to modify a writable property	Supported
FlashEraseAllUnsecure	Erase the entire flash array, including protected sectors	Supported

14.3 Functional Description

The following sub-sections describe the Kinetis Bootloader in K27 ROM functionality.

14.3.1 Memory Maps

While executing, the Kinetis Bootloader uses ROM and RAM memory.

Figure 14-1. Kinetis Bootloader ROM/RAM Memory Maps

14.3.2 The Kinetis Bootloader Configuration Area (BCA)

The Kinetis Bootloader reads data from the Bootloader Configuration Area (BCA) to configure various features of the bootloader. The BCA resides in flash memory at offset 0x3C0, and provides all of the parameters needed to configure the Kinetis Bootloader operation. For uninitialized flash, the Kinetis Bootloader uses a predefined default configuration. A host application can use the Kinetis Bootloader to program the BCA for use during subsequent initializations of the bootloader.

Table 14-3. Configuration Fields for the Kinetis Bootloader

Offset	Size (bytes)	Configuration Field	Description
0x00 - 0x03	4	tag	Magic number to verify bootloader configuration is valid. Must be set to 'kcfg'.

Table continues on the next page...

Table 14-3. Configuration Fields for the Kinetis Bootloader (continued)

Offset	Size (bytes)	Configuration Field	Description
0x04 - 0x07	4	crcStartAddress	Start address for application image CRC check. To generate the CRC, refer to the CRC chapter. If the bits are all set then Kinetis bootloader by default will not perform any CRC check.
0x08 - 0x0B	4	crcByteCount	Byte count for application image CRC check. If the bits are all set then Kinetis bootloader by default will not perform any CRC check.
0x0C - 0x0F	4	crcExpectedValue	Expected CRC value for application CRC check. If the bits are all set then Kinetis bootloader by default will not perform any CRC check.
0x10	1	enabledPeripherals	Bitfield of peripherals to enable. bit 0 LPUART bit 1 I2C bit 2 SPI bit 4 USB Kinetis bootloader will enable the peripheral if corresponding bit is set to 1.
0x11	1	i2cSlaveAddress	If not 0xFF, used as the 7-bit I2C slave address. If 0xFF, defaults to 0x10 for I2C slave address
0x12 - 0x13	2	peripheralDetectionTimeout	Timeout in milliseconds for active peripheral detection. If 0xFFFF, defaults to 5 seconds.
0x14 - 0x15	2	usbVid	Sets the USB Vendor ID reported by the device during enumeration. If 0xFFFF, it defaults to 0x15A2.
0x16 - 0x17	2	usbPid	Sets the USB Product ID reported by the device during enumeration.
0x18 - 0x1B	4	usbStringsPointer	Sets the USB Strings reported by the device during enumeration. Default string values are described in the USB peripheral section.
0x1C	1	clockFlags	See Table 14-5 , clockFlags Configuration Field
0x1D	1	clockDivider	Inverted value of the divider to use for core and bus clocks when in high speed mode
0x1E	1	bootFlags	If bit 0 is cleared, then Kinetis bootloader will jump to either Quad SPI Flash or internal flash image depending on FOPT BOOTSRC_SEL bits. If the bit is set, then Kinetis

Table continues on the next page...

Table 14-3. Configuration Fields for the Kinetis Bootloader (continued)

Offset	Size (bytes)	Configuration Field	Description
			bootloader will prepare for host communication over serial peripherals.
0x1F	1	pad byte	N/A
0x24 - 0x27	8	Reserved	-
0x29 - 0x2F	7	Reserved	-
0x28	1	qspiPort	Selects the default QSPI port: - If bit 0 is cleared, then the bootloader will choose PORTC as the default QSPI port. - If bit 0 is not cleared, then the default QSPI port is PORTE.
0x30	4	qspiConfigBlockPointer	A pointer to the QSPI config block in internal flash array.
0x34	12	Reserved	-

NOTE

The flash sector containing the BCA should not be located in the execute-only region, because the Kinetis bootloader cannot read an execute-only region.

The first configuration field 'tag' is a tag value or magic number. The tag value must be set to 'kcfg' for the bootloader configuration data to be recognized as valid. If tag-field verification fails, then the Kinetis Bootloader assumes that the flash is not initialized and uses a predefined default configuration. The tag value is treated as a character string, so bytes 0-3 must be set as shown in the table.

Table 14-4. tag Configuration Field

Offset	tag Byte Value
0	'k' (0x6B)
1	'c' (0x63)
2	'f' (0x66)
3	'g' (0x67)

The flags in the clockFlags configuration field are enabled if the corresponding bit is cleared (0).

Table 14-5. clockFlags Configuration Field

Bit	Flag	Description
0	HighSpeed	Enable high speed mode (i.e., 48 MHz). Read Clock Configuration section for more information on the high speed mode.
1 - 7	Reserved	

14.3.3 Start-up Process

Any of the following conditions will force the hardware to start the Kinetis Bootloader:

- FOPT [7] is set to 1. This forces the ROM to run out of reset.
- The BOOTCFG0 pin is asserted. The pin must be configured as BOOTCFG0 by setting the BOOTPIN_OPT bit of FOPT to 0.
- A user applications running on flash or RAM calls into the Kinetis Bootloader entry point address in ROM, to start Kinetis Bootloader execution.

The FOPT[BOOTSRC_SEL] determines the boot source. The FOPT register is located in the flash configuration field at address 0x40D in the flash memory array. For a complete list of options, see the Boot options section in the Reset and Boot chapter. If FOPT [7] is set to 1, then the device will boot to ROM out of reset. Flash memory defaults to all 1s when erased, so a blank chip will automatically boot to ROM.

The BOOTCFG0 pin is shared with the NMI pin, with NMI being the default usage. Regardless of whether the NMI pin is enabled or not, the NMI functionality is disabled if the ROM is executed out of reset, for as long as the ROM is running.

When the ROM is executed out of reset, vector fetches from the CPU are redirected to the ROM's vector table in ROM memory at offset 0x1C00_0000. This ensures that any exceptions will be handled by the ROM.

After the Kinetis Bootloader has started, the following procedure starts bootloader operations:

1. The RCM_MR [BOOTROM] bits are set, so that the device will reboot back into the ROM if/when the device is reset.
2. Initializes the bootloader's .data and .bss sections.
3. Reads bootloader configuration data from flash at address 0x3C0. The configuration data is only used if the tag field is set to the expected 'kcfg' value. If the tag is incorrect, then the configuration values are set to default, as if the data was all 0xFF bytes.

4. Clocks are configured. See the [Clock Configuration](#) section.
5. If `BOOTSRC_SEL` is set to `0b10`, then the QSPI0 interface is configured by reading the configuration block from the base address of the external QuadSPI, or from the address pointed by the `qspiConfigBlockPointer` in the BCA.
6. Enabled peripherals are initialized.
7. The bootloader waits for communication to begin on a peripheral.
 - If detection times out, then the bootloader jumps to the user application in flash. See [Bootloader Exit state](#) section.
 - If communication is detected, then all inactive peripherals are shut down, and the command phase is entered.

NOTE

The flash sector containing the vector table should not be located in the execute-only region, because the Kinetis bootloader cannot read the PC and SP addresses in an execute-only region.

Figure 14-2. Kinetis Bootloader Start-up Flowchart

14.3.4 Clock Configuration

By default, the bootloader does not modify clocks. The Kinetis Bootloader in ROM will use the clock configuration of the chip out of reset unless the clock configuration bits in the FOPT register are cleared, or if a USB peripheral is enabled, or if a QuadSPI peripheral is enabled.

- Alternate clock configurations are supported, by setting fields in the Bootloader Configuration Area (BCA) shown in [Table 14-3](#).
- If the HighSpeed flag of the clockFlags configuration value is cleared, or if a USB peripheral is enabled, the bootloader will enable the internal 48 MHz reference clock.
- In high speed mode, the core and bus clock frequencies are determined by the clockDivider configuration value.
- The core clock divider is set directly from the inverted value of the clockDivider unless a USB peripheral is enabled. If a USB peripheral is enabled and the inverted value of the clockDivider is greater than 2, then the value is reduced to 2, in order to keep the CPU clock above 20 MHz.
- The bus clock divider is set to 1, unless the resulting bus clock frequency would be greater than the maximum supported value. In this case, the bus clock divider is increased until the bus clock frequency is at or below the maximum.
- Note that the maximum baud rate of serial peripherals is related to the core and bus clock frequencies. To achieve the desired baud rates, high speed mode should be enabled in BCA.

14.3.5 Bootloader Entry Point / API Tree

To run the Kinetis Bootloader, a user application simply calls the runBootloader function. To get the address of the entry point, the user application reads the word containing the pointer to the bootloader API tree at offset 0x1C of the bootloader's vector table. The vector table is placed at the base of the bootloader's address range, which for the ROM is 0x1C00_0000; the API tree pointer is at address 0x1C00_001C.

The bootloader API tree is a structure that contains pointers to other structures, which have the function and data addresses for the bootloader. The bootloader entry point is always the 1st word of the API tree.

```
typedef struct BootloaderTree
{
    void (*runBootloader)(void *arg);           //!< Function to start the bootloader
    executing.
    standard_version_t version;                 //!< Bootloader version number.
    const char *copyright;                     //!< Copyright string.
    const bootloader_context_t *runtimeContext; //!< Pointer to the bootloader's runtime
    context.
    const flash_driver_interface_t *flashDriver; //!< Flash driver API.
    const aes_driver_interface_t *aesDriver;    //!< AES driver API.
```

```
} bootloader_tree_t;
```

The prototype of the entry point is:

```
void run_bootloader(void * arg);
```

The `arg` parameter is currently unused, and is intended for future expansion (for example, passing options to the bootloader). To ensure future compatibility, a value of `NULL` should be passed for `arg`.

Example: code to get the entry pointer address from the ROM and start the bootloader.

NOTE

This entry must be called in supervisor (privileged) mode.

```
// Variables

uint32_t runBootloaderAddress;

void (*runBootloader)(void * arg);

// Read the function address from the ROM API tree.
runBootloaderAddress = **(uint32_t **) (0x1c00001c);

runBootloader = (void (*)(void * arg))runBootloaderAddress;

// Start the bootloader.
runBootloader(NULL);
```

14.3.6 Bootloader Protocol

This section explains the general protocol for the packet transfers between the host and the Kinetis Bootloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands may include an optional data phase:

- If the data phase is **incoming** (from host to bootloader), then the data phase is part of the **original command**.
- If the data phase is **outgoing** (from bootloader to host), then the data phase is part of the **response command**.

NOTE

In all protocols (described in the next subsections), the Ack sent in response to a Command or Data packet can arrive at any time *before, during, or after* the Command/Data packet has processed.

14.3.6.1 Command with no data phase

The protocol for a command with no data phase contains:

- Command packet (from host)
- Generic response command packet (to host)

Figure 14-3. Command with No Data Phase

14.3.6.2 Command with incoming data phase

The protocol for a command with an incoming data phase contains:

- Command packet (from host)
- Generic response command packet (to host)
- Incoming data packets (from host)
- Generic response command packet (to host)

Figure 14-4. Command with incoming data phase

NOTE

- The host may not send any further packets while it (the host) is waiting for the response to a command.
- If the Generic Response packet prior to the start of the data phase does not have a status of `kStatus_Success`, then the data phase is aborted.
- Data phases may be aborted by the receiving side by sending the final Generic Response early with a status of

kStatus_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.

- The final Generic Response packet *sent after the data phase* includes the status for the entire operation.

14.3.6.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:

- Command packet (from host)
- ReadMemory Response command packet (to host) (kCommandFlag_HasDataPhase set)
- Outgoing data packets (to host)
- Generic response command packet (to host)

Figure 14-5. Command with outgoing data phase

NOTE

- For the outgoing data phase sequence above, the data phase is really considered part of the response command.
- The host may not send any further packets while it (the host) is waiting for the response to a command.
- If the ReadMemory Response command packet prior to the start of the data phase does not contain the `kCommandFlag_HasDataPhase` flag, then the data phase is aborted.

- Data phases may be aborted by the host sending the final Generic Response early with a status of `kStatus_AbortDataPhase`. The sending side may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet *sent after the data phase* includes the status for the entire operation.

14.3.7 Bootloader Packet Types

The Kinetis Bootloader device works in slave mode. All data communication is initiated by a host, which is either a PC or an embedded host (note that QuadSPI is treated like a storage device, like flash). The Kinetis Bootloader device is the target, which receives a command or data packet. All data communication between host and target is packetized.

NOTE

The term "target" refers to the "Kinetis Bootloader device."

There are 6 types of packets used in the device:

- Ping packet
- Ping Response packet
- Framing packet
- Command packet
- Data packet
- Response packet

All fields in the packets are in little-endian byte order.

14.3.7.1 Ping packet

The Ping packet is the first packet sent from a host to the target (Kinetis Bootloader), to establish a connection on a selected peripheral. For a LPUART peripheral, the Ping packet is used to determine the baudrate. A Ping packet must be sent before any other communications. In response to a Ping packet, the target sends a Ping Response packet.

Table 14-6. Ping Packet Format

Byte #	Value	Name
0	0x5A	start byte
1	0xA6	ping

Figure 14-6. Ping Packet Protocol Sequence

14.3.7.2 Ping Response Packet

The target (Kinetis Bootloader) sends a Ping Response packet back to the host after receiving a Ping packet. If communication is over a LPUART peripheral, the target uses the incoming Ping packet to determine the baud rate before replying with the Ping Response packet. Once the Ping Response packet is received by the host, the connection is established, and the host starts sending commands to the target (Kinetis Bootloader).

Table 14-7. Ping Response Packet Format

Byte #	Value	Parameter
0	0x5A	start byte
1	0xA7	Ping response code
2		Protocol bugfix
3		Protocol minor
4		Protocol major
5		Protocol name = 'P' (0x50)
6		Options low
7		Options high
8		CRC16 low
9		CRC16 high

14.3.7.3 Framing Packet

The framing packet is used for flow control and error detection, and it (the framing packet) wraps command and data packets as well.

The framing packet described in this section is used for serial peripherals including LPUART, I2C and SPI. The USB HID peripheral does not use framing packets. Instead, the packetization inherent in the USB protocol itself is used. Please refer to the [USB peripheral](#) section for details.

Table 14-8. Framing Packet Format

Byte #	Value	Parameter	
0	0x5A	start byte	
1		packetType	
2		length_low	Length is a 16-bit field that specifies the entire command or data packet size in bytes.
3		length_high	
4		crc16_low	This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See the CRC16 algorithm after this table.
5		crc16_high	
6 . . . n		Command or Data packet payload	

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

Table 14-9. Special Framing Packet Format

Byte #	Value	Parameter
0	0x5A	start byte
1	0xA n	packetType

The Packet Type field specifies the type of the packet from one of the defined types (below):

Table 14-10. packetType Field

packetType	Name	Description
0xA1	kFramingPacketType_Ack	The previous packet was received successfully; the sending of more packets is allowed.
0xA2	kFramingPacketType_Nak	The previous packet was corrupted and must be re-sent.
0xA3	kFramingPacketType_AckAbort	Data phase is being aborted.
0xA4	kFramingPacketType_Command	The framing packet contains a command packet payload.
0xA5	kFramingPacketType_Data	The framing packet contains a data packet payload.

Table continues on the next page...

Table 14-10. packetType Field (continued)

packetType	Name	Description
0xA6	kFramingPacketType_Ping	Sent to verify the other side is alive. Also used for UART autobaud.
0xA7	kFramingPacketType_PingResponse	A response to Ping; contains the framing protocol version number and options.

This device uses the Cyclic Redundancy Check module (CRC) to perform the CRC algorithm. See the CRC chapter for more details.

14.3.7.4 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

Table 14-11. Command Packet Format

Command Packet Format (32 bytes)										
Command Header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param1 (32-bit)	Param2 (32-bit)	Param3 (32-bit)	Param4 (32-bit)	Param5 (32-bit)	Param6 (32-bit)	Param7 (32-bit)
byte 0	byte 1	byte 2	byte 3							

Table 14-12. Command Header Format

Byte #	Command Header Field	
0	Command or Response tag	The command header is 4 bytes long, with these fields.
1	Flags	
2	Reserved. Should be 0x00.	
3	ParameterCount	

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. As mentioned earlier, command packets and data packets are embedded into framing packets for all of the transfers.

Table 14-13. Commands that are supported

Command	Name
0x01	FlashEraseAll

Table continues on the next page...

Table 14-13. Commands that are supported (continued)

Command	Name
0x02	FlashEraseRegion
0x03	ReadMemory
0x04	WriteMemory
0x05	FillMemory
0x06	FlashSecurityDisable
0x07	GetProperty
0x08	ReceiveSBFile
0x09	Execute
0x0A	Call
0x0B	Reset
0x0C	SetProperty
0x0D	FlashEraseAllUnsecure
0x0E	FlashProgramOnce
0x0F	FlashReadOnce
0x10	FlashReadResource
0x11	ConfigureQuadSpi
0x12	ReliableUpdate

Table 14-14. Responses that are supported

Response	Name
0xA0	GenericResponse
0xA3	ReadMemoryResponse (used for sending responses to ReadMemory command only)
0xA7	GetPropertyResponse (used for sending responses to GetProperty command only)
0xAF	FlashReadOnceResponse (used for sending responses to FlashReadOnce command only)
0xB0	FlashReadResourceResponse (used for sending responses to FlashReadResource command only)

Flags: Each command packet contains a Flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets will follow in the command sequence. The number of bytes that will be transferred in the data phase is determined by a command-specific parameter in the parameters array.

ParameterCount: The number of parameters included in the command packet.

Parameters: The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to 7 parameters.

14.3.7.5 Data packet

The data packet carries just the data, either host sending data to target, or target sending data to host. The data transfer direction is determined by the last command sent from the host. The data packet is also wrapped within a framing packet, to ensure the correct packet data is received.

The contents of a data packet are simply the data itself. There are no other fields, so that the most data per packet can be transferred. Framing packets are responsible for ensuring that the correct packet data is received.

14.3.7.6 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse
- GetPropertyResponse
- ReadMemoryResponse
- FlashReadOnceResponse
- FlashReadResourceResponse

GenericResponse: After the Kinetis Bootloader has processed a command, the bootloader will send a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

Table 14-15. GenericResponse Parameters

Byte #	Parameter	Description
0 - 3	Status code	The Status codes are errors encountered during the execution of a command by the target (Kinetis Bootloader). If a command succeeds, then a kStatus_Success code is returned. Table 14-63 , Kinetis Bootloader Status Error Codes, lists the status codes returned to the host by the Kinetis Bootloader for K27 ROM.
4 - 7	Command tag	The Command tag parameter identifies the response to the command sent by the host.

GetPropertyResponse: The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

Table 14-16. GetPropertyResponse Parameters

Byte #	Value	Parameter
0 - 3		Status code
4 - 7		Property value
...		...
		Can be up to maximum 6 property values, limited to the size of the 32-bit command packet and property type.

ReadMemoryResponse: The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a ReadMemoryResponse tag value (0xA3), the flags field set to kCommandFlag_HasDataPhase (1).

The parameter count set to 2 for the status code and the data byte count parameters shown below.

Table 14-17. ReadMemoryResponse Parameters

Byte #	Parameter	Description
0 - 3	Status code	The status of the associated Read Memory command.
4 - 7	Data byte count	The number of bytes sent in the data phase.

FlashReadOnceResponse: The FlashReadOnceResponse packet is sent by the target in response to the host sending a FlashReadOnce command. The FlashReadOnceResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a FlashReadOnceResponse tag value (0xAF), and the flags field set to 0. The parameter count is set to 2 plus *the number of words* requested to be read in the FlashReadOnceCommand.

Table 14-18. FlashReadOnceResponse Parameters

Byte #	Value	Parameter
0 - 3		Status Code

Table continues on the next page...

Table 14-18. FlashReadOnceResponse Parameters (continued)

4 – 7		Byte count to read
...		...
		Can be up to 20 bytes of requested read data.

The FlashReadResourceResponse packet is sent by the target in response to the host sending a FlashReadResource command. The FlashReadResourceResponse packet contains the framing packet data and command packet data, with the command/response tag set to a FlashReadResourceResponse tag value (0xB0), and the flags field set to kCommandFlag_HasDataPhase (1).

Table 14-19. FlashReadResourceResponse Parameters

Byte #	Value	Parameter
0 – 3		Status Code
4 – 7		Data byte count

14.3.8 Bootloader Command API

All Kinetis Bootloader command APIs follow the command packet format that is wrapped by the framing packet, as explained in previous sections.

- For a list of commands supported by the Kinetis Bootloader in K27 ROM, see [Table 14-2](#), Commands supported.
- For a list of status codes returned by the Kinetis Bootloader in K27 ROM, see [Table 14-63](#), Kinetis Bootloader Status Error Codes.

NOTE

All the examples in this section depict byte traffic on serial peripherals that use framing packets. USB HID transactions use the USB HID report packets instead of the serial framing packets shown in this section. Please refer to the [HID reports](#) section for details of the USB HID packet structure.

14.3.8.1 ReliableUpdate command

The Reliable Update command performs the reliable update operation.

- **For a hardware implementation:** the swap indicator address is the parameter that is required for the Reliable Update command.

- If the flash swap system is **uninitialized**, then the swap indicator address can be arbitrarily specified.
- If the flash swap system has been **initialized**, then the swap indicator must be aligned with the swap system.

Table 14-20. Parameters for Reliable Update command

Byte number	Command
0 - 3	• For a hardware implementation: the value is the swap indicator address.

Response: The target returns a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command, or set to an appropriate error status code.

14.3.8.2 Call command

The Call command will execute a function that is written in memory at the address sent in the command. The address needs to be a valid memory location residing in accessible flash (internal or external) or in RAM. The command supports the passing of one 32-bit argument. Although the command supports a stack address, at this time the call will still take place using the current stack pointer. After execution of the function, a 32-bit return value will be returned in the generic response message.

Table 14-21. Parameters for Call Command

Byte #	Command
0 - 3	Call address
4 - 7	Argument word
8 - 11	Stack pointer

Figure 14-7. Protocol Sequence for Call Command

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to the return value of the function called or set to kStatus_InvalidArgument (105).

14.3.8.3 ConfigureQuadSPI command

The ConfigureQuadSPI command will configure the QuadSPI device using a pre-programmed configuration image. The parameters passed in the command are the QuadSPI memory ID, which should always be 1 for the current release of the bootloader, and then the memory address from which the configuration data can be loaded from. Options for loading the data can be a scenario where the configuration data is written to a RAM or flash location and then this command will direct the bootloader to use the data at that location to configure the QuadSPI.

Table 14-22. Parameters for ConfigureQuadSPI Command

Byte #	Command
0 – 3	Flash Memory ID (Should always be 1)
4 – 7	Configuration block address

Figure 14-8. Protocol Sequence for Configure QuadSPI Command

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to `kStatus_Success` upon successful execution of the command, or set to an appropriate error code.

14.3.8.4 ReceiveSBFile command

The ReceiveSBFile command (ReceiveSbFile) will start the transfer of an SB file to the target. The command only specifies the size in bytes of the SB file that will be sent in the data phase. The SB file will be processed as it is received by the Bootloader .

Table 14-23. Parameters for ReceiveSBFile Command

Byte #	Command
0 - 3	Byte count

Data Phase: The Receive SB file command has a data phase; the host will send data packets until the number of bytes of data specified in the `byteCount` parameter of the Receive SB File command are received by the target.

Response: The target (Bootloader) will return a GenericResponse packet with a status code set to the `kStatus_Success` upon successful execution of the command, or set to an appropriate error code.

14.3.8.5 Execute command

The execute command results in the bootloader setting the program counter to the code at the provided jump address, R0 to the provided argument, and a Stack pointer to the provided stack pointer address. Prior to the jump, the system is returned to the reset state.

The Jump address, function argument pointer, and stack pointer are the parameters required for the Execute command.

Table 14-24. Parameters for Execute Command

Byte #	Command
0 - 3	Jump address
4 - 7	Argument word
8 - 11	Stack pointer address

The Execute command has no data phase.

Response: Before executing the Execute command, the target (Kinetis Bootloader) will validate the parameters and return a GenericResponse packet with a status code either set to kStatus_Success or an appropriate error status code.

14.3.8.6 Reset command

The Reset command will result in bootloader resetting the chip.

The Reset command requires no parameters.

Figure 14-9. Protocol Sequence for Reset Command

Table 14-25. Reset Command Packet Format (Example)

Reset	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x04 0x00
	crc16	0x6F 0x46
Command packet	commandTag	0x0B - reset
	flags	0x00
	reserved	0x00
	parameterCount	0x00

The Reset command has no data phase.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with status code set to kStatus_Success, before resetting the chip.

14.3.8.7 GetProperty command

The GetProperty command is used to query the bootloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

For a list of properties and their associated 32-bit property tags supported by the Kinetis Bootloader in K27 ROM, see [Table 14-58](#).

The 32-bit property tag is the only parameter required for GetProperty command.

Table 14-26. Parameters for GetProperty Command

Byte #	Command
0 - 3	Property tag
4 - 7	Memory identifier, which is only valid when using the GetProperty command for an external memory ¹ or an internal memory region. ²

1. Valid for GetProperty ExternalMemoryAttributes (19h or 25 decimal). Returns the QSPI property if the identifier is 1. See [ExternalMemoryAttributes Property](#).
2. Valid for GetProperty "start of RAM" (0Eh or 14 decimal) and "size of RAM" (0Fh or 15 decimal). Returns the OCRAM property if the identifier is 1. Returns the TCRAM property if the identifier is not 1.

Figure 14-10. Protocol Sequence for GetProperty Command

Table 14-27. GetProperty Command Packet Format (Example)

GetProperty	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x08 0x00
	crc16	0x73 0xD4
Command packet	commandTag	0x07 – GetProperty
	flags	0x00

Table continues on the next page...

Table 14-27. GetProperty Command Packet Format (Example) (continued)

GetProperty	Parameter	Value
	reserved	0x00
	parameterCount	0x01
	propertyTag	0x00000001 - CurrentVersion

The GetProperty command has no data phase.

Response: In response to a GetProperty command, the target will send a GetPropertyResponse packet with the response tag set to 0xA7. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). The next table shows an example of a GetPropertyResponse packet.

Table 14-28. GetProperty Response Packet Format (Example)

GetPropertyResponse	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0c 0x00 (12 bytes)
	crc16	0x07 0x7a
Command packet	responseTag	0xA7
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	status	0x00000000
	propertyValue	0x0000014b - CurrentVersion

14.3.8.8 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options in the Kinetis Bootloader ROM. However, the SetProperty command can only change the value of properties that are writable—see [Table 14-58](#), Properties used by Get/SetProperty Commands. If you try to set a value for a read-only property, then the Kinetis Bootloader will return an error.

The property tag and the new value to set are the 2 parameters required for the SetProperty command.

Table 14-29. Parameters for SetProperty Command

Byte #	Command
0 - 3	Property tag
4 - 7	Property value

Figure 14-11. Protocol Sequence for SetProperty Command

Table 14-30. SetProperty Command Packet Format (Example)

SetProperty	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x67 0x8D
Command packet	commandTag	0x0C – SetProperty with property tag 10
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	propertyTag	0x0000000A - VerifyWrites
	propertyValue	0x00000001

The SetProperty command has no data phase.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with one of following status codes:

Table 14-31. SetProperty Response Status Codes

Status Code
kStatus_Success
kStatus_ReadOnly
kStatus_UnknownProperty
kStatus_InvalidArgument

14.3.8.9 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory or of QuadSPI memory (if that is the case). If any flash regions are protected, then the FlashEraseAll command will fail and return an error status code. Executing the FlashEraseAll command will release flash security if it (flash security) was enabled, by setting the FTFE_FSEC register. However, the FSEC field of the flash configuration field is erased, so unless it is reprogrammed, the flash security will be re-enabled after the next system reset. The Command tag for FlashEraseAll command is 0x01 set in the commandTag field of the command packet.

The FlashEraseAll command requires 1 parameter: memoryId.

Table 14-32. Parameters for FlashEraseAll command

Bytes	Parameter
0 - 3	MemoryId • 0x00 - Internal PFlash • 0x01 - QuadSPI memory

Figure 14-12. Protocol Sequence for FlashEraseAll Command

Table 14-33. FlashEraseAll Command Packet Format (Example)

FlashEraseAll	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x04 0x00
	crc16	- If MemoryID = 0 (internal flash), then crc16 = 0x0C 0x22 - If MemoryID = 1 (QSPI0 memory), then crc16 = 0xB8 0x54
Command packet	commandTag	0x01 - FlashEraseAll
	flags	0x00
	reserved	0x00
	parameterCount	0x00
	MemoryID	- If MemoryID = 0x00h, then internal flash. - If MemoryID = 0x01h, then QSPI0 memory.

The FlashEraseAll command has no data phase.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command, or set to an appropriate error status code.

14.3.8.10 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory or a specified range of flash within the connected SPI flash devices.

The start address and number of bytes are the 2 parameters required for the FlashEraseRegion command. The start and byte count parameters must be , or the FlashEraseRegion command will fail and return kStatus_FlashAlignmentError (0x101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command will fail and return kStatus_FlashAddressError (0x102). If any part of the region specified is protected, the FlashEraseRegion command will fail and return kStatus_MemoryRangeInvalid (0x10200).

Table 14-34. Parameters for FlashEraseRegion Command

Byte #	Parameter
0 - 3	Start address
4 - 7	Byte count

Figure 14-13. Protocol Sequence for FlashEraseRegion Command

Table 14-35. FlashEraseRegion Command Packet Format (Example)

FlashEraseRegion	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0xF9 0x A6
Command packet	commandTag	0x02, kCommandTag_FlashEraseRegion
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	startAddress	0x00 0x00 0x00 0x00 (0x0000_0000)
	byte count	0x00 0x04 0x00 0x00 (0x400)

The FlashEraseRegion command has no data phase.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with one of following error status codes.

Table 14-36. FlashEraseRegion Response Status Codes

Status Code
kStatus_Success (0x0)
kStatus_MemoryRangeInvalid (0x10200)
kStatus_FlashAlignmentError (0x101)
kStatus_FlashAddressError (0x102)
kStatus_FlashAccessError (0x103)
kStatus_FlashProtectionViolation (0x104)
kStatus_FlashCommandFailure (0x105)

14.3.8.11 FlashEraseAllUnsecure command

The FlashEraseAllUnsecure command performs a mass erase of the flash memory, including protected sectors. Flash security is immediately disabled if it (flash security) was enabled, and the FSEC byte in the flash configuration field at address 0x40C is programmed to 0xFE. However, if the mass erase enable option in the FSEC field is disabled, then the FlashEraseAllUnsecure command will fail.

The FlashEraseAllUnsecure command requires no parameters.

Figure 14-14. Protocol Sequence for FlashEraseAll Command

Table 14-37. FlashEraseAllUnsecure Command Packet Format (Example)

FlashEraseAllUnsecure	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x04 0x00
	crc16	0xF6 0x61
Command packet	commandTag	0x0D - FlashEraseAllUnsecure
	flags	0x00
	reserved	0x00
	parameterCount	0x00

The FlashEraseAllUnsecure command has no data phase.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command, or set to an appropriate error status code.

14.3.8.12 FlashProgramOnce command

The FlashProgramOnce command writes data (that is provided in a command packet) to a specified range of bytes in the program once field. Special care must be taken when writing to the program once field.

- The program once field only supports programming once, so any attempted to reprogram a program once field will get an error response.
- Writing to the program once field requires the byte count to be 4-byte aligned or 8-byte aligned.

The FlashProgramOnce command uses 3 parameters: index, byteCount, data.

Table 14-38. Parameters for FlashProgramOnce Command

Byte #	Command
0 - 3	Index of program once field
4 - 7	Byte count (must be evenly divisible by 4)
8 - 11	Data
12 - 16	Data

Figure 14-15. Protocol Sequence for FlashProgramOnce Command

Table 14-39. FlashProgramOnce Command Packet Format (Example)

FlashProgramOnce	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00
	crc16	0x7E4 0x89
Command packet	commandTag	0x0E – FlashProgramOnce
	flags	0
	reserved	0
	parameterCount	3
	index	0x0000_0000
	byteCount	0x0000_0004
	data	0x1234_5678

Response: upon successful execution of the command, the target (Kinetis Bootloader) will return a **GenericResponse** packet with a status code set to **kStatus_Success**, or to an appropriate error status code.

14.3.8.13 FlashReadOnce command

The **FlashReadOnce** command returns the contents of the program once field by given index and byte count. The **FlashReadOnce** command uses 2 parameters: index and byteCount.

Table 14-40. Parameters for FlashReadOnce Command

Byte #	Parameter	Description
0 - 3	index	Index of the program once field (to read from)
4 - 7	byteCount	Number of bytes to read and return to the caller

**Figure 14-16. Protocol Sequence for FlashReadOnce Command****Table 14-41. FlashReadOnce Command Packet Format (Example)**

FlashReadOnce	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4
	length	0x0C 0x00
	crc	0xC1 0xA5
Command packet	commandTag	0x0F – FlashReadOnce
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	index	0x0000_0000
	byteCount	0x0000_0004

Table 14-42. FlashReadOnce Response Format (Example)

FlashReadOnce Response	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4

Table continues on the next page...

Table 14-42. FlashReadOnce Response Format (Example) (continued)

FlashReadOnce Response	Parameter	Value
	length	0x10 0x00
	crc	0x3F 0x6F
Command packet	commandTag	0xAF
	flags	0x00
	reserved	0x00
	parameterCount	0x03
	status	0x0000_0000
	byteCount	0x0000_0004
	data	0x1234_5678

Response: upon successful execution of the command, the target (Kinetis Bootloader) will return a FlashReadOnceResponse packet with a status code set to kStatus_Success, a byte count and corresponding data read from Program Once Field upon successful execution of the command, or will return with a status code set to an appropriate error status code and a byte count set to 0.

14.3.8.14 FlashReadResource command

The FlashReadResource command returns the contents of the IFR field or Flash firmware ID, by given offset, byte count, and option. The FlashReadResource command uses 3 parameters: start address, byteCount, option.

Table 14-43. Parameters for FlashReadResource Command

Byte #	Parameter	Command
0 - 3	start address	Start address of specific non-volatile memory to be read
4 - 7	byteCount	Byte count to be read
8 - 11	option	0: IFR 1: Flash firmware ID

Figure 14-17. Protocol Sequence for FlashReadResource Command

Table 14-44. FlashReadResource Command Packet Format (Example)

FlashReadResource	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4
	length	0x10 0x00
	crc	0xB3 0xCC
Command packet	commandTag	0x10 – FlashReadResource
	flags	0x00
	reserved	0x00
	parameterCount	0x03
	startAddress	0x0000_0000
	byteCount	0x0000_0008
	option	0x0000_0001

Table 14-45. FlashReadResource Response Format (Example)

FlashReadResource Response	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4
	length	0x0C 0x00
	crc	0xD2 0xB0
Command packet	commandTag	0xB0
	flags	0x01
	reserved	0x00
	parameterCount	0x02
	status	0x0000_0000
	byteCount	0x0000_0008

Data phase: The FlashReadResource command has a data phase. Because the target (Kinetis Bootloader) works in slave mode, the host must pull data packets until the number of bytes of data *specified in the byteCount parameter of FlashReadResource command* are received by the host.

14.3.8.15 FlashSecurityDisable command

The FlashSecurityDisable command performs the flash security disable operation, by comparing the 8-byte backdoor key (provided in the command) against the backdoor key stored in the flash configuration field (at address 0x400 in the flash).

The backdoor low and high words are the only parameters required for FlashSecurityDisable command.

Table 14-46. Parameters for FlashSecurityDisable Command

Byte #	Command
0 - 3	Backdoor key low word
4 - 7	Backdoor key high word

Figure 14-18. Protocol Sequence for FlashSecurityDisable Command

Table 14-47. FlashSecurityDisable Command Packet Format (Example)

FlashSecurityDisable	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x43 0x7B
Command packet	commandTag	0x06 - FlashSecurityDisable
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	Backdoorkey_low	0x04 0x03 0x02 0x01
	Backdoorkey_high	0x08 0x07 0x06 0x05

The FlashSecurityDisable command has no data phase.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command, or set to an appropriate error status code.

14.3.8.16 FillMemory command

The FillMemory command fills a range of bytes in memory with a data pattern. It follows the same rules as the WriteMemory command. The difference between FillMemory and WriteMemory is that a data pattern is included in FillMemory command parameter, and there is no data phase for the FillMemory command, while WriteMemory does have a data phase.

Table 14-48. Parameters for FillMemory Command

Byte #	Command
0 - 3	Start address of memory to fill
4 - 7	Number of bytes to write with the pattern - The start address should be 32-bit aligned. - The number of bytes must be evenly divisible by 4. (Note: for a part that uses FTFE flash, the start address should be 64-bit aligned, and the number of bytes must be evenly divisible by 8).
8 - 11	32-bit pattern

- To fill with a byte pattern (8-bit), the byte must be replicated 4 times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated 2 times in the 32-bit pattern.

For example, to fill a byte value with 0xFE, the word pattern would be 0xFEFEFEFE; to fill a short value 0x5AFE, the word pattern would be 0x5AFE5AFE.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll, FlashEraseRegion, or FlashEraseAllUnsecure command.
- Writing to flash requires the start address to be 32-bit or 64-bit aligned.
- If the VerifyWrites property is set to true, then writes to flash will also perform a flash verify program operation.

When writing to RAM, the start address need not be aligned, and the data will not be padded.

Figure 14-19. Protocol Sequence for FillMemory Command

Table 14-49. FillMemory Command Packet Format (Example)

FillMemory	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00
	crc16	0xE4 0x57
Command packet	commandTag	0x05 – FillMemory
	flags	0x00
	Reserved	0x00
	parameterCount	0x03
	startAddress	0x00007000
	byteCount	0x00000800
	patternWord	0x12345678

The FillMemory command has no data phase.

Response: upon successful execution of the command, the target (Kinetis Bootloader) will return a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

14.3.8.17 WriteMemory command

The WriteMemory command writes data provided in the data phase to a specified range of bytes in memory (flash or RAM or QuadSPI memory). However, if flash protection is enabled, then writes to protected sectors will fail.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll, FlashEraseRegion, or FlashEraseAllUnsecure command.
- Writing to flash requires the start address to be 4-byte aligned ([1:0] = 00).
- The byte count will be rounded up to a multiple of 4, and the trailing bytes will be filled with the flash erase pattern (0xff).
- If the VerifyWrites property is set to true, then writes to flash will also perform a flash verify program operation.

When writing to RAM, the start address need not be aligned, and the data will not be padded.

The start address and number of bytes are the 2 parameters required for WriteMemory command.

Table 14-50. Parameters for WriteMemory Command

Byte #	Command
0 - 3	Start address
4 - 7	Byte count

Figure 14-20. Protocol Sequence for WriteMemory Command

Table 14-51. WriteMemory Command Packet Format (Example)

WriteMemory	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x06 0x5A
Command packet	commandTag	0x04 - writeMemory
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	startAddress	0x20000400
	byteCount	0x00000064

Data Phase: The WriteMemory command has a data phase; the host will send data packets until the number of bytes of data specified in the byteCount parameter of the WriteMemory command are received by the target.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with a status code set to kStatus_Success upon successful execution of the command, or to an appropriate error status code.

14.3.8.18 Read memory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory accessible by the CPU and not protected by security.

The start address and number of bytes are the 2 parameters required for ReadMemory command.

Table 14-52. Parameters for read memory command

Byte	Parameter	Description
0-3	Start address	Start address of memory to read from
4-7	Byte count	Number of bytes to read and return to caller

Figure 14-21. Command sequence for read memory

ReadMemory	Parameter	Value
Framing packet	Start byte	0x5A0xA4,
	packetType	kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x1D 0x23
Command packet	commandTag	0x03 - readMemory
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	startAddress	0x20000400
	byteCount	0x00000064

Data Phase: The ReadMemory command has a data phase. Since the target (Kinetis Bootloader) works in slave mode, the host need pull data packets until the number of bytes of data specified in the byteCount parameter of ReadMemory command are received by host.

Response: The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command, or set to an appropriate error status code.

14.3.9 Bootloader Exit state

The Kinetis Bootloader tries to reconfigure the system back to the reset state in the following situations:

- After completion of an Execute command, but before jumping to the specified entry point.
- After a peripheral detection timeout, but before jumping to the application entry point.

14.4 Peripherals Supported

This section describes the peripherals supported by the Kinetis ROM Bootloader. To use an interface for bootloader communications, the peripheral must be enabled in the BCA, as shown in [Table 14-3](#). If the BCA is invalid (such as all 0xFF bytes), then all peripherals will be enabled by default.

14.4.1 I2C Peripheral

The Kinetis Bootloader in ROM supports loading data into flash via the I2C peripheral, where the I2C peripheral serves as the I2C slave. A 7-bit slave address is used during the transfer.

Customizing an I2C slave address is also supported. This feature is enabled if the Bootloader Configuration Area (BCA) (shown in [Table 14-3](#)) is enabled (tag field is filled with 'kcfg') and the i2cSlaveAddress field is filled with a value other than 0xFF. 0x10 is used as the default I2C slave address.

The maximum supported I2C baud rate depends on corresponding clock configuration field in the BCA. Typical supported baud rate is 400 kbps with factory settings. Actual supported baud rate may be lower or higher than 400 kbps, depending on the actual value of the clockFlags and the clockDivider fields.

Because the I2C peripheral serves as an I2C slave device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

- An incoming packet is sent by the host with a selected I2C slave address and the direction bit is set as write.
- An outgoing packet is read by the host with a selected I2C slave address and the direction bit is set as read.
- 0x00 will be sent as the response to host if the target is busy with processing or preparing data.

The following flow charts demonstrate the communication flow of how the host reads ping packet, ACK and response from the target.

Figure 14-22. Host reads ping response from target via I2C

Figure 14-23. Host reads ACK packet from target via I2C

Figure 14-24. Host reads response from target via I2C

14.4.2 SPI Peripheral

The Kinetis Bootloader in K27 ROM supports loading data into flash via the SPI peripheral, where the SPI peripheral serves as a SPI slave.

Maximum supported baud rate of SPI depends on the clock configuration fields in the Bootloader Configuration Area (BCA) shown in [Table 14-3](#). The typical supported baud rate is 400 kbps with the factory settings. The actual baud rate is lower or higher than 400 kbps, depending on the actual value of the clockFlags and clockDivider fields in the BCA.

The SPI peripheral uses the following bus attributes:

- Clock Phase = 1 (Second Edge)
- Clock Polarity = 1 (Active Low)

Because the SPI peripheral in K27 ROM serves as a SPI slave device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

The transfer on SPI is slightly different from I2C:

- Host will receive 1 byte after it sends out any byte.
- Received bytes should be ignored when host is sending out bytes to target
- Host starts reading bytes by sending 0x00s to target
- The byte 0x00 will be sent as response to host if target is under the following conditions:

- Processing incoming packet
- Preparing outgoing data
- Received invalid data

The SPI bus configuration is:

- Phase = 1; data is sampled on rising edges
- Polarity = 1; idle is high
- MSB is transmitted first

For any transfer where the target does not have actual data to send, the target (slave) is responsible for ensuring that 0x00 bytes will be returned to the host (master). The host uses framing packets to identify real data and not "dummy" 0x00 bytes (which do not have framing packets).

The following flowcharts demonstrate how the host reads a ping response, an ACK and a command response from target via SPI.

Figure 14-25. Host reads ping packet from target via SPI

Figure 14-26. Host reads ACK from target via SPI

Figure 14-27. Host reads response from target via SPI

14.4.3 QuadSPI Peripheral

The Kinetis Bootloader supports read, write, and erase external SPI flash devices (QuadSPI memory) via the QuadSPI module. It supports booting directly to external SPI flash and XIP in QuadSPI memory. Before accessing external SPI flash devices, the QuadSPI module must be configured properly, using the QSPI configuration block.

14.4.3.1 QSPI configuration block

The QSPI config block (QCB) provides many configuration parameters, which support many types of serial flash. All fields in the QSPI config block must be configured according to the specific flash device provided by your specific vendor, and all of them are related to the configuration for registers in the QuadSPI module. Also see the QuadSPI section.

NOTE

To correctly configure the QuadSPI, **all *unused* QuadSPI configuration fields should be set to 0.**

Table 14-53. Configuration fields in QSPI config block

Offset	Size (bytes)	Configuration Field	Description
0x00 – 0x03	4	tag	A magic number to verify whether the QSPI config block (QCB) is valid. Must be set to 'kqcf' [31:24] - 'f' (0x66) [23:16] - 'c' (0x63) [15: 8] - 'q' (0x71) [7: 0] - 'k' (0x6B)
0x04 – 0x07	4	version	Version number of the QSPI config block [31:24] - name: must be 'Q' (0x51) [23:16] - major: must be 1 [15: 8] - minor: must be 0 [7: 0] - bugfix: must be 0
0x08 – 0x0b	4	lengthInBytes	Size of QSPI config block, in bytes Must be 512
0x0c – 0x0f	4	dqs_loopback	Enable DQS loopback support 0 DQS loopback is disabled 1 DQS loopback is enabled, the DQS loopback mode is determined by subsequent ' dqs_loopback_internal ' field
0x10 – 0x13	4	data_hold_time	Serial Flash data in-hold-time; valid values (0, 1, 2). In SDR mode, data_hold_time must be set to 0.

Table continues on the next page...

**Table 14-53. Configuration fields in QSPI config block
(continued)**

Offset	Size (bytes)	Configuration Field	Description
0x14 – 0x1b	8	-	Reserved
0x1c – 0x1f	4	device_mode_config_en	Configure work mode Enable for external SPI flash devices 0 Disabled - ROM will not configure work mode of external flash devices. 1 Enabled - ROM will configure work mode of external flash devices, based on “device_cmd” and the LUT entry indicated by” write_cmd_ipcr”.
0x20 – 0x23	4	device_cmd	Command to configure the work mode of external flash devices. Effective only if “device_mode_config_en” is set to 1. It also depends on your specific external SPI flash device.
0x24 – 0x27	4	write_cmd_ipcr	IPCR pointed to LUT index for quad mode enablement Value = index << 24
0x28 – 0x2b	4	word_addressable	Word Addressable 0 Byte-addressable serial flash mode 1 Word-addressable serial flash mode
0x2c – 0x2f	4	cs_hold_time	Serial flash CS hold time, in number of flash clock cycles
0x30 – 0x33	4	cs_setup_time	Serial flash CS setup time, in number of flash clock cycles
0x34 – 0x37	4	sflash_A1_size	Size of external flash connected to ports of QSPI0A and QSPI0A_CS0, in bytes
0x38 – 0x3b	4	sflash_A2_size	Size of external flash connected to ports of QSPI0A and quadSPI0A_CS1, in bytes sflash_A2_size field must be set to 0 if the serial flash device is not present.
0x3c – 0x3f	4	sflash_B1_size	Size of external flash connected to ports of QSPI0B and quadSPI0B_CS0, in bytes sflash_B1_size field must be set to 0 if the serial flash device is not present.
0x40 – 0x43	4	sflash_B2_size	Size of external flash connected to ports of QSPI0B and quadSPI0B_CS1, in bytes sflash_B2_size field must be set to 0 if the serial flash device is not present.
0x44 – 0x47	4	sclk_freq	Frequency of QuadSPI serial clock 1 0 Low frequency 1 Mid frequency 2 High frequency
0x48 – 0x4b	4	busy_bit_offset	Busy bit offset in status register of Serial flash [31:16] :

Table continues on the next page...

**Table 14-53. Configuration fields in QSPI config block
(continued)**

Offset	Size (bytes)	Configuration Field	Description
			0 - Busy flag in status register is 1 when flash devices are busy. 1 - Busy flag in status register is 0 when flash devices are busy. [15:0]: The offset of busy flag in status register; valid range is 0 - 31.
0x4c – 0x4f	4	sflash_type	Type of serial flash 0 Single mode 1 Dual mode 2 Quad mode 3 Octal mode
0x50 – 0x53	4	sflash_port	Port enablement for QuadSPI module 0 Only pins for QSPI0A are enabled 1 Pins for both QSPI0A and QSPI0B are enabled 2 Only pins for QSPI0A are enabled; pins are on PORTC.
0x54 – 0x57	4	ddr_mode_enable	Enable DDR mode 0 DDR mode is disabled 1 DDR mode is enabled
0x58 – 0x5b	4	dqs_enable	Enable DQS 0 DQS is disabled 1 DQS is enabled
0x5c – 0x5f	4	parallel_mode_enable	Enable Parallel Mode 0 Parallel mode is disabled 1 Parallel mode is enabled ¹
0x60 – 0x63	4	portA_cs1	Enable QuadSPI0A_CS1 0 QuadSPI0A_CS1 is disabled 1 QuadSPI0A_CS1 is enabled portA_cs1 field must be set to 1 if sflash_A2_size is not equal to 0.
0x64 – 0x67	4	portB_cs1	Enable QuadSPI0B_CS1 0 QuadSPI0B_CS1 is disabled 1 QuadSPI0B_CS1 is enabled portB_cs1 field must be set to 1 if sflash_B2_size is not equal to 0.
0x68 – 0x6b	4	fsphs	Full Speed Phase selection for SDR instructions 0 Select sampling at non-inverted clock 1 Select sampling at inverted clock

Table continues on the next page...

**Table 14-53. Configuration fields in QSPI config block
(continued)**

Offset	Size (bytes)	Configuration Field	Description
0x6c – 0x6f	4	fsdly	Full Speed Delay selection for SDR instructions 0 One clock cycle delay 1 Two clock cycles delay.
0x70 – 0x73	4	ddrsmp	DDR sampling point Valid range: 0 - 7
0x74 – 0x173	4	look_up_table	Look-up-table for sequences of instructions
0x174 – 0x177	4	column_address_space	Column Address Space Defines the width of the column address
0x178 – 0x17b	4	config_cmd_en	Enable additional configuration command 0 Additional configuration command is not needed 1 Additional configuration command is needed
0x17c – 0x18b	16	config_cmds	IPCR arrays for each connected SPI flash All fields must be set to 0 if config_cmd_en is not asserted.
0x18c - 0x19b	16	config_cmds_args	Command arrays needed to be transferred to external spi flash All fields must be set to 0 if config_cmd_en is not asserted.
0x19c – 0x19f	4	differential_clock_pin_enable	Enable differential flash clock pin 0 Differential flash clock pin is disabled 1 Differential flash clock pin is enabled
0x1a0 – 0x1a3	4	flash_CK2_clock_pin_enable	Enable Flash CK2 Clock pin 0 Flash CK2 Clock pin is disabled 1 Flash CK2 Clock pin is enabled
0x1a4 – 0x1a7	4	dqs_inverse_sel	Select clock source for internal DQS generation 0 Use 1x internal reference clock for DQS generation 1 Use inverse 1x internal reference clock for DQS generation
0x1a8 – 0x1ab	4	dqs_latency_enable	DQS Latency Enable 0 DQS latency disabled 1 DQS feature with latency included enabled
0x1ac – 0x1af	4	dqs_loopback_internal	DQS loopback from internal DQS signal or DQS Pad 0 DQS loopback is sent to DQS pad first and then looped back to QuadSPI 1 DQS loopback from internal DQS signal directly
0x1b0 – 0x1b3	4	dqs_phase_sel	Select Phase Shift for internal DQS generation 0 No Phase shift 1 Select 45° phase shift

Table continues on the next page...

**Table 14-53. Configuration fields in QSPI config block
(continued)**

Offset	Size (bytes)	Configuration Field	Description
			2 Select 90° phase shift 3 Select 135° phase shift
0x1b4 – 0x1b7	4	dqs_fa_delay_chain_sel	Delay chain tap number selection for QuadSPI0A DQS Valid range: 0 - 63
0x1b8 – 0x1bb	4	dqs_fb_delay_chain_sel	Delay chain tap number selection for QuadSPI0B DQS Valid range: 0 - 63
0x1bc – 0x1c3	8	-	Reserved
0x1c4 – 0x1c7	4	page_size	Page size of external SPI flash. ¹ Page size of all SPI flash devices must be the same
0x1c8 – 0x1cb	4	sector_size	Sector size of external SPI flash. ¹ Sector size of all SPI flash devices must be the same.
0x1cc - 0x1cf	4	timeout_milliseconds	Timeout in terms of milliseconds. 0 Timeout check is disabled. NOTE: If the time that the external SPI device is busy is more than this timeout value, then the QuadSPI driver returns a timeout.
0x1d0 – 0x1d3	4	ips_cmd_second_divider	Second divider for IPs command based on QSPI_MCR[SCLKCFG]; the maximum value of QSPI_MCR[SCLKCFG] depends on the specific device.
0x1d4 – 0x1d7	4	need_multi_phase	0 Only 1 phase is necessary to access external flash devices 1 Multiple phases are necessary to erase/program external flash devices
0x1d8 – 0x1db	4	is_spansion_hyperflash	0 External flash devices is not in the Spansion Hyperflash family 1 External flash devices is in the Spansion Hyperflash family
0x1dc – 0x1df	4	pre_read_status_cmd_address_offset ²	Additional address for the PreReadStatus command. Set this field to 0xFFFF FFFF if it is not required.
0x1e0 – 0x1e3	4	pre_unlock_cmd_address_offset ²	Additional address for PreWriteEnable command. Set this field to 0xFFFF FFFF if it is not required.
0x1e4 – 0x1e7	4	unlock_cmd_address_offset ²	Additional address for WriteEnable command. Set this field to 0xFFFF FFFF if it is not required.
0x1e8 – 0x1eb	4	pre_program_cmd_address_offset ²	Additional address for PrePageProgram command. Set this field to 0xFFFF FFFF if it is not required.
0x1ec – 0x1ef	4	pre_erase_cmd_address_offset ²	Additional address for PreErase command. Set this field to 0xFFFF FFFF if it is not required.
0x1f0 – 0x1f3	4	erase_all_cmd_address_offset ²	Additional address for EraseAll command. Set this field to 0xFFFF FFFF if it is not required.
0x1f4 – 0x1ff	12	-	Reserved

1. If parallel mode is enabled, then page size and sector size must be twice the actual size.

2. These fields are effective only if “need_multi_phase” field is set to 1.

14.4.3.2 Look-up-table

The look-up table (LUT) is a part of the QCB, and contains sequences for instructions, such as read and write instructions. The Kinetis Bootloader defines LUT entries to support erase, program and read operations.

NOTE

The sequence in each LUT entry is target-specific. See the datasheet or reference manual of the corresponding serial flash device.

Table 14-54. Look-up table entries for bootloader

Index	Field	Description
0	Read	Sequence for read instructions
1	WriteEnable	Sequence for WriteEnable instructions
2	EraseAll	Sequence for EraseAll instructions
3	ReadStatus	Sequence for ReadStatus instructions
4	PageProgram	Sequence for Page Program instructions
6	PreErase ¹	Sequence for Pre-Erase instructions
7	SectorErase	Sequence for Sector Erase
8	Dummy	Sequence for dummy operation if needed. For example, if continuous read is configured in index 0, then the dummy LUT should be configured to force the external SPI flash to exit continuous read mode. If a dummy operation is not required, then this LUT entry must be set to 0.
9	PreWriteEnable ¹	Sequence for Pre-WriteEnable instructions
10	PrePageProgram ¹	Sequence for Pre-PageProgram instructions
11	PreReadStatus ¹	Sequence for Pre-ReadStatus instructions
5, 12, 13, 14, 15	Undefined ¹	All of these sequences are free to be used for other purpose. For example, index 5 can be used for enabling the Quad mode of SPI flash devices.

1. If these LUT entries are not required, then these LUT entries can be used for other purposes.

NOTE

All LUT indexes *that are not listed in the previous table* are allowed to be used for other purposes.

14.4.3.3 Configure QuadSPI module

The Kinetis Bootloader is able to access external SPI devices via the QuadSPI module, but only after the QuadSPI module is configured. There are 2 ways to configure the QuadSPI module:

- Configure QuadSPI module at runtime
- Configure QuadSPI module at start-up

Table 14-55. Configuring the QuadSPI module

Configure QuadSPI at	Procedure	Clock updates during QuadSPI module configuration
runtime	1. Use a WriteMemory command to program the QCB to either a region of RAM or internal flash. 2. Use the ConfigQuadSPI command to configure the QuadSPI module with the QCB that was programmed before. 3. After the above operations, the QuadSPI module has been set to an expected mode specified by the QCB, so the Kinetis bootloader is now able to access all connected SPI flash devices.	If QuadSPI module is configured at runtime: The System Core clock will not be updated if the QuadSPI module is configured at runtime; only QUADSPI_MCR [SCLKCFG] is updated according to sclk_freq field within the QCB. In this case, the clock source for QuadSPI module is , (QUADSPI0_SOCCR [QSPISRC] equals 4).
start-up	The steps of configuring QuadSPI at startup is based on the runtime procedure, if the QCB is not present at address 0 of the 1st external SPI flash device. 1. Configure the QuadSPI module at runtime (procedure above). 2. Erase the 1st sector of the 1st connected external SPI flash device using the FlashEraseRegion command. 3. Program the QCB to address 0 of the 1st connected external SPI flash device using the WriteMemory command. NOTE: For some types of SPI flash devices (like Spansion Hyperflash) which do not support basic reads (0x03) with 24-bit addresses, an alternative is available: for this step, program the QCB to internal flash, set the "qspiConfigBlockPointer" in the BCA to the start address of QCB, and program the BCA to 0x3c0. 4. Update BOOTSRC_SEL field (bits [7:6]) in FOPTregister at the address 0x40D to "0b'10", which means "boot from ROM with QuadSPI configured". 5. Reset the target. 6. After start-up, ROM code reads the QCB from address 0 of the external SPI flash and then configures the QuadSPI according to the QCB. 7. Now, the Kinetis Bootloader is able to access all connected SPI flash devices.	If QuadSPI module is configured at start-up: The System Core clock will be updated to MHz, if the QuadSPI module is configured at start-up. In this case, the clock source of the QuadSPI module switches to MCGFLL. The corresponding registers are updated with the values listed in the table <i>Register value updates when the QuadSPI module is configured at start-up</i>.

Table 14-55. Configuring the QuadSPI module

Configure QuadSPI at	Procedure	Clock updates during QuadSPI module configuration
	The QuadSPI module will be configured automatically out of reset, if the QCB is already present and the BOOTSRC_SEL field (bits [7:6]) in FOPTregister at the address 0x40D equals to "0'b10".	

NOTE

The user application boot from QuadSPI in XIP mode should not change the QuadSPI source clock from what ROM has configured (as shown in the previous table); otherwise a hard fault may occur. However, the QuadSPI source clocks (listed in the next table) can be changed successfully, if the application avoids shutting down the QSPI clock during clock switching; for example, if the clock switch related codes are relocated in either internal flash or SRAM.

Table 14-56. Register value updates when the QuadSPI module is configured at start-up

Register	Field	Value	Description
MCG_C7	OSCSEL	2	IRC48M is chosen as external reference clock
MCG_C1	FRDIV	6	Combined with MCG_C2[RANGE] to divide IRC48M with 1280
MCG_C4	DMX32	0	
MCG_C4	DRST_DRS	1	Combined with MCG_C4[DMX32] to multiply divided clock with 2560 , then MCGOUT clock is equal to 96 MHz.
MCG_C6	PLLS	0	Disable PLL
MCG_C1	IREFS	0	Switch to external reference clock
SIM_CLKDIV1	OUTDIV1	0	
SIM_CLKDIV1	OUTDIV2	0	
SIM_CLKDIV1	OUTDIV3	0	
SIM_CLKDIV1	OUTDIV4	1	
QUADSPI0_SOCCR	QSPISRC	1	MCGFLL clock is selected as the clock source for QuadSPI module

14.4.3.4 Access external SPI flash devices using QuadSPI module

The Kinetis Bootloader supports access to external SPI flash devices using the following commands:

- **Flash-erase-all:** This command can erase all SPI flash devices defined in the QCB. For example, if "flash-erase-all 1", the 1 represents the source of the erasure command is QuadSPI memory.

- **Flash-erase-region:** This command can erase a specified range of flash within connected SPI flash devices. For example “flash-erase-region 0x68000000 0x10000”.
- **Write-memory:** The Kinetis Bootloader calls the Write-memory command to program specified data to a given region of connected SPI flash devices. For example, “write-memory 0x68001000 led_demo.bin”.
- **Read-memory:** The Kinetis Bootloader calls the Read-memory command to read data from a given region of connected SPI flash devices. For example, “read-memory 0x68000000 1024 temp.bin”.

These commands return error codes.

Table 14-57. Status Error Codes for accessing QuadSPI memory

Error Code	Value	Description
kStatus_Success	0	Operation succeeded without error
kStatus_QspiFlashSizeError	400	Size of external SPI flash is invalid
kStatus_QspiFlashAlignmentError	401	Start Address for program is not page-aligned
kStatus_QspiFlashAddressError	402	The address is invalid
kStatus_QspiFlashCommandFailure	403	The operation failed
kStatus_QspiNotConfigured	405	QSPI module is not successfully configured
kStatus_QspiCommandNotSupported	406	The command is not supported under certain modes
kStatus_QspiCommandTimeout	407	The time that the external SPI device is busy more than the timeout value (timeout_milliseconds).
kStatus_QspiWriteFailure	408	QSPI module cannot perform a program command at the current clock frequency

14.4.3.5 Boot directly from QuadSPI

The Kinetis Bootloader supports booting directly from QuadSPI. To boot directly from QuadSPI, the following conditions must be met:

- The bootFlags field in BCA is set to 0xFE, which means "boot directly from QuadSPI".
- The BOOTSRC_SEL field (bits [7:6]) in the FOPT register at address 0x40D is set to “0'b10”, which means "boot from ROM with QuadSPI configured".
- User application is valid.
- QuadSPI configuration block (QCB) is valid
- CRC check passed if the CRC check feature is enabled.

14.4.4 LPUART Peripheral

The Kinetis Bootloader integrates an autobaud detection algorithm for the LPUART peripheral, thereby providing flexible baud rate choices.

Autobaud feature: If LPUART n is used to connect to the bootloader, then the LPUART n _RX pin must be kept high and not left floating during the detection phase in order to comply with the autobaud detection algorithm. After the bootloader detects the ping packet (0x5A 0xA6) on LPUART n _RX, the bootloader firmware executes the autobaud sequence. If the baudrate is successfully detected, then the bootloader will send a ping packet response [(0x5A 0xA7), protocol version (4 bytes), protocol version options (2 bytes) and crc16 (2 bytes)] at the detected baudrate. The Kinetis Bootloader then enters a loop, waiting for bootloader commands via the LPUART peripheral.

NOTE

- The autobaud feature requires a ping packet with a higher accuracy (+/-3%), or the ping packet will be ignored as noise.
- The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed LPUART transmission mode (8-bit data, no parity bit and 1 stop bit). If the bytes of the ping packet are sent one-by-one with more than 80 ms delay between them, then the autobaud detection algorithm may calculate an incorrect baud rate. In this case, the autobaud detection state machine should be reset.

Supported baud rates: The baud rate is closely related to the MCU core and system clock frequencies. Typical baud rates supported are 9600, 19200, 38400, 57600, and 115200. Of course, to influence the performance of autobaud detection, the clock configuration in BCA can be changed.

Packet transfer: After autobaud detection succeeds, bootloader communications can take place over the LPUART peripheral. The following flow charts show:

- How the host detects an ACK from the target
- How the host detects a ping response from the target
- How the host detects a command response from the target

Figure 14-28. Host reads an ACK from target via LPUART

Figure 14-29. Host reads a ping response from target via LPUART

Figure 14-30. Host reads a command response from target via LPUART

14.4.5 USB peripheral

The Kinetis Bootloader in the ROM supports loading data into flash via the USB peripheral. The target is implemented as a USB HID class.

USB HID does not use framing packets; instead the packetization inherent in the USB protocol itself is used. The ability for the device to NAK Out transfers (until they can be received) provides the required flow control; the built-in CRC of each USB packet provides the required error detection.

14.4.5.1 Clock configuration

The K27 ROM supports the crystal-less USB feature. If the USB peripheral is enabled, then the ROM enables the 48-MHz IRC. The ROM also enables the USB clock recovery feature (by setting `USBx_CLK_RECOVER_CTRL[CLOCK_RECOVER_EN]` to 1 and `USB_CLK_RECOVER_IRC_EN[IRC_EN]` to 1).

14.4.5.2 Device descriptor

The Kinetis ROM configures the default USB VID/PID/Strings as below:

Default VID/PID:

- VID = 0x15A2
- PID = 0x0073

Default Strings:

- Manufacturer [1] = "Freescale Semiconductor Inc." (Note that Freescale Semiconductor is now NXP Semiconductors.)
- Product [2] = "Kinetis Bootloader"

You can customize the USB VID/PID/Strings with the Bootloader Configuration Area (BCA) of the flash. See [Table 14-3](#). For example, the USB VID and PID can be customized by writing the new VID to the usbPid(BCA + 0x14) field and the new PID to the usbPid(BCA + 0x16) field of the BCA in flash. To change the USB strings, you need to prepare a structure (like the one shown below) in the flash, and then write the address of the g_languages structure to the usbStringsPointer(BCA + 0x18) field of the BCA.

```
g_languages = { USB_STR_0,
sizeof(USB_STR_0),
(uint_16)0x0409,
(const uint_8 **)g_string_descriptors,
g_string_desc_size};
the USB_STR_0, g_string_descriptors and g_string_desc_size are defined as below.
USB_STR_0[4] = {0x02,
0x03,
0x09,
0x04
};
g_string_descriptors[4] =
{ USB_STR_0,
USB_STR_1,
USB_STR_2,
USB_STR_3};
g_string_desc_size[4] =
{ sizeof(USB_STR_0),
sizeof(USB_STR_1),
sizeof(USB_STR_2),
sizeof(USB_STR_3)};
```

You can make your own structure of USB_STR_1, USB_STR_2, USB_STR_3:

- USB_STR_1 is used for the manufacturer string.
- USB_STR_2 is used for the product string.
- USB_STR_3 is used for the serial number string.

By default, the 3 strings are defined as below:

```
USB_STR_1[] =
{ sizeof(USB_STR_1),
USB_STRING_DESCRIPTOR,
'F',0,
'r',0,
'e',0,
'e',0,
's',0,
```

Peripherals Supported

```
'c',0,
'a',0,
'l',0,
'e',0,
' ',0,
's',0,
'e',0,
'm',0,
'i',0,
'c',0,
'o',0,

```

```
'E',0,
'V',0,
'I',0,
'C',0,
'E',0
};
```

14.4.5.3 Endpoints

The HID peripheral uses 3 endpoints:

- Control (0)
- Interrupt IN (1)
- Interrupt OUT (2)

The Interrupt OUT endpoint is optional for HID class devices, but the Kinetis Bootloader uses it as a pipe, where the firmware can NAK send requests from the USB host.

14.4.5.4 HID reports

There are 4 HID reports defined and used by the bootloader USB HID peripheral. The report ID determines the direction and type of packet sent in the report; otherwise, the contents of all reports are the same.

Report ID	Packet Type	Direction
1	Command	OUT
2	Data	OUT
3	Command	IN
4	Data	IN

For all reports, these properties apply:

Usage Min	1
Usage Max	1
Logical Min	0
Logical Max	255
Report Size	8
Report Count	34

Each report has a maximum size of 34 bytes. This is derived from the minimum bootloader packet size of 32 bytes, plus a 2-byte report header that indicates the length (in bytes) of the packet sent in the report.

NOTE

In the future, the maximum report size may be increased, to support transfers of larger packets. Alternatively, additional reports may be added with larger maximum sizes.

The actual data sent in all of the reports looks like:

0	Report ID
1	Packet Length LSB
2	Packet Length MSB
3	Packet[0]
4	Packet[1]
5	Packet[2]
	...
N+3-1	Packet[N-1]

This data includes the Report ID, which is required if more than one report is defined in the HID report descriptor. The actual data sent and received has a maximum length of 35 bytes. The Packet Length header is written in little-endian format, and it is set to the size (in bytes) of the packet sent in the report. This size does not include the Report ID or the Packet Length header itself. During a data phase, a packet size of 0 indicates a data phase abort request from the receiver.

14.5 Get/SetProperty Command Properties

This section lists the properties of the GetProperty and SetProperty commands.

Table 14-58. Properties used by Get/SetProperty Commands, sorted by Value

Property	Writable	Tag Value	Size	Description
CurrentVersion	No	01h	4	Current bootloader version.
AvailablePeripherals	No	02h	4	The set of peripherals supported on this chip.
FlashStartAddress	No	03h	4	Start address of program flash.
FlashSizeInBytes	No	04h	4	Size in bytes of program flash.
FlashSectorSize	No	05h	4	The size in bytes of one sector of program flash. This is the minimum erase size.
FlashBlockCount	No	06h	4	Number of blocks in the flash array.

Table continues on the next page...

Table 14-58. Properties used by Get/SetProperty Commands, sorted by Value (continued)

Property	Writable	Tag Value	Size	Description
AvailableCommands	No	07h	4	The set of commands supported by the bootloader.
CRCCheckStatus	No	08h	4	The status of the application CRC check.
VerifyWrites	Yes	0Ah	4	Controls whether the bootloader will verify writes to flash. VerifyWrites feature is enabled by default. 0 - No verification is done. 1 - Enable verification.
MaxPacketSize	No	0Bh	4	Maximum supported packet size for the currently active peripheral interface.
ReservedRegions	No	0Ch	16	List of memory regions reserved by the bootloader. Returned as value pairs (<start-address-of-region>, <end-address-of-region>). - If HasDataPhase flag is not set, then the Response packet parameter count indicates the number of pairs. - If HasDataPhase flag is set, then the second parameter is the number of bytes in the data phase.
RAMStartAddress	No	0Eh	4	Start address of RAM segment. The first parameter to GetProperty command identifies the segment. See the device specific memory map for number of RAM segments the device contains.
RAMSizeInBytes	No	0Fh	4	Size in bytes of RAM segment. The first parameter to GetProperty command identifies the segment. See the device specific memory map for number of RAM segments the device contains.
SystemDeviceId	No	10h	4	Value of the Kinetis System Device Identification register.
FlashSecurityState	No	11h	4	Indicates whether Flash security is enabled 0 - Flash security is disabled 1 - Flash security is enabled
UniqueDeviceId	No	12h	16	Unique device identification, value of Kinetis Unique Identification registers (16 for K series devices, 12 for KL series devices)
FacSupport	No	13h	4	FAC (Flash Access Control) support flag 0 - FAC not supported 1 - FAC supported
FlashAccessSegmentSize	No	14h	4	The size in bytes of 1 segment of flash
FlashAccessSegmentCount	No	15h	4	FAC segment count (The count of flash access segments within the flash model.)
FlashReadMargin	Yes	16h	4	The margin level setting for flash erase and program verify commands. 0 = Normal 1 = User (default) 2 = Factory

Table continues on the next page...

Table 14-58. Properties used by Get/SetProperty Commands, sorted by Value (continued)

Property	Writable	Tag Value	Size	Description
QspiInitStatus	No	17h	4	The result of the QSPI initialization process during startup. 405 - QSPI is not initialized 0 - QSPI is initialized
ExternalMemoryAttributes	No	19h	24	List of attributes supported by the specified memory Id (1=QuadSpi0). See description for the return value in the section ExternalMemoryAttributes Property .

14.5.1 Property Definitions

Get/Set property definitions are provided in this section.

14.5.1.1 CurrentVersion Property

The value of this property is a 4-byte structure containing the current version of the bootloader.

Table 14-59. Fields of CurrentVersion property:

Bits	[31:24]	[23:16]	[15:8]	[7:0]
Field	Name = 'K' (0x4B)	Major version	Minor version	Bugfix version

14.5.1.2 AvailablePeripherals Property

The value of this property is a bitfield that lists the peripherals supported by the bootloader and the hardware on which it is running.

Table 14-60. Peripheral bits:

Bit	[31:7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]
Peripheral	Reserved	Reserved	Reserved	USB HID	Reserved	SPI Slave	I2C Slave	LPUART

If the peripheral is available, then the corresponding bit will be set in the property value. All reserved bits must be set to 0.

14.5.1.3 AvailableCommands Property

This property value is a bitfield with set bits indicating the commands enabled in the bootloader. Only commands that can be sent from the host to the target are listed in the bitfield. Response commands such as GenericResponse are excluded.

The bit number that identifies whether a command is present is the command's tag value minus 1. 1 is subtracted from the command tag because the lowest command tag value is 0x01. To get the bit mask for a given command, use this expression:

$$\text{mask} = 1 \ll (\text{tag} - 1)$$

Table 14-61. Command bits:

Bit	[31:18]	[17]	[16]	[15]	[14]	[13]	[12]	[11]	[10]	[9]	[8]	[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]
Command	Reserved	ReliableUpdate	ConfigureQuadSPI	FlashReadResource	FlashReadOnce	FlashProgramOnce	FlashEraseAllUnsecure	SetProperty	Reset	Call	Execute	ReceiveSBFile	GetProperty	FlashSecurityDisable	FillMemory	WriteMemory	ReadMemory	FlashEraseRegion	FlashEraseAll

14.5.1.4 ExternalMemoryAttributes Property

The value returned by this property is a 24-byte data structure containing available external memory attributes: start address, total size in KB, page size, sector size, and block size. Below is the breakdown of 24-byte structure:

Table 14-62. Fields of ExternalMemoryAttributes property:

Field Offset	Field Description
0 - 3	The value returned is a bitmap showing the supported attributes for the external memory, with the corresponding bit-field set. 0x00000001 - start address 0x00000002 - total size 0x00000004 - page size 0x00000008 - sector size

Table continues on the next page...

Table 14-62. Fields of ExternalMemoryAttributes property: (continued)

Field Offset	Field Description
	0x00000010 - block size
4 - 7	Start address of external memory
8 - 11	Total size of external memory in terms of kilobytes
12 - 15	Page size of external memory in terms of bytes
16 - 19	Sector size of external memory in terms of bytes
20 - 23	Block size of external memory in terms of bytes

14.6 Verifying the application in flash using CRC-32

Using CRC-32 and a given address range, the ROM bootloader supports performing an application integrity check.

Before application integrity testing: the following fields in the bootloader configuration area must be set:

- Set `crcStartAddress` to the start address that should be used for the CRC check.
- Set `crcByteCount` to the number of bytes to run the CRC check on, from the start address.
- Set `crcExpectedValue` to the value that the CRC calculation should result in.

Application integrity testing:

- If all of the above fields are unset (all 0xFF bytes for `crcStartAddress`, `crcByteCount`, and `crcExpectedValue`), then the ROM bootloader returns `kStatus_AppCrcCheckInvalid`.
- If any one of the above fields are set (`crcStartAddress`, `crcByteCount`, and `crcExpectedValue`), then the ROM bootloader checks if the given address range of the application is valid, and if the application resides in internal flash or external QSPI flash, by running a CRC check on the image in flash:
 - If the the given address range of the application is not valid (false), then the bootloader returns `kStatus_AppCrcCheckOutOfRange`.
 - If the given address range of the application is valid (true), then the CRC check is performed. The CRC32 algorithm in ROM uses a polynomial (0x04C1_1DB7), and the initial seed is 0xFFFF_FFFF.
 - If the CRC check fails, then the bootloader returns `kStatus_AppCrcCheckFailed`;
 - If the CRC check succeeds, then it returns `kStatus_AppCrcCheckPassed`.

After application integrity testing:

- If the bootloader returns `kStatus_AppCrcCheckOutOfRange` or `kStatus_AppCrcCheckFailed`, then an external pin will also be asserted, to indicate CRC check failure.
- The bootloader will only jump to the application if `kStatus_AppCrcCheckPassed` is returned; if `kStatus_AppCrcCheckPassed` is not returned, then the bootloader will stay active, and wait for further commands.

14.7 Kinetis Bootloader Status Error Codes

This section describes the status error codes that the Kinetis Bootloader returns to the host.

Table 14-63. Kinetis Bootloader Status Error Codes, sorted by Value

Error Code	Value	Description
<code>kStatus_Success</code>	0	Operation succeeded without error.
<code>kStatus_Fail</code>	1	Operation failed with a generic error.
<code>kStatus_ReadOnly</code>	2	Requested value cannot be changed because it is read-only.
<code>kStatus_OutOfRange</code>	3	Requested value is out of range.
<code>kStatus_InvalidArgument</code>	4	The requested command's argument is undefined.
<code>kStatus_Timeout</code>	5	A timeout occurred.
<code>kStatus_FlashSizeError</code>	100	Not used.
<code>kStatus_FlashAlignmentError</code>	101	Address or length does not meet required alignment.
<code>kStatus_FlashAddressError</code>	102	Address or length is outside addressable memory.
<code>kStatus_FlashAccessError</code>	103	The <code>FTFE_FSTAT[ACCERR]</code> bit is set.
<code>kStatus_FlashProtectionViolation</code>	104	The <code>FTFE_FSTAT[FPVIOL]</code> bit is set.
<code>kStatus_FlashCommandFailure</code>	105	The <code>FTFE_FSTAT[MGSTAT0]</code> bit is set.
<code>kStatus_FlashUnknownProperty</code>	106	Unknown Flash property.
<code>kStatus_FlashEraseKeyError</code>	107	The key provided does not match the programmed flash key.
<code>kStatus_FlashRegionExecuteOnly</code>	108	The area of flash is protected as execute only.
<code>kStatus_I2C_SlaveTxUnderrun</code>	200	I2C Slave TX Underrun error.
<code>kStatus_I2C_SlaveRxOverrun</code>	201	I2C Slave RX Overrun error.
<code>kStatus_I2C_ArbitrationLost</code>	202	I2C Arbitration Lost error.
<code>kStatus_SPI_SlaveTxUnderrun</code>	300	SPI Slave TX Underrun error.
<code>kStatus_SPI_SlaveRxOverrun</code>	301	SPI Slave RX Overrun error.
<code>kStatus_SPI_Timeout</code>	302	SPI transfer timed out.
<code>kStatus_SPI_Busy</code>	303	SPI instance is already busy performing a transfer.
<code>kStatus_SPI_NoTransferInProgress</code>	304	Attempt to abort a transfer when no transfer was in progress.

Table continues on the next page...

Table 14-63. Kinetis Bootloader Status Error Codes, sorted by Value (continued)

Error Code	Value	Description
kStatus_QspiFlashSizeError	400	The detected flash size is incorrect.
kStatus_QspiFlashAlignmentError	401	The address that is being written to is not properly aligned.
kStatus_QspiFlashAddressError	402	The QSPI address is invalid.
kStatus_QspiFlashCommandFailure	403	The QSPI command failed.
kStatus_QspiFlashUnknownProperty	404	The property is not supported.
kStatus_QspiNotConfigured	405	The QSPI has not been configured.
kStatus_QspiCommandNotSupported	406	The operation is not supported.
kStatus_QspiCommandTimeout	407	The time that external SPI devices are busy is more than the specified timeout value.
kStatus_QspiWriteFailure	408	The QSPI module cannot perform a program command at the current clock frequency.
kStatus_UnknownCommand	10000	The requested command value is undefined.
kStatus_SecurityViolation	10001	Command is disallowed because flash security is enabled.
kStatus_AbortDataPhase	10002	Abort the data phase early.
kStatus_Ping	10003	Internal: received ping during command phase.
kStatusRomLdrSectionOverrun	10100	The loader has finished processing the SB file.
kStatusRomLdrSignature	10101	The signature of the SB file is incorrect.
kStatusRomLdrSectionLength	10102	The section length in chunks is invalid.
kStatusRomLdrUnencryptedOnly	10103	An encrypted SB file has been sent and decryption support is not available.
kStatusRomLdrEOFReached	10104	The end of the SB file has been reached.
kStatusRomLdrChecksum	10105	The checksum of a command tag block is invalid.
kStatusRomLdrCrc32Error	10106	The CRC-32 of the data for a load command is incorrect.
kStatusRomLdrUnknownCommand	10107	An unknown command was found in the SB file.
kStatusRomLdrIdNotFound	10108	There was no bootable section found in the SB file.
kStatusRomLdrDataUnderrun	10109	The SB state machine is waiting for more data.
kStatusRomLdrJumpReturned	10110	The function that was jumped to by the SB file has returned.
kStatusRomLdrCallFailed	10111	The call command in the SB file failed.
kStatusRomLdrKeyNotFound	10112	A matching key was not found in the SB file's key dictionary to unencrypt the section.
kStatusRomLdrSecureOnly	10113	The SB file sent is unencrypted and security on the target is enabled.
kStatusRomLdrResetReturned	10114	The SB file reset operation has unexpectedly returned.
kStatusMemoryRangeInvalid	10200	Memory range conflicts with a protected region.
kStatus_UnknownProperty	10300	The requested property value is undefined.
kStatus_ReadOnlyProperty	10301	The requested property value cannot be written.
kStatus_InvalidPropertyValue	10302	The specified property value is invalid.

Table continues on the next page...

Table 14-63. Kinetis Bootloader Status Error Codes, sorted by Value (continued)

Error Code	Value	Description
kStatus_AppCrcCheckPassed	10400	CRC check is valid and passed.
kStatus_AppCrcCheckFailed	10401	CRC check is valid but failed.
kStatus_AppCrcCheckInactive	10402	CRC check is inactive.
kStatus_AppCrcCheckInvalid	10403	CRC check is invalid, because the BCA is invalid or the CRC parameters are unset (all 0xFF bytes).
kStatus_AppCrcCheckOutOfRange	10404	CRC check is valid but addresses are out of range.
kStatus_ReliableUpdateSuccess	10600	Reliable update process has completed successfully.
kStatus_ReliableUpdateFail	10601	Reliable update process has failed.
kStatus_ReliableUpdateInactive	10602	Reliable update feature is inactive.
kStatus_ReliableUpdateBackupApplicationInvalid	10603	Backup application image is invalid.
kStatus_ReliableUpdateStillInMainApplication	10604	The next boot will still use the main application image.
kStatus_ReliableUpdateSwapSystemNotReady	10605	Cannot swap flash by default, because the swap system is not ready.
kStatus_ReliableUpdateBackupBootloaderNotReady	10606	Cannot swap flash, because there is no valid backup bootloader image.
kStatus_ReliableUpdateSwapIndicatorAddressInvalid	10607	Cannot swap flash, because the provided swap indicator is invalid.

Chapter 15

Reset Control Module (RCM)

15.1 Introduction

Information found here describes the registers of the Reset Control Module (RCM). The RCM implements many of the reset functions for the chip. See the chip's reset chapter for more information.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the RCM.

15.2 Reset memory map and register descriptions

The RCM Memory Map/Register Definition can be found here.

The Reset Control Module (RCM) registers provide reset status information and reset filter control.

NOTE

The RCM registers can be written only in supervisor mode.
Write accesses in user mode are blocked and will result in a bus error.

RCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4007_F000	System Reset Status Register 0 (RCM_SRS0)	8	R	82h	15.2.1/298
4007_F001	System Reset Status Register 1 (RCM_SRS1)	8	R	00h	15.2.2/299
4007_F004	Reset Pin Filter Control register (RCM_RPFC)	8	R/W	00h	15.2.3/301
4007_F005	Reset Pin Filter Width register (RCM_RPFW)	8	R/W	00h	15.2.4/302

Table continues on the next page...

RCM memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4007_F006	Force Mode Register (RCM_FM)	8	R/W	00h	15.2.5/303
4007_F007	Mode Register (RCM_MR)	8	R/W	See section	15.2.6/304
4007_F008	Sticky System Reset Status Register 0 (RCM_SSRS0)	8	R/W	82h	15.2.7/305
4007_F009	Sticky System Reset Status Register 1 (RCM_SSRS1)	8	R/W	00h	15.2.8/306

15.2.1 System Reset Status Register 0 (RCM_SRS0)

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

NOTE

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x82
- LVD (without POR) — 0x02
- VLLS mode wakeup due to $\overline{\text{RESET}}$ pin assertion — 0x41
- VLLS mode wakeup due to other wakeup sources — 0x01
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: 4007_F000h base + 0h offset = 4007_F000h

Bit	7	6	5	4	3	2	1	0
Read	POR	PIN	WDOG	0	LOL	LOC	LVD	WAKEUP
Write								
Reset	1	0	0	0	0	0	1	0

RCM_SRS0 field descriptions

Field	Description
7 POR	Power-On Reset Indicates a reset has been caused by the power-on detection logic. Because the internal supply voltage was ramping up at the time, the low-voltage reset (LVD) status bit is also set to indicate that the reset occurred while the internal supply was below the LVD threshold. 0 Reset not caused by POR 1 Reset caused by POR
6 PIN	External Reset Pin Indicates a reset has been caused by an active-low level on the external $\overline{\text{RESET}}$ pin. 0 Reset not caused by external reset pin 1 Reset caused by external reset pin

Table continues on the next page...

RCM_SRS0 field descriptions (continued)

Field	Description
5 WDOG	Watchdog Indicates a reset has been caused by the watchdog timer timing out. This reset source can be blocked by disabling the watchdog. 0 Reset not caused by watchdog timeout 1 Reset caused by watchdog timeout
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 LOL	Loss-of-Lock Reset Indicates a reset has been caused by a loss of lock in the MCG PLL. See the MCG description for information on the loss-of-clock event. 0 Reset not caused by a loss of lock in the PLL 1 Reset caused by a loss of lock in the PLL
2 LOC	Loss-of-Clock Reset Indicates a reset has been caused by a loss of external clock. The MCG clock monitor must be enabled for a loss of clock to be detected. Refer to the detailed MCG description for information on enabling the clock monitor. 0 Reset not caused by a loss of external clock. 1 Reset caused by a loss of external clock.
1 LVD	Low-Voltage Detect Reset If PMC_LVDSC1[LVDRE] is set and the supply drops below the LVD trip voltage, an LVD reset occurs. This field is also set by POR. 0 Reset not caused by LVD trip or POR 1 Reset caused by LVD trip or POR
0 WAKEUP	Low Leakage Wakeup Reset Indicates a reset has been caused by an enabled LLWU module wakeup source while the chip was in a low leakage mode. In LLS mode, the $\overline{\text{RESET}}$ pin is the only wakeup source that can cause this reset. Any enabled wakeup source in a VLLSx mode causes a reset. This bit is cleared by any reset except WAKEUP. 0 Reset not caused by LLWU module wakeup source 1 Reset caused by LLWU module wakeup source

15.2.2 System Reset Status Register 1 (RCM_SRS1)

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

NOTE

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x00

Reset memory map and register descriptions

- LVD (without POR) — 0x00
- VLLS mode wakeup — 0x00
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: 4007_F000h base + 1h offset = 4007_F001h

Bit	7	6	5	4	3	2	1	0
Read	0	0	SACKERR	0	MDM_AP	SW	LOCKUP	JTAG
Write								
Reset	0	0	0	0	0	0	0	0

RCM_SRS1 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SACKERR	Stop Mode Acknowledge Error Reset Indicates that after an attempt to enter Stop mode, a reset has been caused by a failure of one or more peripherals to acknowledge within approximately one second to enter stop mode. 0 Reset not caused by peripheral failure to acknowledge attempt to enter stop mode 1 Reset caused by peripheral failure to acknowledge attempt to enter stop mode
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 MDM_AP	MDM-AP System Reset Request Indicates a reset has been caused by the host debugger system setting of the System Reset Request bit in the MDM-AP Control Register. 0 Reset not caused by host debugger system setting of the System Reset Request bit 1 Reset caused by host debugger system setting of the System Reset Request bit
2 SW	Software Indicates a reset has been caused by software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register in the ARM core. 0 Reset not caused by software setting of SYSRESETREQ bit 1 Reset caused by software setting of SYSRESETREQ bit
1 LOCKUP	Core Lockup Indicates a reset has been caused by the ARM core indication of a LOCKUP event. 0 Reset not caused by core LOCKUP event 1 Reset caused by core LOCKUP event
0 JTAG	JTAG Generated Reset Indicates a reset has been caused by JTAG selection of certain IR codes: EXTEST, HIGHZ, and CLAMP.

Table continues on the next page...

RCM_SRS1 field descriptions (continued)

Field	Description
0	Reset not caused by JTAG
1	Reset caused by JTAG

15.2.3 Reset Pin Filter Control register (RCM_RPFC)**NOTE**

The reset values of bits 2-0 are for Chip POR only. They are unaffected by other reset types.

NOTE

The bus clock filter is reset when disabled or when entering stop mode. The LPO filter is reset when disabled .

Address: 4007_F000h base + 4h offset = 4007_F004h

Bit	7	6	5	4	3	2	1	0
Read	0					RSTFLTSS	RSTFLTSRW	
Write								
Reset	0	0	0	0	0	0	0	0

RCM_RPFC field descriptions

Field	Description
7-3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 RSTFLTSS	Reset Pin Filter Select in Stop Mode Selects how the reset pin filter is enabled in Stop and VLPS modes , and also during LLS and VLLS modes. On exit from VLLS mode, this bit should be reconfigured before clearing PMC_REGSC[ACKISO]. 0 All filtering disabled 1 LPO clock filter enabled
RSTFLTSRW	Reset Pin Filter Select in Run and Wait Modes Selects how the reset pin filter is enabled in run and wait modes. 00 All filtering disabled 01 Bus clock filter enabled for normal operation 10 LPO clock filter enabled for normal operation 11 Reserved

15.2.4 Reset Pin Filter Width register (RCM_RPFW)

NOTE

The reset values of the bits in the RSTFLTSEL field are for Chip POR only. They are unaffected by other reset types.

Address: 4007_F000h base + 5h offset = 4007_F005h

Bit	7	6	5	4	3	2	1	0
Read	0				RSTFLTSEL			
Write								
Reset	0	0	0	0	0	0	0	0

RCM_RPFW field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RSTFLTSEL	Reset Pin Filter Bus Clock Select Selects the reset pin bus clock filter width. 00000 Bus clock filter count is 1 00001 Bus clock filter count is 2 00010 Bus clock filter count is 3 00011 Bus clock filter count is 4 00100 Bus clock filter count is 5 00101 Bus clock filter count is 6 00110 Bus clock filter count is 7 00111 Bus clock filter count is 8 01000 Bus clock filter count is 9 01001 Bus clock filter count is 10 01010 Bus clock filter count is 11 01011 Bus clock filter count is 12 01100 Bus clock filter count is 13 01101 Bus clock filter count is 14 01110 Bus clock filter count is 15 01111 Bus clock filter count is 16 10000 Bus clock filter count is 17 10001 Bus clock filter count is 18 10010 Bus clock filter count is 19 10011 Bus clock filter count is 20 10100 Bus clock filter count is 21 10101 Bus clock filter count is 22 10110 Bus clock filter count is 23 10111 Bus clock filter count is 24 11000 Bus clock filter count is 25

Table continues on the next page...

RCM_RPFW field descriptions (continued)

Field	Description
11001	Bus clock filter count is 26
11010	Bus clock filter count is 27
11011	Bus clock filter count is 28
11100	Bus clock filter count is 29
11101	Bus clock filter count is 30
11110	Bus clock filter count is 31
11111	Bus clock filter count is 32

15.2.5 Force Mode Register (RCM_FM)**NOTE**

The reset values of the bits in the FORCEROM field are for Chip POR only. They are unaffected by other reset types.

Address: 4007_F000h base + 6h offset = 4007_F006h

Bit	7	6	5	4	3	2	1	0
Read	0					FORCEROM		0
Write								
Reset	0	0	0	0	0	0	0	0

RCM_FM field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–1 FORCEROM	Force ROM Boot When either bit is set, will force boot from ROM during all subsequent system resets. 00 No effect 01 Force boot from ROM with RCM_MR[1] set. 10 Force boot from ROM with RCM_MR[2] set. 11 Force boot from ROM with RCM_MR[2:1] set.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

15.2.6 Mode Register (RCM_MR)

This register includes status flags to indicate the state of the mode pins during the last Chip Reset.

Address: 4007_F000h base + 7h offset = 4007_F007h

Bit	7	6	5	4	3	2	1	0
Read	0					BOOTROM		0
Write						w1c		
Reset	0	0	0	0	0	*	*	0

- * Notes:
- BOOTROM field: The reset state of this register depends on the boot mode.

RCM_MR field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–1 BOOTROM	Boot ROM Configuration Indicates the boot source, the boot source remains set until the next System Reset or software can write logic one to clear the corresponding mode bit. While either bit is set, the NMI input is disabled and the vector table is relocated to the ROM base address at 0x1C00_0000. These bits should be cleared by writing logic one before executing any code from either Flash or SRAM. 00 Boot from Flash 01 Boot from ROM due to BOOTCFG0 pin assertion 10 Boot form ROM due to FOPT[7] configuration 11 Boot from ROM due to both BOOTCFG0 pin assertion and FOPT[7] configuration
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

15.2.7 Sticky System Reset Status Register 0 (RCM_SSRS0)

This register includes status flags to indicate all reset sources since the last POR, LVD or VLLS Wakeup that have not been cleared by software. Software can clear the status flags by writing a logic one to a flag.

Address: 4007_F000h base + 8h offset = 4007_F008h

Bit	7	6	5	4	3	2	1	0
Read	SPOR	SPIN	SWDOG	0	SLOL	SLOC	SLVD	SWAKEUP
Write	w1c	w1c	w1c		w1c	w1c	w1c	w1c
Reset	1	0	0	0	0	0	1	0

RCM_SSRS0 field descriptions

Field	Description
7 SPOR	Sticky Power-On Reset Indicates a reset has been caused by the power-on detection logic. Because the internal supply voltage was ramping up at the time, the low-voltage reset (LVD) status bit is also set to indicate that the reset occurred while the internal supply was below the LVD threshold. 0 Reset not caused by POR 1 Reset caused by POR
6 SPIN	Sticky External Reset Pin Indicates a reset has been caused by an active-low level on the external <code>RESET</code> pin. 0 Reset not caused by external reset pin 1 Reset caused by external reset pin
5 SWDOG	Sticky Watchdog Indicates a reset has been caused by the watchdog timer timing out. This reset source can be blocked by disabling the watchdog. 0 Reset not caused by watchdog timeout 1 Reset caused by watchdog timeout
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 SLOL	Sticky Loss-of-Lock Reset Indicates a reset has been caused by a loss of lock in the MCG PLL. See the MCG description for information on the loss-of-clock event. 0 Reset not caused by a loss of lock in the PLL 1 Reset caused by a loss of lock in the PLL
2 SLOC	Sticky Loss-of-Clock Reset

Table continues on the next page...

RCM_SSRS0 field descriptions (continued)

Field	Description
	Indicates a reset has been caused by a loss of external clock. The MCG clock monitor must be enabled for a loss of clock to be detected. Refer to the detailed MCG description for information on enabling the clock monitor. 0 Reset not caused by a loss of external clock. 1 Reset caused by a loss of external clock.
1 SLVD	Sticky Low-Voltage Detect Reset If PMC_LVDSC1[LVDRE] is set and the supply drops below the LVD trip voltage, an LVD reset occurs. This field is also set by POR. 0 Reset not caused by LVD trip or POR 1 Reset caused by LVD trip or POR
0 SWAKEUP	Sticky Low Leakage Wakeup Reset Indicates a reset has been caused by an enabled LLWU modulewakeup source while the chip was in a low leakage mode. In LLS mode, the RESET pin is the only wakeup source that can cause this reset. Any enabled wakeup source in a VLLSx mode causes a reset. 0 Reset not caused by LLWU module wakeup source 1 Reset caused by LLWU module wakeup source

15.2.8 Sticky System Reset Status Register 1 (RCM_SSRS1)

This register includes status flags to indicate all reset sources since the last POR, LVD or VLLS Wakeup that have not been cleared by software. Software can clear the status flags by writing a logic one to a flag.

Address: 4007_F000h base + 9h offset = 4007_F009h

Bit	7	6	5	4	3	2	1	0
Read	0	0	SSACKERR	0	SMDM_AP	SSW	SLOCKUP	SJTAG
Write			w1c		w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

RCM_SSRS1 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SSACKERR	Sticky Stop Mode Acknowledge Error Reset

Table continues on the next page...

RCM_SSRS1 field descriptions (continued)

Field	Description
	Indicates that after an attempt to enter Stop mode, a reset has been caused by a failure of one or more peripherals to acknowledge within approximately one second to enter stop mode. 0 Reset not caused by peripheral failure to acknowledge attempt to enter stop mode 1 Reset caused by peripheral failure to acknowledge attempt to enter stop mode
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 SMDM_AP	Sticky MDM-AP System Reset Request Indicates a reset has been caused by the host debugger system setting of the System Reset Request bit in the MDM-AP Control Register. 0 Reset not caused by host debugger system setting of the System Reset Request bit 1 Reset caused by host debugger system setting of the System Reset Request bit
2 SSW	Sticky Software Indicates a reset has been caused by software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register in the ARM core. 0 Reset not caused by software setting of SYSRESETREQ bit 1 Reset caused by software setting of SYSRESETREQ bit
1 SLOCKUP	Sticky Core Lockup Indicates a reset has been caused by the ARM core indication of a LOCKUP event. 0 Reset not caused by core LOCKUP event 1 Reset caused by core LOCKUP event
0 SJTAG	Sticky JTAG Generated Reset Indicates a reset has been caused by JTAG selection of certain IR codes: EXTEST, HIGHZ, and CLAMP. 0 Reset not caused by JTAG 1 Reset caused by JTAG

Chapter 16

System Mode Controller (SMC)

16.1 Introduction

The System Mode Controller (SMC) is responsible for sequencing the system into and out of all low-power Stop and Run modes.

Specifically, it monitors events to trigger transitions between power modes while controlling the power, clocks, and memories of the system to achieve the power consumption and functionality of that mode.

This chapter describes all the available low-power modes, the sequence followed to enter/exit each mode, and the functionality available while in each of the modes.

The SMC is able to function during even the deepest low power modes.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the SMC.

16.2 Modes of operation

The ARM CPU has three primary modes of operation:

- Run
- Sleep
- Deep Sleep

The WFI or WFE instruction is used to invoke Sleep and Deep Sleep modes. Run, Wait, and Stop are the common terms used for the primary operating modes of Kinetis microcontrollers.

The following table shows the translation between the ARM CPU modes and the Kinetis MCU power modes.

ARM CPU mode	MCU mode
Sleep	Wait
Deep Sleep	Stop

Accordingly, the ARM CPU documentation refers to sleep and deep sleep, while the Kinetis MCU documentation normally uses wait and stop.

In addition, Kinetis MCUs also augment Stop, Wait, and Run modes in a number of ways. The power management controller (PMC) contains a run and a stop mode regulator. Run regulation is used in normal run, wait and stop modes. Stop mode regulation is used during all very low power and low leakage modes. During stop mode regulation, the bus frequencies are limited in the very low power modes.

The SMC provides the user with multiple power options. The Very Low Power Run (VLPR) mode can drastically reduce run time power when maximum bus frequency is not required to handle the application needs. From Normal Run mode, the Run Mode (RUNM) field can be modified to change the MCU into VLPR mode when limited frequency is sufficient for the application. From VLPR mode, a corresponding wait (VLPW) and stop (VLPS) mode can be entered.

Depending on the needs of the user application, a variety of stop modes are available that allow the state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. Several registers are used to configure the various modes of operation for the device.

The following table describes the power modes available for the device.

Table 16-1. Power modes

Mode	Description
RUN	The MCU can be run at full speed and the internal supply is fully regulated, that is, in run regulation. This mode is also referred to as Normal Run mode.
HSRUN	The MCU can be run at a faster frequency compared with RUN mode and the internal supply is fully regulated. See the Power Management chapter for details about the maximum allowable frequencies.
WAIT	The core clock is gated off. The system clock continues to operate. Bus clocks, if enabled, continue to operate. Run regulation is maintained.
STOP	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.
VLPR	The core, system, bus, and flash clock maximum frequencies are restricted in this mode. See the Power Management chapter for details about the maximum allowable frequencies.
VLPW	The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted. See the Power Management chapter for details on the maximum allowable frequencies.
VLPS	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.

Table continues on the next page...

Table 16-1. Power modes (continued)

Mode	Description
LLS3	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by reducing the voltage to internal logic. All system RAM contents, internal logic and I/O states are retained.
LLS2	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by reducing the voltage to internal logic and powering down the system RAM3 partition. The system RAM1 partition, internal logic and I/O states are retained. ¹
VLLS3	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic. All system RAM contents are retained and I/O states are held. Internal logic states are not retained.
VLLS2	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and the system RAM3 partition. The system RAM1 partition contents are retained in this mode. Internal logic states are not retained. ¹
VLLS1	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and all system RAM. I/O states are held. Internal logic states are not retained.
VLLS0	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and all system RAM. I/O states are held. Internal logic states are not retained. The 1kHz LPO clock is disabled and the power on reset (POR) circuit can be optionally enabled using STOPCTRL[PORPO].

1. See the devices' chip configuration details for the size and location of the system RAM partitions.

16.3 Memory map and register descriptions

Information about the registers related to the system mode controller can be found here.

Different SMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

NOTE

The SMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

NOTE

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode.

Failure to do this may result in the low power mode not being entered correctly.

SMC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4007_E000	Power Mode Protection register (SMC_PMPROT)	8	R/W	See section	16.3.1/312
4007_E001	Power Mode Control register (SMC_PMCTRL)	8	R/W	See section	16.3.2/313
4007_E002	Stop Control Register (SMC_STOPCTRL)	8	R/W	03h	16.3.3/315
4007_E003	Power Mode Status register (SMC_PMSTAT)	8	R	See section	16.3.4/316

16.3.1 Power Mode Protection register (SMC_PMPROT)

This register provides protection for entry into any low-power run or stop mode. The enabling of the low-power run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

The PMPROT register can be written only once after any system reset.

If the MCU is configured for a disallowed or reserved power mode, the MCU remains in its current power mode. For example, if the MCU is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the MCU is still in Normal Run mode.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the Reset section details for more information.

Address: 4007_E000h base + 0h offset = 4007_E000h

Bit	7	6	5	4	3	2	1	0
Read	AHSRUN	0	AVLP	0	ALLS	0	AVLLS	0
Write								
Reset	0	0	*	0	0	0	0	0

* Notes:

- AVLP field: When booting in run mode, the reset value is 0. When booting in VLPR mode, the reset value is 1.

SMC_PMPROT field descriptions

Field	Description
7 AHSRUN	Allow High Speed Run mode

Table continues on the next page...

SMC_PMPROT field descriptions (continued)

Field	Description
	Provided the appropriate control bits are set up in PMCTRL, this write-once field allows the MCU to enter High Speed Run mode (HSRUN). 0 HSRUN is not allowed 1 HSRUN is allowed
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 AVLP	Allow Very-Low-Power Modes Provided the appropriate control bits are set up in PMCTRL, this write-once field allows the MCU to enter any very-low-power mode (VLPR, VLPW, and VLPS). 0 VLPR, VLPW, and VLPS are not allowed. 1 VLPR, VLPW, and VLPS are allowed.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ALLS	Allow Low-Leakage Stop Mode Provided the appropriate control bits are set up in PMCTRL, this write-once field allows the MCU to enter any low-leakage stop mode (LLS). 0 Any LLSx mode is not allowed 1 Any LLSx mode is allowed
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 AVLLS	Allow Very-Low-Leakage Stop Mode Provided the appropriate control bits are set up in PMCTRL, this write once bit allows the MCU to enter any very-low-leakage stop mode (VLLSx). 0 Any VLLSx mode is not allowed 1 Any VLLSx mode is allowed
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

16.3.2 Power Mode Control register (SMC_PMCTRL)

The PMCTRL register controls entry into low-power Run and Stop modes, provided that the selected power mode is allowed via an appropriate setting of the protection (PMPROT) register.

NOTE

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

Memory map and register descriptions

SMC_PMCTRL field descriptions

Field	Description
7 Reserved	This field is reserved. This bit is reserved for future expansion. Software should write 0 to this bit to maintain compatibility.
6–5 RUNM	Run Mode Control When written, causes entry into the selected run mode. Writes to this field are blocked if the protection level has not been enabled using the PMPROT register. NOTE: RUNM may be set to VLPR only when PMSTAT=RUN. After being written to VLPR, RUNM should not be written back to RUN until PMSTAT=VLPR. NOTE: RUNM may be set to HSRUN only when PMSTAT=RUN. After being programmed to HSRUN, RUNM should not be programmed back to RUN until PMSTAT=HSRUN. Also, stop mode entry should not be attempted while RUNM=HSRUN or PMSTAT=HSRUN. 00 Normal Run mode (RUN) 01 Reserved 10 Very-Low-Power Run mode (VLPR) 11 High Speed Run mode (HSRUN)
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 STOPA	Stop Aborted When set, this read-only status bit indicates an interrupt occurred during the previous stop mode entry sequence, preventing the system from entering that mode. This field is cleared by reset or by hardware at the beginning of any stop mode entry sequence and is set if the sequence was aborted. 0 The previous stop mode entry was successful. 1 The previous stop mode entry was aborted.
STOPM	Stop Mode Control When written, controls entry into the selected stop mode when Sleep-Now or Sleep-On-Exit mode is entered with SLEEPDEEP=1. Writes to this field are blocked if the protection level has not been enabled using the PMPROT register. After any system reset, this field is cleared by hardware on any successful write to the PMPROT register. NOTE: When set to VLLSx or LLSx, the LLSM in the STOPCTRL register is used to further select the particular VLLS or LLS submode which will be entered. NOTE: When set to STOP, the PSTOPO bits in the STOPCTRL register can be used to select a Partial Stop mode if desired. 000 Normal Stop (STOP) 001 Reserved

Field	Description
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 LPOPO	LPO Power Option Controls whether the 1 kHz LPO clock is enabled in LLS/VLLSx modes. NOTE: During VLLS0 mode, the LPO clock is disabled by hardware and this bit has no effect. 0 LPO clock is enabled in LLS/VLLSx 1 LPO clock is disabled in LLS/VLLSx
LLSM	LLS or VLLS Mode Control This field controls which LLS or VLLS sub-mode to enter if STOPM = LLSx or VLLSx. 000 VLLS0 if PMCTRL[STOPM]=VLLSx, reserved if PMCTRL[STOPM]=LLSx 001 VLLS1 if PMCTRL[STOPM]=VLLSx, reserved if PMCTRL[STOPM]=LLSx 010 VLLS2 if PMCTRL[STOPM]=VLLSx, LLS2 if PMCTRL[STOPM]=LLSx 011 VLLS3 if PMCTRL[STOPM]=VLLSx, LLS3 if PMCTRL[STOPM]=LLSx 100 Reserved 101 Reserved 110 Reserved 111 Reserved

16.3.4 Power Mode Status register (SMC_PMSTAT)

PMSTAT is a read-only, one-hot register which indicates the current power mode of the system.

NOTE

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

Address: 4007_E000h base + 3h offset = 4007_E003h

Bit	7	6	5	4	3	2	1	0
Read	PMSTAT							
Write								
Reset	*	*	*	*	*	*	*	*

* Notes:

- PMSTAT field: When booting in run mode, the reset value is 0x01. When booting in VLPR mode, the reset value is 0x04.

SMC_PMSTAT field descriptions

Field	Description
PMSTAT	Power Mode Status NOTE: When debug is enabled, the PMSTAT will not update to STOP or VLPS NOTE: When a PSTOP mode is enabled, the PMSTAT will not update to STOP or VLPS NOTE: Since the RUNM bits in the PMCTRL register are reset to VLPR on any Chip Reset not VLLS, the PMSTAT will update to VLPR shortly after the reset sequence is complete. 0000_0001 Current power mode is RUN. 0000_0010 Current power mode is STOP. 0000_0100 Current power mode is VLPR. 0000_1000 Current power mode is VLPW. 0001_0000 Current power mode is VLPS. 0010_0000 Current power mode is LLS. 0100_0000 Current power mode is VLLS. 1000_0000 Current power mode is HSRUN

16.4 Functional description

16.4.1 Power mode transitions

The following figure shows the power mode state transitions available on the chip. Any reset will initially bring the MCU back to the normal RUN state. However, in order to minimize peak power consumption, the RUNM bits in the PMCTRL register can be reset to VLPR via Flash IFR settings, causing the SMC to begin transitioning the MCU into VLPR mode during the reset recovery sequence.

Figure 16-1. Power mode state diagram

The following table defines triggers for the various state transitions shown in the previous figure.

Table 16-2. Power mode transition triggers

Transition #	From	To	Trigger conditions
1	RUN	WAIT	Sleep-now or sleep-on-exit modes entered with SLEEPDEEP clear, controlled in System Control Register in ARM core. See note. ¹
	WAIT	RUN	Interrupt or Reset
2	RUN	STOP	PMCTRL[RUNM]=00, PMCTRL[STOPM]=000 ²

Table continues on the next page...

Table 16-2. Power mode transition triggers (continued)

Transition #	From	To	Trigger conditions
			Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core. See note. ¹
	STOP	RUN	Interrupt or Reset
3	RUN	VLPR	The core, system, bus and flash clock frequencies and MCG clocking mode are restricted in this mode. See the Power Management chapter for the maximum allowable frequencies and MCG modes supported. Set PMPROT[AVLP]=1, PMCTRL[RUNM]=10. NOTE: In order to limit peak current, PMPROT[AVLP] and PMCTRL[RUNM] bits can be set on any Reset via Flash IFR settings, causing the SMC to transition the MCU from RUN->VLPR during the reset recovery sequence.
	VLPR	RUN	Set PMCTRL[RUNM]=00 or Reset.
4	VLPR	VLPW	Sleep-now or sleep-on-exit modes entered with SLEEPDEEP clear, which is controlled in System Control Register in ARM core. See note. ¹
	VLPW	VLPR	Interrupt
5	VLPW	RUN	Reset
6	VLPR	VLPS	PMCTRL[STOPM]=000 ³ or 010, Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core. See note. ¹
	VLPS	VLPR	Interrupt NOTE: If VLPS was entered directly from RUN (transition #4), hardware forces exit back to RUN and does not allow a transition to VLPR.
7	RUN	VLPS	PMPROT[AVLP]=1, PMCTRL[STOPM]=010, Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core. See note. ¹
	VLPS	RUN	Interrupt and VLPS mode was entered directly from RUN or Reset
8	RUN	VLLSx	PMPROT[AVLLS]=1, PMCTRL[STOPM]=100, STOPCTRL[LLSM]=x (VLLSx), Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.
	VLLSx	RUN	Wakeup from enabled LPTMR input source or RESET pin

Table continues on the next page...

Table 16-2. Power mode transition triggers (continued)

Transition #	From	To	Trigger conditions
9	VLPR	VLLSx	PMPROT[AVLLS]=1, PMCTRL[STOPM]=100, STOPCTRL[LLSM]=x (VLLSx), Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.
10	RUN	LLSx	PMPROT[ALLS]=1, PMCTRL[STOPM]=011, STOPCTRL[LLSM]=x (LLSx), Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.
	LLSx	RUN	Wakeup from enabled LLWU input source and LLSx mode was entered directly from RUN or RESET pin.
11	VLPR	LLSx	PMPROT[ALLS]=1, PMCTRL[STOPM]=011, Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.
	LLSx	VLPR	Wakeup from enabled LLWU input source and LLSx mode was entered directly from VLPR NOTE: If LLSx was entered directly from RUN, hardware will not allow this transition and will force exit back to RUN
12	RUN	HSRUN	Set PMPROT[AHSRUN]=1, PMCTRL[RUNM]=11.
	HSRUN	RUN	Set PMCTRL[RUNM]=00 or Reset

1. If debug is enabled, the core clock remains to support debug.
2. If PMCTRL[STOPM]=000 and STOPCTRL[PSTOPO]=01 or 10, then only a Partial Stop mode is entered instead of STOP
3. If PMCTRL[STOPM]=000 and STOPCTRL[PSTOPO]=00, then VLPS mode is entered instead of STOP. If PMCTRL[STOPM]=000 and STOPCTRL[PSTOPO]=01 or 10, then only a Partial Stop mode is entered instead of VLPS

16.4.2 Power mode entry/exit sequencing

When entering or exiting low-power modes, the system must conform to an orderly sequence to manage transitions safely.

The SMC manages the system's entry into and exit from all power modes. This diagram illustrates the connections of the SMC with other system components in the chip that are necessary to sequence the system through all power modes.

Figure 16-2. Low-power system components and connections

16.4.2.1 Stop mode entry sequence

Entry into a low-power stop mode (Stop, VLPS, LLS, VLLSx) is initiated by a CPU executing the WFI instruction. After the instruction is executed, the following sequence occurs:

1. The CPU clock is gated off immediately.
2. Requests are made to all non-CPU bus masters to enter Stop mode.
3. After all masters have acknowledged they are ready to enter Stop mode, requests are made to all bus slaves to enter Stop mode.
4. After all slaves have acknowledged they are ready to enter Stop mode, all system and bus clocks are gated off.
5. Clock generators are disabled in the MCG.
6. The on-chip regulator in the PMC and internal power switches are configured to meet the power consumption goals for the targeted low-power mode.

16.4.2.2 Stop mode exit sequence

Exit from a low-power stop mode is initiated either by a reset or an interrupt event. The following sequence then executes to restore the system to a run mode (RUN or VLPR):

1. The on-chip regulator in the PMC and internal power switches are restored.
2. Clock generators are enabled in the MCG.
3. System and bus clocks are enabled to all masters and slaves.
4. The CPU clock is enabled and the CPU begins servicing the reset or interrupt that initiated the exit from the low-power stop mode.

16.4.2.3 Aborted stop mode entry

If an interrupt occurs during a stop entry sequence, the SMC can abort the transition early and return to RUN mode without completely entering the stop mode. An aborted entry is possible only if the interrupt occurs before the PMC begins the transition to stop mode regulation. After this point, the interrupt is ignored until the PMC has completed its transition to stop mode regulation. When an aborted stop mode entry sequence occurs, SMC_PMCCTRL[STOPA] is set to 1.

16.4.2.4 Transition to wait modes

For wait modes (WAIT and VLPW), the CPU clock is gated off while all other clocking continues, as in RUN and VLPR mode operation. Some modules that support stop-in-wait functionality have their clocks disabled in these configurations.

16.4.2.5 Transition from stop modes to Debug mode

The debugger module supports a transition from STOP, WAIT, VLPS, and VLPW back to a Halted state when the debugger has been enabled. As part of this transition, system clocking is re-established and is equivalent to the normal RUN and VLPR mode clocking configuration.

16.4.3 Run modes

The run modes supported by this device can be found here.

- Run (RUN)

- Very Low-Power Run (VLPR)
- High Speed Run (HSRUN)

16.4.3.1 RUN mode

This mode is selected after any reset. In order to reduce peak power consumption, however, the SMC begins transitioning the device into VLPR mode during the reset recovery sequence. When the ARM processor exits reset, it sets up the stack, program counter (PC), and link register (LR):

- The processor reads the start SP (SP_main) from vector-table offset 0x000
- The processor reads the start PC from vector-table offset 0x004
- LR is set to 0xFFFF_FFFF.

To reduce power in this mode, disable the clocks to unused modules.

16.4.3.2 Very-Low Power Run (VLPR) mode

In VLPR mode, the on-chip voltage regulator is put into a stop mode regulation state. In this state, the regulator is designed to supply enough current to the MCU over a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules using their corresponding clock gating control bits in the SIM's registers.

Before entering this mode, the following conditions must be met:

- The MCG must be configured in a mode which is supported during VLPR. See the Power Management details for information about these MCG modes.
- All clock monitors in the MCG must be disabled.
- The maximum frequencies of the system, bus, flash, and core are restricted. See the Power Management details about which frequencies are supported.
- Mode protection must be set to allow VLP modes, that is, PMPROT[AVLP] is 1.
- PMCTRL[RUNM] must be set to 10b to enter VLPR.
- Flash programming/erasing is not allowed.

NOTE

Do not increase the clock frequency while in VLPR mode, because the regulator is slow in responding and cannot manage fast load transitions. In addition, do not modify the clock source in the MCG module or any clock divider registers. Module clock enables in the SIM can be set, however should only be cleared one at a time to limit load transitions.

To reenter Normal Run mode, clear PMCTRL[RUNM]. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. When PMSTAT=RUN, the system is in run regulation and the MCU can run at full speed in any clock mode. If a higher execution frequency is desired, poll PMSTAT until it is set to RUN when returning from VLPR mode.

Any reset will initially cause the device to exit to RUN mode, however Flash IFR settings can be used to return the part to VLPR during the MCU reset flow.

16.4.3.3 High Speed Run (HSRUN) mode

In HSRUN mode, the on-chip voltage regulator remains in a run regulation state, but with a slightly elevated voltage output. In this state, the MCU is able to operate at a faster frequency compared to normal RUN mode. For the maximum allowable frequencies, see the Power Management chapter.

While in this mode, the following restrictions must be adhered to:

- The maximum allowable change in frequency of the system, bus, flash or core clocks is restricted to 2x (double the frequency).
- Before exiting HSRUN mode, clock frequencies should be reduced back down to those acceptable in RUN mode.
- Stop mode entry is not supported from HSRUN.
- Modifications to clock gating control bits are prohibited.
- Flash programming/erasing is not allowed.

To enter HSRUN mode, set PMPROT[AHSRUN] to allow HSRUN and then set PMCTRL[RUNM]=HSRUN. Before increasing clock frequencies, the PMSTAT register should be polled to determine when the system has completed entry into HSRUN mode. To reenter normal RUN mode, clear PMCTRL[RUNM]. Any reset also clears PMCTRL[RUNM] and causes the system to exit to normal RUN mode after the MCU exits its reset flow.

16.4.4 Wait modes

This device contains two different wait modes which are listed here.

- Wait
- Very-Low Power Wait (VLPW)

16.4.4.1 WAIT mode

WAIT mode is entered when the ARM core enters the Sleep-Now or Sleep-On-Exit modes while SLEEPDEEP is cleared. The ARM CPU enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled.

When an interrupt request occurs, the CPU exits WAIT mode and resumes processing in RUN mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset causes an exit from WAIT mode, temporarily returning the device to RUN mode before transitioning into VLPR during the device reset flow.

16.4.4.2 Very-Low-Power Wait (VLPW) mode

VLPW mode is entered by entering the Sleep-Now or Sleep-On-Exit mode while SLEEPDEEP is cleared and the device is in VLPR mode.

In VLPW, the on-chip voltage regulator remains in its stop regulation state. In this state, the regulator is designed to supply enough current to the device at a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules.

VLPR mode restrictions also apply to VLPW.

When an interrupt from VLPW occurs, the device returns to VLPR mode to execute the interrupt service routine.

A system reset causes an exit from VLPW mode, temporarily returning the device to RUN mode before transitioning into VLPR during the device reset flow.

16.4.5 Stop modes

This device contains a variety of stop modes to meet your application needs.

The stop modes range from:

- a stopped CPU, with all I/O, logic, and memory states retained, and certain asynchronous mode peripherals operating

to:

- a powered down CPU, with only I/O and a small register file retained, very few asynchronous mode peripherals operating, while the remainder of the MCU is powered down.

The choice of stop mode depends upon the user's application, and how power usage and state retention versus functional needs and recovery time may be traded off.

The various stop modes are selected by setting the appropriate fields in PMPROT and PMCTRL. The selected stop mode is entered during the sleep-now or sleep-on-exit entry with the SLEEPDEEP bit set in the System Control Register in the ARM core.

The available stop modes are:

- Normal Stop (STOP)
- Very-Low Power Stop (VLPS)
- Low-Leakage Stop (LLS)
- Very-Low-Leakage Stop (VLLSx)

16.4.5.1 STOP mode

STOP mode is entered via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core.

The MCG module can be configured to leave the reference clocks running.

A module capable of providing an asynchronous interrupt to the device takes the device out of STOP mode and returns the device to normal RUN mode. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in STOP mode. When an interrupt request occurs, the CPU exits STOP mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from STOP mode, temporarily returning the device to RUN mode before transitioning into VLPR during the MCU reset flow.

16.4.5.2 Very-Low-Power Stop (VLPS) mode

The two ways in which VLPS mode can be entered are listed here.

- Entry into stop via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core while the MCU is in VLPR mode and PMCTRL[STOPM] = 010 or 000.
- Entry into stop via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core while the MCU is in normal RUN mode and PMCTRL[STOPM] = 010. When VLPS is entered directly from RUN mode, exit to VLPR is disabled by hardware and the system will always exit back to RUN.

In VLPS, the on-chip voltage regulator remains in its stop regulation state as in VLPR.

A module capable of providing an asynchronous interrupt to the device takes the device out of VLPS and returns the device to VLPR mode.

A system reset will cause an exit from VLPS mode, temporarily returning the device to RUN mode before transitioning into VLPR during the MCU reset flow.

16.4.5.3 Low-Leakage Stop (LLSx) modes

This device contains two Low-Leakage Stop modes: LLS3 and LLS2. LLS or LLSx is often used in this document to refer to both modes. All LLS modes can be entered from normal RUN or VLPR modes.

The MCU enters LLS mode if:

- In Sleep-Now or Sleep-On-Exit mode, SLEEPDEEP is set in the System Control Register in the ARM core, and
- The device is configured as shown in [Table 16-2](#).

In LLS, the on-chip voltage regulator is in stop regulation. Most of the peripherals are put in a state-retention mode that does not allow them to operate while in LLS.

Before entering LLS mode, the user should configure the Low-Leakage Wake-up (LLWU) module to enable the desired wake-up sources. The available wake-up sources in LLS are detailed in the chip configuration details for this device.

After wakeup from LLS, the device returns to the run mode from which LLS was entered (either normal RUN or VLPR) with a pending LLWU module interrupt. If LLS was entered from VLPR mode, then the MCU will begin VLPR entry shortly after wake-up. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wake-up flags to determine the source of the wakeup.

NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit Stop mode on an LLS recovery.

An asserted $\overline{\text{RESET}}$ pin will cause an exit from LLS mode, temporarily returning the device to normal RUN mode before transitioning into VLPR during the MCU reset flow. When LLS is exiting via the $\overline{\text{RESET}}$ pin, RCM_SRS[PIN] and RCM_SRS[WAKEUP] are set.

16.4.5.4 Very-Low-Leakage Stop (VLLSx) modes

This device contains these very low leakage modes:

- VLLS3
- VLLS2
- VLLS1
- VLLS0

VLLSx is often used in this document to refer to all of these modes.

All VLLSx modes can be entered from normal RUN or VLPR modes.

The MCU enters the configured VLLS mode if:

- In Sleep-Now or Sleep-On-Exit mode, the SLEEPDEEP bit is set in the System Control Register in the ARM core, and
- The device is configured as shown in [Table 16-2](#).

In VLLS, the on-chip voltage regulator is in its stop-regulation state while most digital logic is powered off.

Before entering VLLS mode, the user should configure the Low-Leakage Wake-up (LLWU) module to enable the desired wakeup sources. The available wake-up sources in VLLS are detailed in the chip configuration details for this device.

After wakeup from VLLS, the device returns to normal RUN mode with a pending LLWU interrupt. If VLLS was entered from VLPR mode, then the MCU will begin VLPR entry shortly after wakeup. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wake-up flags to determine the source of the wake-up.

When entering VLLS, each I/O pin is latched as configured before executing VLLS. Because all digital logic in the MCU is powered off, all port and peripheral data is lost during VLLS. This information must be restored before PMC_REGSC[ACKISO] is set.

An asserted $\overline{\text{RESET}}$ pin will cause an exit from any VLLS mode, temporarily returning the device to normal RUN mode before transitioning into VLPR during the MCU reset flow. When exiting VLLS via the $\overline{\text{RESET}}$ pin, RCM_SRS[PIN] and RCM_SRS[WAKEUP] are set.

16.4.6 Debug in low power modes

When the MCU is secure, the device disables/limits debugger operation. When the MCU is unsecure, the ARM debugger can assert two power-up request signals:

- System power up, via SYSPWR in the Debug Port Control/Stat register
- Debug power up, via CDBGPWRUPREQ in the Debug Port Control/Stat register

When asserted while in RUN, WAIT, VLPR, or VLPW the mode controller drives a corresponding acknowledge for each signal, that is, both CDBGPWRUPACK and CSYSPWRUPACK. When both requests are asserted, the mode controller handles attempts to enter STOP and VLPS by entering an emulated stop state. In this emulated stop state:

- the regulator is in run regulation,
- the MCG-generated clock source is enabled,
- all system clocks, except the core clock, are disabled,
- the debug module has access to core registers, and
- access to the on-chip peripherals is blocked.

No debug is available while the MCU is in LLS or VLLS modes. LLS is a state-retention mode and all debug operation can continue after waking from LLS, even in cases where system wakeup is due to a system reset event.

Entering into a VLLS mode causes all of the debug controls and settings to be powered off. To give time to the debugger to sync with the MCU, the MDM AP Control Register includes a Very-Low-Leakage Debug Request (VLLDBGREQ) bit that is set to configure the Reset Controller logic to hold the system in reset after the next recovery from a VLLS mode. This bit allows the debugger time to reinitialize the debug module before the debug session continues.

The MDM AP Control Register also includes a Very Low Leakage Debug Acknowledge (VLLDBGACK) bit that is set to release the ARM core being held in reset following a VLLS recovery. The debugger reinitializes all debug IP, and then asserts the VLLDBGACK control bit to allow the RCM to release the ARM core from reset and allow CPU operation to begin.

The VLLDBGACK bit is cleared by the debugger (or can be left set as is) or clears automatically due to the reset generated as part of the next VLLS recovery.

Chapter 17

Power Management Controller (PMC)

17.1 Chip-specific PMC information

17.1.1 Instantiation Information

The PMC on this device has flexible options on various RAM arrays in LLS2 and VLLS2 stop modes to optimize current consumption versus RAM retention. See [K27 RAM arrays](#) table. See [SRAM retention in low power modes](#) for mapping of these configuration bits to SRAM.

17.2 Introduction

The power management controller (PMC) contains the internal voltage regulator, power on reset (POR), and low voltage detect system (LVD) and high voltage detect system (HVD) for the VDD domain.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the PMC.

17.3 Features

A list of included PMC features can be found here.

- Internal voltage regulator
- Active POR providing brown-out detect
- Low-voltage detect (LVD) on VDD supporting two low-voltage trip points with four warning levels per trip point

- High-voltage detect (HVD) on VDD supporting two high-voltage trip points
- RAM retention options to disable specific RAM arrays in LLS2 mode and VLLS2 mode and reduce power consumption

17.4 Low-voltage detect (LVD) system

This device includes a system to guard against low-voltage conditions on the VDD supply. When the VDD supply falls below a specific trip point, the LVD circuit puts the device into a reset state, preventing the device from attempting to operate below its operating voltage range.

The system is comprised of a power-on reset (POR) circuit and a LVD circuit with a user-selectable trip voltage: high (V_{LVDH}) or low (V_{LVDL}). The trip voltage is selected by LVDSC1[LVDF]. The LVD is disabled upon entering VLPx, LLS, and VLLSx modes.

Two flags are available to indicate the status of the low-voltage detect system:

- The Low Voltage Detect Flag in the Low Voltage Status and Control 1 Register (LVDSC1[LVDF]) operates in a level sensitive manner. LVDSC1[LVDF] is set when the supply voltage falls below the selected trip point (VLVD). LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDAK], but only if the internal supply has returned above the trip point; otherwise, LVDSC1[LVDF] remains set.
- The Low Voltage Warning Flag (LVWF) in the Low Voltage Status and Control 2 Register (LVDSC2[LVWF]) operates in a level sensitive manner. LVDSC2[LVWF] is set when the supply voltage falls below the selected monitor trip point (VLVW). LVDSC2[LVWF] is cleared by writing one to LVDSC2[LVWACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC2[LVWF] remains set.

17.4.1 LVD reset operation

By setting LVDSC1[LVDR], the LVD generates a reset upon detection of a low-voltage condition. The low-voltage detection threshold is determined by LVDSC1[LVDF]. After an LVD reset occurs, the LVD system holds the MCU in reset until the supply voltage rises above this threshold. The LVD field in the SRS register of the RCM module (RCM_SRS[LVD]) is set following an LVD or power-on reset.

17.4.2 LVD interrupt operation

By configuring the LVD circuit for interrupt operation (LVDSC1[LVDIE] set and LVDSC1[LVDRE] clear), LVDSC1[LVDF] is set and an LVD interrupt request occurs upon detection of a low voltage condition. LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK].

17.4.3 Low-voltage warning (LVW) interrupt operation

The LVD system that monitors the VDD supply contains a Low-Voltage Warning Flag (LVWF) in the Low Voltage Detect Status and Control 2 Register to indicate that the supply voltage is approaching, but is above, the LVD voltage. The LVW also has an interrupt, which is enabled by setting LVDSC2[LVWIE]. If enabled, an LVW interrupt request occurs when LVDSC2[LVWF] is set. LVDSC2[LVWF] is cleared by writing 1 to LVDSC2[LVWACK].

LVDSC2[LVWV] selects one of the four trip voltages:

- Highest: V_{LVW4}
- Two mid-levels: V_{LVW3} and V_{LVW2}
- Lowest: V_{LVW1}

17.5 High-voltage detect (HVD) system

This device includes a system to guard against high-voltage conditions on the VDD supply.

The system is comprised of a HVD circuit with a user-selectable trip voltage: high (V_{HVDH}) or low (V_{HVDL}). The trip voltage is selected by HVDSC1[HVDV]. The HVD is disabled upon entering VLPx, LLS, and VLLSx modes.

A flag is available to indicate the status of the high-voltage detect system:

- The High Voltage Detect Flag in the High Voltage Status and Control 1 Register (HVDSC1[HVDF]) operates in a level sensitive manner. HVDSC1[HVDF] is set when the supply voltage rises above the selected trip point (VHVD). HVDSC1[HVDF] is cleared by writing 1 to HVDSC1[HVDACK], but only if the internal supply has returned below the trip point; otherwise, HVDSC1[HVDF] remains set.

17.5.1 HVD reset operation

By setting HVDSC1[HVDRE], the HVD generates a reset upon detection of a high-voltage condition. The high-voltage detection threshold is determined by HVDSC1[HVDV]. After an HVD reset occurs, the HVD system holds the MCU in reset until the supply voltage falls below this threshold. The LVD field in the SRS register of the RCM module (RCM_SRS[LVD]) is set following an HVD reset.

17.5.2 HVD interrupt operation

By configuring the HVD circuit for interrupt operation (HVDSC1[HVDIE] set and HVDSC1[HVDRE] clear), HVDSC1[HVDF] is set and an HVD interrupt request occurs upon detection of a high voltage condition. HVDSC1[HVDF] is cleared by writing 1 to HVDSC1[HVDACK].

17.6 I/O retention

When in LLS mode, the I/O pins are held in their input or output state.

Upon wakeup, the PMC is re-enabled, goes through a power up sequence to full regulation, and releases the logic from state retention mode. The I/O are released immediately after a wake-up or reset event. In the case of LLS exit via a RESET pin, the I/O default to their reset state.

When in VLLS modes, the I/O states are held on a wake-up event (with the exception of wake-up by reset event) until the wake-up has been acknowledged via a write to REGSC[ACKISO]. In the case of VLLS exit via a RESET pin, the I/O are released and default to their reset state. In this case, no write to REGSC[ACKISO] is needed.

17.7 Memory map and register descriptions

Details about the PMC registers can be found here.

NOTE

Different portions of PMC registers are reset only by particular reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

The PMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

PMC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4007_D000	Low Voltage Detect Status And Control 1 register (PMC_LVDSC1)	8	R/W	10h	17.7.1/335
4007_D001	Low Voltage Detect Status And Control 2 register (PMC_LVDSC2)	8	R/W	00h	17.7.2/337

17.7.1 Low Voltage Detect Status And Control 1 register (PMC_LVDSC1)

This register contains status and control bits to support the low voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC1 settings. To protect systems that must have LVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact LVD trip voltages.

NOTE

The LVDV bits are reset solely on a POR Only event. The register's other bits are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the Reset section details.

4 LVDRE	Low-Voltage Detect Reset Enable This write-once bit enables LVDF events to generate a hardware reset. Additional writes are ignored. 0 LVDF does not generate hardware resets 1 Force an MCU reset when LVDF = 1
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
LVDV	Low-Voltage Detect Voltage Select Selects the LVD trip point voltage (V_{LVD}). 00 Low trip point selected ($V_{LVD} = V_{LVDL}$) 01 High trip point selected ($V_{LVD} = V_{LVDH}$) 10 Reserved 11 Reserved

17.7.2 Low Voltage Detect Status And Control 2 register (PMC_LVDSC2)

This register contains status and control bits to support the low voltage warning function.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC2 settings.

See the device's data sheet for the exact LVD trip voltages.

NOTE

The LVW trip voltages depend on LVWV and LVDV.

NOTE

LVWV is reset solely on a POR Only event. The other fields of the register are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the Reset section details.

The actual voltage for the warning depends on LVDSC1[LVDV]. 00 Low trip point selected ($V_{LVW} = V_{LVW1}$) 01 Mid 1 trip point selected ($V_{LVW} = V_{LVW2}$) 10 Mid 2 trip point selected ($V_{LVW} = V_{LVW3}$) 11 High trip point selected ($V_{LVW} = V_{LVW4}$)

17.7.3 Regulator Status And Control register (PMC_REGSC)

The PMC contains an internal voltage regulator. The voltage regulator design uses a bandgap reference that is also available through a buffer as input to certain internal peripherals, such as the CMP and ADC. The internal regulator provides a status bit (REGONS) indicating the regulator is in run regulation.

NOTE

This register is reset on Chip Reset Not VLLS and by reset types that trigger Chip Reset not VLLS. See the Reset section details for more information.

Address: 4007_D000h base + 2h offset = 4007_D002h

Bit	7	6	5	4	3	2	1	0

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved.
4 BGEN	Bandgap Enable In VLPx Operation BGEN controls whether the bandgap is enabled in lower power modes of operation (VLPx, LLS, and VLLSx). When on-chip peripherals require the bandgap voltage reference in low power modes of operation, set BGEN to continue to enable the bandgap operation.

Table continues on the next page...

PMC_REGSC field descriptions (continued)

Field	Description
	NOTE: When the bandgap voltage reference is not needed in low power modes, clear BGEN to avoid excess power consumption. 0 Bandgap voltage reference is disabled in VLPx , LLS , and VLLSx modes. 1 Bandgap voltage reference is enabled in VLPx , LLS , and VLLSx modes.
3 ACKISO	Acknowledge Isolation Reading this field indicates whether certain peripherals and the I/O pads are in a latched state as a result of having been in a VLLS mode. Writing 1 to this field when it is set releases the I/O pads and certain peripherals to their normal run mode state. NOTE: After recovering from a VLLS mode, user should restore chip configuration before clearing ACKISO. In particular, pin configuration for enabled LLWU wakeup pins should be restored to avoid any LLWU flag from being falsely set when ACKISO is cleared. 0 Peripherals and I/O pads are in normal run state. 1 Certain peripherals and I/O pads are in an isolated and latched state.
2 REGONS	Regulator In Run Regulation Status This read-only field provides the current status of the internal voltage regulator. 0 Regulator is in stop regulation or in transition to/from it 1 Regulator is in run regulation
1 Reserved	This field is reserved. NOTE: This reserved bit must remain cleared (set to 0).
0 BGBE	Bandgap Buffer Enable Enables the bandgap buffer. 0 Bandgap buffer not enabled 1 Bandgap buffer enabled

17.7.4 High Voltage Detect Status And Control 1 register (PMC_HVDSC1)

This register contains status and control bits to support the high voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

While the device is in the very low power or low leakage modes, the HVD system is disabled regardless of HVDSC1 settings. To protect systems that must have HVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact HVD trip voltages.

NOTE

This register is reset solely on a POR Only event. For more information about these reset types, refer to the Reset section details.

Address: 4007_D000h base + Bh offset = 4007_D00Bh

Bit	7	6	5	4	3	2	1	0

Chapter 18

Low-Leakage Wakeup Unit (LLWU)

18.1 Chip-specific LLWU information

18.1.1 Wake-up Sources

The device uses the following internal peripheral and external pin inputs as wakeup sources to the LLWU module. LLWU_Px are external pin inputs, and LLWU_M0IF-M7IF are connections to the internal peripheral interrupt flags.

NOTE

In addition to the LLWU wakeup sources, the device also wakes from low power modes when NMI or RESET pins are enabled and the respective pin is asserted.

Table 18-1. Wakeup Sources for LLWU inputs

LLWU pin	Module source or pin name
LLWU_P0	PTE1
LLWU_P1	PTE2
LLWU_P2	PTE4

LLWU_M6IF	Reserved
LLWU_M7IF	RTC Seconds

1. A LLWU wakeup source VREGIN is not available for VLLS1 or VLLS0 mode.
2. As a wakeup source of LLWU, USB0_DP and USB0_DM are only available when the chip is in USB host mode.
3. Requires the peripheral and the peripheral interrupt to be enabled. The LLWU's WUME bit enables the internal module flag as a wakeup input. After wakeup, the flags are cleared based on the peripheral clearing mechanism.

18.2 Introduction

The LLWU module allows the user to select up to 29 external pins and up to 8 internal modules as interrupt wake-up sources from low-leakage power modes.

The input sources are described in the device's chip configuration details. Each of the available wake-up sources can be individually enabled.

The $\overline{\text{RESET}}$ pin is an additional source for triggering an exit from low-leakage power modes, and causes the MCU to exit both LLS and VLLS through a reset flow.

The LLWU module also includes optional digital pin filters for the external wakeup pins.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the LLWU.

18.2.1 Features

The LLWU module features include:

- Support for up to 29 external input pins and up to 8 internal modules with individual enable bits for MCU interrupt from low leakage modes
- Input sources may be external pins or from internal peripherals capable of running in LLS or VLLS. See the chip configuration information for wakeup input sources for this device.
- External pin wake-up inputs, each of which is programmable as falling-edge, rising-edge, or any change
- Wake-up inputs that are activated after MCU enters a low-leakage power mode
- Optional digital filters provided to qualify an external pin detect. Note that when the LPO clock is disabled, the filters are disabled and bypassed.

18.2.2 Modes of operation

The LLWU module becomes functional on entry into a low-leakage power mode. After recovery from LLS, the LLWU is immediately disabled. After recovery from VLLS, the LLWU continues to detect wake-up events until the user has acknowledged the wake-up via a write to `PMC_REGSC[ACKISO]`.

18.2.2.1 LLS mode

Wake-up events due to external pin inputs (`LLWU_Px`) and internal module interrupt inputs (`LLWU_MxIF`) result in an interrupt flow when exiting LLS.

NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit Stop mode on an LLS recovery.

18.2.2.2 VLLS modes

All wakeup and reset events result in VLLS exit via a reset flow.

18.2.2.3 Non-low leakage modes

The LLWU is not active in all non-low leakage modes where detection and control logic are in a static state. The LLWU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

When the wake-up pin filters are enabled, filter operation begins immediately. If a low leakage mode is entered within five LPO clock cycles of an active edge, the edge event will be detected by the LLWU.

18.2.2.4 Debug mode

When the chip is in Debug mode and then enters LLS or a VLLSx mode, no debug logic works in the fully-functional low-leakage mode. Upon an exit from the LLS or VLLSx mode, the LLWU becomes inactive.

18.2.3 Block diagram

The following figure is the block diagram for the LLWU module.

Figure 18-1. LLWU block diagram

18.3 LLWU signal descriptions

The signal properties of LLWU are shown in the table found [here](#).

The external wakeup input pins can be enabled to detect either rising-edge, falling-edge, or on any change.

Table 18-2. LLWU signal descriptions

Signal	Description	I/O
LLWU_Pn	Wakeup inputs (n = 0- 28)	I

18.4 Memory map/register definition

The LLWU includes the following registers:

- Wake-up source enable registers
 - Enable external pin input sources
 - Enable internal peripheral interrupt sources
- Wake-up flag registers
 - Indication of wakeup source that caused exit from a low-leakage power mode includes external pin or internal module interrupt
- Wake-up pin filter enable registers

NOTE

The LLWU registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. Each register's displayed reset value represents this subset of reset types. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS. For more information about the types of reset on this chip, refer to the [Introduction](#) details.

18.4.10 LLWU Pin Flag 1 register (LLWU_PF1)

LLWU_PF1 contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

18.4.14 LLWU Module Flag 5 register (LLWU_MF5)

LLWU_MF5 contains the wakeup flags indicating which internal wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

For internal peripherals that are capable of running in a low-leakage power mode, such as a real time clock module or CMP module, the flag from the associated peripheral is accessible as the MWUFx bit. The flag will need to be cleared in the peripheral instead of writing a 1 to the MWUFx bit.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

18.5 Functional description

This low-leakage wakeup unit (LLWU) module allows internal peripherals and external input pins as a source of wakeup from low-leakage modes.

It is operational only in LLS and VLLSx modes.

The LLWU module contains pin enables for each external pin and internal module. For each external pin, the user can disable or select the edge type for the wakeup with the following options:

- Falling-edge
- Rising-edge
- Either-edge

When an external pin is enabled as a wakeup source, the pin must be configured as an input pin.

The LLWU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup or reset event when the filter function is enabled. wakeup detect filters are available for selected external pins. Glitch filtering is not provided on the internal modules.

For internal module interrupts, the WUMEx bit enables the associated module interrupt as a wakeup source.

18.5.1 LLS mode

Wakeup events triggered from either an external pin input or an internal module interrupt, result in a CPU interrupt flow to begin user code execution.

18.5.2 VLLS modes

For any wakeup from VLLS, recovery is always via a reset flow and RCM_SRS[WAKEUP] is set indicating the low-leakage mode was active. State retention data is lost and I/O will be restored after PMC_REGSC[ACKISO] has been written.

A VLLS exit event due to $\overline{\text{RESET}}$ pin assertion causes an exit via a system reset. State retention data is lost and the I/O states immediately return to their reset state. The RCM_SRS[WAKEUP] and RCM_SRS[PIN] bits are set and the system executes a reset flow before CPU operation begins with a reset vector fetch.

18.5.3 Initialization

For an enabled peripheral wakeup input, the peripheral flag must be cleared by software before entering LLS or VLLSx mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to LLS or VLLSx mode.

After enabling an external pin filter or changing the source pin, wait at least five LPO clock cycles before entering LLS or VLLSx mode to allow the filter to initialize.

NOTE

After recovering from a VLLS mode, user must restore chip configuration before clearing PMC_REGSC[ACKISO]. In particular, pin configuration for enabled LLWU wake-up pins must be restored to avoid any LLWU flag from being falsely set when PMC_REGSC[ACKISO] is cleared.

The signal selected as a wake-up source pin must be a digital pin, as selected in the pin mux control.

Chapter 19

Miscellaneous Control Module (MCM)

19.1 Introduction

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

19.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Floating Point Exception monitor and interrupt control
- AHBS WABORTS (imprecise write fault) monitor and interrupt control

19.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

MCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_0008	Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)	16	R	003Fh	19.2.1/376
E008_000A	Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)	16	R	001Fh	19.2.2/377
E008_000C	Control Register (MCM_CR)	32	R/W	0000_0200h	19.2.3/378
E008_0010	Interrupt Status Register (MCM_ISCR)	32	R	0000_0000h	19.2.4/380

19.2.1 Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device's crossbar switch.

Address: E008_0000h base + 8h offset = E008_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ASC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1

MCM_PLASC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ASC	Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port. 0 A bus slave connection to AXBS input port <i>n</i> is absent 1 A bus slave connection to AXBS input port <i>n</i> is present

19.2.2 Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008_0000h base + Ah offset = E008_000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MCM_CR field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 SRAMLWP	SRAM_L Write Protect When this bit is set, writes to SRAM_L array generates a bus error.
29–28 SRAMLAP	SRAM_L arbitration priority Defines the arbitration scheme and priority for the processor and SRAM backdoor accesses to the SRAM_L array. 00 Round robin 01 Special round robin (favors SRAM backdoor accesses over the processor) 10 Fixed priority. Processor has highest, backdoor has lowest 11 Fixed priority. Backdoor has highest, processor has lowest
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MCM_CR field descriptions (continued)

Field	Description
26 SRAMUWP	SRAM_U write protect When this bit is set, writes to SRAM_U array generates a bus error.
25–24 SRAMUAP	SRAM_U arbitration priority Defines the arbitration scheme and priority for the processor and SRAM backdoor accesses to the SRAM_U array. 00 Round robin 01 Special round robin (favors SRAM backdoor accesses over the processor) 10 Fixed priority. Processor has highest, backdoor has lowest 11 Fixed priority. Backdoor has highest, processor has lowest
23–10 Reserved	This field is reserved.
9 Reserved	This field is reserved.
Reserved	This field is reserved.

19.2.4 Interrupt Status Register (MCM_ISCR)

Address: E008_0000h base + 10h offset = E008_0010h

MCM_ISCR field descriptions

Field	Description
31 FIDCE	FPU input denormal interrupt enable 0 Disable interrupt 1 Enable interrupt
30–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 FIXCE	FPU inexact interrupt enable 0 Disable interrupt 1 Enable interrupt

Table continues on the next page...

MCM_ISCR field descriptions (continued)

Field	Description
27 FUFCE	FPU underflow interrupt enable 0 Disable interrupt 1 Enable interrupt
26 FOFCE	FPU overflow interrupt enable 0 Disable interrupt 1 Enable interrupt
25 FDZCE	FPU divide-by-zero interrupt enable 0 Disable interrupt 1 Enable interrupt
24 FIOCE	FPU invalid operation interrupt enable 0 Disable interrupt 1 Enable interrupt
23–16 Reserved	This field is reserved.
15 FIDC	FPU input denormal interrupt status This read-only bit is a copy of the core's FPSCR[IDC] bit and signals input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit. 0 No interrupt 1 Interrupt occurred
14–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FIXC	FPU inexact interrupt status This read-only bit is a copy of the core's FPSCR[IXC] bit and signals an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit. 0 No interrupt 1 Interrupt occurred
11 FUFC	FPU underflow interrupt status This read-only bit is a copy of the core's FPSCR[UFC] bit and signals an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit. 0 No interrupt 1 Interrupt occurred
10 FOFC	FPU overflow interrupt status This read-only bit is a copy of the core's FPSCR[OFC] bit and signals an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit. 0 No interrupt 1 Interrupt occurred
9 FDZC	FPU divide-by-zero interrupt status

Table continues on the next page...

MCM_ISCR field descriptions (continued)

Field	Description
	This read-only bit is a copy of the core's FPSCR[DZC] bit and signals a divide by zero has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[DZC] bit. 0 No interrupt 1 Interrupt occurred
8 FIOC	FPU invalid operation interrupt status This read-only bit is a copy of the core's FPSCR[IOC] bit and signals an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit. 0 No interrupt 1 Interrupt occurred
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 WABORTS_ OVERRUN	WABORTS is an imprecise write fault from the TCM backdoor (AHBS, that is, AHB Slave Interface). The assertion of this field means that more than one WABORTS assertion has occurred. Writing 1 to ISCR[WABORTS] also clears this field. For more information, see ISCR[WABORTS_EN] and ISCR[WABORTS]. 0 One or less than one WABORTS assertion has occurred 1 More than 1 WABORTS assertion has occurred before clearing ISCR[WABORTS]
5 WABORTS	WABORTS is an imprecise write fault from the TCM backdoor (AHBS, that is, AHB Slave Interface). Writing 1 to clear this field also clears ISCR[WABORTS_OVERRUN]. If ISCR[WABORTS_EN] is set to 1, a WABORTS occurrence will generate an MCM interrupt. For more information, see ISCR[WABORTS_EN] and ISCR[WABORTS_OVERRUN]. 0 A WABORTS assertion has not occurred 1 A WABORTS assertion has occurred
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

19.2.5 Fault address register (MCM_FADR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM_ISCR[CWBER] indicator cleared, the MCM_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes have no effect.

Address: E008_0000h base + 20h offset = E008_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MCM_FATR field descriptions

Field	Description
31 BEOVR	Bus error overrun Indicates if another cache write buffer bus error is detected before system software has retrieved all the error information from the original event, this overrun flag is set. The window of time is defined from the detection of the original cache write buffer error termination until the MCM_ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the CWBER bit. 0 No bus error overrun 1 Bus error overrun occurred. The FADR and FDR registers and the other FATR bits are not updated to reflect this new bus error.
30–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 BEMN	Bus error master number Crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.
7 BEWT	Bus error write Indicates the type of system bus access when the error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, signaling a write operation. 0 Read access 1 Write access
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 BESZ	Bus error size Indicates the size of the cache write buffer access when the error was detected. 00 8-bit access 01 16-bit access

Table continues on the next page...

MCM_FATR field descriptions (continued)

Field	Description
10 32-bit access 11 Reserved	
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BEMD	Bus error privilege level Indicates the privilege level of the cache write buffer access when the error was detected. 0 User mode 1 Supervisor/privileged mode
0 BEDA	Bus error access type Indicates the type of cache write buffer access when the error was detected. This attribute is always a logical one signaling a data reference. 0 Instruction 1 Data

19.2.7 Fault data register (MCM_FDR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes have no effect.

Address: E008_0000h base + 28h offset = E008_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

19.3 Functional description

This section describes the functional description of MCM module.

Chapter 20

Crossbar Switch (AXBS)

20.1 Chip-specific AXBS information

20.1.1 Crossbar Switch Master Assignments - with System MPU

The masters connected to the crossbar switch are assigned as follows:

Master port number	Master module	Default Priority
0	ARM core code bus	0
1	ARM core system bus	1
2	DMA	2
3	USB FS/LS OTG	3
4	SDHC	4
5	USB HS/FS/LS OTG	5
6	—	0
7	—	0

20.1.2 Crossbar Switch Slave Assignments - with System MPU

The slaves connected to the crossbar switch are assigned as follows:

Slave module	Slave port number	Protected by MPU?
0	Flash memory controller / Boot ROM	Yes
1	SRAM backdoor	Yes
2	Peripheral bridge 0	No. Protection built into bridge.
3	Peripheral bridge 1 / GPIO1	No. Protection built into bridge.
4	FlexBus/SDRAM memory controller	Yes

Table continues on the next page...

Slave module	Slave port number	Protected by MPU?
5	QSPI	Yes
6	OCRAM	Yes
7	—	

20.1.3 PRS and CRS register reset values

This device contains six bus AXBS masters and seven AXBS slaves.

The AXBS_PRSn (n=0,1,2..6) reset to 0054_3210h. AXBS_PRS7 register reset to 0000_0000h.

AXBS_CRSn where n is 0 to 7 reset to 0000_0000h.

20.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

20.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
 - Allows concurrent accesses from different masters to different slaves
 - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 32-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support

20.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS_n and PRS_n registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

20.3.1 Priority Registers Slave (AXBS_PRSn)

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

NOTE

Valid values for the Mn priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three masters, only one bit is valid.
- If the chip contains fewer than five masters, only two bits are valid.
- If five or more masters are present, all three bits of the priority field are used.

NOTE

See the chip-specific crossbar information for the reset value of this register.

Field	Description
	10 Reserved 11 Reserved
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 PCTL	Parking Control Determines the slave port's parking control. The low-power park feature results in an overall power savings if the slave port is not saturated. However, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK field 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state 11 Reserved
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. NOTE: Select only master ports that are present on the chip. Otherwise, undefined behavior might occur. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

20.3.3 Master General Purpose Control Register (AXBS_MGPCRn)

The MGPCR controls only whether the master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters. The MGPCR can be accessed only in Supervisor mode with 32-bit accesses.

NOTE

If there are fewer than eight master ports, only the registers associated with those masters are present. Register addresses associated with master ports that are not present are reserved.

Please see this module's chip-specific information for which master ports are present on this module.

AULB	Arbitrates On Undefined Length Bursts Determines whether, and when, the crossbar switch arbitrates away the slave port the master owns when the master is performing undefined length burst accesses. 000 No arbitration is allowed during an undefined length burst 001 Arbitration is allowed at any time during an undefined length burst 010 Arbitration is allowed after four beats of an undefined length burst 011 Arbitration is allowed after eight beats of an undefined length burst 100 Arbitration is allowed after 16 beats of an undefined length burst 101 Reserved 110 Reserved 111 Reserved

20.4 Functional Description

20.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer it retains control of the slave port until that transfer completes. Based on MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS n [PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS n [PCTL].

20.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCR x [AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCR x [AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

20.4.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

20.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

Figure 20-1. Undefined length burst example

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

Note

Fixed-length burst accesses are not affected by the AULB bits.
All fixed-length burst accesses lock out arbitration until the last beat of the fixed-length burst.

20.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRSn). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 20-1. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: - The current master is not running a transfer. - The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: - The current master is running a fixed length burst transfer or a locked transfer. - The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
Both of the following are true: - The current master is running an undefined length burst transfer. - The requesting master's priority level is higher than that of the current master.	At the next arbitration point for the undefined length burst transfer NOTE: Arbitration points for an undefined length burst are defined in the MGPCR for each master.
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: - An IDLE cycle - A non-IDLE cycle to a location other than the current slave port

20.4.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

20.4.3.4 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRSn), the crossbar switch responds with a bus error and the registers are not updated.

20.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

NOTE

- During configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS_n[RO].

Chapter 21

Peripheral Bridge (AIPS-Lite)

21.1 Chip-specific AIPS-Lite information

21.1.1 Number of peripheral bridges

This device contains two identical peripheral bridges.

21.1.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See [AIPS0 Memory Map](#) and [AIPS1 Memory Map](#) for the memory slot assignment for each module.

21.1.3 AIPS_Lite MPRA register reset value

- AIPS_x_MPRA reset value is 0x7770_0000

Therefore, masters 0, 1, and 2 are trusted bus masters after reset.

Table 21-1. Master Logical ID assignment table

Logical ID	Master
0	CPU I/D bus
1	CPU system bus
2	eDMA

21.1.4 AIPS_Lite PACRE-P register reset values

The AIPS_x_PACRE-P reset values depend on if the module is available on your particular device. For each populated slot in slots 32-127 in and [Peripheral Bridge 1 \(AIPS-Lite 1\) Memory Map](#), the corresponding module's PACR[32:127] field resets to 0x4.

21.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 4 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

21.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Programming model provides memory protection functionality

21.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 4-KB boundaries. Each peripheral is allocated one or more 4-KB block(s) of the memory map.

21.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

21.3.1 Master Privilege Register A (AIPSx_MPRA)

The MPRA specifies identical 4-bit fields defining the access-privilege level associated with a bus master to various peripherals on the chip. The register provides one field per bus master.

NOTE

At reset, the default value loaded into the MPRA fields is chip-specific. See the chip configuration details for the value of a particular device.

A register field that maps to an unimplemented master or peripheral behaves as read-only-zero.

Each master is assigned a logical ID from 0 to 15. See the master logical ID assignment table in the chip-specific AIPS information.

Address: Base address + 0h offset

21.3.2 Peripheral Access Control Register (AIPSx_PACRn)

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular peripheral. The mapping between a peripheral and its PACR field is shown in the table below. The peripheral assignment to each PACR is defined by the memory map slot that the peripheral is assigned to. See this chip's memory map for the assignment of a particular peripheral.

The following table shows the location of each peripheral slot's PACR field in the PACR registers.

Offset	Register	[31:28]	[27:24]	[23:20]	[19:16]	[15:12]	[11:8]	[7:4]	[3:0]

26 SP1	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for access. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPLn] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
25 WP1	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
24 TP1	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 SP2	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for access. When this bit is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPLn] control bit for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
21 WP2	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
20 TP2	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

Field	Description
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 SP7	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
1 WP7	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
0 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

21.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

21.4.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. All accesses are performed with a single transfer.

Functional description

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

Chapter 22

Memory Protection Unit (MPU)

22.1 Chip-specific MPU information

22.1.1 MPU Slave Port Assignments

The memory-mapped resources protected by the MPU are:

Table 22-1. MPU Slave Port Assignments

Source	MPU Slave Port Assignment	Destination
Crossbar slave port 0	MPU slave port 0	Flash Controller
Crossbar slave port 1	MPU slave port 1	SRAM backdoor
Code Bus	MPU slave port 2	All CM4 code(I/D) bus range
System Bus	MPU slave port 3	All CM4 system bus range
Crossbar slave port 4	MPU slave port 4	FlexBus/SDRAM Controller
Crossbar slave port 5	MPU slave port 5	QSPI
Crossbar slave port 6	MPU slave port 6	OCRAM

22.1.2 MPU Logical Bus Master Assignments

The logical bus master assignments for the MPU are:

Table 22-2. MPU Logical Bus Master Assignments

MPU Logical Bus Master Number	Bus Master
0	Core
1	Debugger
2	eDMA
3	USBOTG (FS/LS)

Table continues on the next page...

**Table 22-2. MPU Logical Bus Master Assignments
(continued)**

MPU Logical Bus Master Number	Bus Master
4	eSDHC
5	USBOTG (HS/FS/LS)

22.1.3 Reset Values for RGD0 Registers

At reset, the MPU is enabled with a single region descriptor (RGD0) that maps the entire 4 GB address space with read, write and execute permissions given to the core, debugger and the DMA bus masters.

The following table shows the chip-specific reset values for RGD0 and RGDAAC0.

Table 22-3. Reset Values for RGD0 Registers

Register	Reset value
RGD0_WORD0	0000_0000h
RGD0_WORD1	FFFF_FFFFh
RGD0_WORD2	0061_F7DFh
RGD0_WORD3	0000_0001h
RGDAAC0	0061_F7DFh

22.1.4 Write Access Restrictions for RGD0 Registers

In addition to configuring the initial state of RGD0, the MPU implements further access control on writes to the RGD0 registers. Specifically, the MPU assigns a priority scheme where the debugger is treated as the highest priority master followed by the core and then all the remaining masters.

The MPU does not allow writes from the core to affect the RGD0 start or end addresses nor the permissions associated with the debugger; it can only write the permission fields associated with the other masters.

These protections (summarized below) guarantee that the debugger always has access to the entire address space and those rights cannot be changed by the core or any other bus master.

Table 22-4. Write Access to RGD0 Registers

Bus Master	Write Access?
Core	Partial. The Core cannot write to the following registers or register fields: • RGD0_WORD0, RGD0_WORD1, RGD0_WORD3 • RGD0_WORD2[M1SM, M1UM] • RGDAAC0[M1SM, M1UM] NOTE: Changes to the RGD0_WORD2 alterable fields should be done via a write to RGDAAC0.
Debugger	Yes
All other masters	No

22.2 Introduction

The memory protection unit (MPU) provides hardware access control for all memory references generated in the device.

22.3 Overview

The MPU concurrently monitors all system bus transactions and evaluates their appropriateness using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with a protection error response.

22.3.1 Block diagram

A simplified block diagram of the MPU module is shown in the following figure.

Figure 22-1. MPU block diagram

The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and the access protection error. For details of the access evaluation macro, see [Access evaluation macro](#).

22.3.2 Features

The MPU implements a two-dimensional hardware array of memory region descriptors and the crossbar slave ports to continuously monitor the legality of every memory reference generated by each bus master in the system.

The feature set includes:

- 12 program-visible 128-bit region descriptors, accessible by four 32-bit words each
 - Each region descriptor defines a modulo-32 byte space, aligned anywhere in memory

- Region sizes can vary from 32 bytes to 4 Gbytes
- Two access control permissions defined in a single descriptor word
 - Masters 0–3: read, write, and execute attributes for supervisor and user accesses
 - Masters 4–7: read and write attributes
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
- Alternate programming model view of the access control permissions word
- Priority given to granting permission over denying access for overlapping region descriptors
- Detects access protection errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the MPU inhibits the bus cycle being sent to the targeted slave device.
- Error registers, per slave port, capture the last faulting address, attributes, and other information
- Global MPU enable/disable control bit

22.4 Memory map/register definition

The programming model is partitioned into three groups:

- Control/status registers
- The data structure containing the region descriptors
- The alternate view of the region descriptor access control values

The programming model can be referenced using only 32-bit accesses. The programming model can be accessed only in supervisor mode.

Attempted references of the following types generate an error termination:

- Non-32-bit references
- Accesses in user mode
- References to undefined—that is, reserved—addresses
- References with a non-supported access type, such as a write access to a read-only register or a read access of a write-only register

NOTE

See the chip configuration details for any chip-specific register information in this module.

MPU_CESR field descriptions

Field	Description
31–25 SPERR	Slave Port n Error Indicates a captured error in EARN and EDRn. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error. The following shows the correspondence between the bit number and slave port number: • Bit 31 corresponds to slave port 0. • Bit 30 corresponds to slave port 1. • Bit 29 corresponds to slave port 2. • Bit 28 corresponds to slave port 3. • Bit 27 corresponds to slave port 4.

Table continues on the next page...

MPU_CESR field descriptions (continued)

Field	Description
	• Bit 26 corresponds to slave port 5. • Bit 25 corresponds to slave port 6. 0 No error has occurred for slave port n. 1 An error has occurred for slave port n.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 HRL	Hardware Revision Level Specifies the MPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
15–12 NSP	Number Of Slave Ports Specifies the number of slave ports connected to the MPU.
11–8 NRGD	Number Of Region Descriptors Indicates the number of region descriptors implemented in the MPU. 0000 8 region descriptors 0001 12 region descriptors 0010 16 region descriptors
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 VLD	Valid Global enable/disable for the MPU. 0 MPU is disabled. All accesses from all bus masters are allowed. 1 MPU is enabled

22.4.2 Error Address Register, slave port n (MPU_EAR_n)

When the MPU detects an access error on slave port n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR[SPERR_n] is set. Additional information about the faulting access is captured in the corresponding EDR_n at the same time. This register and the corresponding EDR_n contain the most recent access error; there are no hardware interlocks with CESR[SPERR_n], as the error registers are always loaded upon the occurrence of each protection violation.

Address: 4000_D000h base + 10h offset + (8d × i), where i=0d to 6d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MPU_EAR_n field descriptions

Field	Description
EADDR	Error Address Indicates the reference address from slave port n that generated the access error

22.4.3 Error Detail Register, slave port n (MPU_EDR_n)

When the MPU detects an access error on slave port n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR[SPERR_n] is set. Information on the faulting address is captured in the corresponding EAR_n register at the same time. This register and the corresponding EAR_n register contain the most recent access error; there are no hardware interlocks with CESR[SPERR_n] as the error registers are always loaded upon the occurrence of each protection violation.

Address: 4000_D000h base + 14h offset + (8d × i), where i=0d to 6d

MPU_EDR_n field descriptions

Field	Description
31–16 EACD	Error Access Control Detail Indicates the region descriptor with the access error. • If EDR_n contains a captured error and EACD is cleared, an access did not hit in any region descriptor. • If only a single EACD bit is set, the protection error was caused by a single non-overlapping region descriptor. • If two or more EACD bits are set, the protection error was caused by an overlapping set of region descriptors.
15–8 EPID	Error Process Identification Records the process identifier of the faulting reference. The process identifier is typically driven only by processor cores; for other bus masters, this field is cleared.
7–4 EMN	Error Master Number Indicates the bus master that generated the access error.
3–1 EATTR	Error Attributes Indicates attribute information about the faulting reference. NOTE: All other encodings are reserved. 000 User mode, instruction access 001 User mode, data access 010 Supervisor mode, instruction access 011 Supervisor mode, data access
0 ERW	Error Read/Write Indicates the access type of the faulting reference. 0 Read 1 Write

22.4.4 Region Descriptor n, Word 0 (MPU_RGD_n_WORD0)

The first word of the region descriptor defines the 0-modulo-32 byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGD_n_WORD3[VLD]).

Address: 4000_D000h base + 400h offset + (16d × i), where i=0d to 11d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MPU_RGDn_WORD1 field descriptions

Field	Description
31–5 ENDADDR	End Address Defines the most significant bits of the 31-modulo-32 byte end address of the memory region. NOTE: The MPU does not verify that ENDADDR ≥ SRTADDR.
Reserved	This field is reserved.

22.4.6 Region Descriptor n, Word 2 (MPU_RGDn_WORD2)

The third word of the region descriptor defines the access control rights of the memory region. The access control privileges depend on two broad classifications of bus masters:

- Bus masters 0–3 have a 5-bit field defining separate privilege rights for user and supervisor mode accesses. Each of these bus masters optionally includes a process identification field (if implemented for the master) within the definition.
- Bus masters 4–7 are limited to separate read and write permissions.

For the privilege rights of bus masters 0–3, there are three flags associated with this function:

- Read (r) refers to accessing the referenced memory address using an operand (data) fetch
- Write (w) refers to updating the referenced memory address using a store (data) instruction
- Execute (x) refers to reading the referenced memory address using an instruction fetch

Writes to RGDn_WORD2 clear the region descriptor's valid bit (RGDn_WORD3[VLD]). If only updating the access controls, write to RGDAACn instead because stores to these locations do not affect the descriptor's valid bit.

Address: 4000_D000h base + 408h offset + (16d × i), where i=0d to 11d

22.5 Functional description

In this section, the functional operation of the MPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

22.5.1 Access evaluation macro

The basic operation of the MPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in the following figure, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD_n) and performs two major functions:

- Region hit determination
- Detection of an access protection violation

The following figure shows a functional block diagram.

Figure 22-2. MPU access evaluation macro

22.5.1.1 Hit determination

To determine whether the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[31:5] >= RGDn_Word0[SRTADDR]) & (addr[31:5] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

where *addr* is the current reference address, *RGDn_Word0*[SRTADDR] and *RGDn_Word1*[ENDADDR] are the start and end addresses, and *RGDn_Word3*[VLD] is the valid bit.

NOTE

The MPU does not verify that $\text{ENDADDR} \geq \text{SRTADDR}$.

In addition to the comparison of the reference address versus the region descriptor's start and end addresses, the optional process identifier is examined against the region descriptor's PID and PIDMASK fields. A process identifier hit term is formed as follows:

```
pid_hit = ~RGDn_Word2[MxPE] |  
          ((current_pid |  
            RGDn_Word3[PIDMASK]) == (RGDn_Word3[PID] | RGDn_Word3[PIDMASK]))
```

where the `current_pid` is the selected process identifier from the current bus master, and `RGD $n$ _Word3[PID]` and `RGD $n$ _Word3[PIDMASK]` are the process identifier fields from region descriptor n . For bus masters that do not output a process identifier, the MPU forces the `pid_hit` term to assert.

22.5.1.2 Privilege violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master and supervisor/user mode signals, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

Table 22-5. Protection violation definition

Description	MxUM			Protection violation?
	r	w	x	
Instruction fetch read	—	—	0	Yes, no execute permission
	—	—	1	No, access is allowed
Data read	0	—	—	Yes, no read permission
	1	—	—	No, access is allowed
Data write	—	0	—	Yes, no write permission
	—	1	—	No, access is allowed

22.5.2 Putting it all together and error terminations

For each slave port monitored, the MPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports a protection error for three conditions:

- If the access does not hit in any region descriptor, a protection error is reported.
- If the access hits in a single region descriptor and that region signals a protection violation, a protection error is reported.
- If the access hits in multiple (overlapping) regions and all regions signal protection violations, a protection error is reported.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see [Application information](#).

22.5.3 Power management

Disabling the MPU by clearing CESR[VLD] minimizes power dissipation. To minimize the power dissipation of an enabled MPU, invalidate unused region descriptors by clearing the associated RGDn_Word3[VLD] bits.

22.6 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGDn_Word3[VLD]. Setting CESR[VLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire MPU is disabled (CESR[VLD]=0).

Note

A region descriptor must be set to allow access to the MPU registers if further changes are needed.

22.7 Application information

In an operational system, interfacing with the MPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGDn, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes. (Clearing RGDn_Word3[VLD] deletes/removes an existing memory region.)
- Altering only access privileges—To not affect the valid bit, write to the alternate version of the access control word (RGDAACn), so there are no coherency issues involved with the update. When the write completes, the memory region's access rights switch instantaneously to the new value.

- Changing a region's start and end addresses—Write a minimum of three words to the region descriptor (RGD n _Word{0,1,3}). Word 0 and 1 redefine the start and end addresses, respectively. Word 3 re-enables the region descriptor valid bit. In most situations, all four words of the region descriptor are rewritten.
- Accessing the MPU—Allocate a region descriptor to restrict MPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and EAR n and EDR n capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R n . CESR[SPERR] signals which error registers contain captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters:

- The two processors: CP0, CP1
- Two DMA engines: DMA1, a traditional data movement engine transferring data between RAM and peripherals and DMA2, a second engine transferring data to/from the RAM only

Consider the following region descriptor assignments:

Table 22-6. Overlapping region descriptor example

Region description	RGDn		CP0	CP1	DMA1	DMA2	
CP0 code	0		rwX	r--	—	—	Flash
CP1 code	1		r--	rwX	—	—	
CP0 data & stack	2		rw-	—	—	—	RAM
CP0 → CP1 shared data	2	3	r--	r--	—	—	
CP1 → CP0 shared data	4						
CP1 data & stack	4		—	rw-	—	—	
Shared DMA data	5		rw-	rw-	rw	rw	
MPU	6		rw-	rw-	—	—	Peripheral space
Peripherals	7		rw-	rw-	rw	—	

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map: flash, RAM, and peripheral space. Each region indicates the specific permissions for each of the four bus masters and this definition provides an appropriate set of shared, private and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1 and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has $(rw- \mid r--)$ = $(rw-)$ permissions, while CP1 has $(--- \mid r--)$ = $(r--)$ permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has $(r-- \mid ---)$ = $(r--)$ permission, while CP1 has $(rw- \mid r--)$ = $(rw-)$ permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the IPS bus is partitioned into two regions:

- One containing the MPU's programming model accessible only to the two processor cores
- The remaining peripheral region accessible to both processors and the traditional DMA1 master

This example shows one possible application of the capabilities of the MPU in a typical system.

Chapter 23

Bit Manipulation Engine2 (BME2)

23.1 Introduction

The Bit Manipulation Engine with the BME2 definition (BME2) provides hardware support for atomic read-modify-write memory operations to the first 1 Mbyte of slave peripheral address space in Cortex-M based microcontrollers. The second generation BME2 provides similar atomic read-modify-write capabilities to a larger peripheral address space versus the original implementation. The BME terminology is meant to be equivalent to BME2 throughout this chapter.

This architectural capability is also known as "decorated storage" as it defines a mechanism for providing additional semantics for load and store operations to memory-mapped peripherals beyond just the reading and writing of data values to the addressed memory locations. In the BME definition, the "decoration", that is, the additional semantic information, is encoded into the peripheral address used to reference the memory. The BME2 definition supports up to two AIPS bus controllers, each capable of addressing 512 KB of peripheral address space. BME2 supports an 8-bit or less data field width for bit field inserts and extracts, regardless of reference size. All other BME2 operations are exactly the same as the original definition.

By combining the basic load and store instructions of the ARM Cortex-M instruction set architecture (v6M, v7M) with the concept of decorated storage provided by BME, the resulting implementation provides a robust and efficient read-modify-write capability. The resulting architectural capability defined by this core platform function is targeted at the manipulation of n-bit fields in peripheral registers and is consistent with I/O hardware addressing in the Embedded C standard. For most BME commands, a single core read or write bus cycle is converted into an atomic read-modify-write, that is, an indivisible "read followed by a write" bus sequence.

BME decorated references are only available on system bus transactions generated by the processor core and DMA, and targeted at the 1024 KB peripheral address space based at 0x4000_0000. The decoration semantic is embedded into address bits[28:20], creating a

448 MB space at addresses 0x4400_0000–0x5FFF_FFFF; these bits are stripped out of the actual address sent to the peripheral bus controller and used by the BME to define and control its operation.

23.1.1 Features

The key features of the BME2 include:

- Lightweight implementation of decorated storage for selected address spaces
- Additional access semantics encoded into the reference address
- Resides between crossbar switch slave port(s) and their associated peripheral bridge bus controller(s)
- Two-stage pipeline design matching the AHB system bus protocol
- Combinationally passes non-decorated accesses to peripheral bridge bus controllers
- Conversion of decorated loads and stores from processor core into atomic read-modify-writes
- Decorated loads support unsigned bit field extracts, load-and-`{set,clear}` 1-bit operations
- Decorated stores support bit field inserts, logical AND, OR, and XOR operations
- Support for byte, halfword and word-sized decorated operations
- Supports minimum signal toggling on AHB output bus to reduce power dissipation

23.1.2 Modes of operation

The BME modules do not support any special modes of operation. As memory-mapped devices located on crossbar slave AHB system bus ports, BME responds strictly on the basis of memory addresses for accesses to the AIPS controllers.

All functionality associated with the BME modules reside in the core platform's clock domain; this includes their connections with the crossbar slave ports and the AIPS controllers.

23.2 Memory map and register definition

The BME module provides a memory-mapped capability and does not include any programming model registers.

The exact set of functions supported by the BME are detailed in the [Functional description](#).

The generic BME2 definition supports a 1024 KB address space based at 0x4000_0000.... For K27 device, the upper 16 KB of this address space is not supported, so the BME2 functionality covers the $(512 + 512 - 16 = 1008)$ KB space at 0x4000_0000 - 0x400F_BFFF. The decorated address space is mapped to the 448 MB region located at 0x4400_0000–0x5FFF_FFFF.

23.3 Functional description

Information found here details the specific functions supported by the BME.

Recall the combination of the basic load and store instructions of the Cortex-M instruction set architecture (v6M, v7M) plus the concept of decorated storage provided by the BME provides a robust and efficient read-modify-write capability. The resulting architectural capability defined by this core platform function is targeted at the manipulation of n-bit fields in peripheral registers and is consistent with I/O hardware addressing in the Embedded C standard. For most BME commands, a single core read or write bus cycle is converted into an atomic read-modify-write, that is, an indivisible "read followed by a write" bus sequence.

Consider decorated store operations first, then decorated loads.

23.3.1 BME decorated stores

The functions supported by the BME's decorated stores include three logical operators (AND, OR, XOR) plus a bit field insert.

For all these operations, BME converts a single decorated AHB store transaction into a 2-cycle atomic read-modify-write sequence, where the combined read-modify operation is performed in the first AHB data phase, and then the write is performed in the second AHB data phase.

A generic timing diagram of a decorated store showing a peripheral bit field insert operation is shown as follows:

Functional description

Figure 23-1. Decorated store: bit field insert timing diagram

All the decorated store operations follow the same execution template shown in [Figure 23-1](#), a two-cycle read-modify-write operation:

1. Cycle x, 1st AHB address phase: Write from input bus is translated into a read operation on the output bus using the actual memory address (with the decoration removed) and then captured in a register.
2. Cycle x+1, 2nd AHB address phase: Write access with the registered (but actual) memory address is output
3. Cycle x+1, 1st AHB data phase: Memory read data is modified using the input bus write data and the function defined by the decoration and captured in a data register; the input bus cycle is stalled.
4. Cycle x+2, 2nd AHB data phase: Registered write data is sourced onto the output write data bus.

NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

23.3.1.1 Decorated store logical AND (AND)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read;
2. It is then modified by performing a logical AND operation using the write data operand sourced for the system bus cycle
3. Finally, the result of the AND operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ioandb	0	1	0	0	0	1	-	-	-	-	-	-	mem_addr																			
ioandh	0	1	0	0	0	1	-	-	-	-	-	-	mem_addr																		0	
ioandw	0	1	0	0	0	1	-	-	-	-	-	-	mem_addr																		0	0

Figure 23-2. Decorated store address: logical AND

See [Figure 23-2](#) where `addr[30:29] = 10` for peripheral, `addr[28:26] = 001` specifies the AND operation, and `mem_addr[19:0]` specifies the address offset into the space based at a `0x4000_0000` for peripherals. The "-" indicates an address bit "don't care".

The decorated AND write operation is defined in the following pseudo-code as:

```
ioand<sz>(accessAddress, wdata)           // decorated store AND
tmp  = mem[accessAddress & 0xE0FFFFFF, size] // memory read
tmp  = tmp & wdata                         // modify
mem[accessAddress & 0xE0FFFFFF, size] = tmp // memory write
```

where the operand size `<sz>` is defined as `b`(yte, 8-bit), `h`(alfword, 16-bit) and `w`(ord, 32-bit). This notation is used throughout the document.

In the cycle definition tables, the notations `AHB_ap` and `AHB_dp` refer to the address and data phases of the BME AHB transaction. The cycle-by-cycle BME operations are detailed in the following table.

Table 23-1. Cycle definitions of decorated store: logical AND

Pipeline stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert	Recirculate captured addr + attr to memory as slave_wt	<next>

Table continues on the next page...

Table 23-1. Cycle definitions of decorated store: logical AND (continued)

Pipeline stage	Cycle		
	x	x+1	x+2
	master_wt to slave_rd; Capture address, attributes		
BME AHB_dp	<previous>	Perform memory read; Form (rdata & wdata) and capture destination data in register	Perform write sending registered data to memory

23.3.1.2 Decorated store logical OR (OR)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read.
2. It is then modified by performing a logical OR operation using the write data operand sourced for the system bus cycle.
3. Finally, the result of the OR operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ioorb	0	1	0	0	1	0	-	-	-	-	-	-	mem_addr																			
ioorh	0	1	0	0	1	0	-	-	-	-	-	-	mem_addr															0				
ioorw	0	1	0	0	1	0	-	-	-	-	-	-	mem_addr															0 0				

Figure 23-3. Decorated address store: logical OR

See [Figure 23-3](#), where $\text{addr}[30:29] = 10$ for peripheral, $\text{addr}[28:26] = 010$ specifies the OR operation, and $\text{mem\_addr}[19:0]$ specifies the address offset into the space based at a $0x4000\_0000$ for peripherals. The "-" indicates an address bit "don't care".

The decorated OR write operation is defined in the following pseudo-code as:

```
ioor<sz>(accessAddress, wdata)           // decorated store OR

tmp   = mem[accessAddress & 0xE00FFFFF, size] // memory read
tmp   = tmp | wdata                          // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp  // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

Table 23-2. Cycle definitions of decorated store: logical OR

Pipeline stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form (rdata wdata) and capture destination data in register	Perform write sending registered data to memory

23.3.1.3 Decorated store logical XOR (XOR)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read.
2. It is then modified by performing a logical XOR (exclusive-OR) operation using the write data operand sourced for the system bus cycle.
3. Finally, the result of the XOR operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ioxorb	0	1	0	0	1	1	-	-	-	-	-	-	mem_addr																			
ioxorh	0	1	0	0	1	1	-	-	-	-	-	-	mem_addr															0				
ioxorw	0	1	0	0	1	1	-	-	-	-	-	-	mem_addr															0	0			

Figure 23-4. Decorated address store: logical XOR

See [Figure 23-4](#), where `addr[30:29] = 10` for peripheral, `addr[28:26] = 011` specifies the XOR operation, and `mem_addr[19:0]` specifies the address offset into the peripheral space based at a `0x4000_0000` for peripherals. The "-" indicates an address bit "don't care".

The decorated XOR write operation is defined in the following pseudo-code as:

```

ioxor<sz>(accessAddress, wdata)           // decorated store XOR

tmp    = mem[accessAddress & 0xE0FFFFFF, size] // memory read
tmp    = tmp ^ wdata                          // modify
mem[accessAddress & 0xE0FFFFFF, size] = tmp    // memory write

```

The cycle-by-cycle BME operations are detailed in the following table.

Table 23-3. Cycle definitions of decorated store: logical XOR

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form (rdata ^ wdata) and capture destination data in register	Perform write sending registered data to memory

23.3.1.4 Decorated store bit field insert (BFI)

This command inserts a bit field contained in the write data operand, defined by LSB position (b) and the bit field width (w+1), into the memory "container" defined by the access size associated with the store instruction using an atomic read-modify-write sequence.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). For BME2, the data field width (addr[22:20]) for bit field inserts and extracts is limited to an 8-bit or less value, regardless of reference size.

NOTE

The maximum bit field width is 8 bits. The core performs the required write data lane replication on byte and halfword transfers.

The BFI operation can be used to insert a single bit into a peripheral. For this case, the w field is simply set to 0, indicating a bit field width of 1.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
iobfib	0	1	0	1	-	-	b	b	b	w	w	w	mem_addr																			
iobfih	0	1	0	1	-	b	b	b	b	w	w	w	mem_addr															0				
iobfiw	0	1	0	1	b	b	b	b	b	w	w	w	mem_addr															00				

Figure 23-5. Decorated address store: bit field insert

where addr[30:29]=10 for peripheral, addr[28]=1 signals a BFI operation, addr[27:23] is "b", the LSB identifier, addr[22:20] is "w", the bit field width minus 1 identifier, and addr[19:0] specifies the address offset into the peripheral space based at 0x4000_0000. The "-" indicates an address bit "don't care".

The decorated BFI write operation is defined in the following pseudo-code as:

```
iobfi<sz>(accessAddress, wdata)           // decorated bit field insert

tmp    = mem[accessAddress & 0xE00FFFFF, size] // memory read
mask   = ((1 << (w+1)) - 1) << b           // generate bit mask
tmp    = tmp & ~mask                        // modify
        | wdata & mask
mem[accessAddress & 0xE00FFFFF, size] = tmp // memory write
```

The write data operand (wdata) associated with the store instruction contains the bit field to be inserted. It must be properly aligned within the right-aligned container, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword, or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, w is 2, signaling a bit field width of 3.

```
if b = 0 and the decorated store (strb) Rt register[7:0] = ----_xyz,
    then destination is "abcd_ xyz"
if b = 1 and the decorated store (strb) Rt register[7:0] = ----_xyz-,
    then destination is "abcd_ xyzh"
if b = 2 and the decorated store (strb) Rt register[7:0] = ---x_ yz--,
    then destination is "abcx_ yzgh"
if b = 3 and the decorated store (strb) Rt register[7:0] = --xy_ z---,
    then destination is "abxy_ z fgh"
if b = 4 and the decorated store (strb) Rt register[7:0] = -xyz_ ----,
    then destination is "axyz_ efgh"
if b = 5 and the decorated store (strb) Rt register[7:0] = xyz- _----,
    then destination is "xyzd_ efgh"
if b = 6 and the decorated store (strb) Rt register[7:0] = yz-- _----,
    then destination is "yzcd_ efgh"
if b = 7 and the decorated store (strb) Rt register[7:0] = z--- _----,
    then destination is "zbcd_ efgh"
```

Note from the example, when the starting bit position plus the field width exceeds the container size, only part of the source bit field is inserted into the destination memory location. Stated differently, if $(b + w + 1) > \text{container\_width}$, only the low-order "container_width - b" bits are actually inserted.

The cycle-by-cycle BME operations are detailed in the following table.

Table 23-4. Cycle definitions of decorated store: bit field insert

Pipeline stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Form bitwise $((\text{mask}) ? \text{wdata} : \text{rdata})$ and capture destination data in register	Perform write sending registered data to memory

23.3.2 BME decorated loads

The functions supported by the BME's decorated loads include two single-bit load-and-
{set, clear} operators plus unsigned bit field extracts.

For the two load-and-
{set, clear} operations, BME converts a single decorated AHB load transaction into a two-cycle atomic read-modify-write sequence, where the combined read-modify operations are performed in the first AHB data phase, and then the write is performed in the second AHB data phase as the original read data is returned to the processor core. For an unsigned bit field extract, the decorated load transaction is stalled for one cycle in the BME as the data field is extracted, then aligned and returned to the processor in the second AHB data phase. This is the only decorated transaction that is not an atomic read-modify-write, as it is a simple data read.

A generic timing diagram of a decorated load showing a peripheral load-and-set 1-bit operation is shown as follows.

Figure 23-6. Decorated load: load-and-set 1-bit field insert timing diagram

Decorated load-and-**{set, clear}** 1-bit operations follow the execution template shown in the above figure: a 2-cycle read-modify-write operation:

1. Cycle x, first AHB address phase: Read from input bus is translated into a read operation on the output bus with the actual memory address (with the decoration removed) and then captured in a register
2. Cycle x+1, second AHB address phase: Write access with the registered (but actual) memory address is output
3. Cycle x+1, first AHB data phase: The "original" 1-bit memory read data is captured in a register, while the 1-bit field is set or clear based on the function defined by the decoration with the modified data captured in a register; the input bus cycle is stalled
4. Cycle x+2, second AHB data phase: The selected original 1-bit is right-justified, zero-filled and then driven onto the input read data bus, while the registered write data is sourced onto the output write data bus

NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

A generic timing diagram of a decorated load showing an unsigned peripheral bit field operation is shown in the following figure.

Figure 23-7. Decorated load: unsigned bit field insert timing diagram

The decorated unsigned bit field extract follows the same execution template shown in the above figure, a 2-cycle read operation:

- Cycle x, 1st AHB address phase: Read from input bus is translated into a read operation on the output bus with the actual memory address (with the decoration removed) and then captured in a register
- Cycle x+1, 2nd AHB address phase: Idle cycle

- Cycle x+1, 1st AHB data phase: A bit mask is generated based on the starting bit position and the field width; the mask is AND'ed with the memory read data to isolate the bit field; the resulting data is captured in a data register; the input bus cycle is stalled
- Cycle x+2, 2nd AHB data phase: Registered data is logically right-aligned for proper alignment and driven onto the input read data bus

NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

23.3.2.1 Decorated load: load-and-clear 1 bit (LAC1)

This command loads a 1-bit field defined by the LSB position (b) into the core's general purpose destination register (Rt) and zeroes the bit in the memory space after performing an atomic read-modify-write sequence.

The extracted 1-bit data field from the memory address is right-justified and zero-filled in the operand returned to the core.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ol ac1b	0	1	0	0	1	0	-	-	b	b	b	-	mem_addr																			
ol ac1h	0	1	0	0	1	0	-	b	b	b	b	-	mem_addr															0				
ol ac1w	0	1	0	0	1	0	b	b	b	b	b	-	mem_addr															0		0		

Figure 23-8. Decorated load address: load-and-clear 1 bit

See [Figure 23-8](#) where $\text{addr}[30:29] = 10$ for peripherals, $\text{addr}[28:26] = 010$ specifies the load-and-clear 1 bit operation, $\text{addr}[25:21]$ is "b", the bit identifier, and $\text{mem\_addr}[19:0]$ specifies the address offset into the space based at $0x4000\_0000$ for peripherals. The "-" indicates an address bit "don't care".

The decorated load-and-clear 1-bit read operation is defined in the following pseudo-code as:

```

rdata = iolac1<sz>(accessAddress)           // decorated load-and-clear 1

tmp    = mem[accessAddress & 0xE00FFFFF, size] // memory read
mask   = 1 << b                               // generate bit mask
rdata  = (tmp & mask) >> b                     // read data returned to core
tmp    = tmp & ~mask                           // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp    // memory write

```

The cycle-by-cycle BME operations are detailed in the following table.

Table 23-5. Cycle definitions of decorated load: load-and-clear 1 bit

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Extract bit from rdata; Form (rdata & ~mask) and capture destination data in register	Return extracted bit to master; Perform write sending registered data to memory

23.3.2.2 Decorated Load: Load-and-Set 1 Bit (LAS1)

This command loads a 1-bit field defined by the LSB position (b) into the core's general purpose destination register (Rt) and sets the bit in the memory space after performing an atomic read-modify-write sequence.

The extracted one bit data field from the memory address is right justified and zero filled in the operand returned to the core.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
iolaslb	0	1	0	0	1	1	-	-	b	b	b	-	mem_addr																			
iolaslh	0	1	0	0	1	1	-	b	b	b	b	-	mem_addr															0				
iolaslw	0	1	0	0	1	1	b	b	b	b	b	-	mem_addr															0		0		

Figure 23-9. Decorated load address: load-and-set 1 bit

where $\text{addr}[30:29] = 10$ for peripherals, $\text{addr}[28:26] = 011$ specifies the load-and-set 1 bit operation, $\text{addr}[25:21]$ is "b", the bit identifier, and $\text{mem\_addr}[19:0]$ specifies the address offset into the space based at $0x4000\_0000$ for peripherals. The "-" indicates an address bit "don't care".

The decorated Load-and-Set 1 Bit read operation is defined in the following pseudo-code as:

```

rdata = iolas1<sz>(accessAddress)           // decorated load-and-set 1

tmp    = mem[accessAddress & 0xE00FFFFF, size] // memory read
mask   = 1 << b                               // generate bit mask
rdata  = (tmp & mask) >> b                     // read data returned to core

```

```
tmp = tmp | mask // modify
mem[accessAddress & 0xE0FFFFFF, size] = tmp // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

Table 23-6. Cycle definitions of decorated load: load-and-set 1-bit

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Extract bit from rdata; Form (rdata mask) and capture destination data in register	Return extracted bit to master; Perform write sending registered data to memory

23.3.2.3 Decorated load unsigned bit field extract (UBFX)

This command extracts a bit field defined by LSB position (b) and the bit field width (w +1) from the memory "container" defined by the access size associated with the load instruction using a two-cycle read sequence.

The extracted bit field from the memory address is right-justified and zero-filled in the operand returned to the core. Recall this is the only decorated operation that does not perform a memory write, that is, UBFX only performs a read.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The maximum bit field width is 8 bits, regardless of reference size.

The use of a UBFX operation is recommended to extract a single bit. For this case, the w field is simply set to 0, indicating a bit field width of 1.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ioubfxb	0	1	0	1	-	-	b	b	b	w	w	w	mem_addr																			
ioubfxh	0	1	0	1	-	b	b	b	b	w	w	w	mem_addr															0				
ioubfxw	0	1	0	1	b	b	b	b	b	w	w	w	mem_addr															0		0		

Figure 23-10. Decorated load address: unsigned bit field extract

See [Figure 23-10](#), where $\text{addr}[30:29] = 10$ for peripherals, $\text{addr}[28] = 1$ specifies the unsigned bit field extract operation, $\text{addr}[27:23]$ is "b", the LSB identifier, $\text{addr}[22:20]$ is "w", the bit field width minus 1 identifier, and $\text{mem\_addr}[19:0]$ specifies the address offset into the space based at 0x4000_0000 for peripherals. The "-" indicates an address bit "don't care".

The decorated unsigned bit field extract read operation is defined in the following pseudo-code as:

```
rdata = ioubfx<sz>(accessAddress)           // unsigned bit field extract

tmp   = mem[accessAddress & 0xE0FFFFFF, size] // memory read
mask  = ((1 << (w+1)) - 1) << b              // generate bit mask
rdata = (tmp & mask) >> b                    // read data returned to core
```

Like the BFI operation, when the starting bit position plus the field width exceeds the container size, only part of the source bit field is extracted from the destination memory location. Stated differently, if $(b + w + 1) > \text{container\_width}$, only the low-order "container_width - b" bits are actually extracted. The cycle-by-cycle BME operations are detailed in the following table.

Table 23-7. Cycle definitions of decorated load: unsigned bit field extract

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Capture address, attributes	Idle AHB address phase	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Form (rdata & mask) and capture destination data in register	Logically right shift registered data; Return justified rdata to master

23.4 Application information

In this section, GNU assembler macros with C expression operands are presented as examples of the required instructions to perform decorated operations.

This section specifically presents a partial bme.h file defining the assembly language expressions for decorated logical stores: AND, OR, and XOR. Comparable functions for BFI and the decorated loads are more complex and available in the complete BME header file.

These macros use the same function names presented in [Functional description](#).

```

Chapter 24

Direct Memory Access Multiplexer (DMAMUX)

24.1 Chip-specific DMAMUX information

24.1.1 DMA MUX request sources

This device includes a DMA request MUX that allows up to 126 DMA request signals to be mapped to any of the 32 DMA channels in two groups. Because of the mux there is not a hard correlation between any of the DMA request sources and a specific DMA channel. The first group is connected to channels 0-15 and the second group is connected to channels 16-31. To allow for flexibility and optimal usage of the available DMA channels some of the DMA request sources may be available on both groups.

Some of the modules support Asynchronous DMA operation as indicated by the last column in the following DMA source assignment table.

Table 24-1. DMA request sources - DMA Channels 0-15

1. Configuring a DMA channel to select source 0 or any of the reserved sources disables that DMA channel.

24.1.2 DMA transfers via PIT trigger

The PIT module can trigger a DMA transfer on the first four DMA channels. The assignments are detailed at [PIT/DMA Periodic Trigger Assignments](#).

24.2 Introduction

24.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 32 DMA channels. This process is illustrated in the following figure.

Figure 24-1. DMAMUX block diagram

24.2.2 Features

The DMAMUX module provides these features:

- Up to 59 peripheral slots and up to four always-on slots can be routed to 32 channels.
- 32 independently selectable DMA channel routers.
 - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

24.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

24.3 External signal description

The DMAMUX has no external pins.

24.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

4002_101E	Channel Configuration register (DMAMUX_CHCFG30)	8	R/W	00h	24.4.1/470
4002_101F	Channel Configuration register (DMAMUX_CHCFG31)	8	R/W	00h	24.4.1/470

24.4.1 Channel Configuration register (DMAMUX_CHCFGn)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 4002_1000h base + 0h offset + (1d × i), where i=0d to 31d

Bit	7	6	5	4	3	2	1	0
Read	ENBL	TRIG	SOURCE					
Write								
Reset	0	0	0	0	0	0	0	0

DMAMUX_CHCFGn field descriptions

Field	Description
7 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled
6 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

24.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

24.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 24-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

Figure 24-3. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

Figure 24-4. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 μ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

24.5.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in [Modes of operation](#).

24.5.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are four additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

24.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

24.6.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

24.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.

3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

Chapter 25

Enhanced Direct Memory Access (eDMA)

25.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
 - Source address and destination address calculations
 - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

25.1.1 eDMA system block diagram

[Figure 25-1](#) illustrates the components of the eDMA system, including the eDMA module ("engine").

Figure 25-1. eDMA system block diagram

25.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 25-1. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI_n[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes

Table continues on the next page...

Table 25-1. eDMA engine submodules (continued)

Submodule	Function
	the new values for the TCDn_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCDn_CITER field, and a possible fetch of the next TCDn from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 25-2. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

25.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
 - Programmable source and destination addresses and transfer size
 - Support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
 - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
 - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
 - 32-byte TCD stored in local memory for each channel
 - An inner data transfer loop defined by a minor byte transfer count
 - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
 - Explicit software initiation
 - Initiation via a channel-to-channel linking mechanism for continuous transfers
 - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
 - One interrupt per channel, which can be asserted at completion of major iteration count
 - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, n is used to reference the channel number.

25.2 Modes of operation

The eDMA operates in the following modes:

Table 25-3. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

25.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

25.3.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD_{*n*} definition is presented as 11 registers of 16 or 32 bits.

25.3.2 TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

25.3.3 TCD structure

25.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

25.3.5 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned

in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

Address: 4000_8000h base + 0h offset = 4000_8000h

DMA_CR field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 CX	Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
16 ECX	Error Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
7 EMLM	Enable Minor Loop Mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
6 CLM	Continuous Link Mode NOTE: Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
5 HALT	Halt DMA Operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
4 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
3 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
2 ERCA	Enable Round Robin Channel Arbitration 0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
1 EDBG	Enable Debug 0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
0 Reserved	This field is reserved. Reserved

25.3.6 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
 - An illegal setting in the transfer-control descriptor, or
 - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See [Fault reporting and handling](#) for more details.

DMA_ES field descriptions

Field	Description
31 VLD	Logical OR of all ERR status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
30–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ECX	Transfer Canceled 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
15 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
14 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
7 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
6 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
5 DAE	Destination Address Error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
4 DOE	Destination Offset Error

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
	0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
3 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or • TCDn_CITER[CITER] is equal to zero, or • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
2 SGE	Scatter/Gather Configuration Error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
1 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

25.3.7 Enable Request Register (DMA_ERQ)

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

NOTE

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

25.3.8 Enable Error Interrupt Register (DMA_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

DMA_EEI field descriptions (continued)

Field	Description
3 EEI3	Enable Error Interrupt 3 0 The error signal for corresponding channel does not generate an error interrupt 1 The assertion of the error signal for corresponding channel generates an error interrupt request
2 EEI2	Enable Error Interrupt 2 0 The error signal for corresponding channel does not generate an error interrupt 1 The assertion of the error signal for corresponding channel generates an error interrupt request
1 EEI1	Enable Error Interrupt 1 0 The error signal for corresponding channel does not generate an error interrupt 1 The assertion of the error signal for corresponding channel generates an error interrupt request
0 EEI0	Enable Error Interrupt 0 0 The error signal for corresponding channel does not generate an error interrupt 1 The assertion of the error signal for corresponding channel generates an error interrupt request

25.3.9 Clear Enable Error Interrupt Register (DMA_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 18h offset = 4000_8018h

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAEE	0			CEEI		
Reset	0	0	0	0	0	0	0	0

DMA_CEEI field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAEE	Clear All Enable Error Interrupts

Table continues on the next page...

DMA_CEEI field descriptions (continued)

Field	Description
	0 Clear only the EEI bit specified in the CEEI field 1 Clear all bits in EEI
5 Reserved	This field is reserved.
CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI

25.3.10 Set Enable Error Interrupt Register (DMA_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 19h offset = 4000_8019h

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	SAEE	0			SEEI		
Reset	0	0	0	0	0	0	0	0

DMA_SEEI field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 SAEE	Sets All Enable Error Interrupts 0 Set only the EEI bit specified in the SEEI field. 1 Sets all bits in EEI
5 Reserved	This field is reserved.
SEEI	Set Enable Error Interrupt Sets the corresponding bit in EEI

25.3.11 Clear Enable Request Register (DMA_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

NOTE

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

Address: 4000_8000h base + 1Ah offset = 4000_801Ah

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAER	0			CERQ		
Reset	0	0	0	0	0	0	0	0

DMA_CERQ field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAER	Clear All Enable Requests 0 Clear only the ERQ bit specified in the CERQ field 1 Clear all bits in ERQ
5 Reserved	This field is reserved.
CERQ	Clear Enable Request Clears the corresponding bit in ERQ.

25.3.12 Set Enable Request Register (DMA_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 1Bh offset = 4000_801Bh

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	SAER	0			SERQ		
Reset	0	0	0	0	0	0	0	0

DMA_SERQ field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 SAER	Set All Enable Requests 0 Set only the ERQ bit specified in the SERQ field 1 Set all bits in ERQ
5 Reserved	This field is reserved.
SERQ	Set Enable Request Sets the corresponding bit in ERQ.

25.3.13 Clear DONE Status Bit Register (DMA_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 1Ch offset = 4000_801Ch

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CADN	0			CDNE		
Reset	0	0	0	0	0	0	0	0

DMA_CDNE field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
5 Reserved	This field is reserved.
CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

25.3.14 Set START Bit Register (DMA_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 1Dh offset = 4000_801Dh

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	SAST	0			SSRT		
Reset	0	0	0	0	0	0	0	0

DMA_SSRT field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 SAST	Set All START Bits (activates all channels) 0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
5 Reserved	This field is reserved.
SSRT	Set START Bit Sets the corresponding bit in TCDn_CSR[START]

25.3.15 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 1Eh offset = 4000_801Eh

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAEI	0			CERR		
Reset	0	0	0	0	0	0	0	0

DMA_CERR field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAEI	Clear All Error Indicators 0 Clear only the ERR bit specified in the CERR field 1 Clear all bits in ERR
5 Reserved	This field is reserved.
CERR	Clear Error Indicator Clears the corresponding bit in ERR

25.3.16 Clear Interrupt Request Register (DMA_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000_8000h base + 1Fh offset = 4000_801Fh

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAIR	0			CINT		
Reset	0	0	0	0	0	0	0	0

DMA_CINT field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAIR	Clear All Interrupt Requests 0 Clear only the INT bit specified in the CINT field 1 Clear all bits in INT
5 Reserved	This field is reserved.
CINT	Clear Interrupt Request Clears the corresponding bit in INT

25.3.17 Interrupt Request Register (DMA_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

Address: 4000_8000h base + 24h offset = 4000_8024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.3.18 Error Register (DMA_ERR)

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEL. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

Address: 4000_8000h base + 2Ch offset = 4000_802Ch

25.3.19 Hardware Request Status Register (DMA_HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Address: 4000_8000h base + 34h offset = 4000_8034h

25.3.21 Channel n Priority Register (DMA_DCHPRIn)

When fixed-priority channel arbitration is enabled ($CR[ERCA] = 0$), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: $4000\_8000h \text{ base} + 100h \text{ offset} + (1d \times i)$, where $i=0d$ to $31d$

Bit	7	6	5	4	3	2	1	0
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

* Notes:

- GRPPRI field: See bit field description.
- CHPRI field: See bit field description.

DMA_DCHPRIn field descriptions

Field	Description
7 ECP	Enable Channel Preemption. 0 Channel n cannot be suspended by a higher priority channel's service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.
6 DPA	Disable Preempt Ability. 0 Channel n can suspend a lower priority channel. 1 Channel n cannot suspend any channel, regardless of channel priority.
5–4 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored. NOTE: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled NOTE: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.

25.3.22 TCD Source Address (DMA_TCDn_SADDR)

Address: 4000_8000h base + 1000h offset + (32d × i), where i=0d to 31d

* Notes:

- x = Undefined at reset.

DMA_TCDn_ATTR field descriptions

Field	Description
15–11 SMOD	Source Address Modulo 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
10–8 SSIZE	Source data transfer size NOTE: Using a Reserved value causes a configuration error.

Table continues on the next page...

DSIZE	Destination data transfer size See the SSIZE definition

25.3.25 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCDn_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 4000_8000h base + 1008h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DMA_TCDn_NBYTES_MLNO field descriptions

Field	Description
NBYTES	Minor Byte Transfer Count

DMA_TCDn_NBYTES_MLNO field descriptions (continued)

Field	Description
	Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. NOTE: An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

25.3.26 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCDn_NBYTES_MLOFFNO)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 4000_8000h base + 1008h offset + (32d × i), where i=0d to 31d

DMA_TCDn_NBYTES_MLOFFNO field descriptions

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

25.3.27 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCDn_NBYTES_MLOFFYES)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 4000_8000h base + 1008h offset + (32d × i), where i=0d to 31d

DMA_TCDn_NBYTES_MLOFFYES field descriptions

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
29–10 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

25.3.28 TCD Last Source Address Adjustment (DMA_TCDn_SLAST)

Address: 4000_8000h base + 100Ch offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DMA_TCDn_SLAST field descriptions

Field	Description
SLAST	Last Source Address Adjustment Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure. This register uses two's complement notation; the overflow bit is discarded.

25.3.29 TCD Destination Address (DMA_TCDn_DADDR)

Address: 4000_8000h base + 1010h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DMA_TCDn_DOFF field descriptions

Field	Description
DOFF	Destination Address Signed Offset Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

25.3.31 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_CITER_ELINKYES)

If TCDn_CITER[ELINK] is set, the TCDn_CITER register is defined as follows.

Address: 4000_8000h base + 1016h offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8

DMA_TCDn_CITER_ELINKYES field descriptions

Field	Description
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.

Table continues on the next page...

DMA_TCDn_CITER_ELINKYES field descriptions (continued)

Field	Description
	If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. NOTE: This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
14 Reserved	This field is reserved.
13–9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. NOTE: When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. NOTE: If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

25.3.32 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCDn_CITER_ELINKNO)

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Address: 4000_8000h base + 1016h offset + (32d × i), where i=0d to 31d

DMA_TCDn_DLASTSGA field descriptions

Field	Description
DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment.

DMA_TCDn_DLASTSGA field descriptions (continued)

Field	Description
	Otherwise: This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

25.3.34 TCD Control and Status (DMA_TCDn_CSR)

Address: 4000_8000h base + 101Ch offset + (32d × i), where i=0d to 31d

DMA_TCDn_CSR field descriptions

Field	Description
15–14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. NOTE: If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls. 01 Reserved 10 eDMA engine stalls for 4 cycles after each R/W. 11 eDMA engine stalls for 8 cycles after each R/W.
13 Reserved	This field is reserved.
12–8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted.

Table continues on the next page...

DMA_TCDn_CSR field descriptions (continued)

Field	Description
	Otherwise: After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. The access of this field is W0C, write-zero-to-clear. NOTE: This bit must be cleared to write the MAJORELINK or ESG bits.
6 ACTIVE	Channel Active This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
5 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. NOTE: To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. NOTE: To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
3 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0 The channel's ERQ bit is not affected. 1 The channel's ERQ bit is cleared when the major loop is complete.
2 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is $(CITER == (BITER >> 1))$. This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. NOTE: If BITER = 1, do not use INTHALF. Use INTMAJOR instead.

Table continues on the next page...

DMA_TCDn_CSR field descriptions (continued)

Field	Description
	0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
1 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
0 START	Channel Start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

25.3.35 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_BITER_ELINKYES)

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Address: 4000_8000h base + 101Eh offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8
Read	ELINK				LINKCH			BITER
Write		0						
Reset	x*	x*	x*	x*	x*	x*	x*	x*

Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

DMA_TCDn_BITER_ELINKYES field descriptions

Field	Description
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.

Table continues on the next page...

DMA_TCDn_BITER_ELINKYES field descriptions (continued)

Field	Description
	NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
14 Reserved	This field is reserved.
13–9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

25.3.36 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCDn_BITER_ELINKNO)

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

Address: 4000_8000h base + 101Eh offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8
Read	ELINK				BITER			
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

Read	BITER							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

DMA_TCDn_BITER_ELINKNO field descriptions

Field	Description
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

25.4 Functional description

The operation of the eDMA is described in the following subsections.

25.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

Figure 25-2. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel n . Channel activation via software and the $\text{TCD}_n\text{-CSR}[\text{START}]$ bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD_n . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

Figure 25-3. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

Figure 25-4. eDMA operation, part 3

25.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error

occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

25.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

25.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

25.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

NOTE

All architectures will not meet the assumptions listed above.
See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

Table 25-4. eDMA peak transfer rates (Mbytes/sec)

System Speed, Width	Internal SRAM-to-Internal SRAM	32 bit internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32 bit internal peripheral bus
48 MHz, 32 bit	96.0	48.0	38.4
66.7 MHz, 32 bit	133.3	66.7	53.3
83.3 MHz, 32 bit	166.7	83.3	66.7
100.0 MHz, 32 bit	200.0	100.0	80.0
133.3 MHz, 32 bit	266.7	133.3	106.7
150.0 MHz, 32 bit	300.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

25.4.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 25-5. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD _n _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD _n word 7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD _n fields into the local memory. The TCD _n word 7 is read and checked for channel linking or scatter/gather requests.
14	15	The appropriate fields in the first part of the TCD _n are written back into the local memory.
15	16	The fields in the second part of the TCD _n are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can

be processed every 11.5 cycles ($4 + (4+5)/2 + 3$). This is the time from Cycle 4 to Cycle $x + 5$. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

Table 25-6. eDMA peak request rate (MReq/sec)

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
48.0	5.3	4.2
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

$$\text{PEAKreq} = \text{freq} / [\text{entry} + (1 + \text{read\_ws}) + (1 + \text{write\_ws}) + \text{exit}]$$

where:

Table 25-7. Peak request formula operands

Operand	Description
PEAKreq	Peak request rate
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase
exit	Channel shutdown (3 cycles)

25.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 1) + (1 + 3) + 3] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an internal peripheral bus to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 2) + (1 + 1) + 3] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate would be:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD n _CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

25.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

25.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI n registers if a configuration other than the default is desired.

3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
 - Software: setting the TCDn_CSR[START]
 - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCDn_SADDR, to the destination, as defined by TCDn_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 25-8. TCD Control and Status fields

TCDn_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 25-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

Figure 25-6. Memory array terms

25.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

25.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

25.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

25.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration, Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

25.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

25.5.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one ($\text{TCDn\_CITER} = \text{TCDn\_BITER} = 1$). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the $\text{TCDn\_CSR}[\text{DONE}]$ bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCDn_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn_CSR[DONE] = 0, TCDn_CSR[START] = 0, TCDn_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
 - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
 - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
 - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
 - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
 - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
 - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
 - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
 - h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: $\text{TCDn\_SADDR} = 0\text{x}1000$, $\text{TCDn\_DADDR} = 0\text{x}2000$, $\text{TCDn\_CITER} = 1$ (TCDn_BITER).
7. The eDMA engine writes: $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$, $\text{TCDn\_CSR}[\text{DONE}] = 1$, $\text{INT}[n] = 1$.
8. The channel retires and the eDMA goes idle or services the next channel.

25.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: $\text{TCDn\_CSR}[\text{DONE}] = 0$, $\text{TCDn\_CSR}[\text{START}] = 0$, $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$.
4. eDMA engine reads: channel TCDn data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
 - a. Read byte from location $0\text{x}1000$, read byte from location $0\text{x}1001$, read byte from $0\text{x}1002$, read byte from $0\text{x}1003$.
 - b. Write 32-bits to location $0\text{x}2000 \rightarrow$ first iteration of the minor loop.
 - c. Read byte from location $0\text{x}1004$, read byte from location $0\text{x}1005$, read byte from $0\text{x}1006$, read byte from $0\text{x}1007$.
 - d. Write 32-bits to location $0\text{x}2004 \rightarrow$ second iteration of the minor loop.
 - e. Read byte from location $0\text{x}1008$, read byte from location $0\text{x}1009$, read byte from $0\text{x}100A$, read byte from $0\text{x}100B$.
 - f. Write 32-bits to location $0\text{x}2008 \rightarrow$ third iteration of the minor loop.

- g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
- h. Write 32-bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: $TCDn\_SADDR = 0x1010$, $TCDn\_DADDR = 0x2010$, $TCDn\_CITER = 1$.
7. eDMA engine writes: $TCDn\_CSR[ACTIVE] = 0$.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: $TCDn\_CSR[DONE] = 0$, $TCDn\_CSR[START] = 0$, $TCDn\_CSR[ACTIVE] = 1$.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
 - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
 - b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
 - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
 - d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
 - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
 - f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
 - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
 - h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: $TCDn\_SADDR = 0x1000$, $TCDn\_DADDR = 0x2000$, $TCDn\_CITER = 2$ ($TCDn\_BITER$).
15. eDMA engine writes: $TCDn\_CSR[ACTIVE] = 0$, $TCDn\_CSR[DONE] = 1$, $INT[n] = 1$.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

25.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2⁴ byte (16-byte) size queue.

Table 25-9. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

25.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

25.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD_n_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD_n_CSR[START] bit and the TCD_n_CSR[ACTIVE] bit. The minor-loop-

complete condition is indicated by both bits reading zero after the `TCDn_CSR[START]` was set. Polling the `TCDn_CSR[ACTIVE]` bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCDn_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the `TCDn_CSR[DONE]` bit.

The `TCDn_CSR[START]` bit is cleared automatically when the channel begins execution regardless of how the channel activates.

25.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_NBYTES` values if read while a channel executes. The true values of the `SADDR`, `DADDR`, and `NBYTES` are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, `SADDR` and

DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

25.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The `TCDn_CSR[ACTIVE]` bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two `TCDn_CSR[ACTIVE]` bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

25.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the `TCDn_CSR[START]` bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The `TCDn_CITER[E_LINK]` field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set `TCD12_CSR[START]` bit

2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled ($\text{TCDn\_CITER[E\_LINK]} = 1$), the TCDn_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled ($\text{TCDn\_CITER[E\_LINK]} = 0$), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the $\text{TCDn\_CITER[LINKCH]}$ field are concatenated onto the CITER value to increase the range of the CITER.

Note

The $\text{TCDn\_CITER[E\_LINK]}$ bit and the $\text{TCDn\_BITER[E\_LINK]}$ bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e., use another channel's TCD, at the end of a loop.

Table 25-10. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

25.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

25.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

25.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution (see the diagram in [TCD structure](#)). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e_link bit.
2. Read back the TCD.major.e_link bit.
3. Test the TCD.major.e_link request status:
 - If TCD.major.e_link = 1, the dynamic link attempt was successful.
 - If TCD.major.e_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

25.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

25.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCD.dlast_sga field with the scatter/gather address.
4. Write 1b to the TCD.e_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e_sg request status and TCD.major.linkch value:

If e_sg = 1b, the dynamic link attempt was successful.

If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

25.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

1. Write 1b to the TCD.d_req bit.

Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

2. Write the TCD.dlast_sga field with the scatter/gather address.
3. Write 1b to the TCD.e_sg bit.
4. Read back the TCD.e_sg bit.
5. Test the TCD.e_sg request status:

If e_sg = 1b, the dynamic link attempt was successful.

If e_sg = 0b, read the 32 bit TCD dlast_sga field.

If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If `e_sg = 0b` and the `dlast_sga` changed, the dynamic link attempt was successful (the new TCD's `e_sg` value cleared the `e_sg` bit).

25.5.8 Suspend/resume a DMA channel with active hardware service requests

The DMA allows the user to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. Once the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (DSPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

25.5.8.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check [Hardware Request Status Register \(DMA_HRS\)](#) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on the appropriate DMA channel.

25.5.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the its ERQ bit.
2. Enable the DMA service request at the peripheral.

For example, assume a DSPI module is set as a master for transmitting data via a DMA service request when the `DSPI_TXFIFO` has an empty slot. The DMA will transfer the next command and data to the `TXFIFO` upon the request. If the user needs to suspend the DMA/DSPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the DSPI by verifying that DMA_HRS[HRS_n] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

Chapter 26

External Watchdog Monitor (EWM)

26.1 Chip-specific EWM information

26.1.1 EWM clocks

This table shows the EWM clocks and the corresponding chip clocks.

Table 26-1. EWM clock connections

Module clock	Chip clock
Low Power Clock	1 kHz LPO Clock

NOTE

lpo_clk[0] is the only available low power clock source on this chip. lpo_clk[3:1] clocks are reserved.

26.1.2 EWM low-power modes

This table shows the EWM low-power modes and the corresponding chip low-power modes.

Table 26-2. EWM low-power modes

Module mode	Chip mode
Wait	Wait, VLPW
Stop	Stop, VLPS, LLS

26.1.3 $\overline{\text{EWM\_OUT}}$ pin state in low power modes

During Wait, Stop and Power Down modes the $\overline{\text{EWM\_OUT}}$ pin preserves its state before entering Wait or Stop mode. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

26.2 Introduction

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the $\overline{\text{RESET}}$ pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent $\overline{\text{EWM\_out}}$ signal that when asserted resets or places an external circuit into a safe mode. The $\overline{\text{EWM\_out}}$ signal is asserted upon the EWM counter time-out. An optional external input $\overline{\text{EWM\_in}}$ is provided to allow additional control of the assertion of $\overline{\text{EWM\_out}}$ signal.

26.2.1 Features

Features of EWM module include:

- Independent LPO_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO_CLK clock cycles.
- Windowed refresh option
 - Provides robust check that program flow is faster than expected.
 - Programmable window.
 - Refresh outside window leads to assertion of $\overline{\text{EWM\_out}}$.
- Robust refresh mechanism

- Write values of 0xB4 and 0x2C to EWM Refresh Register within 15 (*EWM_refresh_time*) peripheral bus clock cycles.
- One output port, $\overline{\text{EWM\_out}}$, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, $\overline{\text{EWM\_in}}$, allows an external circuit to control the assertion of the $\overline{\text{EWM\_out}}$ signal.

26.2.2 Modes of Operation

This section describes the module's operating modes.

26.2.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 15 (*EWM_refresh_time*) peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

26.2.2.2 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

26.2.3 Block Diagram

This figure shows the EWM block diagram.

Figure 26-1. EWM Block Diagram

26.3 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

Table 26-3. EWM Signal Descriptions

Signal	Description	I/O
EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low.	I
$\overline{\text{EWM\_out}}$	EWM reset out signal	O

Table continues on the next page...

Table 26-3. EWM Signal Descriptions (continued)

Signal	Description	I/O
lpo_clk[3:0]	Low power clock sources for running counter	I

26.4 Memory Map/Register Definition

This section contains the module memory map and registers.

EWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_1000	Control Register (EWM_CTRL)	8	R/W	00h	26.4.1/589
4006_1001	Service Register (EWM_SERV)	8	W (always reads 0)	00h	26.4.2/590
4006_1002	Compare Low Register (EWM_CMPL)	8	R/W	00h	26.4.3/590
4006_1003	Compare High Register (EWM_CMPH)	8	R/W	FFh	26.4.4/591
4006_1004	Clock Control Register (EWM_CLKCTRL)	8	R/W	00h	26.4.5/592
4006_1005	Clock Prescaler Register (EWM_CLKPRESCALER)	8	R/W	00h	26.4.6/592

26.4.1 Control Register (EWM_CTRL)

The CTRL register is cleared by any reset.

NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

Address: 4006_1000h base + 0h offset = 4006_1000h

Bit	7	6	5	4	3	2	1	0
Read	0				INTEN	INEN	ASSIN	EWMEN
Write								
Reset	0	0	0	0	0	0	0	0

EWM_CTRL field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

EWM_CTRL field descriptions (continued)

Field	Description
3 INTEN	Interrupt Enable. This bit when set and $\overline{\text{EWM\_out}}$ is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.
2 INEN	Input Enable. This bit when set, enables the EWM_in port.
1 ASSIN	EWM_in's Assertion State Select. Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one.
0 EWMEN	EWM enable. This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the $\overline{\text{EWM\_out}}$ signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit.

26.4.2 Service Register (EWM_SERV)

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

Address: 4006_1000h base + 1h offset = 4006_1001h

Bit	7	6	5	4	3	2	1	0
Read	0							
Write	SERVICE							
Reset	0	0	0	0	0	0	0	0

EWM_SERV field descriptions

Field	Description
SERVICE	The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true. - The first or second data byte is not written correctly. - The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called <i>EWM_refresh_time</i>.

26.4.3 Compare Low Register (EWM_CMPL)

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

This register can be written only once after a CPU reset.
Writing this register more than once generates a bus transfer error.

Address: 4006_1000h base + 2h offset = 4006_1002h

Bit	7	6	5	4	3	2	1	0
Read	COMPAREL							
Write								
Reset	0	0	0	0	0	0	0	0

EWM_CMPL field descriptions

Field	Description
COMPAREL	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required.

26.4.4 Compare High Register (EWM_CMPH)

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

NOTE

This register can be written only once after a CPU reset.
Writing this register more than once generates a bus transfer error.

NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

Address: 4006_1000h base + 3h offset = 4006_1003h

Bit	7	6	5	4	3	2	1	0
Read	COMPAREH							
Write								
Reset	1	1	1	1	1	1	1	1

EWM_CMPH field descriptions

Field	Description
COMPAREH	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required.

26.4.5 Clock Control Register (EWM_CLKCTRL)

This CLKCTRL register is reset to 0x00 after a CPU reset.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

User should select the required low power clock before enabling the EWM.

Address: 4006_1000h base + 4h offset = 4006_1004h

EWM_CLKCTRL field descriptions

Field	Description
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CLKSEL	EWM has 4 possible low power clock sources for running EWM counter. One of the clock source can be selected by writing into this field. • 00 - lpo_clk[0] will be selected for running EWM counter. • 01 - lpo_clk[1] will be selected for running EWM counter. • 10 - lpo_clk[2] will be selected for running EWM counter. • 11 - lpo_clk[3] will be selected for running EWM counter.

26.4.6 Clock Prescaler Register (EWM_CLKPRESCALER)

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

Write the required prescaler value before enabling the EWM.

NOTE

The implementation of this register is chip-specific. See the chip-specific information for details.

Address: 4006_1000h base + 5h offset = 4006_1005h

Bit	7	6	5	4	3	2	1	0
Read	CLK_DIV							
Write								
Reset	0	0	0	0	0	0	0	0

EWM_CLKPRESCALER field descriptions

Field	Description
CLK_DIV	Selected low power clock source for running the EWM counter can be prescaled as below. Prescaled clock frequency = low power clock source frequency / (1 + CLK_DIV)

26.5 Functional Description

The following sections describe functional details of the EWM module.

NOTE

When the BUS_CLK is lost, then EWM module doesn't generate the EWM_out signal and no refresh operation is possible

26.5.1 The EWM_out Signal

The EWM_out is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM_out could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM_out signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM_out signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM_in pin is enabled and EWM_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM_out pin)

The $\overline{\text{EWM\_out}}$ is asserted after any reset by the virtue of the external pull-down mechanism on the $\overline{\text{EWM\_out}}$ signal. Then, to deassert the $\overline{\text{EWM\_out}}$ signal, set EWMEN bit in the CTRL register to enable the EWM.

If the $\overline{\text{EWM\_out}}$ signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the $\overline{\text{EWM\_out}}$ signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

Note

$\overline{\text{EWM\_out}}$ pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

26.5.2 The EWM_in Signal

The EWM_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the $\overline{\text{EWM\_out}}$ signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the $\overline{\text{EWM\_out}}$ signal that controls the gating circuit.

The EWM_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM_in functionality (setting the CTRL[INEN] bit), the EWM_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the $\overline{\text{EWM\_out}}$ stays in the deasserted state; otherwise, the $\overline{\text{EWM\_out}}$ output signal is asserted.

Note

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM_in pin is deasserted.

26.5.3 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

26.5.4 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), $\overline{\text{EWM\_out}}$ is asserted.

26.5.5 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

Table 26-4. EWM Refresh Mechanisms

Condition	Mechanism
An EWM refresh action completes when: $\text{CMPL} < \text{Counter} < \text{CMPH}$.	The software behaves as expected and the EWM counter is reset to zero. The $\overline{\text{EWM\_out}}$ output signal remains in the deasserted state if, during the EWM refresh action, the $\overline{\text{EWM\_in}}$ input has been in deasserted state..
An EWM refresh action completes when $\text{Counter} < \text{CMPL}$	The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the $\overline{\text{EWM\_out}}$ output signal is asserted irrespective of the input $\overline{\text{EWM\_in}}$.
Counter value reaches CMPH prior to completion of EWM refresh action.	Software has not refreshed the EWM. The EWM counter is reset to zero and the $\overline{\text{EWM\_out}}$ output signal is asserted irrespective of the input $\overline{\text{EWM\_in}}$.

26.5.6 EWM Interrupt

When $\overline{\text{EWM\_out}}$ is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect $\overline{\text{EWM\_out}}$. The $\overline{\text{EWM\_out}}$ signal can be deasserted only by forcing a system reset.

26.5.7 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

26.5.8 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK_DIV]. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

Chapter 27

Watchdog Timer (WDOG)

27.1 Chip-specific WDOG information

27.1.1 WDOG clocks

This table shows the WDOG module clocks and the corresponding chip clocks.

Table 27-1. WDOG clock connections

Module clock	Chip clock
LPO Oscillator	1 kHz LPO Clock
Alt Clock	Bus Clock
Fast Test Clock	Bus Clock
System Bus Clock	Bus Clock

27.1.2 WDOG low-power modes

This table shows the WDOG low-power modes and the corresponding chip low-power modes.

Table 27-2. WDOG low-power modes

Module mode	Chip mode
Wait	Wait, VLPW
Stop	Stop, VLPS
Power Down	LLS, VLLSx

27.2 Introduction

The Watchdog Timer (WDOG) keeps a watch on the system functioning and resets it in case of its failure. Reasons for failure include run-away software code and the stoppage of the system clock that in a safety critical system can lead to serious consequences. In such cases, the watchdog brings the system into a safe state of operation. The watchdog monitors the operation of the system by expecting periodic communication from the software, generally known as servicing or refreshing the watchdog. If this periodic refreshing does not occur, the watchdog resets the system.

27.3 Features

The features of the Watchdog Timer (WDOG) include:

- Clock source input independent from CPU/bus clock. Choice between two clock sources:
 - Low-power oscillator (LPO)
 - External system clock
- Unlock sequence for allowing updates to write-once WDOG control/configuration bits.
- All WDOG control/configuration bits are writable once only within 256 bus clock cycles of being unlocked.
 - You need to always update these bits after unlocking within 256 bus clock cycles. Failure to update these bits resets the system.
- Programmable time-out period specified in terms of number of WDOG clock cycles.
- Ability to test WDOG timer and reset with a flag indicating watchdog test.
 - Quick test—Small time-out value programmed for quick test.
 - Byte test—Individual bytes of timer tested one at a time.
 - Read-only access to the WDOG timer—Allows dynamic check that WDOG timer is operational.

NOTE

Reading the watchdog timer counter while running the watchdog on the bus clock might not give the accurate counter value.

- Windowed refresh option
 - Provides robust check that program flow is faster than expected.
 - Programmable window.
 - Refresh outside window leads to reset.
- Robust refresh mechanism
 - Write values of 0xA602 and 0xB480 to WDOG Refresh Register within 20 bus clock cycles.
- Count of WDOG resets as they occur.
- Configurable interrupt on time-out to provide debug breadcrumbs. This is followed by a reset after 256 bus clock cycles.

27.4 Functional overview

Functional overview

Figure 27-1. WDOG operation

The preceding figure shows the operation of the watchdog. The values for N and K are:

- N = 256
- K = 20

The watchdog is a fail safe mechanism that brings the system into a known initial state in case of its failure due to CPU clock stopping or a run-away condition in code execution. In its simplest form, the watchdog timer runs continuously off a clock source and expects to be serviced periodically, failing which it resets the system. This ensures that the software is executing correctly and has not run away in an unintended direction. Software can adjust the period of servicing or the time-out value for the watchdog timer to meet the needs of the application.

You can select a windowed mode of operation that expects the servicing to be done only in a particular window of the time-out period. An attempted servicing of the watchdog outside this window results in a reset. By operating in this mode, you can get an indication of whether the code is running faster than expected. The window length is also user programmable.

If a system fails to update/refresh the watchdog due to an unknown and persistent cause, it will be caught in an endless cycle of resets from the watchdog. To analyze the cause of such conditions, you can program the watchdog to first issue an interrupt, followed by a reset. In the interrupt service routine, the software can analyze the system stack to aid debugging.

To enhance the independence of watchdog from the system, it runs off an independent LPO oscillator clock. You can also switch over to an alternate clock source if required, through a control register bit.

27.4.1 Unlocking and updating the watchdog

As long as `ALLOW_UPDATE` in the watchdog control register is set, you can unlock and modify the write-once-only control and configuration registers:

1. Write `0xC520` followed by `0xD928` within 20 bus clock cycles to a specific unlock register (`WDOG_UNLOCK`).
2. Wait one bus clock cycle. You cannot update registers on the bus clock cycle immediately following the write of the unlock sequence.
3. An update window equal in length to the watchdog configuration time (`WCT`) opens. Within this window, you can update the configuration and control register bits.

These register bits can be modified only once after unlocking.

If none of the configuration and control registers is updated within the update window, the watchdog issues a reset, that is, interrupt-then-reset, to the system. Trying to unlock the watchdog within the `WCT` after an initial unlock has no effect. During the update operation, the watchdog timer is not paused and continues running in the background. After the update window closes, the watchdog timer restarts and the watchdog functions according to the new configuration.

The update feature is useful for applications that have an initial, non-safety critical part, where the watchdog is kept disabled or with a conveniently long time-out period. This means the application coder does not have to frequently service the watchdog. After the critical part of the application begins, the watchdog can be reconfigured as needed.

The watchdog issues a reset, that is, interrupt-then-reset if enabled, to the system for any of these invalid unlock sequences:

- Write any value other than 0xC520 or 0xD928 to the unlock register.
- ALLOW_UPDATE is set and a gap of more than 20 bus clock cycles is inserted between the writing of the unlock sequence values.

An attempted refresh operation between the two writes of the unlock sequence and in the WCT time following a successful unlock, goes undetected. Also, see [Watchdog Operation with 8-bit access](#) for guidelines related to 8-bit accesses to the unlock register.

Note

A context switch during unlocking and refreshing may lead to a watchdog reset.

27.4.2 Watchdog configuration time (WCT)

To prevent unintended modification of the watchdog's control and configuration register bits, you are allowed to update them only within a period of 256 bus clock cycles after unlocking. This period is known as the watchdog configuration time (WCT). In addition, these register bits can be modified only once after unlocking them for editing, even after reset.

You must unlock the registers within WCT after system reset, failing which the WDOG issues a reset to the system. In other words, you must write at least the first word of the unlocking sequence within the WCT after reset. After this is done, you have a further 20 bus clock cycles, the maximum allowed gap between the words of the unlock sequence, to complete the unlocking operation. Thereafter, to make sure that you do not forget to configure the watchdog, the watchdog issues a reset if none of the WDOG control and configuration registers is updated in the WCT after unlock. After the close of this window or after the first write, these register bits are locked out from any further changes.

The watchdog timer keeps running according to its default configuration through unlocking and update operations that can extend up to a maximum total of $2 \times \text{WCT} + 20$ bus clock cycles. Therefore, it must be ensured that the time-out value for the watchdog is always greater than $2 \times \text{WCT} + 20$ bus clock cycles.

Updates in the write-once registers take effect only after the WCT window closes with the following exceptions for which changes take effect immediately:

- Stop, Wait, and Debug mode enable
- IRQ_RST_EN

The operations of refreshing the watchdog goes undetected during the WCT.

27.4.3 Refreshing the watchdog

A robust refreshing mechanism has been chosen for the watchdog. A valid refresh is a write of 0xA602 followed by 0xB480 within 20 bus clock cycles to watchdog refresh register. If these two values are written more than 20 bus cycles apart or if something other than these two values is written to the register, a watchdog reset, or interrupt-then-reset if enabled, is issued to the system. A valid refresh makes the watchdog timer restart on the next bus clock. Also, an attempted unlock operation in between the two writes of the refresh sequence goes undetected. See [Watchdog Operation with 8-bit access](#) for guidelines related to 8-bit accesses to the refresh register.

27.4.4 Windowed mode of operation

In this mode of operation, a restriction is placed on the point in time within the time-out period at which the watchdog can be refreshed. The refresh is considered valid only when the watchdog timer increments beyond a certain count as specified by the watchdog window register. This is known as refreshing the watchdog within a window of the total time-out period. If a refresh is attempted before the timer reaches the window value, the watchdog generates a reset, or interrupt-then-reset if enabled. If there is no refresh at all, the watchdog times out and generates a reset or interrupt-then-reset if enabled.

27.4.5 Watchdog disabled mode of operation

When the watchdog is disabled through the WDOG_EN bit in the watchdog status and control register, the watchdog timer is reset to zero and is disabled from counting until you enable it or it is enabled again by the system reset. In this mode, the watchdog timer cannot be refreshed—there is no requirement to do so while the timer is disabled. However, the watchdog still generates a reset, or interrupt-then-reset if enabled, on a non-time-out exception. See [Generated Resets and Interrupts](#). You need to unlock the watchdog before enabling it. A system reset brings the watchdog out of the disabled mode.

27.4.6 Low-power modes of operation

The low-power modes of operation of the watchdog are described in the following table:

Table 27-3. Low-power modes of operation

Mode	Behavior
Wait	If the WDOG is enabled (WAIT_EN = 1), it can run on bus clock or low-power oscillator clock (CLK_SRC = x) to generate interrupt (IRQ_RST_EN=1) followed by a reset on time-out. After reset the WDOG reset counter increments by one.
Stop	Where the bus clock is gated, the WDOG can run only on low-power oscillator clock (CLK_SRC=0) if it is enabled in stop (STOP_EN=1). In this case, the WDOG runs to time-out twice, and then generates a reset from its backup circuitry. Therefore, if you program the watchdog to time-out after 100 ms and then enter such a stop mode, the reset will occur after 200 ms. Also, in this case, no interrupt will be generated irrespective of the value of IRQ_RST_EN bit. After WDOG reset, the WDOG reset counter will also not increment.
Power-Down	The watchdog is - static in LLS mode - powered off in VLLSx mode

27.4.7 Debug modes of operation

You can program the watchdog to disable in debug modes through DBG_EN in the watchdog control register. This results in the watchdog timer pausing for the duration of the mode. Register read/writes are still allowed, which means that operations like refresh, unlock, and so on are allowed. Upon exit from the mode, the timer resumes its operation from the point of pausing.

The entry of the system into the debug mode does not excuse it from compulsorily configuring the watchdog in the WCT time after unlock, unless the system bus clock is gated off, in which case the internal state machine pauses too. Failing to do so still results in a reset, or interrupt-then-reset, if enabled, to the system. Also, all of the exception conditions that result in a reset to the system, as described in [Generated Resets and Interrupts](#), are still valid in this mode. So, if an exception condition occurs and the system bus clock is on, a reset occurs, or interrupt-then-reset, if enabled.

The entry into Debug mode within WCT after reset is treated differently. The WDOG timer is kept reset to zero and there is no need to unlock and configure it within WCT. You must not try to refresh or unlock the WDOG in this state or unknown behavior may result. Upon exit from this mode, the WDOG timer restarts and the WDOG has to be unlocked and configured within WCT.

27.5 Testing the watchdog

For IEC 60730 and other safety standards, the expectation is that anything that monitors a safety function must be tested, and this test is required to be fault tolerant. To test the watchdog, its main timer and its associated compare and reset logic must be tested. To

this end, two tests are implemented for the watchdog, as described in [Quick Test](#) and [Byte Test](#). A control bit is provided to put the watchdog into functional test mode. There is also an overriding test-disable control bit which allows the functional test mode to be disabled permanently. After it is set, this test-disable bit can only be cleared by a reset.

These two tests achieve the overall aim of testing the counter functioning and the compare and reset logic.

Note

Do not enable the watchdog interrupt during these tests. If required, you must ensure that the effective time-out value is greater than WCT time. See [Generated Resets and Interrupts](#) for more details.

To run a particular test:

1. Select either quick test or byte test..
2. Set a certain test mode bit to put the watchdog in the functional test mode. Setting this bit automatically switches the watchdog timer to a fast clock source. The switching of the clock source is done to achieve a faster time-out and hence a faster test.

In a successful test, the timer times out after reaching the programmed time-out value and generates a system reset.

Note

After emerging from a reset due to a watchdog test, unlock and configure the watchdog. The refresh and unlock operations and interrupt are not automatically disabled in the test mode.

27.5.1 Quick test

In this test, the time-out value of watchdog timer is programmed to a very low value to achieve quick time-out. The only difference between the quick test and the normal mode of the watchdog is that TESTWDOG is set for the quick test. This allows for a faster test of the watchdog reset mechanism.

27.5.2 Byte test

The byte test is a more thorough a test of the watchdog timer. In this test, the timer is split up into its constituent byte-wide stages that are run independently and tested for time-out against the corresponding byte of the time-out value register. The following figure explains the splitting concept:

Figure 27-2. Watchdog timer byte splitting

Each stage is an 8-bit synchronous counter followed by combinational logic that generates an overflow signal. The overflow signal acts as an enable to the $N + 1$ th stage.

In the test mode, when an individual byte, N , is tested, byte $N - 1$ is loaded forcefully with 0xFF, and both these bytes are allowed to run off the clock source. By doing so, the overflow signal from stage $N - 1$ is generated immediately, enabling counter stage N . The N th stage runs and compares with the N th byte of the time-out value register. In this way, the byte N is also tested along with the link between it and the preceding stage. No other stages, $N - 2$, $N - 3$... and $N + 1$, $N + 2$... are enabled for the test on byte N . These disabled stages, except the most significant stage of the counter, are loaded with a value of 0xFF.

27.6 Backup reset generator

The backup reset generator generates the final reset which goes out to the system. It has a backup mechanism which ensures that in case the bus clock stops and prevents the main state machine from generating a reset exception/interrupt, the watchdog timer's time-out is separately routed out as a reset to the system. Two successive timer time-outs without an intervening system reset result in the backup reset generator routing out the time-out signal as a reset to the system.

27.7 Generated resets and interrupts

The watchdog generates a reset in the following events, also referred to as exceptions:

- A watchdog time-out
- Failure to unlock the watchdog within WCT time after system reset deassertion
- No update of the control and configuration registers within the WCT window after unlocking. At least one of the following registers must be written to within the WCT window to avoid reset:
 - WDOG_ST_CTRL_H, WDOG_ST_CTRL_L
 - WDOG_TO_VAL_H, WDOG_TO_VAL_L
 - WDOG_WIN_H, WDOG_WIN_L
 - WDOG_PRESCALER
- A value other than the unlock sequence or the refresh sequence is written to the unlock and/or refresh registers, respectively.
- A gap of more than 20 bus cycles exists between the writes of two values of the unlock sequence.
- A gap of more than 20 bus cycles exists between the writes of two values of the refresh sequence.

The watchdog can also generate an interrupt. If IRQ_RST_EN is set, then on the above mentioned events WDOG_ST_CTRL_L[INT_FLG] is set, generating an interrupt. A watchdog reset is also generated WCT time later to ensure the watchdog is fault tolerant. The interrupt can be cleared by writing 1 to INT_FLG.

The gap of WCT between interrupt and reset means that the WDOG time-out value must be greater than WCT. Otherwise, if the interrupt was generated due to a time-out, a second consecutive time-out will occur in that WCT gap. This will trigger the backup reset generator to generate a reset to the system, prematurely ending the interrupt service routine execution. Also, jobs such as counting the number of watchdog resets would not be done.

27.8 Memory map and register definition

This section consists of the memory map and register descriptions.

WDOG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_2000	Watchdog Status and Control Register High (WDOG_STCTRLH)	16	R/W	01D3h	27.8.1/609
4005_2002	Watchdog Status and Control Register Low (WDOG_STCTRLLL)	16	R/W	0001h	27.8.2/610
4005_2004	Watchdog Time-out Value Register High (WDOG_TOVALH)	16	R/W	004Ch	27.8.3/611
4005_2006	Watchdog Time-out Value Register Low (WDOG_TOVALL)	16	R/W	4B4Ch	27.8.4/611
4005_2008	Watchdog Window Register High (WDOG_WINH)	16	R/W	0000h	27.8.5/612
4005_200A	Watchdog Window Register Low (WDOG_WINL)	16	R/W	0010h	27.8.6/612
4005_200C	Watchdog Refresh register (WDOG_REFRESH)	16	R/W	B480h	27.8.7/613
4005_200E	Watchdog Unlock register (WDOG_UNLOCK)	16	R/W	D928h	27.8.8/613
4005_2010	Watchdog Timer Output Register High (WDOG_TMROUTH)	16	R/W	0000h	27.8.9/613
4005_2012	Watchdog Timer Output Register Low (WDOG_TMROUTL)	16	R/W	0000h	27.8.10/614
4005_2014	Watchdog Reset Count register (WDOG_RSTCNT)	16	R/W	0000h	27.8.11/614
4005_2016	Watchdog Prescaler register (WDOG_PRESC)	16	R/W	0400h	27.8.12/614

27.8.1 Watchdog Status and Control Register High (WDOG_STCTRLH)

Address: 4005_2000h base + 0h offset = 4005_2000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0	DISTESTWDOG	BYTESEL[1:0]		TESTSEL	TESTWDOG	0	Reserved	WAITEN	STOPEN	DBGEN	ALLOWUPDATE	WINEN	IRQRSTEN	CLKSRC	WDOGEN
Write																
Reset	0	0	0	0	0	0	0	1	1	1	0	1	0	0	1	1

WDOG_STCTRLH field descriptions

Field	Description
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DISTESTWDOG	Allows the WDOG's functional test mode to be disabled permanently. After it is set, it can only be cleared by a reset. It cannot be unlocked for editing after it is set. 0 WDOG functional test mode is not disabled. 1 WDOG functional test mode is disabled permanently until reset.
13–12 BYTESEL[1:0]	This 2-bit field selects the byte to be tested when the watchdog is in the byte test mode. 00 Byte 0 selected 01 Byte 1 selected 10 Byte 2 selected 11 Byte 3 selected
11 TESTSEL	Effective only if TESTWDOG is set. Selects the test to be run on the watchdog timer. 0 Quick test. The timer runs in normal operation. You can load a small time-out value to do a quick test. 1 Byte test. Puts the timer in the byte test mode where individual bytes of the timer are enabled for operation and are compared for time-out against the corresponding byte of the programmed time-out value. Select the byte through BYTESEL[1:0] for testing.
10 TESTWDOG	Puts the watchdog in the functional test mode. In this mode, the watchdog timer and the associated compare and reset generation logic is tested for correct operation. The clock for the timer is switched from the main watchdog clock to the fast clock input for watchdog functional test. The TESTSEL bit selects the test to be run.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 Reserved	This field is reserved.
7 WAITEN	Enables or disables WDOG in Wait mode. 0 WDOG is disabled in CPU Wait mode. 1 WDOG is enabled in CPU Wait mode.
6 STOPEN	Enables or disables WDOG in Stop mode.

Table continues on the next page...

WDOG_STCTRLH field descriptions (continued)

Field	Description
	0 WDOG is disabled in CPU Stop mode. 1 WDOG is enabled in CPU Stop mode.
5 DBGEN	Enables or disables WDOG in Debug mode. 0 WDOG is disabled in CPU Debug mode. 1 WDOG is enabled in CPU Debug mode.
4 ALLOWUPDATE	Enables updates to watchdog write-once registers, after the reset-triggered initial configuration window (WCT) closes, through unlock sequence. 0 No further updates allowed to WDOG write-once registers. 1 WDOG write-once registers can be unlocked for updating.
3 WINEN	Enables Windowing mode. 0 Windowing mode is disabled. 1 Windowing mode is enabled.
2 IRQRSTEN	Used to enable the debug breadcrumbs feature. A change in this bit is updated immediately, as opposed to updating after WCT. 0 WDOG time-out generates reset only. 1 WDOG time-out initially generates an interrupt. After WCT, it generates a reset.
1 CLKSRC	Selects clock source for the WDOG timer and other internal timing operations. 0 WDOG clock sourced from LPO . 1 WDOG clock sourced from alternate clock source.
0 WDOGEN	Enables or disables the WDOG's operation. In the disabled state, the watchdog timer is kept in the reset state, but the other exception conditions can still trigger a reset/interrupt. A change in the value of this bit must be held for more than one WDOG_CLK cycle for the WDOG to be enabled or disabled. 0 WDOG is disabled. 1 WDOG is enabled.

27.8.2 Watchdog Status and Control Register Low (WDOG_STCTRL)

Address: 4005_2000h base + 2h offset = 4005_2002h

Bit	15	14	13	12	11	10	9	8
Read	INTFLG				Reserved			
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	1

WDOG_STCTRL field descriptions

Field	Description
15 INTFLG	Interrupt flag. It is set when an exception occurs. IRQRSTEN = 1 is a precondition to set this flag. INTFLG = 1 results in an interrupt being issued followed by a reset, WCT later. The interrupt can be cleared by writing 1 to this bit. It also gets cleared on a system reset.
Reserved	This field is reserved. NOTE: Do not modify this field value.

27.8.3 Watchdog Time-out Value Register High (WDOG_TOVALH)

Address: 4005_2000h base + 4h offset = 4005_2004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	TOVALHIGH															
Write																
Reset	0	0	0	0	0	0	0	0	0	1	0	0	1	1	0	0

WDOG_TOVALH field descriptions

Field	Description
TOVALHIGH	Defines the upper 16 bits of the 32-bit time-out value for the watchdog timer. It is defined in terms of cycles of the watchdog clock.

27.8.4 Watchdog Time-out Value Register Low (WDOG_TOVALL)

The time-out value of the watchdog must be set to a minimum of four watchdog clock cycles. This is to take into account the delay in new settings taking effect in the watchdog clock domain.

Address: 4005_2000h base + 6h offset = 4005_2006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	TOVALL															
Write																
Reset	0	1	0	0	1	0	1	1	0	1	0	0	1	1	0	0

WDOG_TOVALL field descriptions

Field	Description
TOVALL	Defines the lower 16 bits of the 32-bit time-out value for the watchdog timer. It is defined in terms of cycles of the watchdog clock.

27.8.5 Watchdog Window Register High (WDOG_WINH)

NOTE

You must set the Window Register value lower than the Time-out Value Register.

Address: 4005_2000h base + 8h offset = 4005_2008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WINHIGH															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_WINH field descriptions

Field	Description
WINHIGH	Defines the upper 16 bits of the 32-bit window for the windowed mode of operation of the watchdog. It is defined in terms of cycles of the watchdog clock. In this mode, the watchdog can be refreshed only when the timer has reached a value greater than or equal to this window length. A refresh outside this window resets the system or if IRQRSTEN is set, it interrupts and then resets the system.

27.8.6 Watchdog Window Register Low (WDOG_WINL)

NOTE

You must set the Window Register value lower than the Time-out Value Register.

Address: 4005_2000h base + Ah offset = 4005_200Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WINLOW															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

WDOG_WINL field descriptions

Field	Description
WINLOW	Defines the lower 16 bits of the 32-bit window for the windowed mode of operation of the watchdog. It is defined in terms of cycles of the pre-scaled watchdog clock. In this mode, the watchdog can be refreshed only when the timer reaches a value greater than or equal to this window length value. A refresh outside of this window resets the system or if IRQRSTEN is set, it interrupts and then resets the system.

27.8.7 Watchdog Refresh register (WDOG_REFRESH)

Address: 4005_2000h base + Ch offset = 4005_200Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WDOGREFRESH															
Write																
Reset	1	0	1	1	0	1	0	0	1	0	0	0	0	0	0	0

WDOG_REFRESH field descriptions

Field	Description
WDOGREFRESH	Watchdog refresh register. A sequence of 0xA602 followed by 0xB480 within 20 bus clock cycles written to this register refreshes the WDOG and prevents it from resetting the system. Writing a value other than the above mentioned sequence or if the sequence is longer than 20 bus cycles, resets the system, or if IRQRSTEN is set, it interrupts and then resets the system.

27.8.8 Watchdog Unlock register (WDOG_UNLOCK)

Address: 4005_2000h base + Eh offset = 4005_200Eh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WDOGUNLOCK															
Write																
Reset	1	1	0	1	1	0	0	1	0	0	1	0	1	0	0	0

WDOG_UNLOCK field descriptions

Field	Description
WDOGUNLOCK	Writing the unlock sequence values to this register to makes the watchdog write-once registers writable again. The required unlock sequence is 0xC520 followed by 0xD928 within 20 bus clock cycles. A valid unlock sequence opens a window equal in length to the WCT within which you can update the registers. Writing a value other than the above mentioned sequence or if the sequence is longer than 20 bus cycles, resets the system or if IRQRSTEN is set, it interrupts and then resets the system. The unlock sequence is effective only if ALLOWUPDATE is set.

27.8.9 Watchdog Timer Output Register High (WDOG_TMROUTH)

Address: 4005_2000h base + 10h offset = 4005_2010h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	TIMEROUTHIGH															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_TMROUTH field descriptions

Field	Description
TIMEROUTHIGH	Shows the value of the upper 16 bits of the watchdog timer.

27.8.10 Watchdog Timer Output Register Low (WDOG_TMROUTL)

During Stop mode, the WDOG_TIMER_OUT will be caught at the pre-stop value of the watchdog timer. After exiting Stop mode, a maximum delay of 1 WDOG_CLK cycle + 3 bus clock cycles will occur before the WDOG_TIMER_OUT starts following the watchdog timer.

Address: 4005_2000h base + 12h offset = 4005_2012h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	TIMEROUTLOW															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_TMROUTL field descriptions

Field	Description
TIMEROUTLOW	Shows the value of the lower 16 bits of the watchdog timer.

27.8.11 Watchdog Reset Count register (WDOG_RSTCNT)

Address: 4005_2000h base + 14h offset = 4005_2014h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	RSTCNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_RSTCNT field descriptions

Field	Description
RSTCNT	Counts the number of times the watchdog resets the system. This register is reset only on a POR. Writing 1 to the bit to be cleared enables you to clear the contents of this register.

27.8.12 Watchdog Prescaler register (WDOG_PRESC)

Address: 4005_2000h base + 16h offset = 4005_2016h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0					PRESCVAL			0							
Write																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

WDOG_PRESC field descriptions

Field	Description
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 PRESCVAL	3-bit prescaler for the watchdog clock source. A value of zero indicates no division of the input WDOG clock. The watchdog clock is divided by (PRESCVAL + 1) to provide the prescaled WDOG_CLK.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27.9 Watchdog operation with 8-bit access

27.9.1 General guideline

When performing 8-bit accesses to the watchdog's 16-bit registers where the intention is to access both the bytes of a register, place the two 8-bit accesses one after the other in your code.

27.9.2 Refresh and unlock operations with 8-bit access

One exception condition that generates a reset to the system is the write of any value other than those required for a legal refresh/update sequence to the respective refresh and unlock registers.

For an 8-bit access to these registers, writing a correct value requires at least two bus clock cycles, resulting in an invalid value in the registers for one cycle. Therefore, the system is reset even if the intention is to write a correct value to the refresh/unlock register. Keeping this in mind, the exception condition for 8-bit accesses is slightly modified.

Whereas the match for a correct value for a refresh/unlock sequence is as according to the original definition, the match for an incorrect value is done byte-wise on the refresh/unlock rather than for the whole 16-bit value. This means that if the high byte of the refresh/unlock register contains any value other than high bytes of the two values that make up the sequence, it is treated as an exception condition, leading to a reset or interrupt-then-reset. The same holds true for the lower byte of the refresh or unlock register. Take the refresh operation that expects a write of 0xA602 followed by 0xB480 to the refresh register, as an example.

Table 27-4. Refresh for 8-bit access

	WDOG_REFRESH[15:8]	WDOG_REFRESH[7:0]	Sequence value1 or value2 match	Mismatch exception
Current Value	0xB4	0x80	Value2 match	No
Write 1	0xB4	0x02	No match	No
Write 2	0xA6	0x02	Value1 match	No
Write 3	0xB4	0x02	No match	No
Write 4	0xB4	0x80	Value2 match. Sequence complete.	No
Write 5	0x02	0x80	No match	Yes

As shown in the preceding table, the refresh register holds its reset value initially. Thereafter, two 8-bit accesses are performed on the register to write the first value of the refresh sequence. No mismatch exception is registered on the intermediate write, Write1. The sequence is completed by performing two more 8-bit accesses, writing in the second value of the sequence for a successful refresh. It must be noted that the match of value2 takes place only when the complete 16-bit value is correctly written, write4. Hence, the requirement of writing value2 of the sequence within 20 bus clock cycles of value1 is checked by measuring the gap between write2 and write4.

It is reiterated that the condition for matching values 1 and 2 of the refresh or unlock sequence remains unchanged. The difference for 8-bit accesses is that the criterion for detecting a mismatch is less strict. Any 16-bit access still needs to adhere to the original guidelines, mentioned in the sections [Refreshing the Watchdog](#).

27.10 Restrictions on watchdog operation

This section mentions some exceptions to the watchdog operation that may not be apparent to you.

- **Restriction on unlock/refresh operations**—In the period between the closure of the WCT window after unlock and the actual reload of the watchdog timer, unlock and refresh operations need not be attempted.
- **The update and reload of the watchdog timer happens two to three watchdog clocks after WCT window closes**, following a successful configuration on unlock.
- **Clock Switching Delay**—The watchdog uses glitch-free multiplexers at two places – one to choose between the LPO oscillator input and alternate clock input, and the other to choose between the watchdog functional clock and fast clock input for

watchdog functional test. A maximum time period of ~2 clock A cycles plus ~2 clock B cycles elapses from the time a switch is requested to the occurrence of the actual clock switch, where clock A and B are the two input clocks to the clock mux.

- For the windowed mode, there is a two to three bus clock latency between the watchdog counter going past the window value and the same registering in the bus clock domain.
- For proper operation of the watchdog, the watchdog clock must be at least five times slower than the system bus clock at all times. An exception is when the watchdog clock is synchronous to the bus clock wherein the watchdog clock can be as fast as the bus clock.
- WCT must be equivalent to at least three watchdog clock cycles. If not ensured, this means that even after the close of the WCT window, you have to wait for the synchronized system reset to deassert in the watchdog clock domain, before expecting the configuration updates to take effect.
- The time-out value of the watchdog should be set to a minimum of four watchdog clock cycles. This is to take into account the delay in new settings taking effect in the watchdog clock domain.
- You must take care not only to refresh the watchdog within the watchdog timer's actual time-out period, but also provide enough allowance for the time it takes for the refresh sequence to be detected by the watchdog timer, on the watchdog clock.
- Updates cannot be made in the bus clock cycle immediately following the write of the unlock sequence, but one bus clock cycle later.
- It should be ensured that the time-out value for the watchdog is always greater than $2 \times \text{WCT time} + 20$ bus clock cycles.
- An attempted refresh operation, in between the two writes of the unlock sequence and in the WCT time following a successful unlock, will go undetected.
- Trying to unlock the watchdog within the WCT time after an initial unlock has no effect.
- The refresh and unlock operations and interrupt are not automatically disabled in the watchdog functional test mode.
- After emerging from a reset due to a watchdog functional test, you are still expected to go through the mandatory steps of unlocking and configuring the watchdog. The watchdog continues to be in its functional test mode and therefore you should pull the watchdog out of the functional test mode within WCT time of reset.

- After emerging from a reset due to a watchdog functional test, you still need to go through the mandatory steps of unlocking and configuring the watchdog.
- You must ensure that both the clock inputs to the glitchless clock multiplexers are alive during the switching of clocks. Failure to do so results in a loss of clock at their outputs.
- There is a gap of two to three watchdog clock cycles from the point that stop mode is entered to the watchdog timer actually pausing, due to synchronization. The same holds true for an exit from the stop mode, this time resulting in a two to three watchdog clock cycle delay in the timer restarting. In case the duration of the stop mode is less than one watchdog clock cycle, the watchdog timer is not guaranteed to pause.
- Consider the case when the first refresh value is written, following which the system enters stop mode with system bus clk still on. If the second refresh value is not written within 20 bus cycles of the first value, the system is reset, or interrupt-then-reset if enabled.

Chapter 28

Multipurpose Clock Generator (MCG)

28.1 Chip-specific MCG information

28.1.1 MCG oscillator clock input options

The MCG has multiple oscillator input clock sources. Within the context of the MCG these are all referred to as the external reference clock and selection is determined by MCG_C7[OSCSSEL] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

Table 28-1. MCG Oscillator Reference Options

MCG_C7[OSCSSEL]	MCG defined selection	Chip clock
00	OSCCLK0 - System Oscillator	OSCCLK - System oscillator output. Derived from external crystal circuit or directly from EXTAL.
01	OSC2/RTC Oscillator	RTC 32kHz oscillator output. RTC clock is derived from external crystal circuit associated with RTC.
10	OSCCLK1 - Oscillator	IRC48MCLK. Derived from internal 48 MHz oscillator.
11	Reserved	—

See [Clock Distribution](#) for more details on these clocks.

28.1.2 MCG External PLL Clock Source

The MCG External PLL source comes from USB1PFDCLK. See USB HS PHY chapter for more details about how to setup USB1PFDCLK.

28.2 Introduction

The multipurpose clock generator (MCG) module provides several clock source choices for the MCU.

The module contains a frequency-locked loop (FLL) and a phase-locked loop (PLL). The FLL is controllable by either an internal or an external reference clock. The PLL is controllable by the external reference clock. The module can select either an FLL or PLL output clock, or a reference clock (internal or external) as a source for the MCU system clock. The MCG operates in conjunction with a crystal oscillator, which allows an external crystal, ceramic resonator, or another external clock source to produce the external reference clock.

28.2.1 Features

Key features of the MCG module are:

- Frequency-locked loop (FLL):
 - Digitally-controlled oscillator (DCO)
 - DCO frequency range is programmable for up to four different frequency ranges.
 - Option to program and maximize DCO output frequency for a low frequency external reference clock source.
 - Option to prevent FLL from resetting its current locked frequency when switching clock modes if FLL reference frequency is not changed.
 - Internal or external reference clock can be used as the FLL source.
 - Can be used as a clock source for other on-chip peripherals.
- Phase-locked loop (PLL):
 - Voltage-controlled oscillator (VCO)
 - External reference clock is used as the PLL source.
 - Modulo VCO frequency divider
 - Phase/Frequency detector

- Integrated loop filter
- Can be used as a clock source for other on-chip peripherals.
- Internal reference clock generator:
 - Slow clock with nine trim bits for accuracy
 - Fast clock with four trim bits
 - Can be used as source clock for the FLL. In FEI mode, only the slow Internal Reference Clock (IRC) can be used as the FLL source.
 - Either the slow or the fast clock can be selected as the clock source for the MCU.
 - Can be used as a clock source for other on-chip peripherals.
- External PLL clock
 - Can be used as a second PLL source
 - Can be selected as the clock source for the MCU.
- External clock from the Oscillator :
 - Can be used as a source for the FLL and/or the PLL.
 - Can be selected as the clock source for the MCU.
- External clock from the Real Time Counter (RTC):
 - Can be used as a source for the FLL only.
 - Can be selected as the clock source for the MCU.
- External clock monitor with reset and interrupt request capability to check for external clock failure when running in FBE, PEE, BLPE, or FEE modes
- Lock detector with interrupt request capability for use with the PLL
- Internal Reference Clocks Auto Trim Machine (ATM) capability using an external clock as a reference
- Reference dividers for both the FLL and the PLL are provided
- Reference dividers for the Fast Internal Reference Clock are provided
- MCG PLL Clock (MCGPLLCLK) is provided as a clock source for other on-chip peripherals

- MCG FLL Clock (MCGFLLCLK) is provided as a clock source for other on-chip peripherals
- MCG Internal Reference Clock (MCGIRCLK) is provided as a clock source for other on-chip peripherals

This figure presents the block diagram of the MCG module.

Figure 28-1. Multipurpose Clock Generator (MCG) block diagram

28.2.2 Modes of Operation

The MCG has the following modes of operation: FEI, FEE, FBI, FBE, PBE, PEE, BLPI, BLPE, and Stop. For details, see [MCG modes of operation](#).

28.3 External Signal Description

There are no MCG signals that connect off chip.

28.4 Memory Map/Register Definition

This section includes the memory map and register definition.

The MCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus error. Read accesses may be performed in both supervisor and user mode.

MCG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_4000	MCG Control 1 Register (MCG_C1)	8	R/W	04h	28.4.1/625

MCG_C1 field descriptions

Field	Description
7–6 CLKS	Clock Source Select Selects the clock source for MCGOUTCLK . 00 Encoding 0 — Output of FLL or PLLCS is selected (depends on PLLS control bit). 01 Encoding 1 — Internal reference clock is selected. 10 Encoding 2 — External reference clock is selected. 11 Encoding 3 — Reserved.
5–3 FRDIV	FLL External Reference Divider Selects the amount to divide down the external reference clock for the FLL. The resulting frequency must be in the range 31.25 kHz to 39.0625 kHz (This is required when FLL/DCO is the clock source for MCGOUTCLK . In FBE mode, it is not required to meet this range, but it is recommended in the cases when trying to enter a FLL mode from FBE). 000 If RANGE = 0 or OSCSEL=1 , Divide Factor is 1; for all other RANGE values, Divide Factor is 32. 001 If RANGE = 0 or OSCSEL=1 , Divide Factor is 2; for all other RANGE values, Divide Factor is 64. 010 If RANGE = 0 or OSCSEL=1 , Divide Factor is 4; for all other RANGE values, Divide Factor is 128. 011 If RANGE = 0 or OSCSEL=1 , Divide Factor is 8; for all other RANGE values, Divide Factor is 256. 100 If RANGE = 0 or OSCSEL=1 , Divide Factor is 16; for all other RANGE values, Divide Factor is 512. 101 If RANGE = 0 or OSCSEL=1 , Divide Factor is 32; for all other RANGE values, Divide Factor is 1024. 110 If RANGE = 0 or OSCSEL=1 , Divide Factor is 64; for all other RANGE values, Divide Factor is 1280 . 111 If RANGE = 0 or OSCSEL=1 , Divide Factor is 128; for all other RANGE values, Divide Factor is 1536 .
2 IREFS	Internal Reference Select

Table continues on the next page...

MCG_C1 field descriptions (continued)

Field	Description
	Selects the reference clock source for the FLL. 0 External reference clock is selected. 1 The slow internal reference clock is selected.
1 IRCLKEN	Internal Reference Clock Enable Enables the internal reference clock for use as MCGIRCLK. 0 MCGIRCLK inactive. 1 MCGIRCLK active.
0 IREFSTEN	Internal Reference Stop Enable Controls whether or not the internal reference clock remains enabled when the MCG enters Stop mode. 0 Internal reference clock is disabled in Stop mode. 1 Internal reference clock is enabled in Stop mode if IRCLKEN is set or if MCG is in FEI, FBI, or BLPI modes before entering Stop mode.

28.4.2 MCG Control 2 Register (MCG_C2)

Address: 4006_4000h base + 1h offset = 4006_4001h

Bit	7	6	5	4	3	2	1	0
Read	LOCRE0	FCFTRIM	RANGE		HGO	EREFS	LP	IRCS
Write								
Reset	1	0	0	0	0	0	0	0

MCG_C2 field descriptions

Field	Description
7 LOCRE0	Loss of Clock Reset Enable Determines whether an interrupt or a reset request is made following a loss of OSC0 external reference clock. The LOCRE0 only has an affect when CME0 is set. 0 Interrupt request is generated on a loss of OSC0 external reference clock. 1 Generate a reset request on a loss of OSC0 external reference clock.
6 FCFTRIM	Fast Internal Reference Clock Fine Trim FCFTRIM controls the smallest adjustment of the fast internal reference clock frequency. Setting FCFTRIM increases the period and clearing FCFTRIM decreases the period by the smallest amount possible. If an FCFTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this bit.
5–4 RANGE	Frequency Range Select Selects the frequency range for the crystal oscillator or external clock source. See the Oscillator (OSC) chapter for more details and the device data sheet for the frequency ranges used. 00 Encoding 0 — Low frequency range selected for the crystal oscillator .

Table continues on the next page...

MCG_C2 field descriptions (continued)

Field	Description
	01 Encoding 1 — High frequency range selected for the crystal oscillator . 1X Encoding 2 — Very high frequency range selected for the crystal oscillator .
3 HGO	High Gain Oscillator Select Controls the crystal oscillator mode of operation. See the Oscillator (OSC) chapter for more details. 0 Configure crystal oscillator for low-power operation. 1 Configure crystal oscillator for high-gain operation.
2 EREFS	External Reference Select Selects the source for the external reference clock. See the Oscillator (OSC) chapter for more details. 0 External reference clock requested. 1 Oscillator requested.
1 LP	Low Power Select Controls whether the FLL or PLL is disabled in BLPI and BLPE modes. In FBE or PBE modes, setting this bit to 1 will transition the MCG into BLPE mode; in FBI mode, setting this bit to 1 will transition the MCG into BLPI mode. In any other MCG mode, LP bit has no affect. 0 FLL or PLL is not disabled in bypass modes. 1 FLL or PLL is disabled in bypass modes (lower power)
0 IRCS	Internal Reference Clock Select Selects between the fast or slow internal reference clock source. 0 Slow internal reference clock selected. 1 Fast internal reference clock selected.

28.4.3 MCG Control 3 Register (MCG_C3)

Address: 4006_4000h base + 2h offset = 4006_4002h

Bit	7	6	5	4	3	2	1	0
Read	SCTRIM							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

MCG_C3 field descriptions

Field	Description
SCTRIM	Slow Internal Reference Clock Trim Setting SCTRIM ¹ controls the slow internal reference clock frequency by controlling the slow internal reference clock period. The SCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period.

MCG_C3 field descriptions (continued)

Field	Description
	An additional fine trim bit is available in C4 register as the SCFTRIM bit. Upon reset, this value is loaded with a factory trim value. If an SCTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register.

1. A value for SCTRIM is loaded during reset from a factory programmed location.

28.4.4 MCG Control 4 Register (MCG_C4)

Address: 4006_4000h base + 3h offset = 4006_4003h

Bit	7	6	5	4	3	2	1	0
Read	DMX32	DRST_DRS			FCTRIM			SCFTRIM
Write								
Reset	0	0	0	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

MCG_C4 field descriptions

Field	Description																																									
7 DMX32	DCO Maximum Frequency with 32.768 kHz Reference The DMX32 bit controls whether the DCO frequency range is narrowed to its maximum frequency with a 32.768 kHz reference. The following table identifies settings for the DCO frequency range. NOTE: The system clocks derived from this source should not exceed their specified maximums. <table><tr><th>DRST_DRS</th><th>DMX32</th><th>Reference Range</th><th>FLL Factor</th><th>DCO Range</th></tr><tr><td rowspan="2">00</td><td>0</td><td>31.25–39.0625 kHz</td><td>640</td><td>20–25 MHz</td></tr><tr><td>1</td><td>32.768 kHz</td><td>732</td><td>24 MHz</td></tr><tr><td rowspan="2">01</td><td>0</td><td>31.25–39.0625 kHz</td><td>1280</td><td>40–50 MHz</td></tr><tr><td>1</td><td>32.768 kHz</td><td>1464</td><td>48 MHz</td></tr><tr><td rowspan="2">10</td><td>0</td><td>31.25–39.0625 kHz</td><td>1920</td><td>60–75 MHz</td></tr><tr><td>1</td><td>32.768 kHz</td><td>2197</td><td>72 MHz</td></tr><tr><td rowspan="2">11</td><td>0</td><td>31.25–39.0625 kHz</td><td>2560</td><td>80–100 MHz</td></tr><tr><td>1</td><td>32.768 kHz</td><td>2929</td><td>96 MHz</td></tr></table> 0 DCO has a default range of 25%. 1 DCO is fine-tuned for maximum frequency with 32.768 kHz reference. 6–5 DRST_DRS	DCO Range Select The DRS bits select the frequency range for the FLL output, DCOOUT. When the LP bit is set, writes to the DRS bits are ignored. The DRST read field indicates the current frequency range for DCOOUT. The																																									

Table continues on the next page...

MCG_C4 field descriptions (continued)

Field	Description
	DRST field does not update immediately after a write to the DRS field due to internal synchronization between clock domains. See the DCO Frequency Range table for more details. 00 Encoding 0 — Low range (reset default). 01 Encoding 1 — Mid range. 10 Encoding 2 — Mid-high range. 11 Encoding 3 — High range.
4–1 FCTRIM	Fast Internal Reference Clock Trim Setting FCTRIM¹ controls the fast internal reference clock frequency by controlling the fast internal reference clock period. The FCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period. If an FCTRIM[3:0] value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register.
0 SCFTRIM	Slow Internal Reference Clock Fine Trim SCFTRIM² controls the smallest adjustment of the slow internal reference clock frequency. Setting SCFTRIM increases the period and clearing SCFTRIM decreases the period by the smallest amount possible. If an SCFTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this bit.

1. A value for FCTRIM is loaded during reset from a factory programmed location.
2. A value for SCFTRIM is loaded during reset from a factory programmed location.

28.4.5 MCG Control 5 Register (MCG_C5)

Address: 4006_4000h base + 4h offset = 4006_4004h

Bit	7	6	5	4	3	2	1	0
Read	0	PLLCLKEN	PLLSTEN	0			PRDIV	
Write								
Reset	0	0	0	0	0	0	0	0

MCG_C5 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 PLLCLKEN	PLL Clock Enable Enables PLL independent of PLLS and enables the PLL clock for use as MCGPLLCLK. (PRDIV needs to be programmed to the correct divider to generate a PLL reference clock in a valid reference range prior to setting the PLLCLKEN bit). Setting PLLCLKEN will enable the external oscillator if not already enabled. Whenever the PLL is being enabled by means of the PLLCLKEN bit, and the external oscillator is being used as the reference clock, the OSCINIT 0 bit should be checked to make sure it is set. 0 MCGPLLCLK is inactive. 1 MCGPLLCLK is active.

Table continues on the next page...

MCG_C5 field descriptions (continued)

Field	Description																		
5 PLLSTEN	PLL Stop Enable Enables the PLL Clock during Normal Stop (In Low Power Stop mode, the PLL clock gets disabled even if PLLSTEN=1). All other power modes, PLLSTEN bit has no affect and does not enable the PLL Clock to run if it is written to 1. 0 MCGPLLCLK and MCGPLLCLK2X are disabled in any of the Stop modes. 1 MCGPLLCLK and MCGPLLCLK2X are enabled if system is in Normal Stop mode.																		
4–3 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.																		
PRDIV	PLL External Reference Divider Selects the amount to divide down the external reference clock for the PLL0. The resulting frequency must be in the range of 8 MHz to 16 MHz. After the PLL0 is enabled (by setting either PLLCLKEN0 or PLLS), the PRDIV0 value must not be changed when LOCK0 is zero. Table 28-2. 28.4.6 MCG Control 6 Register (MCG_C6)

Address: 4006_4000h base + 5h offset = 4006_4005h

Bit	7	6	5	4	3	2	1	0
Read	LOLIE0	PLLS	CME0					
Write						VDIV		
Reset	0	0	0	0	0	0	0	0

MCG_C6 field descriptions

Field	Description
7 LOLIE0	Loss of Lock Interrupt Enable Determines if an interrupt request is made following a loss of lock indication. This bit only has an effect when LOLS 0 is set.

Table continues on the next page...

MCG_C6 field descriptions (continued)

Field	Description																																																																																																			
	0 No interrupt request is generated on loss of lock. 1 Generate an interrupt request on loss of lock.																																																																																																			
6 PLLS	PLL Select Controls whether the PLLCS or FLL output is selected as the MCG source when CLKS[1:0]=00. If the PLLS bit is cleared and PLLCLKEN is not set, the PLLCS output clock is disabled in all modes. If the PLLS is set, the FLL is disabled in all modes. 0 FLL is selected. 1 PLLCS output clock is selected (PRDIV0 bits of PLL in the C5 register need to be programmed to the correct divider to generate a PLL reference clock in the range specified in the data sheet ($f_{\text{pll\_ref}}$) prior to setting the PLLS bit).																																																																																																			
5 CME0	Clock Monitor Enable Enables the loss of clock monitoring circuit for the OSC0 external reference mux select. The LOCRE0 bit will determine if a interrupt or a reset request is generated following a loss of OSC0 indication. The CME0 bit must only be set to a logic 1 when the MCG is in an operational mode that uses the external clock (FEE, FBE, PEE, PBE, or BLPE) . Whenever the CME0 bit is set to a logic 1, the value of the RANGE0 bits in the C2 register should not be changed. CME0 bit should be set to a logic 0 before the MCG enters any Stop mode. Otherwise, a reset request may occur while in Stop mode. CME0 should also be set to a logic 0 before entering VLPW or VLPW power modes if the MCG is in BLPE mode. 0 External clock monitor is disabled for OSC0. 1 External clock monitor is enabled for OSC0.																																																																																																			
VDIV	VCO Divider Selects the amount to divide the VCO output of the PLL. The VDIV bits establish the multiplication factor (M) applied to the reference clock frequency. After the PLL is enabled (by setting either PLLCLKEN or PLLS), the VDIV value must not be changed when LOCK is zero. Table 28-3. PLL VCO Divide Factor <table><tr><th>VDIV</th><th>Multiply Factor</th><th></th><th>VDIV</th><th>Multiply Factor</th><th></th><th>VDIV</th><th>Multiply Factor</th><th></th><th>VDIV</th><th>Multiply Factor</th></tr><tr><td>00000</td><td>16</td><td></td><td>01000</td><td>24</td><td></td><td>10000</td><td>32</td><td></td><td>11000</td><td>40</td></tr><tr><td>00001</td><td>17</td><td></td><td>01001</td><td>25</td><td></td><td>10001</td><td>33</td><td></td><td>11001</td><td>41</td></tr><tr><td>00010</td><td>18</td><td></td><td>01010</td><td>26</td><td></td><td>10010</td><td>34</td><td></td><td>11010</td><td>42</td></tr><tr><td>00011</td><td>19</td><td></td><td>01011</td><td>27</td><td></td><td>10011</td><td>35</td><td></td><td>11011</td><td>43</td></tr><tr><td>00100</td><td>20</td><td></td><td>01100</td><td>28</td><td></td><td>10100</td><td>36</td><td></td><td>11100</td><td>44</td></tr><tr><td>00101</td><td>21</td><td></td><td>01101</td><td>29</td><td></td><td>10101</td><td>37</td><td></td><td>11101</td><td>45</td></tr><tr><td>00110</td><td>22</td><td></td><td>01110</td><td>30</td><td></td><td>10110</td><td>38</td><td></td><td>11110</td><td>46</td></tr><tr><td>00111</td><td>23</td><td></td><td>01111</td><td>31</td><td></td><td>10111</td><td>39</td><td></td><td>11111</td><td>47</td></tr></table>	VDIV	Multiply Factor		VDIV	Multiply Factor		VDIV	Multiply Factor		VDIV	Multiply Factor	00000	16		01000	24		10000	32		11000	40	00001	17		01001	25		10001	33		11001	41	00010	18		01010	26		10010	34		11010	42	00011	19		01011	27		10011	35		11011	43	00100	20		01100	28		10100	36		11100	44	00101	21		01101	29		10101	37		11101	45	00110	22		01110	30		10110	38		11110	46	00111	23		01111	31		10111	39		11111	47

28.4.7 MCG Status Register (MCG_S)

Address: 4006_4000h base + 6h offset = 4006_4006h

Bit	7	6	5	4	3	2	1	0
Read	LOLS0	LOCK0	PLLST	IREFST	CLKST		OSCINIT0	IRCST
Write								
Reset	0	0	0	1	0	0	0	0

MCG_S field descriptions

Field	Description
7 LOLS0	Loss of Lock Status This bit is a sticky bit indicating the lock status for the PLL. LOLS is set if after acquiring lock, the PLL output frequency has fallen outside the lock exit frequency tolerance, D_{unl}. LOLIE determines whether an interrupt request is made when LOLS is set. LOLRE determines whether a reset request is made when LOLS is set. This bit is cleared by reset or by writing a logic 1 to it when set. Writing a logic 0 to this bit has no effect. 0 PLL has not lost lock since LOLS 0 was last cleared. 1 PLL has lost lock since LOLS 0 was last cleared.
6 LOCK0	Lock Status This bit indicates whether the PLL has acquired lock. Lock detection is disabled when not operating in either PBE or PEE mode unless PLLCLKEN=1 and the MCG is not configured in BLPI or BLPE mode. While the PLL clock is locking to the desired frequency, MCGPLLCLK and MCGPLLCLK2X will be gated off until the LOCK bit gets asserted. If the lock status bit is set, changing the value of the PRDIV[2:0] bits in the C5 register or the VDIV[4:0] bits in the C6 register causes the lock status bit to clear and stay cleared until the PLL has reacquired lock. Loss of PLL reference clock will also cause the LOCK bit to clear until PLL has reacquired lock. Entry into LLS, VLPS, or regular Stop with PLLSTEN=0 also causes the lock status bit to clear and stay cleared until the Stop mode is exited and the PLL has reacquired lock. Any time the PLL is enabled and the LOCK bit is cleared, the MCGPLLCLK and MCGPLLCLK2X will be gated off until the LOCK bit is asserted again. 0 PLL is currently unlocked. 1 PLL is currently locked.
5 PLLST	PLL Select Status This bit indicates the clock source selected by PLLS. The PLLST bit does not update immediately after a write to the PLLS bit due to internal synchronization between clock domains. 0 Source of PLLS clock is FLL clock. 1 Source of PLLS clock is PLLCS output clock.
4 IREFST	Internal Reference Status This bit indicates the current source for the FLL reference clock. The IREFST bit does not update immediately after a write to the IREFS bit due to internal synchronization between clock domains. 0 Source of FLL reference clock is the external reference clock. 1 Source of FLL reference clock is the internal reference clock.

Table continues on the next page...

MCG_S field descriptions (continued)

Field	Description
3–2 CLKST	Clock Mode Status These bits indicate the current clock mode. The CLKST bits do not update immediately after a write to the CLKS bits due to internal synchronization between clock domains. 00 Encoding 0 — Output of the FLL is selected (reset default). 01 Encoding 1 — Internal reference clock is selected. 10 Encoding 2 — External reference clock is selected. 11 Encoding 3 — Output of the PLL is selected.
1 OSCINIT0	OSC Initialization This bit, which resets to 0, is set to 1 after the initialization cycles of the oscillator clock have completed. After being set, the bit is cleared to 0 if the OSC is subsequently disabled. See the OSC module's detailed description for more information.
0 IRCST	Internal Reference Clock Status The IRCST bit indicates the current source for the internal reference clock select clock (IRCSCLK). The IRCST bit does not update immediately after a write to the IRCS bit due to internal synchronization between clock domains. The IRCST bit will only be updated if the internal reference clock is enabled, either by the MCG being in a mode that uses the IRC or by setting the C1[IRCLKEN] bit. 0 Source of internal reference clock is the slow clock (32 kHz IRC). 1 Source of internal reference clock is the fast clock (4 MHz IRC).

28.4.8 MCG Status and Control Register (MCG_SC)

Address: 4006_4000h base + 8h offset = 4006_4008h

Bit	7	6	5	4	3	2	1	0
Read	ATME	ATMS	ATMF	FLTPRSRV	FCRDIV			LOCS0
Write			w1c					w1c
Reset	0	0	0	0	0	0	1	0

MCG_SC field descriptions

Field	Description
7 ATME	Automatic Trim Machine Enable Enables the Auto Trim Machine to start automatically trimming the selected Internal Reference Clock. NOTE: ATME deasserts after the Auto Trim Machine has completed trimming all trim bits of the IRCS clock selected by the ATMS bit. Writing to C1, C3, C4, and SC registers or entering Stop mode aborts the auto trim operation and clears this bit. 0 Auto Trim Machine disabled. 1 Auto Trim Machine enabled.

Table continues on the next page...

MCG_SC field descriptions (continued)

Field	Description
6 ATMS	Automatic Trim Machine Select Selects the IRCS clock for Auto Trim Test. 0 32 kHz Internal Reference Clock selected. 1 4 MHz Internal Reference Clock selected.
5 ATMF	Automatic Trim Machine Fail Flag Fail flag for the Automatic Trim Machine (ATM). This bit asserts when the Automatic Trim Machine is enabled, ATME=1, and a write to the C1, C3, C4, and SC registers is detected or the MCG enters into any Stop mode. A write to ATMF clears the flag. 0 Automatic Trim Machine completed normally. 1 Automatic Trim Machine failed.
4 FLTPRSRV	FLL Filter Preserve Enable This bit will prevent the FLL filter values from resetting allowing the FLL output frequency to remain the same during clock mode changes where the FLL/DCO output is still valid. (Note: This requires that the FLL reference frequency to remain the same as what it was prior to the new clock mode switch. Otherwise FLL filter and frequency values will change.) 0 FLL filter and FLL frequency will reset on changes to current clock mode. 1 FLL filter and FLL frequency retain their previous values during new clock mode change.
3–1 FCRDIV	Fast Clock Internal Reference Divider Selects the amount to divide down the fast internal reference clock. The resulting frequency will be in the range 31.25 kHz to 4 MHz (Note: Changing the divider when the Fast IRC is enabled is not supported). 000 Divide Factor is 1 001 Divide Factor is 2. 010 Divide Factor is 4. 011 Divide Factor is 8. 100 Divide Factor is 16 101 Divide Factor is 32 110 Divide Factor is 64 111 Divide Factor is 128.
0 LOCS0	OSC0 Loss of Clock Status The LOCS0 indicates when a loss of OSC0 reference clock has occurred. The LOCS0 bit only has an effect when CME0 is set. This bit is cleared by writing a logic 1 to it when set. 0 Loss of OSC0 has not occurred. 1 Loss of OSC0 has occurred.

28.4.9 MCG Auto Trim Compare Value High Register (MCG_ATCVH)

Address: 4006_4000h base + Ah offset = 4006_400Ah

Bit	7	6	5	4	3	2	1	0
Read	ATCVH							
Write								
Reset	0	0	0	0	0	0	0	0

MCG_ATCVH field descriptions

Field	Description
ATCVH	ATM Compare Value High Values are used by Auto Trim Machine to compare and adjust Internal Reference trim values during ATM SAR conversion.

28.4.10 MCG Auto Trim Compare Value Low Register (MCG_ATCVL)

Address: 4006_4000h base + Bh offset = 4006_400Bh

Bit	7	6	5	4	3	2	1	0
Read	ATCVL							
Write								
Reset	0	0	0	0	0	0	0	0

MCG_ATCVL field descriptions

Field	Description
ATCVL	ATM Compare Value Low Values are used by Auto Trim Machine to compare and adjust Internal Reference trim values during ATM SAR conversion.

28.4.11 MCG Control 7 Register (MCG_C7)

Address: 4006_4000h base + Ch offset = 4006_400Ch

Bit	7	6	5	4	3	2	1	0
Read	0		0				OSCSEL	
Write								
Reset	0	0	0	0	0	0	0	0

MCG_C7 field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–2 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
OSCSEL	MCG OSC Clock Select Selects the MCG FLL external reference clock NOTE: The OSCSEL field can't be changed during MCG modes (like PBE), when external clock is serving as the clock source for MCG. 00 Selects Oscillator (OSCCLK0). 01 Selects 32 kHz RTC Oscillator. 10 Selects Oscillator (OSCCLK1). 11 RESERVED

28.4.12 MCG Control 8 Register (MCG_C8)

Address: 4006_4000h base + Dh offset = 4006_400Dh

Bit	7	6	5	4	3	2	1	0
Read	LOCRE1	LOLRE	CME1	0				LOCS1
Write								w1c
Reset	1	0	0	0	0	0	0	0

MCG_C8 field descriptions

Field	Description
7 LOCRE1	Loss of Clock Reset Enable Determines if a interrupt or a reset request is made following a loss of RTC external reference clock. The LOCRE1 only has an affect when CME1 is set. 0 Interrupt request is generated on a loss of RTC external reference clock. 1 Generate a reset request on a loss of RTC external reference clock
6 LOLRE	PLL Loss of Lock Reset Enable Determines if an interrupt or a reset request is made following a PLL loss of lock. 0 Interrupt request is generated on a PLL loss of lock indication. The PLL loss of lock interrupt enable bit must also be set to generate the interrupt request. 1 Generate a reset request on a PLL loss of lock indication.
5 CME1	Clock Monitor Enable1 Enables the loss of clock monitoring circuit for the output of the RTC external reference clock. The LOCRE1 bit will determine whether an interrupt or a reset request is generated following a loss of RTC

Table continues on the next page...

MCG_C8 field descriptions (continued)

Field	Description
	clock indication. The CME1 bit should be set to a logic 1 when the MCG is in an operational mode that uses the RTC as its external reference clock or if the RTC is operational. CME1 bit must be set to a logic 0 before the MCG enters any Stop mode. Otherwise, a reset request may occur when in Stop mode. CME1 should also be set to a logic 0 before entering VLPR or VLPW power modes. 0 External clock monitor is disabled for RTC clock. 1 External clock monitor is enabled for RTC clock.
4–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LOCS1	RTC Loss of Clock Status This bit indicates when a loss of clock has occurred. This bit is cleared by writing a logic 1 to it when set. 0 Loss of RTC has not occur. 1 Loss of RTC has occur

28.4.13 MCG Control 9 Register (MCG_C9)

Address: 4006_4000h base + Eh offset = 4006_400Eh

MCG_C9 field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 PLL_CME	MCG External PLL Clock Monitor Enable Enables the loss of clock monitoring circuit for the MCG External PLL (EXT_PLL) reference clock. The PLL_LOCRE bit will determine whether an interrupt or a reset request is generated following a loss of EXT_PLL clock indication. The PLL_CME bit should be set to a logic 1 when the MCG is in an operational mode that uses the EXT_PLL as the CLKS source. 0 External clock monitor is disabled for EXT_PLL clock. 1 External clock monitor is enabled for EXT_PLL clock.
4 PLL_LOCRE	MCG External PLL Loss of Clock Reset Enable

Table continues on the next page...

MCG_C9 field descriptions (continued)

Field	Description
	Determines whether an interrupt or a reset request is made following a loss of the MCG External PLL clock when the MCG is running in PEE (CLKST=11) mode with the External PLL selected (PLLCS=1). 0 Interrupt request is generated on a invalid or loss of the MCG external PLL clock. 1 Generates a system reset request on a invalid or loss of the MCG external PLL clock.
3–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 EXT_PLL_LOCS	External PLL Loss of Clock Status The EXT_PLL_LOCS indicates when a loss of MCG EXT_PLL clock has occurred. This bit is cleared by writing a logic 1 to it when set. 0 Loss of MCG EXT_PLL has not occurred. 1 Loss of MCG EXT_PLL has occurred.

28.4.14 MCG Control 11 Register (MCG_C11)

Address: 4006_4000h base + 10h offset = 4006_4010h

Bit	7	6	5	4	3	2	1	0
Read		0		PLLCS		0		
Write								
Reset	0	0	0	0	0	0	0	0

MCG_C11 field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PLLCS	PLL Clock Select Controls whether the PLL0 output or MCG External PLL input is selected as the MCG source when CLKS are programmed in PLL Engaged External (PEE) mode (CLKS[1:0]=00 and IREFS=0 and PLLS=1). 0 PLL0 output clock is selected. 1 External PLL clock is selected.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.4.15 MCG Control 12 Register (MCG_C12)

Address: 4006_4000h base + 11h offset = 4006_4011h

Write								
Reset	0	0	0	0	0	0	0	0

MCG_S2 field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PLLCS	PLL Clock Select Status The PLLCS indicates the PLL clock selected by PLLCS. The PLLCS bit does not updated immediately after a write to the PLLCS bit due internal synchronization between clock domains. 0 Source of PLLCS is PLL clock. 1 Source of PLLCS is EXT_PLL clock.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.4.16 MCG Test 3 Register (MCG_T3)

Address: 4006_4000h base + 13h offset = 4006_4013h

Bit	7	6	5	4	3	2	1	0
Read				0				
Write								
Reset	0	0	0	0	0	0	0	0

MCG_T3 field descriptions

Field	Description
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.5 Functional description

28.5.1 MCG mode state diagram

The nine states of the MCG are shown in the following figure and are described in [Table 28-4](#). The arrows indicate the permitted MCG mode transitions.

Figure 28-2. MCG mode state diagram

NOTE

- During exits from LLS or VLPS when the MCG is in PEE mode, the MCG will reset to PBE clock mode and the C1[CLKS] and S[CLKST] will automatically be set to 2'b10.
- If entering Normal Stop mode when the MCG is in PEE mode with PLLSTEN=0, the MCG will reset to PBE clock mode and C1[CLKS] and S[CLKST] will automatically be set to 2'b10.

28.5.1.1 MCG modes of operation

The MCG operates in one of the following modes.

Note

The MCG restricts transitions between modes. For the permitted transitions, see [Figure 28-2](#).

Table 28-4. MCG modes of operation

Mode	Description
FLL Engaged Internal (FEI)	FLL engaged internal (FEI) is the default mode of operation and is entered when all the following conditions occur: • 00 is written to C1[CLKS]. • 1 is written to C1[IREFS]. • 0 is written to C6[PLLS]. In FEI mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the 32 kHz Internal Reference Clock (IRC). The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FEI mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN] is set .
FLL Engaged External (FEE)	FLL engaged external (FEE) mode is entered when all the following conditions occur: • 00 is written to C1[CLKS]. • 0 is written to C1[IREFS]. • C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz • 0 is written to C6[PLLS]. In FEE mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the external reference clock. The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the external reference frequency, as specified by C1[FRDIV] and C2[RANGE]. See the C4[DMX32] bit description for more details. In FEE mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN] is set .
FLL Bypassed Internal (FBI)	FLL bypassed internal (FBI) mode is entered when all the following conditions occur: • 01 is written to C1[CLKS]. • 1 is written to C1[IREFS]. • 0 is written to C6[PLLS] • 0 is written to C2[LP]. In FBI mode, the MCGOUTCLK is derived either from the slow (32 kHz IRC) or fast (4 MHz IRC) internal reference clock, as selected by the C2[IRCS] bit. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the C2[IRCS] selected internal reference clock. The FLL clock (DCOCLK) is controlled by the slow internal reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FBI mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN] is set .

Table continues on the next page...

Table 28-4. MCG modes of operation (continued)

Mode	Description
FLL Bypassed External (FBE)	FLL bypassed external (FBE) mode is entered when all the following conditions occur: • 10 is written to C1[CLKS]. • 0 is written to C1[IREFS]. • C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz. • 0 is written to C6[PLLS]. • 0 is written to C2[LP]. In FBE mode, the MCGOUTCLK is derived from the OSCSEL external reference clock. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the external reference clock. The FLL clock (DCOCLK) is controlled by the external reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the divided external reference frequency. See the C4[DMX32] bit description for more details. In FBE mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN] is set .
PLL Engaged External (PEE)	PLL Engaged External (PEE) mode is entered when all the following conditions occur: • 00 is written to C1[CLKS]. • 0 is written to C1[IREFS]. • 1 is written to C6[PLLS]. In PEE mode, the MCGOUTCLK is derived from the output of PLL0 or PLL1 (depending on the C11[PLLC] bit) which are controlled by an external reference clock. The selected PLL clock frequency locks to a multiplication factor, as specified by its corresponding VDIV, times the selected PLL reference frequency, as specified by its corresponding PRDIV. The PLL's programmable reference divider must be configured to produce a valid PLL reference clock. The FLL is disabled in a low-power state.
PLL Bypassed External (PBE)	PLL Bypassed External (PBE) mode is entered when all the following conditions occur: • 10 is written to C1[CLKS]. • 0 is written to C1[IREFS]. • 1 is written to C6[PLLS]. • 0 is written to C2[LP]. In PBE mode, MCGOUTCLK is derived from the OSCSEL external reference clock; the PLL selected by C11[PLLC] is operational, but its output clock is not used. This mode is useful to allow the PLL selected PLL to acquire its target frequency while MCGOUTCLK is driven from the external reference clock. The C11[PLLC] selected PLL clock frequency locks to a multiplication factor, as specified by its [VDIV], times the PLL reference frequency, as specified by its [PRDIV]. In preparation for transition to PEE, the PLL's programmable reference divider must be configured to produce a valid PLL reference clock. The FLL is disabled in a low-power state.
Bypassed Low Power Internal (BLPI) ¹	Bypassed Low Power Internal (BLPI) mode is entered when all the following conditions occur: • 01 is written to C1[CLKS]. • 1 is written to C1[IREFS]. • 0 is written to C6[PLLS]. • 1 is written to C2[LP].

Table continues on the next page...

Table 28-4. MCG modes of operation (continued)

Mode	Description
	In BLPI mode, MCGOUTCLK is derived from the internal reference clock. The FLL is disabled and PLL is disabled even if C5[PLLCLKEN] is set to 1.
Bypassed Low Power External (BLPE) ¹	Bypassed Low Power External (BLPE) mode is entered when all the following conditions occur: • 10 is written to C1[CLKS]. • 0 is written to C1[IREFS]. • 1 is written to C2[LP]. In BLPE mode, MCGOUTCLK is derived from the OSCSEL external reference clock. The FLL is disabled and PLL is disabled even if the C5[PLLCLKEN] is set to 1.
Stop	Entered whenever the MCU enters a Stop state. The power modes are chip specific. For power mode assignments, see the Power management chapter that describes how modules are configured and MCG behavior during Stop recovery. Entering Stop mode, the FLL is disabled, and all MCG clock signals are static except in the following case: MCGPLLCLK is active in Normal Stop mode when PLLSTEN=1 MCGIRCLK is active in Normal Stop mode when all the following conditions become true: • C1[IRCLKEN] = 1 • C1[IREFSTEN] = 1 NOTE: • In VLPS Stop Mode, the MCGIRCLK can be programmed to stay enabled and continue running if C1[IRCLKEN] = 1, C1[IREFSTEN]=1, and Fast IRC clock is selected (C2[IRCS] = 1) NOTE: • When entering Low Power Stop modes (LLS or VLPS) from PEE mode, on exit the MCG clock mode is forced to PBE clock mode. C1[CLKS] and S[CLKST] will be configured to 2'b10 if entering from PEE mode or to 2'b01 if entering from PEI mode, C5[PLLSTEN0] will be force to 1'b0 and S[LOCK] bit will be cleared without setting S[LOLS]. • When entering Normal Stop mode from PEE mode and if C5[PLLSTEN]=0, on exit the MCG clock mode is forced to PBE mode, the C1[CLKS] and S[CLKST] will be configured to 2'b10 and S[LOCK] bit will clear without setting S[LOLS]. If C5[PLLSTEN]=1, the S[LOCK] bit will not get cleared and on exit the MCG will continue to run in PEE mode.

1. **Caution:** If entering VLPR mode, MCG has to be configured and enter BLPE mode or BLPI mode with the Fast IRC clock selected (C2[IRCS]=1). After it enters VLPR mode, writes to any of the MCG control registers that can cause an MCG clock mode switch to a non low power clock mode must be avoided.

NOTE

For the chip-specific modes of operation, see the power management chapter of this MCU.

28.5.1.2 MCG mode switching

C1[IREFS] can be changed at any time, but the actual switch to the newly selected reference clocks is shown by S[IREFST]. When switching between engaged internal and engaged external modes, the FLL will begin locking again after the switch is completed.

C1[CLKS] can also be changed at any time, but the actual switch to the newly selected clock is shown by S[CLKST]. If the newly selected clock is not available, the previous clock will remain selected.

The C4[DRST_DRS] write bits can be changed at any time except when C2[LP] bit is 1. If C4[DRST_DRS] write bits are changed while in FLL engaged internal (FEI) or FLL engaged external (FEE) mode, the MCGOUTCLK switches to the new selected DCO range within three clocks of the selected DCO clock. After switching to the new DCO (indicated by the updated C4[DRST_DRS] read bits), the FLL remains unlocked for several reference cycles. The FLL lock time is provided in the device data sheet as $t_{\text{fll\_acquire}}$.

28.5.2 Low-power bit usage

C2[LP] is provided to allow the FLL or PLL to be disabled and thus conserve power when these systems are not being used. C4[DRST_DRS] can not be written while C2[LP] is 1. However, in some applications, it may be desirable to enable the FLL or PLL and allow it to lock for maximum accuracy before switching to an engaged mode. Do this by writing 0 to C2[LP].

28.5.3 MCG Internal Reference Clocks

This module supports two internal reference clocks with nominal frequencies of 32 kHz (slow IRC) and 4 MHz (fast IRC). The fast IRC frequency can be divided down by programming of the FCRDIV to produce a frequency range of 32 kHz to 4 MHz.

28.5.3.1 MCG Internal Reference Clock

The MCG Internal Reference Clock (MCGIRCLK) provides a clock source for other on-chip peripherals and is enabled when C1[IRCLKEN]=1. When enabled, MCGIRCLK is driven by either the fast internal reference clock (4 MHz IRC which can be divided down by the FRDIV factors) or the slow internal reference clock (32 kHz IRC). The IRCS clock frequency can be re-targeted by trimming the period of its IRCS selected internal reference clock. This can be done by writing a new trim value to the

C3[SCTRIM]:C4[SCFTRIM] bits when the slow IRC clock is selected or by writing a new trim value to C4[FCTRIM]:C2[FCFTRIM] when the fast IRC clock is selected. The internal reference clock period is proportional to the trim value written.

C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) and C4[FCTRIM]:C2[FCFTRIM] (if C2[IRCS]=1) bits affect the MCGOUTCLK frequency if the MCG is in FBI or BLPI modes. C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) bits also affect the MCGOUTCLK frequency if the MCG is in FEI mode.

Additionally, this clock can be enabled in Stop mode by setting C1[IRCLKEN] and C1[IREFSTEN], otherwise this clock is disabled in Stop mode.

28.5.4 External Reference Clock

The MCG module can support an external reference clock in all modes. See the device datasheet for external reference frequency range. When C1[IREFS] is set, the external reference clock will not be used by the FLL or PLL. In these modes, the frequency can be equal to the maximum frequency the chip-level timing specifications will support.

If any of the CME bits are asserted the slow internal reference clock is enabled along with the enabled external clock monitor. For the case when C6[CME0]=1, a loss of clock is detected if the OSC0 external reference falls below a minimum frequency (f_{loc_high} or f_{loc_low} depending on C2[RANGE0]). For the case when C8[CME1]=1, a loss of clock is detected if the RTC external reference falls below a minimum frequency (f_{loc_low}).

NOTE

All clock monitors must be disabled before entering these low-power modes: Stop, VLPS, VLPR, VLPW, LLS, and VLLSx.

On detecting a loss-of-clock event, the MCU generates a system reset if the respective LOCRE bit is set. Otherwise the MCG sets the respective LOCS bit and the MCG generates a LOCS interrupt request. In the case where a OSC loss of clock is detected, the PLL LOCK status bit is cleared.

28.5.5 MCG PLL clock

The MCG PLL Clock (MCGPLLCLK) is available depending on the device's configuration of the MCG module. For more details, see the clock distribution chapter of this MCU. The MCGPLLCLK is prevented from coming out of the MCG until it is enabled and S[LOCK0] is set.

28.5.6 MCG Auto TRIM (ATM)

The MCG Auto Trim (ATM) is a MCG feature that when enabled, it configures the MCG hardware to automatically trim the MCG Internal Reference Clocks using an external clock as a reference. The selection between which MCG IRC clock gets tested and enabled is controlled by the ATC[ATMS] control bit (ATC[ATMS]=0 selects the 32 kHz IRC and ATC[ATMS]=1 selects the 4 MHz IRC). If 4 MHz IRC is selected for the ATM, a divide by 128 is enabled to divide down the 4 MHz IRC to a range of 31.250 kHz.

When MCG ATM is enabled by writing ATC[ATME] bit to 1, The ATM machine will start auto trimming the selected IRC clock. During the autotrim process, ATC[ATME] will remain asserted and will deassert after ATM is completed or an abort occurs. The MCG ATM is aborted if a write to any of the following control registers is detected : C1, C3, C4, or ATC or if Stop mode is entered. If an abort occurs, ATC[ATMF] fail flag is asserted.

The ATM machine uses the bus clock as the external reference clock to perform the IRC auto-trim. Therefore, it is required that the MCG is configured in a clock mode where the reference clock used to generate the system clock is the external reference clock such as FBE clock mode. The MCG must not be configured in a clock mode where selected IRC ATM clock is used to generate the system clock. The bus clock is also required to be running with in the range of 8–16 MHz.

To perform the ATM on the selected IRC, the ATM machine uses the successive approximation technique to adjust the IRC trim bits to generate the desired IRC trimmed frequency. The ATM SARs each of the ATM IRC trim bits starting with the MSB. For each trim bit test, the ATM uses a pulse that is generated by the ATM selected IRC clock to enable a counter that counts number of ATM external clocks. At end of each trim bit, the ATM external counter value is compared to the ATCV[15:0] register value. Based on the comparison result, the ATM trim bit under test will get cleared or stay asserted. This is done until all trim bits have been tested by ATM SAR machine.

Before the ATM can be enabled, the ATM expected count needs to be derived and stored into the ATCV register. The ATCV expected count is derived based on the required target Internal Reference Clock (IRC) frequency, and the frequency of the external reference clock using the following formula:

$$\text{ATCV Expected Count Value} = 21 * (\text{Fe} / \text{Fr})$$

- Fr = Target Internal Reference Clock (IRC) Trimmed Frequency
- Fe = External Clock Frequency

If the auto trim is being performed on the 4 MHz IRC, the calculated expected count value must be multiplied by 128 before storing it in the ATCV register. Therefore, the ATCV Expected Count Value for trimming the 4 MHz IRC is calculated using the following formula.

$$\text{Expected Count Value} = (\text{Fe}/\text{Fr}) * 21 * (128)$$

28.6 Initialization / Application information

This section describes how to initialize and configure the MCG module in an application.

The following sections include examples on how to initialize the MCG and properly switch between the various available modes.

28.6.1 MCG module initialization sequence

The MCG comes out of reset configured for FEI mode.

The internal reference will stabilize in t_{irefstb} microseconds before the FLL can acquire lock. As soon as the internal reference is stable, the FLL will acquire lock in $t_{\text{fll\_acquire}}$ milliseconds.

28.6.1.1 Initializing the MCG

Because the MCG comes out of reset in FEI mode, the only MCG modes that can be directly switched to upon reset are FEE, FBE, and FBI modes (see [Figure 28-2](#)). Reaching any of the other modes requires first configuring the MCG for one of these three intermediate modes. Care must be taken to check relevant status bits in the MCG status register reflecting all configuration changes within each mode.

To change from FEI mode to FEE or FBE modes, follow this procedure:

1. Enable the external clock source by setting the appropriate bits in C2 register.
2. Write to C1 register to select the clock mode.
 - If entering FEE mode, set C1[FRDIV] appropriately, clear C1[IREFS] bit to switch to the external reference, and leave C1[CLKS] at 2'b00 so that the output of the FLL is selected as the system clock source.

- If entering FBE, clear C1[IREFS] to switch to the external reference and change C1[CLKS] to 2'b10 so that the external reference clock is selected as the system clock source. The C1[FRDIV] bits should also be set appropriately here according to the external reference frequency to keep the FLL reference clock in the range of 31.25 kHz to 39.0625 kHz. Although the FLL is bypassed, it is still on in FBE mode.
 - The internal reference can optionally be kept running by setting C1[IRCLKEN]. This is useful if the application will switch back and forth between internal and external modes. For minimum power consumption, leave the internal reference disabled while in an external clock mode.
3. Once the proper configuration bits have been set, wait for the affected bits in the MCG status register to be changed appropriately, reflecting that the MCG has moved into the proper mode.
 - If the MCG is in FEE, FBE, PEE, PBE, or BLPE mode, and C2[EREFS] was also set in step 1, wait here for S[OSCINIT0] bit to become set indicating that the external clock source has finished its initialization cycles and stabilized.
 - If in FEE mode, check to make sure S[IREFST] is cleared before moving on.
 - If in FBE mode, check to make sure S[IREFST] is cleared and S[CLKST] bits have changed to 2'b10 indicating the external reference clock has been appropriately selected. Although the FLL is bypassed, it is still on in FBE mode.
 4. Write to the C4 register to determine the DCO output (MCGFLLCLK) frequency range.
 - By default, with C4[DMX32] cleared to 0, the FLL multiplier for the DCO output is 640. For greater flexibility, if a mid-low-range FLL multiplier of 1280 is desired instead, set C4[DRST_DRS] bits to 2'b01 for a DCO output frequency of 40 MHz. If a mid high-range FLL multiplier of 1920 is desired instead, set the C4[DRST_DRS] bits to 2'b10 for a DCO output frequency of 60 MHz. If a high-range FLL multiplier of 2560 is desired instead, set the C4[DRST_DRS] bits to 2'b11 for a DCO output frequency of 80 MHz.
 - When using a 32.768 kHz external reference, if the maximum low-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b00 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 732 will be 24 MHz.

- When using a 32.768 kHz external reference, if the maximum mid-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b01 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 1464 will be 48 MHz.
 - When using a 32.768 kHz external reference, if the maximum mid high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b10 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2197 will be 72 MHz.
 - When using a 32.768 kHz external reference, if the maximum high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b11 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2929 will be 96 MHz.
5. Wait for the FLL lock time to guarantee FLL is running at new C4[DRST_DRS] and C4[DMX32] programmed frequency.

To change from FEI clock mode to FBI clock mode, follow this procedure:

1. Change C1[CLKS] bits in C1 register to 2'b01 so that the internal reference clock is selected as the system clock source.
2. Wait for S[CLKST] bits in the MCG status register to change to 2'b01, indicating that the internal reference clock has been appropriately selected.
3. Write to the C2 register to determine the IRCS output (IRCSCLK) frequency range.
 - By default, with C2[IRCS] cleared to 0, the IRCS selected output clock is the slow internal reference clock (32 kHz IRC). If the faster IRC is desired, set C2[IRCS] to 1 for a IRCS clock derived from the 4 MHz IRC source.

28.6.2 Using a 32.768 kHz reference

In FEE and FBE modes, if using a 32.768 kHz external reference, at the default FLL multiplication factor of 640, the DCO output (MCGFLLCLK) frequency is 20.97 MHz at low-range.

If C4[DRST_DRS] bits are set to 2'b01, the multiplication factor is doubled to 1280, and the resulting DCO output frequency is 41.94 MHz at mid-low-range. If C4[DRST_DRS] bits are set to 2'b10, the multiplication factor is set to 1920, and the resulting DCO output frequency is 62.91 MHz at mid high-range. If C4[DRST_DRS] bits are set to 2'b11, the multiplication factor is set to 2560, and the resulting DCO output frequency is 83.89 MHz at high-range.

In FBI and FEI modes, setting C4[DMX32] bit is not recommended. If the internal reference is trimmed to a frequency above 32.768 kHz, the greater FLL multiplication factor could potentially push the microcontroller system clock out of specification and damage the part.

28.6.3 MCG mode switching

When switching between operational modes of the MCG, certain configuration bits must be changed in order to properly move from one mode to another.

Each time any of these bits are changed (C6[PLLS], C1[IREFS], C1[CLKS], C2[IRCS], or C2[EREFS], the corresponding bits in the MCG status register (PLLST, IREFST, CLKST, IRCST, or OSCINIT) must be checked before moving on in the application software.

Additionally, care must be taken to ensure that the reference clock divider (C1[FRDIV] and C5[PRDIV0]) is set properly for the mode being switched to. For instance, in PEE mode, if using a 16 MHz crystal, C5[PRDIV0] must be set to 3'b000 (divide-by-1) or 3'b001 (divide-by-2) to divide the external reference down to the required frequency between 8 and 16 MHz.

In FBE, FEE, FBI, and FEI modes, at any time, the application can switch the FLL multiplication factor between 640, 1280, 1920, and 2560 with C4[DRST_DRS] bits. Writes to C4[DRST_DRS] bits will be ignored if C2[LP]=1.

The table below shows MCGOUTCLK frequency calculations using C1[FRDIV], C5[PRDIV0], and C6[VDIV0] settings for each clock mode.

Table 28-5. MCGOUTCLK Frequency Calculation Options

Clock Mode	$f_{\text{MCGOUTCLK}}^1$	Note
FEI (FLL engaged internal)	$f_{\text{int}} \times F$	Typical $f_{\text{MCGOUTCLK}} = 21$ MHz immediately after reset.
FEE (FLL engaged external)	$(f_{\text{ext}} / \text{FLL\_R}) \times F$	$f_{\text{ext}} / \text{FLL\_R}$ must be in the range of 31.25 kHz to 39.0625 kHz
FBE (FLL bypassed external)	OSCCLK	OSCCLK / FLL_R must be in the range of 31.25 kHz to 39.0625 kHz

Table continues on the next page...

Table 28-5. MCGOUTCLK Frequency Calculation Options (continued)

Clock Mode	$f_{\text{MCGOUTCLK}}^1$	Note
FBI (FLL bypassed internal)	MCGIRCLK	Selectable between slow and fast IRC
PEE (PLL engaged external)	$(\text{OSCCLK} / \text{PLL\_R}) \times M / 2$	OSCCLK / PLL_R must be in the range of 8 – 16 MHz
PBE (PLL bypassed external)	OSCCLK	OSCCLK / PLL_R must be in the range of 8 – 16 MHz
BLPI (Bypassed low power internal)	MCGIRCLK	Selectable between slow and fast IRC
BLPE (Bypassed low power external)	OSCCLK	

1. FLL_R is the reference divider selected by the C1[FRDIV] bits, F is the FLL factor selected by C4[DRST_DRS] and C4[DMX32] bits, PLL_R is the reference divider selected by C5[PRDIV0] bits, and M is the multiplier selected by C6[VDIV0] bits.

This section will include several mode switching examples, using an 16 MHz external crystal. If using an external clock source less than 8 MHz, the MCG must not be configured for any of the PLL modes (PEE and PBE).

28.6.3.1 Example 1: Moving from FEI to PEE Mode with OSC0 as the source for the external crystal clock: External Crystal = 16 MHz, MCGOUTCLK frequency = 120 MHz

In this example, the MCG will move through the proper operational modes from FEI to PEE to achieve 120 MHz MCGOUTCLK frequency from 16 MHz external crystal reference. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, FEI must transition to FBE mode:
 - a. C2 = 0x2C
 - C2[RANGE] set to 2'b10 because the frequency of 16 MHz is within the high frequency range.
 - C2[HGO] set to 1 to configure the crystal oscillator for high gain operation.
 - C2[EREFS] set to 1, because a crystal is being used.
 - b. C1 = 0xA0
 - C1[CLKS] set to 2'b10 to select external reference clock as system clock source

- C1[FRDIV] set to 3'b100, or divide-by-512 because $8 \text{ MHz} / 512 = 31.25 \text{ kHz}$ which is in the 31.25 kHz to 39.0625 kHz range required by the FLL
 - C1[IREFS] cleared to 0, selecting the external reference clock and enabling the external oscillator.
- c. Loop until S[OSCINIT0] is 1, indicating the crystal selected by C2[EREFS0] has been initialized.
 - d. Loop until S[IREFST] is 0, indicating the external reference is the current source for the reference clock.
 - e. Loop until S[CLKST] is 2'b10, indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then configure C5[PRDIV0] to generate correct PLL reference frequency.
 - a. C5 = 0x01
 - C5[PRDIV] set to 3'b001, or divide-by-2 resulting in a pll reference frequency of $16\text{MHz}/2 = 8 \text{ MHz}$.
 3. Then, FBE must transition either directly to PBE mode or first through BLPE mode and then to PBE mode:
 - a. BLPE: If a transition through BLPE mode is desired, first set C2[LP] to 1.
 - b. BLPE/PBE: C6 = 0x4E
 - C6[PLLS] set to 1, selects the PLL. At this time, with a C1[PRDIV] value of 2'b001, the PLL reference divider is 2 (see PLL External Reference Divide Factor table), resulting in a reference frequency of $16 \text{ MHz} / 2 = 8 \text{ MHz}$. In BLPE mode, changing the C6[PLLS] bit only prepares the MCG for PLL usage in PBE mode.
 - C6[VDIV] set to 5'b01110, or multiply-by-30 because $8 \text{ MHz reference} * 30 = 240 \text{ MHz}$. This is the MCGPLL0CLK2X frequency, which is the frequency of the VCO. This is divided by 2 to achieve the MCGPLL0CLK frequency of 120 MHz which is later used as the MCGOUTCLK frequency. In BLPE mode, the configuration of the VDIV bits does not matter because the PLL is disabled. Changing them only sets up the multiply value for PLL usage in PBE mode.
 - c. BLPE: If transitioning through BLPE mode, clear C2[LP] to 0 here to switch to PBE mode.

- d. PBE: Loop until S[PLLST] is set, indicating that the current source for the PLLS clock is the PLL.
 - e. PBE: Then loop until S[LOCK0] is set, indicating that the PLL has acquired lock.
4. Lastly, PBE mode transitions into PEE mode:
- a. C1 = 0x20
 - C1[CLKS] set to 2'b00 to select the output of the PLL as the system clock source.
 - b. Loop until S[CLKST] are 2'b11, indicating that the PLL output is selected to feed MCGOUTCLK in the current clock mode.
 - Now, with PRDIV of divide-by-2, and C6[VDIV] of multiply-by-30,
$$\text{MCGOUTCLK} = [(16 \text{ MHz} / 2) * 30] / 2 = 120 \text{ MHz}.$$

Figure 28-3. Flowchart of FEI to PEE mode transition using an 16 MHz crystal
 Kinetis K27F MCU Sub-Family Reference Manual, Rev. 2, 08/2017

28.6.3.2 Example 2: Moving from PEE to BLPI mode: MCGOUTCLK frequency =32 kHz

In this example, the MCG will move through the proper operational modes from PEE mode with a 16 MHz crystal configured for a 120 MHz MCGOUTCLK frequency (see previous example) to BLPI mode with a 32 kHz MCGOUTCLK frequency. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, PEE must transition to PBE mode:
 - a. C1 = 0x40
 - C1[CLKS] set to 2'b10 to switch the system clock source to the external reference clock.
 - b. Loop until S[CLKST] are 2'b10, indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then, PBE must transition either directly to FBE mode or first through BLPE mode and then to FBE mode:
 - a. BLPE: If a transition through BLPE mode is desired, first set C2[LP] to 1.
 - b. BLPE/FBE: C6 = 0x00
 - C6[PLLS] clear to 0 to select the FLL. At this time, with C1[FRDIV] value of 3'b100, the FLL divider is set to 512, resulting in a reference frequency of $16 \text{ MHz} / 512 = 31.25 \text{ kHz}$. If C1[FRDIV] was not previously set to 3'b100 (necessary to achieve required 31.25–39.06 kHz FLL reference frequency with an 16 MHz external source frequency), it must be changed prior to clearing C6[PLLS] bit. In BLPE mode, changing this bit only prepares the MCG for FLL usage in FBE mode. With C6[PLLS] = 0, the C6[VDIV] value does not matter.
 - c. BLPE: If transitioning through BLPE mode, clear C2[LP] to 0 here to switch to FBE mode.
 - d. FBE: Loop until S[PLLST] is cleared, indicating that the current source for the PLLS clock is the FLL.
3. Next, FBE mode transitions into FBI mode:
 - a. C1 = 0x64
 - C1[CLKS] set to 2'b01 to switch the system clock to the internal reference clock.

- C1[IREFS] set to 1 to select the internal reference clock as the reference clock source.
 - C1[FRDIV] remain unchanged because the reference divider does not affect the internal reference.
- b. Loop until S[IREFST] is 1, indicating the internal reference clock has been selected as the reference clock source.
 - c. Loop until S[CLKST] are 2'b01, indicating that the internal reference clock is selected to feed MCGOUTCLK.
4. Lastly, FBI transitions into BLPI mode.
 - a. C2 = 0x22
 - C2[LP] is 1
 - C2[RANGE], C2[HGO], C2[EREFS], C1[IRCLKEN], and C1[IREFSTEN] bits are ignored when the C1[IREFS] bit is set. They can remain set, or be cleared at this point.

Figure 28-4. Flowchart of PEE to BLPI mode transition using an 16 MHz crystal

Chapter 29

Oscillator (OSC)

29.1 Chip-specific OSC information

29.1.1 OSC modes of operation with MCG

The MCG's C2 register bits configure the oscillator frequency range. See the OSC and MCG chapters for more details.

29.2 Introduction

The OSC module is a crystal oscillator. The module, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.

29.3 Features and Modes

Key features of the module are listed here.

- Supports 32 kHz crystals (Low Range mode)
- Supports 3–8 MHz, 8–32 MHz crystals and resonators (High Range mode)
- Automatic Gain Control (AGC) to optimize power consumption in high frequency ranges 3–8 MHz, 8–32 MHz using low-power mode
- High gain option in frequency ranges: 32 kHz, 3–8 MHz, and 8–32 MHz
- Voltage and frequency filtering to guarantee clock frequency and stability
- Optionally external input bypass clock from EXTAL signal directly

Block Diagram

- One clock for MCU clock system
- Two clocks for on-chip peripherals that can work in Stop modes

[Functional Description](#) describes the module's operation in more detail.

29.4 Block Diagram

The OSC module uses a crystal or resonator to generate three filtered oscillator clock signals. Three clocks are output from OSC module: OSCCLK for MCU system, OSCERCLK for on-chip peripherals, and OSC32KCLK. The OSCCLK can only work in run mode. OSCERCLK and OSC32KCLK can work in low power modes. For the clock source assignments, refer to the clock distribution information of this MCU.

Refer to the chip configuration details for the external reference clock source in this MCU.

The figure found here shows the block diagram of the OSC module.

Figure 29-1. OSC Module Block Diagram

29.5 OSC Signal Descriptions

The table found here shows the user-accessible signals available for the OSC module. Refer to signal multiplexing information for this MCU for more details.

Table 29-1. OSC Signal Descriptions

Signal	Description	I/O
EXTAL	External clock/Oscillator input	I
XTAL	Oscillator output	O

29.6 External Crystal / Resonator Connections

The connections for a crystal/resonator frequency reference are shown in the figures found here.

When using low-frequency, low-power mode, the only external component is the crystal or ceramic resonator itself. In the other oscillator modes, load capacitors (C_x , C_y) and feedback resistor (R_F) are required. The following table shows all possible connections.

Table 29-2. External Crystal/Resonator Connections

Oscillator Mode	Connections
Low-frequency (32 kHz), low-power	Connection 1 ¹
Low-frequency (32 kHz), high-gain	Connection 2/Connection 3 ²
High-frequency (3~32 MHz), low-power	Connection 3 ¹
High-frequency (3~32 MHz), high-gain	Connection 3

1. With the low-power mode, the oscillator has the internal feedback resistor R_F . Therefore, the feedback resistor must not be externally with the Connection 3.
2. When the load capacitors (C_x , C_y) are greater than 30 pF, use Connection 3.

Figure 29-2. Crystal/Ceramic Resonator Connections - Connection 1

Figure 29-3. Crystal/Ceramic Resonator Connections - Connection 2

NOTE

Connection 1 and Connection 2 should use internal capacitors as the load of the oscillator by configuring the CR[SCxP] bits.

Figure 29-4. Crystal/Ceramic Resonator Connections - Connection 3

29.7 External Clock Connections

In external clock mode, the pins can be connected as shown in the figure found [here](#).

NOTE

XTAL can be used as a GPIO when the GPIO alternate function is configured for it.

Figure 29-5. External Clock Connections

29.8 Memory Map/Register Definitions

Some oscillator module register bits are typically incorporated into other peripherals such as MCG or SIM.

29.8.1 OSC Memory Map/Register Definition

OSC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_5000	OSC Control Register (OSC_CR)	8	R/W	00h	29.8.1.1/663
4006_5002	OSC_DIV (OSC_OSC_DIV)	8	R/W	00h	29.8.1.2/665

29.8.1.1 OSC Control Register (OSC_CR)

NOTE

After OSC is enabled and starts generating the clocks, the configurations such as low power and frequency range, must not be changed.

Address: 4006_5000h base + 0h offset = 4006_5000h

Bit	7	6	5	4	3	2	1	0

OSC_CR field descriptions

Field	Description
7 ERCLKEN	External Reference Enable Enables external reference clock (OSCERCLK) . 0 External reference clock is inactive. 1 External reference clock is enabled.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 EREFSTEN	External Reference Stop Enable Controls whether or not the external reference clock (OSCERCLK) remains enabled when MCU enters Stop mode. 0 External reference clock is disabled in Stop mode. 1 External reference clock stays enabled in Stop mode if ERCLKEN is set before entering Stop mode.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 SC2P	Oscillator 2 pF Capacitor Load Configure Configures the oscillator load. 0 Disable the selection. 1 Add 2 pF capacitor to the oscillator load.
2 SC4P	Oscillator 4 pF Capacitor Load Configure Configures the oscillator load. 0 Disable the selection. 1 Add 4 pF capacitor to the oscillator load.
1 SC8P	Oscillator 8 pF Capacitor Load Configure Configures the oscillator load. 0 Disable the selection. 1 Add 8 pF capacitor to the oscillator load.
0 SC16P	Oscillator 16 pF Capacitor Load Configure Configures the oscillator load. 0 Disable the selection. 1 Add 16 pF capacitor to the oscillator load.

29.8.1.2 OSC_DIV (OSC_OSC_DIV)

OSC Clock divider register.

Address: 4006_5000h base + 2h offset = 4006_5002h

Bit	7	6	5	4	3	2	1	0
Read	ERPS		0	0	0	0	0	0
Write								
Reset	0	0	0	0	0	0	0	0

OSC_OSC_DIV field descriptions

Field	Description
7–6 ERPS	ERCLK prescaler. These two bits are used to divide the ERCLK output. The un-divided ERCLK output is not affected by these two bits. 00 The divisor ratio is 1. 01 The divisor ratio is 2. 10 The divisor ratio is 4. 11 The divisor ratio is 8.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.9 Functional Description

Functional details of the module can be found here.

29.9.1 OSC module states

The states of the OSC module are shown in the following figure. The states and their transitions between each other are described in this section.

Figure 29-6. OSC Module state diagram

NOTE

XTL_CLK is the clock generated internally from OSC circuits.

29.9.1.1 Off

The OSC enters the Off state when the system does not require OSC clocks. Upon entering this state, XTL_CLK is static unless OSC is configured to select the clock from the EXTAL pad by clearing the external reference clock selection bit. For details regarding the external reference clock source in this MCU, refer to the chip configuration details. The EXTAL and XTAL pins are also decoupled from all other oscillator circuitry in this state. The OSC module circuitry is configured to draw minimal current.

29.9.1.2 Oscillator startup

The OSC enters startup state when it is configured to generate clocks (internally the OSC_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit. In this state, the OSC module is enabled and oscillations are starting up, but have not yet stabilized. When the oscillation amplitude becomes large enough to pass through the input buffer, XTL_CLK begins clocking the counter. When the counter reaches 4096 cycles of XTL_CLK, the oscillator is considered stable and XTL_CLK is passed to the output clock OSC_CLK_OUT.

29.9.1.3 Oscillator Stable

The OSC enters stable state when it is configured to generate clocks (internally the OSC_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit and the counter reaches 4096 cycles of XTL_CLK (when CNT_DONE_4096 is high). In this state, the OSC module is producing a stable output clock on OSC_CLK_OUT. Its frequency is determined by the external components being used.

29.9.1.4 External Clock mode

The OSC enters external clock state when it is enabled and external reference clock selection bit is cleared. For details regarding external reference clock source in this MCU, see the chip configuration details. In this state, the OSC module is set to buffer (with hysteresis) a clock from EXTAL onto the OSC_CLK_OUT. Its frequency is determined by the external clock being supplied.

29.9.2 OSC module modes

The OSC is a pierce-type oscillator that supports external crystals or resonators operating over the frequency ranges shown in [Table 29-3](#). These modes assume the following conditions: OSC is enabled to generate clocks (OSC_EN=1), configured to generate clocks internally (MCG_C2[EREFS] = 1), and some or one of the other peripherals (MCG, Timer, and so on) is configured to use the oscillator output clock (OSC_CLK_OUT).

Table 29-3. Oscillator modes

Mode	Frequency Range
Low-frequency, high-gain	f_{osc_lo} (32.768 kHz) up to f_{osc_lo} (39.0625 kHz)

Table continues on the next page...

Table 29-3. Oscillator modes (continued)

Mode	Frequency Range
High-frequency mode1, high-gain	$f_{osc\_hi\_1}$ (3 MHz) up to $f_{osc\_hi\_1}$ (8 MHz)
High-frequency mode1, low-power	
High-frequency mode2, high-gain	$f_{osc\_hi\_2}$ (8 MHz) up to $f_{osc\_hi\_2}$ (32 MHz)
High-frequency mode2, low-power	

NOTE

For information about low power modes of operation used in this chip and their alignment with some OSC modes, see the chip's Power Management details.

29.9.2.1 Low-Frequency, High-Gain Mode

In Low-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes.

The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used.

29.9.2.2 Low-Frequency, Low-Power Mode

In low-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used, the internal feedback resistor is connected, and no external resistor should be used.

In this mode, the amplifier inputs, gain-control input, and input buffer input are all capacitively coupled for leakage tolerance (not sensitive to the DC level of EXTAL).

Also in this mode, all external components except for the resonator itself are integrated, which includes the load capacitors and feedback resistor that biases EXTAL.

29.9.2.3 High-Frequency, High-Gain Mode

In high-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

29.9.2.4 High-Frequency, Low-Power Mode

In high-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. In this mode, no external resistor should be used.

The oscillator input buffer in this mode is differential. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

29.9.3 Counter

The oscillator output clock (OSC_CLK_OUT) is gated off until the counter has detected 4096 cycles of its input clock (XTL_CLK). After 4096 cycles are completed, the counter passes XTL_CLK onto OSC_CLK_OUT. This counting timeout is used to guarantee output clock stability.

29.9.4 Reference clock pin requirements

The OSC module requires use of both the EXTAL and XTAL pins to generate an output clock in Oscillator mode, but requires only the EXTAL pin in External clock mode. The EXTAL and XTAL pins are available for I/O. For the implementation of these pins on this device, refer to the Signal Multiplexing chapter.

29.10 Reset

There is no reset state associated with the OSC module. The counter logic is reset when the OSC is not configured to generate clocks.

There are no sources of reset requests for the OSC module.

29.11 Low power modes operation

When the MCU enters Stop modes, the OSC is functional depending on CR[ERCLKEN] and CR[EREFSETN] bit settings. If both these bits are set, the OSC is in operation.

In Low Leakage Stop (LLS) modes, the OSC holds all register settings. If CR[ERCLKEN] and CR[EREFSTEN] are set before entry to Low Leakage Stop modes, the OSC is still functional in these modes. After waking up from Very Low Leakage Stop (VLLSx) modes, all OSC register bits are reset and initialization is required through software.

29.12 Interrupts

The OSC module does not generate any interrupts.

Chapter 30

RTC Oscillator (OSC32K)

30.1 Introduction

The RTC oscillator module provides the clock source for the RTC. The RTC oscillator module, in conjunction with an external crystal, generates a reference clock for the RTC.

30.1.1 Features and Modes

The key features of the RTC oscillator are as follows:

- Supports 32 kHz crystals with very low power
- Consists of internal feed back resistor
- Consists of internal programmable capacitors as the C_{load} of the oscillator
- Automatic Gain Control (AGC) to optimize power consumption

The RTC oscillator operations are described in detail in [Functional Description](#) .

30.1.2 Block Diagram

The following is the block diagram of the RTC oscillator.

Figure 30-1. RTC Oscillator Block Diagram

30.2 RTC Signal Descriptions

The following table shows the user-accessible signals available for the RTC oscillator. See the Pinouts or Signal Multiplexing and Pin Assignment section to find out which signals are actually connected to the external pins.

Table 30-1. RTC Signal Descriptions

Signal	Description	I/O
EXTAL32	Oscillator Input	I
XTAL32	Oscillator Output	O

30.2.1 EXTAL32 — Oscillator Input

This signal is the analog input of the RTC oscillator.

30.2.2 XTAL32 — Oscillator Output

This signal is the analog output of the RTC oscillator module.

30.3 External Crystal Connections

The connections with a crystal is shown in the following figure. External load capacitors and feedback resistor are not required.

Figure 30-2. Crystal Connections

30.4 Memory Map/Register Descriptions

RTC oscillator control bits are part of the RTC registers. Refer to RTC Control Register (RTC_CR) in the RTC chapter, or RTC_GP_DATA_REG (if this General Purpose Data Register exists in the RTC registers) description in the chip-specific information section, for more details.

30.5 Functional Description

As shown in [Figure 30-1](#), the module includes an amplifier which supplies the negative resistor for the RTC oscillator. The gain of the amplifier is controlled by the amplitude detector, which optimizes the power consumption. A schmitt trigger is used to translate the sine-wave generated by this oscillator to a pulse clock out, which is a reference clock for the RTC digital core.

The oscillator includes an internal feedback resistor of approximately 100 MΩ between EXTAL32 and XTAL32.

In addition, there are two programmable capacitors with this oscillator, which can be used as the Cload of the oscillator. The programmable range is from 0pF to 30pF.

30.6 Reset Overview

There is no reset state associated with the RTC oscillator.

30.7 Interrupts

The RTC oscillator does not generate any interrupts.

Chapter 31

Local Memory Controller

31.1 Chip-specific LMEM information

31.1.1 Local memory controller region assignment

The following table shows the LMEM's region mode register assignment for each region field. It also shows the available cache modes for each region.

Table 31-1. Cache regions for devices with QSPI

Address range	Destination slave	Region number	Available cache modes
0x0000_0000–0x03FF_FFFF	Program flash and read-only data	R0	Write-through and non-cacheable ¹
0x0400_0000–0x07FF_FFFF	QSPI0 Alias	R0	Write-through and non-cacheable
0x0800_0000–0x0FFF_FFFF	DRAM Controller (Aliased Area)	R1	Write-through and non-cacheable
0x1000_0000–0x17FF_FFFF	Reserved	R2	Reserved
0x1800_0000–0x1BFF_FFFF	FlexBus (Aliased Area)	R3	Write-through and non-cacheable
0x1C00_0000–0x1DFF_FFFF	32kB BOOT ROM	-	Write-through (always)
0x1E00_0000–0x1FFF_FFFF	SRAM_L: Lower SRAM (ICODE/DCODE)	R4	Non-cacheable
0x2000_0000–0x200F_FFFF	SRAM_U: Upper SRAM	R5	Non-cacheable
0x3400_0000–0x3407_FFFF	512KB On-chip RAM	R6	Non-cacheable
0x6000_0000–0x66FF_FFFF	FlexBus (External Memory, Write-back)	R6	Write-back, write-through, and non-cacheable
0x6700_0000–0x677F_FFFF	QSPI0 Rx buffer	R6	Write-back, write-through, and non-cacheable

Table continues on the next page...

Table 31-1. Cache regions for devices with QSPI (continued)

Address range	Destination slave	Region number	Available cache modes
0x6780_0000–0x67FF_FFFF	Reserved	-	-
0x6800_0000–0x6FFF_FFFF	QSPI0	R6	Write-back, write-through, and non-cacheable
0x7000_0000–0x7FFF_FFFF	DRAM Controller	R7	Write-back, write-through, and non-cacheable
0x8000_0000–0x8FFF_FFFF	DRAM Controller - Write-through	R8	Write-through and non-cacheable
0x9000_0000–0x97FF_FFFF	Reserved	-	-
0x9800_0000–0x9FFF_FFFF	FlexBus (External memory - Write-through)	R9	Write-through and non-cacheable

1. Cache write hits do not write-through to program flash or FlexNVM regions because flash writes require flash programming.

31.2 Introduction

The Local Memory Controller provides the processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces.

31.2.1 Block Diagram

The processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000_0000 through 0x1FFF_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000_0000 through 0xFFFF_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled memories for the PC and PS buses. The memories include RAMs and caches. These local memories provide zero wait state access to RAM and cacheable address spaces.

The local memory controller includes four memory controllers and their attached memories:

- SRAM lower (SRAM_L) controller via the PC bus
- SRAM upper (SRAM_U) controller via the PS bus
- Cache memory controller via the PC bus
- Cache memory controller via the PS bus

The local memory controller has the following AMBA_ AHB buses:

- Two inputs are for the core's modified Harvard busses – the Processor Code (PC) and the Processor System (PS) buses.
- One input is for the "backdoor" port used by all other bus masters to access the SRAM controller space.
- Two output ports are the CCM (Core Code Master) bus used for PC accesses that do not hit the PC cache or SRAM_L or are non-cacheable and the CSM (Core System Master) bus used for PS references that do not hit the PS cache or SRAM_U or are non-cacheable.

Figure 31-1. Local memory controller block diagram

NOTE

The SRAM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources. The address spaces are device-specific. See the chip-specific LMEM information for the address space decode details.

31.2.2 Cache features

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- Spatial locality — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports the following modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
 - A write-through read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
 - A write-through read hit to a valid cache location returns data from the cache with no output bus access.
 - A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).

- A write-through write hit updates the cache hit data and writes to the output bus.
 - The caches are processor-local and do not support hardware cache coherency. If the processor has accessed write-through regions and an external bus master (such as DMA) then needs update these regions, software must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before being modified by external masters and subsequent processor accesses will get the updated memory.
2. Write-back — access to address spaces with this cache mode are cacheable.
- Code Cache (PC Side Cache) does not support this mode of operation
 - A write-back read miss on the input bus will cause a line read on the output bus of a 16-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and marked as valid and not modified.
 - A write-back read hit to a valid cache location will return data from the cache with no output bus access.
 - A write-back write miss will do a "read-to-write" (allocate on write miss policy for write-back mode spaces). A line read on the output bus of a 16 byte aligned memory address containing the desired write address is performed. This miss data is loaded into the cache and marked as valid and modified; and the write data will then update the appropriate cache data locations.
 - A write-back write hit updates the cache hit line with the write data plus marks the line as modified.
 - The caches are processor-local and do not support hardware cache coherency. If the processor has written to write-back regions and an external bus master (such as DMA) then needs to see these updates, software must perform explicit cache pushes to any needed cache memory range to ensure all modified cache lines update their associated memories before being read by external masters. Likewise, if the processor has accessed write-back or write-through regions and an external bus master (such as DMA) then needs update these regions, software must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before being modified by external masters and subsequent processor accesses will get the updated memory.
3. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

31.3 Memory Map/Register Definition

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

LMEM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_2000	Cache control register (LMEM_PCCCR)	32	R/W	0000_0000h	31.3.1/680

LMEM_PCCCR field descriptions

Field	Description
31 GO	Initiate Cache Command Setting this bit initiates the cache command indicated by bits 27-24. Reading this bit indicates if a command is active NOTE: This bit stays set until the command completes. Writing zero has no effect. 0 Write: no effect. Read: no cache command active. 1 Write: initiate command indicated by bits 27-24. Read: cache command active.

Table continues on the next page...

LMEM_PCCCR field descriptions (continued)

Field	Description
30–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PUSHW1	Push Way 1 0 No operation 1 When setting the GO bit, push all modified lines in way 1
26 INVW1	Invalidate Way 1 NOTE: If the PUSHW1 and INVW1 bits are set, then after setting the GO bit, push all modified lines in way 1 and invalidate all lines in way 1 (clear way 1). 0 No operation 1 When setting the GO bit, invalidate all lines in way 1
25 PUSHW0	Push Way 0 0 No operation 1 When setting the GO bit, push all modified lines in way 0
24 INVW0	Invalidate Way 0 NOTE: If the PUSHW0 and INVW0 bits are set, then after setting the GO bit, push all modified lines in way 0 and invalidate all lines in way 0 (clear way 0). 0 No operation 1 When setting the GO bit, invalidate all lines in way 0.
23–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 PCCR3	Forces no allocation on cache misses (must also have PCCR2 asserted)
2 PCCR2	Forces all cacheable spaces to write through
1 ENWRBUF	Enable Write Buffer 0 Write buffer disabled 1 Write buffer enabled
0 ENCACHE	Cache enable 0 Cache disabled 1 Cache enabled

31.3.2 Cache line control register (LMEM_PCCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Memory Map/Register Definition

Address: E008_2000h base + 4h offset = E008_2004h

LMEM_PCCLCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL]. When using the physical address, both ways are searched and the command is performed only if a hit. 0 Cache address 1 Physical address
25–24 LCMD	Line Command 00 Search and read or write 01 Invalidate 10 Push 11 Clear

Table continues on the next page...

LMEM_PCCLCR field descriptions (continued)

Field	Description
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LCWAY	Line Command Way Indicates the way used by the line command. If the command used cache address and way, then LCWAY will equal the way it was searched. If the command is a physical address search, then the LCWAY value is only valid if LCIVB=1.
21 LCIMB	Line Command Initial Modified Bit If command used cache address and way, then this bit shows the initial state of the modified bit If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero.
20 LCIVB	Line Command Initial Valid Bit If command used cache address and way, then this bit shows the initial state of the valid bit If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.
19–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TDSEL	Tag/Data Select Selects tag or data for search and read or write commands. 0 Data 1 Tag
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WSEL	Way select Selects the way for line commands. 0 Way 0 1 Way 1
13–2 CACHEADDR	Cache address CLCR[11:4] bits are used to access the tag arrays CLCR[11:2] bits are used to access the data arrays
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active NOTE: This bit stays set until the command completes. Writing zero has no effect. NOTE: This bit is shared with CSAR[LGO] 0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits 27-24. Read: line command active.

31.3.3 Cache search address register (LMEM_PCCSAR)

The CSAR register is used to define the explicit cache address or the physical address for line-sized commands specified in the CLCR[LADSEL] bit.

Address: E008_2000h base + 8h offset = E008_2008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LMEM_PCCSAR field descriptions

Field	Description
31–2 PHYADDR	Physical Address PHYADDR represents bits [31:2] of the system address. CSAR[31:12] bits are used for tag compare CSAR[11:4] bits are used to access the tag arrays CSAR[11:2] bits are used to access the data arrays
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active NOTE: This bit stays set until the command completes. Writing zero has no effect. NOTE: This bit is shared with CLCR[LGO] 0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits CLCR[27:24]. Read: line command active.

31.3.4 Cache read/write value register (LMEM_PCCCVR)

The CCVR register is used to source write data or return read data for the commands specified in the CLCR register.

Address: E008_2000h base + Ch offset = E008_200Ch

LMEM_PCCCVR field descriptions

Field	Description
DATA	Cache read/write Data For tag search, read or write: • CCVR[31:12] bits are used for tag array R/W value • CCVR[11:4] bits are used for tag set address on reads; unused on writes • CCVR[3:2] bits are reserved • CCVR[1] tag modify bit • CCVR[0] tag valid bit For data search, read or write: • CCVR[31:0] bits are used for data array R/W value

31.3.5 Cache regions mode register (LMEM_PCCRMRR)

The CRMR register allows you to demote the cache mode of various subregions within the device's memory map. Demoting the cache mode reduces the cache function applied to a memory region from write-back to write-through to non-cacheable. After a region is demoted, its cache mode can only be raised by a reset, which returns it to its default state.

To maintain cache coherency, changes to the cache mode should be completed while the address space being changed is not being accessed or the cache is disabled. Before a cache mode change, complete a cache clear all command to push and invalidate any cache entries that may have changed.

NOTE

The address/module assignment of the 16 subregions is device-specific. See the chip-specific LMEM information for these details. Some of the regions may not be used (non-cacheable), and some regions may not be capable of write-back.

31.3.7 Cache line control register (LMEM_PSCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008_2000h base + 804h offset = E008_2804h

LMEM_PSCLCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL]. When using the physical address, both ways are searched and the command is performed only if a hit. 0 Cache address 1 Physical address
25–24 LCMD	Line Command 00 Search and read or write 01 Invalidate 10 Push 11 Clear
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LCWAY	Line Command Way Indicates the way used by the line command. If the command used cache address and way, then LCWAY will equal the way it was searched. If the command is a physical address search, then the LCWAY value is only valid if LCIVB=1.
21 LCIMB	Line Command Initial Modified Bit If command used cache address and way, then this bit shows the initial state of the modified bit If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero.
20 LCIVB	Line Command Initial Valid Bit If command used cache address and way, then this bit shows the initial state of the valid bit If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.

1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active NOTE: This bit stays set until the command completes. Writing zero has no effect. NOTE: This bit is shared with CLCR[LGO] 0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits CLCR[27:24]. Read: line command active.

31.3.9 Cache read/write value register (LMEM_PSCCVR)

The CCVR register is used to source write data or return read data for the commands specified in the CLCR register.

Address: E008_2000h base + 80Ch offset = E008_280Ch

LMEM_PSCCVR field descriptions

Field	Description
DATA	Cache read/write Data For tag search, read or write: - CCVR[31:12] bits are used for tag array R/W value - CCVR[11:4] bits are used for tag set address on reads; unused on writes - CCVR[3:2] bits are reserved - CCVR[1] tag modify bit - CCVR[0] tag valid bit For data search, read or write: - CCVR[31:0] bits are used for data array R/W value

31.3.10 Cache regions mode register (LMEM_PSCRMR)

The CRMR register allows you to demote the cache mode of various subregions within the device's memory map. Demoting the cache mode reduces the cache function applied to a memory region from write-back to write-through to non-cacheable. After a region is demoted, its cache mode can only be raised by a reset, which returns it to its default state.

To maintain cache coherency, changes to the cache mode should be completed while the address space being changed is not being accessed or the cache is disabled. Before a cache mode change, complete a cache clear all command to push and invalidate any cache entries that may have changed.

NOTE

The address/module assignment of the 16 subregions is device-specific. See the chip-specific LMEM information for these details. Some of the regions may not be used (non-cacheable), and some regions may not be capable of write-back.

Address: E008_2000h base + 820h offset = E008_2820h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31.4 Functional Description

31.4.1 LMEM Function

The Local Memory Controller receives the following requests:

- Core master bus requests on the Processor Code (PC) bus,
- Core master bus requests on the Processor System (PS) bus, and
- SRAM controller requests from all other bus masters on the backdoor port.

The Local Memory Controller address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all SRAM controller and cacheable accesses.

The programming model for the Code and System Caches is accessed via the core's Private Peripheral Bus (PPB).

31.4.1.1 Processor Code accesses

Processor Code accesses are routed to the SRAM_L if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

31.4.1.2 Processor System accesses

Processor System accesses are routed to the SRAM_U if they are mapped to that space. All other PS accesses are routed to the PS Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master1 port.

31.4.1.3 Backdoor port accesses

All LMEM backdoor port accesses are for the SRAM controller. These accesses go to the SRAM_L or the SRAM_U depending on their specific address.

31.4.2 SRAM Function

31.4.2.1 SRAM Configuration

The figure below shows how the SRAM controller is configured. See chip-specific memory information for on-chip SRAM size details.

Figure 31-2. LMEM Interface to SRAM

31.4.2.2 SRAM Arrays

The on-chip SRAM is split into two logical arrays, SRAM_L and SRAM_U.

Valid address ranges for SRAM_L and SRAM_U are then defined as:

- $\text{SRAM\_L} = (\text{0x20000\_0000} - \text{SRAML\_SIZE}) - \text{0x1fff\_ffff}$
- $\text{SRAM\_U} = \text{0x2000\_0000} - (\text{0x2000\_0000} + \text{SRAMU\_SIZE})$

SRAML_SIZE and SRAMU_SIZE do not have to be equal.

For example, if SRAM_L size is 32 KBytes and SRAM_U size is 64 KBytes. Valid address ranges for SRAM_L and SRAM_U are then defined as:

- $\text{SRAM\_L} = (\text{0x20000\_0000} - 32 \text{ KBytes}) - \text{0x1fff\_ffff}$
- $\text{SRAM\_U} = \text{0x2000\_0000} - (\text{0x2000\_0000} + 64 \text{ KBytes})$

31.4.2.3 SRAM accesses

The SRAM is split into two logical arrays that are 32-bits wide:

- SRAM_L — Accessible by the code bus of the core and by the backdoor port.
- SRAM_U — Accessible by the system bus of the core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

Figure 31-3 illustrates the SRAM accesses within the device.

Figure 31-3. SRAM access diagram

The following simultaneous accesses can be made to different logical halves of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

NOTE

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM_{L,U} arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

NOTE

Burst-access cannot occur across the 0x2000_0000 boundary that separates the two SRAM arrays. The two arrays should be treated as separate memory ranges for burst accesses.

31.4.3 Cache Function

The caches on this device are structured as follows. Both caches have a 2-way set-associative cache structure with a total size of 8 KB. The caches have 32-bit address and data paths and a 16-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For these 8 KB caches, each cache TAG function uses two 256 x 22-bit RAM arrays and the cache DATA function uses two 1024 x 32-bit RAM arrays. The cache TAG entries store 20 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store four bytes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CACHE - 8 KB size = (256 sets) x (16-byte lines) x (2-way set-associative)

TAG:

- address[31:12] used in tag for compare (hit) logic
- address[11:4] used to select 1 of 256 sets
- address[3:0] not used

DATA

- address[31:12] not used
- address[11:4] used to select one of 256 sets
- address[3:2] used to select one of four 32-bit words within a set
- address[1:0] used to select the byte within the 32-bit word

31.4.4 Cache Control

The Code and System Caches are disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the caches, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

31.4.4.1 Cache set commands

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the CCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, CCR[ENCACHE].

A cache set command is initiated by setting the CCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in [Table 31-2](#). Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.
- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

Table 31-2. Cache Set Commands

CCR[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1; clear all way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting CCR to 0x8500_0003 will invalidate the cache and enable the cache and write buffer.

31.4.4.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by bits [11:4] of the physical address. If they hit, the commands perform their action on the hit way.

Cache line commands are specified using the upper bits in the CLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (CCR[ENCACHE]). Using a cache address, the command can be completely specified using the CLCR register. Using a physical address, the command must also use the CSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (CLCR[LGO] or CSAR[LGO]). This bit also acts as a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The CLCR[27:24] bits select the line command as follows:

Table 31-3. Cache Line Commands

CLCR[27:24]			Command
LACC	LADSEL	LCMD	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	xx	Reserved, NOP

31.4.4.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the CLCR.

- Place the command in CLCR[27:24],
- Set the way (CLCR[WSEL]) and tag/data (CLCR[TDSEL]) controls as needed,

- Place the cache address in CLCR[CACHEADDR], and
- Set the line command go bit (CLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CLCR[LGO]).

31.4.4.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the CLCR.
 - Place the command in CLCR[27:24]
 - Set the tag/data (CLCR[TDSEL]) control
- Place the physical address in CSAR[PHYADDR] and set the line command go bit (CSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CSAR[LGO]).

The line command go bit is shared between the CLCR and CSAR registers, so that the above steps can be completed in a single write to the CSAR register.

31.4.4.2.3 Line command results

At completion of a line command, the CLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit cleared if the command misses. In general, if the valid indicator (CLCR[LCIVB]) is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

Table 31-4. Line command results

CLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
0	0	0	Way 0 line was invalid	No hit
0	0	1	Way 0 valid, not modified	Way 0 valid, not modified
0	1	0	Way 0 line was invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line was invalid	No hit
1	0	1	Way 1 valid, not modified	Way 1 valid, not modified
1	1	0	Way 1 line was invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

At completion of a line command other than a write, the CCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the CCVR holds the write data.

Chapter 32

Flash Memory Controller (FMC)

32.1 Chip-specific FMC information

32.1.1 Number of masters

The Flash Memory Controller supports up to eight crossbar switch masters. However, this device has a different number of crossbar switch masters. See chip-specific section of Crossbar Switch for details on the master port assignments.

32.2 Introduction

The Flash Memory Controller (FMC) is a pipelined memory acceleration unit that provides:

- an interface between the device and the four-bank nonvolatile pipelined memory
- in FlexMem mode, up to 3 banks of program flash memory and one bank of FlexNVM
- in PFlash Only mode, 4 banks of program flash memory
- buffers that can accelerate flash memory and FlexNVM data transfers

32.2.1 Overview

The Flash Memory Controller manages the interface between the device and the four bank flash memory. The FMC receives status information detailing the configuration of the memory and uses this information to ensure a proper interface. The following table shows the supported read/write operations.

Table 32-1. Supported Read/Write operations for flash memory

Flash memory type	Read	Write
Program flash memory	8-bit, 16-bit, and 32-bit reads	— ¹
data flash memory	8-bit, 16-bit, and 32-bit reads	— ¹
FlexRAM used as EEPROM	8-bit, 16-bit, and 32-bit reads	8-bit, 16-bit, and 32-bit writes

1. A write operation to program flash memory or to data flash memory results in a bus error.

In addition, for banks 0-2 and bank 3, the FMC provides two separate mechanisms for accelerating the interface between the device and the flash memory. A 128-bit speculation buffer can prefetch the next 128-bit flash memory location, and a 4-way, 4-set cache can store previously accessed flash memory data for quick access times.

32.2.2 Features

The FMC's features include:

- Interface between the device and the 4-bank pipelined flash memory and FlexMemory:
 - 8-bit, 16-bit, and 32-bit read operations to program flash memory and FlexNVM used as data flash memory.
 - 8-bit, 16-bit, and 32-bit read and write operations to FlexRAM. (Note: if EEPROM operation is enabled, then FlexRAM can be used for EEPROM operations; if EEPROM operation is not enabled, then FlexRAM can be used as scratch RAM.)
 - For program and data flash memory, read accesses to consecutive 32-bit spaces in memory return the second, third, and fourth read data with no wait states. The memory returns 128 bits via the 32-bit bus access.
 - Crossbar master access protection for setting no access, read-only access, write-only access, or read/write access for each crossbar master.
- For bank 0-3: Acceleration of data transfer from program flash memory and FlexMemory to the device:
 - 128-bit prefetch speculation buffer with controls for instruction/data access per master and bank

- 4-way, 4-set, 128-bit line size cache for a total of sixteen 128-bit entries with controls for replacement algorithm and lock per way for program and data flash memory
- Invalidation control for the speculation buffer

32.3 Modes of operation

The FMC only operates when the device accesses the flash memory or FlexRAM.

In terms of device power modes, the FMC only operates in run and wait modes, including VLPR and VLPW modes.

For any device power mode where the flash memory or FlexRAM cannot be accessed, the FMC is disabled.

32.4 External signal descriptions

The FMC has no external signals.

32.5 Memory map and register descriptions

The programming model consists of the FMC control registers and the program visible cache (data and tag/valid entries).

NOTE

Program the registers only while the flash controller is idle (for example, execute from RAM). Changing configuration settings while a flash access is in progress can lead to non-deterministic behavior.

Table 32-2. FMC register access

Registers	Read access		Write access	
	Mode	Length	Mode	Length
Control registers (PFAPR, PFB01CR, PFB23CR)	Supervisor (privileged) mode or user mode	32 bits	Supervisor (privileged) mode only	8, 16, or 32 bits
Cache registers	Supervisor (privileged) mode or user mode	32 bits	Supervisor (privileged) mode only	32 bits

NOTE

Accesses to unimplemented registers within the FMC's address space return a bus error.

The 16 cache entries, both data and tag/valid, can be read at any time.

NOTE

System software is required to maintain memory coherence when any segment of the flash cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

The cache is a 4-way, set-associative cache with 4 sets. The ways are numbered 0-3 and the sets are numbered 0-3. The following table elaborates on the tag/valid and data entries.

Table 32-3. Program visible cache registers

Cache storage	Based at offset	Contents of 32-bit read	Nomenclature	Nomenclature example
Tag	100h	10'h0, tag[21:6], 5'h0, valid	In TAGVDWxSy, x denotes the way and y denotes the set.	TAGVDW2S3 is the 16-bit tag and 1-bit valid for cache entry way 2, set 3.
Data	200h	One of the four longwords in a 128-bit cache entry	In DATAWxSyUM, DATAWxSyMU, DATAWxSyML, and DATAWxSyLM, x denotes the way, y denotes the set, and the final two letters identify the word: UM (uppermost), MU (mid-upper), ML (mid-lower), and LM (lowermost).	For data entry way 1, set 3, DATAW1S3UM represents bits [127:96], DATAW1S3MU represents bits [95:64], DATAW1S3ML represents bits [63:32], and DATAW1S3LM represents bits [31:0].

FMC_PFAPR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 M7PFD	Master 7 Prefetch Disable These bits control whether prefetching is enabled based on the logical number of the requesting crossbar switch master. This field is further qualified by the PFBnCR[BxDPE,BxIPE] bits (where n is either "01" or "23" text). 0 Prefetching for this master is enabled. 1 Prefetching for this master is disabled.

32.5.2 Flash Bank 0-1 Control Register (FMC_PFB01CR)

- In FlexMemory mode, where flash memory banks 0, 1, and 2 are used for program flash and flash memory bank 3 is used for FlexNVM, the FMC_PFB01CR register controls the operation of flash memory banks 0, 1, and 2 (all program flash).
- In Program Flash Only mode, where flash memory banks 0, 1, 2, and 3 are used for program flash, the FMC_PFB01CR register controls the operation of flash memory banks 0 and 1.

Address: 4001_F000h base + 4h offset = 4001_F004h

FMC_PFB01CR field descriptions

Field	Description
31–28 B0RWSC[3:0]	Bank 0 Read Wait State Control This read-only field defines the number of wait states required to access bank 0 flash memory. The relationship between the read access time of the flash array (expressed in system clock cycles) and RWSC is defined as: Access time of flash array [system clocks] = RWSC + 1 The FMC automatically calculates this value based on the ratio of the system clock speed to the flash clock speed. For example, when this ratio is 4:1, the field's value is 3h.

Table continues on the next page...

FMC_PFB01CR field descriptions (continued)

Field	Description
27–24 CLKK_WAY[3:0]	Cache Lock Way x These bits determine if the given cache way is locked such that its contents will not be displaced by future misses. The bit setting definitions are for each bit in the field. 0 Cache way is unlocked and may be displaced 1 Cache way is locked and its contents are not displaced
23–20 CINV_WAY[3:0]	Cache Invalidate Way x These bits determine if the given cache way is to be invalidated (cleared). When a bit within this field is written, the corresponding cache way is immediately invalidated: the way's tag, data, and valid contents are cleared. This field always reads as zero. Cache invalidation takes precedence over locking. The cache is invalidated by system reset. System software is required to maintain memory coherency when any segment of the flash memory is programmed or erased. Accordingly, cache invalidations must occur after a programming or erase event is completed and before the new memory image is accessed. The bit setting definitions are for each bit in the field. 0 No cache way invalidation for the corresponding cache 1 Invalidate cache way for the corresponding cache: clear the tag, data, and vld bits of ways selected
19 S_B_INV	Invalidate Prefetch Speculation Buffer This bit determines if the FMC's prefetch speculation buffer is to be invalidated (cleared). When this bit is written, the speculation buffer is immediately cleared. This bit always reads as zero. 0 Speculation buffer is not affected 1 Invalidate (clear) speculation buffer
18–17 BOMW[1:0]	Bank 0 Memory Width This read-only field defines the width of bank 0 memory. 00 32 bits 01 64 bits 10 128 bits 11 Reserved
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–5 CRC[2:0]	Cache Replacement Control This 3-bit field defines the replacement algorithm for accesses that are cached. 000 LRU replacement algorithm per set across all four ways 001 Reserved 010 Independent LRU with ways [0-1] for ifetches, [2-3] for data 011 Independent LRU with ways [0-2] for ifetches, [3] for data 1xx Reserved

Field	Description
4 B0DCE	Bank 0 Data Cache Enable This bit controls whether data references are loaded into the cache. 0 Do not cache data references. 1 Cache data references.
3 B0ICE	Bank 0 Instruction Cache Enable This bit controls whether instruction fetches are loaded into the cache. 0 Do not cache instruction fetches. 1 Cache instruction fetches.
2 B0DPE	Bank 0 Data Prefetch Enable This bit controls whether prefetches (or speculative accesses) are initiated in response to data references. 0 Do not prefetch in response to data references. 1 Enable prefetches in response to data references.
1 B0IPE	Bank 0 Instruction Prefetch Enable This bit controls whether prefetches (or speculative accesses) are initiated in response to instruction fetches. 0 Do not prefetch in response to instruction fetches. 1 Enable prefetches in response to instruction fetches.
0 RFU	Reserved for future use

32.5.3 Flash Bank 2-3 Control Register (FMC_PFB23CR)

The PFB23CR register has a format similar to the PFB01CR register, except that PFB23CR's "global" cache control fields are empty.

- In FlexMemory mode, where flash memory banks 0, 1, and 2 are used for program flash and flash memory bank 3 is used for FlexNVM, the FMC_PFB23CR register controls the operation of flash memory bank 3 (FlexNVM).
- In Program Flash Only mode, where flash memory banks 0, 1, 2, and 3 are used for program flash, the PFB23CR register controls the operation of flash memory banks 2 and 3.

32.6 Functional description

The FMC is a flash acceleration unit with flexible buffers for user configuration. In addition to managing the interface between the device, flash memory and FlexMemory, the FMC can be used to restrict access from crossbar switch masters, and to customize the cache and buffers to provide single-cycle system-clock data-access times. Whenever a hit occurs for the prefetch speculation buffer or the cache, the requested data is transferred within a single system clock.

Upon system reset, the FMC is configured to provide a significant level of buffering for transfers from the flash memory or FlexMemory:

- Crossbar masters 0-2 have read access to program flash memory and FlexNVM *that is used as data flash memory*.
- Crossbar masters 0-2 have read and write access to FlexRAM.
- Prefetch support for data and instructions is enabled for crossbar masters 0-2.
- The cache is configured for least recently used (LRU) replacement for all 4 ways.
- The cache is configured for data or instruction replacement.

Although the default configuration provides a high degree of flash acceleration, advanced users may desire to customize the FMC buffer configurations to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory or FlexMemory is being accessed. Instead, change the control registers with a routine executing from RAM in supervisor mode.

The FMC's cache and buffering controls within PFB01CR and PFB23CR enable you to tune resources to meet specific application needs. The cache and speculation buffer are each controlled individually. The register controls enable buffering and prefetching per memory bank group (in FlexMem mode: PFB01CR for banks 0-2 and PFB23CR for bank 3; in Program Flash Only mode: PFB01CR for banks 0-1 and PFB23CR for banks 2-3) and access type (instruction fetch or data reference). The cache also supports 3 types of LRU replacement algorithms:

- LRU per set across all 4 ways.
- LRU with ways [0-1] for instruction fetches and ways [2-3] for data fetches.
- LRU with ways [0-2] for instruction fetches and way [3] for data fetches.

As an application example: if both instruction fetches and data references are accessing banks 0-1, then control is available to send instruction fetches, data references (or both instruction fetches and data references) to the cache. Likewise, speculation can be

enabled or disabled for either type of access. If both instruction fetches and data references are cached, then the cache's way resources may be divided in several ways between the instruction fetches and data references.

32.7 Initialization and application information

The FMC does not require user initialization; flash acceleration features are enabled by default. However, you can modify the FMC acceleration features if desired; see the FMC Functional Description for details.

The FMC has no visibility into flash memory erase and program cycles, because the Flash Memory module manages them (the flash memory erase and program cycles) directly. As a result, if an application is executing flash memory commands, then the FMC's cache might need to be disabled and/or flushed, to prevent the possibility of returning stale data. Use the PFB01CR[CINV_WAY] field to invalidate the FMC cache in this manner.

Chapter 33

Flash Memory Module (FTFE)

33.1 Introduction

The FTFE module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- Programming acceleration RAM to speed flash programming

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The FTFE module includes a memory controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased with security disabled. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0') states. Therefore, it is recommended that each flash block or sector be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

33.1.1 Features

The FTFE module includes the following features.

NOTE

See Memories and Memory Interfaces chapter for the exact amount of flash memory available on your device.

33.1.1.1 Program Flash Memory Features

- Sector size of 4 Kbytes
- Program flash protection scheme prevents accidental program or erase of stored data
- Program flash access control scheme prevents unauthorized access to selected code segments
- Automated, built-in, program and erase algorithms with verify
- Section programming for faster bulk programming times
- Read access to one program flash block is possible while programming or erasing data in another program flash block

33.1.1.2 Programming Acceleration RAM features

- RAM to support section programming

33.1.1.3 Other FTFE module features

- Internal high-voltage supply generator for flash memory program and erase operations
- Optional interrupt generation upon flash command completion
- Supports MCU security mechanisms which prevent unauthorized access to the flash memory contents

33.1.2 Block diagram

The block diagram of the FTFE module is shown in the following figure.

Figure 33-1. FTFE block diagram

33.1.3 Glossary

Command write sequence — A series of MCU writes to the Flash FCCOB register group that initiates and controls the execution of Flash algorithms that are built into the FTFE module.

Endurance — The number of times that a flash memory location can be erased and reprogrammed.

FCCOB (Flash Common Command Object) — A group of flash registers that are used to pass command, address, data, and any associated parameters to the memory controller in the FTFE module.

Flash block — A macro within the FTFE module which provides the nonvolatile memory storage.

FTFE Module — All flash blocks plus a flash management unit providing high-level control and an interface to MCU buses.

HSRUN — An MCU power mode enabling high-speed access to the memory resources in the FTFE module. The user has no access to the Flash command set when the MCU is in HSRUN mode.

IFR — Nonvolatile information register found in each flash block, separate from the main memory array.

NVM — Nonvolatile memory. A memory technology that maintains stored data during power-off. The flash array is an NVM using NOR-type flash memory technology.

NVM Normal Mode — An NVM mode that provides basic user access to FTFE resources. The CPU or other bus masters initiate flash program and erase operations (or other flash commands) using writes to the FCCOB register group in the FTFE module.

Double-Phrase — 128 bits of data with an aligned double-phrase having byte-address[3:0] = 0000.

Phrase — 64 bits of data with an aligned phrase having byte-address[2:0] = 000.

Longword — 32 bits of data with an aligned longword having byte-address[1:0] = 00.

Word — 16 bits of data with an aligned word having byte-address[0] = 0.

Program flash — The program flash memory provides nonvolatile storage for vectors and code store.

Program flash sector — The smallest portion of the program flash memory (consecutive addresses) that can be erased.

Retention — The length of time that data can be kept in the NVM without experiencing errors upon readout. Since erased (1) states are subject to degradation just like programmed (0) states, the data retention limit may be reached from the last erase operation (not from the programming time).

RWW— Read-While-Write. The ability to simultaneously read from one memory resource while commanded operations are active in another memory resource.

Section program buffer — Lower quarter of the programming acceleration RAM allocated for storing large amounts of data for programming via the Program Section command.

Secure — An MCU state conveyed to the FTFE module as described in the Chip Configuration details for this device. In the secure state, reading and changing NVM contents is restricted.

33.2 External signal description

The FTFE module contains no signals that connect off-chip.

33.3 Memory map and registers

This section describes the memory map and registers for the FTFE module. Data read from unimplemented memory space in the FTFE module is undefined. Writes to unimplemented or reserved memory space (registers) in the FTFE module are ignored.

33.3.1 Flash configuration field description

The program flash memory contains a 16-byte flash configuration field that stores default protection settings (loaded on reset) and security information that allows the MCU to restrict access to the FTFE module.

NOTE

The flash configuration field offset addresses are relative byte addresses. Check your device specific memory map for the location of the program flash memory.

Flash Configuration Field Offset Address	Size (Bytes)	Field Description
0x0_0400 - 0x0_0407	8	Backdoor Comparison Key. Refer to Verify Backdoor Access Key command and Unsecuring the MCU Using Backdoor Key Access .
0x0_0408 - 0x0_040B	4	Program flash protection bytes. Refer to the description of the Program Flash Protection Registers (FPROT0-3).
0x0_040F	1	Reserved
0x0_040E	1	Reserved
0x0_040D	1	Flash nonvolatile option byte. Refer to the description of the Flash Option Register (FOPT).
0x0_040C	1	Flash security byte. Refer to the description of the Flash Security Register (FSEC).

33.3.2 Program flash 0 IFR map

The program flash 0 IFR is a 1 Kbyte nonvolatile information memory that can be read freely, but the user has no erase and limited program capabilities (see the Read Once, Program Once, and Read Resource commands in [Read Once Command](#), [Program Once command](#) and [Read Resource Command](#)). The contents of the program flash 0 IFR are summarized in the following table and further described in the subsequent paragraphs.

The program flash 0 IFR is located within the program flash 0 memory block.

Address Range	Size (Bytes)	Field Description
0x000 – 0x39F	928	Reserved
0x3A0 – 0x3A3	4	Program Once XACCH-1 Field (index = 0x08)
0x3A4 – 0x3A7	4	Program Once XACCL-1 Field (index = 0x08)
0x3A8 – 0x3AB	4	Program Once XACCH-2 Field (index = 0x09)
0x3AC – 0x3AF	4	Program Once XACCL-2 Field (index = 0x09)
0x3B0 – 0x3B3	4	Program Once SACCH-1 Field (index = 0x0A)
0x3B4 – 0x3B7	4	Program Once SACCL-1 Field (index = 0x0A)
0x3B8 – 0x3BB	4	Program Once SACCH-2 Field (index = 0x0B)
0x3BC – 0x3BF	4	Program Once SACCL-2 Field (index = 0x0B)
0x3C0 – 0x3FF	64	Program Once ID Field (index = 0x00 - 0x07)

33.3.2.1 Program Once field

The Program Once field in the program flash 0 IFR provides 96 bytes of user data storage separate from the program flash 0 main array. The user can program the Program Once field one time only as there is no program flash IFR erase mechanism available to the user. The Program Once field can be read any number of times. This section of the program flash 0 IFR is accessed in 8 byte records using the Read Once and Program Once commands (see [Read Once Command](#) and [Program Once command](#)).

33.3.3 Register descriptions

The FTFE module contains a set of memory-mapped control and status registers.

NOTE

While a command is running (FSTAT[CCIF]=0), register writes are not accepted to any register except FCNFG and FSTAT. The no-write rule is relaxed during the start-up reset sequence, prior to the initial rise of CCIF. During this initialization period the user may write any register. All register writes are also disabled (except for registers FCNFG and

FSTAT) whenever an erase suspend request is active (FCNFG[ERSSUSP]=1).

33.3.3.1 Flash Status Register (FTFE_FSTAT)

The FSTAT register reports the operational status of the FTFE module.

The CCIF, RDCOLERR, ACCERR, and FPVIOL bits are readable and writable. The MGSTAT0 bit is read only. The unassigned bits read 0 and are not writable.

NOTE

When set, the Access Error (ACCERR) and Flash Protection Violation (FPVIOL) bits in this register prevent the launch of any more commands until the flag is cleared (by writing a one to it).

Address: 4002_0000h base + 0h offset = 4002_0000h

Bit	7	6	5	4	3	2	1	0
Read	CCIF	RDCOLERR	ACCERR	FPVIOL	0			MGSTAT0
Write	w1c	w1c	w1c	w1c				
Reset	0	0	0	0	0	0	0	0

FTFE_FSTAT field descriptions

Field	Description
7 CCIF	Command Complete Interrupt Flag The CCIF flag indicates that a FTFE command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command, and CCIF stays low until command completion or command violation. The CCIF bit is reset to 0 but is set to 1 by the memory controller at the end of the reset initialization sequence. Depending on how quickly the read occurs after reset release, the user may or may not see the 0 hardware reset value. 0 FTFE command in progress 1 FTFE command has completed
6 RDCOLERR	FTFE Read Collision Error Flag The RDCOLERR error bit indicates that the MCU attempted a read from an FTFE resource that was being manipulated by an FTFE command (CCIF=0). Any simultaneous access is detected as a collision error by the block arbitration logic. The read data in this case cannot be guaranteed. The RDCOLERR bit is cleared by writing a 1 to it. Writing a 0 to RDCOLERR has no effect. 0 No collision error detected 1 Collision error detected
5 ACCERR	Flash Access Error Flag The ACCERR error bit indicates an illegal access has occurred to an FTFE resource caused by a violation of the command write sequence or issuing an illegal FTFE command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR bit has no effect. 0 No access error detected 1 Access error detected
4 FPVIOL	Flash Protection Violation Flag The FPVIOL error bit indicates an attempt was made to program or erase an address in a protected area of program flash memory during a command write sequence. While FPVIOL is set, the CCIF flag cannot be cleared to launch a command. The FPVIOL bit is cleared by writing a 1 to FPVIOL while CCIF is set. Writing a 0 to the FPVIOL bit has no effect. 0 No protection violation detected 1 Protection violation detected

Table continues on the next page...

FTFE_FSTAT field descriptions (continued)

Field	Description
3–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 MGSTAT0	Memory Controller Command Completion Status Flag The MGSTAT0 status flag is set if an error is detected during execution of an FTFE command or during the flash reset sequence. As a status flag, this bit cannot (and need not) be cleared by the user like the other error flags in this register. The value of the MGSTAT0 bit for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the previous result is discarded and any previous error is cleared.

33.3.3.2 Flash Configuration Register (FTFE_FCNFG)

This register provides information on the current functional state of the FTFE module.

The erase control bits (ERSAREQ and ERSSUSP) have write restrictions. SWAP, PFLSH, RAMRDY, and EEERDY are read-only status bits. The reset values for the SWAP, PFLSH, RAMRDY, and EEERDY bits are determined during the reset sequence.

Address: 4002_0000h base + 1h offset = 4002_0001h

Bit	7	6	5	4	3	2	1	0
Read	CCIE	RDCOLLIE	ERSAREQ	ERSSUSP	SWAP	PFLSH	RAMRDY	EEERDY
Write								
Reset	0	0	0	0	0	1	1	0

FTFE_FCNFG field descriptions

Field	Description
7 CCIE	Command Complete Interrupt Enable The CCIE bit controls interrupt generation when an FTFE command completes. 0 Command complete interrupt disabled 1 Command complete interrupt enabled. An interrupt request is generated whenever the FSTAT[CCIF] flag is set.
6 RDCOLLIE	Read Collision Error Interrupt Enable The RDCOLLIE bit controls interrupt generation when an FTFE read collision error occurs. 0 Read collision error interrupt disabled 1 Read collision error interrupt enabled. An interrupt request is generated whenever an FTFE read collision error is detected (see the description of FSTAT[RDCOLERR]).
5 ERSAREQ	Erase All Request

Table continues on the next page...

FTFE_FCNFG field descriptions (continued)

Field	Description
	This bit issues a request to the memory controller to execute the Erase All Blocks command and release security. ERSAREQ is not directly writable but is under indirect user control. Refer to the device's Chip Configuration details on how to request this command. The ERSAREQ bit sets when an erase all request is triggered external to the FTFE and CCIF is set (no command is currently being executed). ERSAREQ is cleared by the FTFE when the operation completes. 0 No request or request complete 1 Request to: 1. run the Erase All Blocks command, 2. verify the erased state, 3. program the security byte in the Flash Configuration Field to the unsecure state, and 4. release MCU security by setting the FSEC[SEC] field to the unsecure state
4 ERSSUSP	Erase Suspend The ERSSUSP bit allows the user to suspend (interrupt) the Erase Flash Sector command while it is executing. 0 No suspend requested 1 Suspend the current Erase Flash Sector command execution
3 SWAP	Swap The SWAP flag indicates which half of the program flash space is located at relative address 0x0000. The state of the SWAP flag is set by the FTFE during the reset sequence. See for information on swap management. 0 Program flash 0/1 blocks are located at relative address 0x0000 1 Program flash 2/3 blocks are located at relative address 0x0000
2 PFLSH	This bit is reserved and always has the value 1.
1 RAMRDY	RAM Ready This flag indicates the current status of the programming acceleration RAM. This bit should always be set. 0 Programming acceleration RAM is not available 1 Programming acceleration RAM is available
0 EEERDY	This bit is reserved and always has the value 0. 0 See RAMRDY for availability of programming acceleration RAM 1 Reserved

33.3.3.3 Flash Security Register (FTFE_FSEC)

This read-only register holds all bits associated with the security of the MCU and FTFE module.

Memory map and registers

During the reset sequence, the register is loaded with the contents of the flash security byte in the Flash Configuration Field located in program flash memory. The Flash basis for the values is signified by X in the reset value.

Address: 4002_0000h base + 2h offset = 4002_0002h

Bit	7	6	5	4	3	2	1	0
Read	KEYEN		MEEN		FSLACC		SEC	
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

FTFE_FSEC field descriptions

Field	Description
7–6 KEYEN	Backdoor Key Security Enable These bits enable and disable backdoor key access to the FTFE module. 00 Backdoor key access disabled 01 Backdoor key access disabled (preferred KEYEN state to disable backdoor key access) 10 Backdoor key access enabled 11 Backdoor key access disabled
5–4 MEEN	Mass Erase Enable Bits Enables and disables mass erase capability of the FTFE module. When the SEC field is set to unsecure, the MEEN setting does not matter. 00 Mass erase is enabled 01 Mass erase is enabled 10 Mass erase is disabled 11 Mass erase is enabled
3–2 FSLACC	Factory Security Level Access Code These bits enable or disable access to the flash memory contents during returned part failure analysis at NXP. When SEC is secure and FSLACC is denied, access to the program flash contents is denied and any failure analysis performed by NXP factory test must begin with a full erase to unsecure the part. When access is granted (SEC is unsecure, or SEC is secure and FSLACC is granted), NXP factory testing has visibility of the current flash contents. The state of the FSLACC bits is only relevant when the SEC bits are set to secure. When the SEC field is set to unsecure, the FSLACC setting does not matter. 00 Factory access granted 01 Factory access denied 10 Factory access denied 11 Factory access granted
SEC	Flash Security These bits define the security state of the MCU. In the secure state, the MCU limits access to FTFE module resources. The limitations are defined per device and are detailed in the Chip Configuration details. If the FTFE module is unsecured using backdoor key access, the SEC bits are forced to 10b.

Table continues on the next page...

FTFE_FSEC field descriptions (continued)

Field	Description
00	MCU security status is secure
01	MCU security status is secure
10	MCU security status is unsecure (The standard shipping condition of the FTFE is unsecure.)
11	MCU security status is secure

33.3.3.4 Flash Option Register (FTFE_FOPT)

The flash option register allows the MCU to customize its operations by examining the state of these read-only bits, which are loaded from NVM at reset. The function of the bits is defined in the device's Chip Configuration details.

All bits in the register are read-only.

During the reset sequence, the register is loaded from the flash nonvolatile option byte in the Flash Configuration Field located in program flash memory. The flash basis for the values is signified by X in the reset value.

Address: 4002_0000h base + 3h offset = 4002_0003h

Bit	7	6	5	4	3	2	1	0
Read	OPT							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

FTFE_FOPT field descriptions

Field	Description
OPT	Nonvolatile Option These bits are loaded from flash to this register at reset. Refer to the device's Chip Configuration details for the definition and use of these bits.

33.3.3.5 Flash Common Command Object Registers (FTFE_FCCOBn)

The FCCOB register group provides 12 bytes for command codes and parameters. The individual bytes within the set append a 0-B hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOBB.

Address: 4002_0000h base + 4h offset + (1d × i), where i=0d to 11d

Bit	7	6	5	4	3	2	1	0
Read	CCOBn							
Write								
Reset	0	0	0	0	0	0	0	0

FTFE_FCCOBn field descriptions

Field	Description																										
CCOBn	The FCCOB register provides a command code and relevant parameters to the memory controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command's execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes. Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1 by the memory controller. The following table shows a generic FTFE command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific FTFE command, typically an address and/or data values. NOTE: The command parameter table is written in terms of FCCOB Number (which is equivalent to the byte number). This number is a reference to the FCCOB register name and is not the register address. <table border="1"> <thead> <tr> <th>FCCOB Number¹</th><th>Typical Command Parameter Contents [7:0]</th></tr> </thead> <tbody> <tr> <td>0</td><td>FCMD (a code that defines the FTFE command)</td></tr> <tr> <td>1</td><td>Flash address [23:16]</td></tr> <tr> <td>2</td><td>Flash address [15:8]</td></tr> <tr> <td>3</td><td>Flash address [7:0]</td></tr> <tr> <td>4</td><td>Data Byte 0</td></tr> <tr> <td>5</td><td>Data Byte 1</td></tr> <tr> <td>6</td><td>Data Byte 2</td></tr> <tr> <td>7</td><td>Data Byte 3</td></tr> <tr> <td>8</td><td>Data Byte 4</td></tr> <tr> <td>9</td><td>Data Byte 5</td></tr> <tr> <td>A</td><td>Data Byte 6</td></tr> <tr> <td>B</td><td>Data Byte 7</td></tr> </tbody> </table>	FCCOB Number ¹	Typical Command Parameter Contents [7:0]	0	FCMD (a code that defines the FTFE command)	1	Flash address [23:16]	2	Flash address [15:8]	3	Flash address [7:0]	4	Data Byte 0	5	Data Byte 1	6	Data Byte 2	7	Data Byte 3	8	Data Byte 4	9	Data Byte 5	A	Data Byte 6	B	Data Byte 7

FTFE_FCCOB_n field descriptions (continued)

Field	Description
	FCCOB Endianness and Multi-Byte Access: The FCCOB register group uses a big endian addressing convention. For all command parameter fields larger than 1 byte, the most significant data resides in the lowest FCCOB register number. The FCCOB register group may be read and written as individual bytes, aligned words (2 bytes) or aligned longwords (4 bytes).

1. Refers to FCCOB register name, not register address

33.3.3.6 Program Flash Protection Registers (FTFE_FPROT_n)

The FPROT registers define which program flash regions are protected from program and erase operations. Protected flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any FTFE command.

Unprotected regions can be changed by program and erase operations.

The four FPROT registers allow up to 32 protectable regions of equal memory size.

Program flash protection register	Program flash protection bits
FPROT0	PROT[31:24]
FPROT1	PROT[23:16]
FPROT2	PROT[15:8]
FPROT3	PROT[7:0]

During the reset sequence, the FPROT registers are loaded with the contents of the program flash protection bytes in the Flash Configuration Field as indicated in the following table.

Program flash protection register	Flash Configuration Field offset address
FPROT0	0x000B
FPROT1	0x000A
FPROT2	0x0009
FPROT3	0x0008

To change the program flash protection that is loaded during the reset sequence, unprotect the sector of program flash memory that contains the Flash Configuration Field. Then, reprogram the program flash protection byte.

Memory map and registers

Address: 4002_0000h base + 10h offset + (1d × i), where i=0d to 3d

* Notes:

- x = Undefined at reset.

FTFE_FPROTn field descriptions

Field	Description
PROT	Program Flash Region Protect Each program flash region can be protected from program and erase operations by setting the associated PROT bit to the protected state. The protection can only be increased, meaning that currently unprotected memory can be protected, but currently protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FPROT bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored. Restriction: The user must never write to any FPROT register while a command is running (CCIF=0). Trying to alter data in any protected area in the program flash memory results in a protection violation error and sets the FSTAT[FPVIOL] bit. A full block erase of a program flash block is not possible if it contains any protected region. 0 Program flash region is protected. 1 Program flash region is not protected

33.3.3.7 Execute-only Access Registers (FTFE_XACCn)

The XACC registers define which program flash segments are restricted to data read or execute only or both data and instruction fetches.

The eight XACC registers allow up to 64 restricted segments of equal memory size.

Execute-only access register	Program flash execute-only access bits
XACCH0	XA[63:56]
XACCH1	XA[55:48]
XACCH2	XA[47:40]
XACCH3	XA[39:32]
XACCL0	XA[31:24]
XACCL1	XA[23:16]
XACCL2	XA[15:8]
XACCL3	XA[7:0]

During the reset sequence, the XACC registers are loaded with the logical AND of Program Flash IFR addresses A and B as indicated in the following table.

Execute-only access register	Program Flash IFR address A	Program Flash IFR address B
XACCH0	0x03A3	0x03AB
XACCH1	0x03A2	0x03AA
XACCH2	0x03A1	0x03A9
XACCH3	0x03A0	0x03A8
XACCL0	0x03A7	0x03AF
XACCL1	0x03A6	0x03AE
XACCL2	0x03A5	0x03AD
XACCL3	0x03A4	0x03AC

Use the Program Once command to program the execute-only access control fields that are loaded during the reset sequence.

Address: 4002_0000h base + 18h offset + (1d × i), where i=0d to 7d

Bit	7	6	5	4	3	2	1	0
Read	XA							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

FTFE_XACC_n field descriptions

Field	Description
XA	Execute-only access control 0 Associated segment is accessible in execute mode only (as an instruction fetch) 1 Associated segment is accessible as data or in execute mode

33.3.3.8 Supervisor-only Access Registers (FTFE_SACC_n)

The SACC registers define which program flash segments are restricted to supervisor only or user and supervisor access.

The eight SACC registers allow up to 64 restricted segments of equal memory size.

Supervisor-only access register	Program flash supervisor-only access bits
SACCH0	SA[63:56]
SACCH1	SA[55:48]

Table continues on the next page...

Memory map and registers

Supervisor-only access register	Program flash supervisor-only access bits
SACCH2	SA[47:40]
SACCH3	SA[39:32]
SACCL0	SA[31:24]
SACCL1	SA[23:16]
SACCL2	SA[15:8]
SACCL3	SA[7:0]

During the reset sequence, the SACC registers are loaded with the logical AND of Program Flash IFR addresses A and B as indicated in the following table.

Supervisor-only access register	Program Flash IFR address A	Program Flash IFR address B
SACCH0	0x03B3	0x03BB
SACCH1	0x03B2	0x03BA
SACCH2	0x03B1	0x03B9
SACCH3	0x03B0	0x03B8
SACCL0	0x03B7	0x03BF
SACCL1	0x03B6	0x03BE
SACCL2	0x03B5	0x03BD
SACCL3	0x03B4	0x03BC

Use the Program Once command to program the supervisor-only access control fields that are loaded during the reset sequence.

Address: 4002_0000h base + 20h offset + (1d × i), where i=0d to 7d

Bit	7	6	5	4	3	2	1	0
Read	SA							
Write

* Notes:

- x = Undefined at reset.

FTFE_SACCN field descriptions

Field	Description
SA	Supervisor-only access control
0	Associated segment is accessible in supervisor mode only
1	Associated segment is accessible in user or supervisor mode

33.3.3.9 Flash Access Segment Size Register (FTFE_FACSS)

The flash access segment size register determines which bits in the address are used to index into the SACC and XACC bitmaps to get the appropriate permission flags.

All bits in the register are read-only.

The contents of this register are loaded during the reset sequence.

Address: 4002_0000h base + 28h offset = 4002_0028h

* Notes:

- x = Undefined at reset.

FTFE_FACSS field descriptions

Field	Description																					
SGSIZE	Segment Size																					
	The segment size is a fixed value based on the available program flash size divided by NUMSG.																					
	<table><tr><th>Program Flash Size</th><th>Segment Size</th><th>Segment Size Encoding</th></tr><tr><td>256 KBytes</td><td>4 KBytes</td><td>0x4</td></tr><tr><td>512 KBytes</td><td>8 KBytes</td><td>0x5</td></tr><tr><td>768 KBytes</td><td>16 KBytes</td><td>0x6</td></tr><tr><td>1 MByte</td><td>16 KBytes</td><td>0x6</td></tr><tr><td>1.5 MBytes</td><td>32 KBytes</td><td>0x7</td></tr><tr><td>2 MBytes</td><td>32 KBytes</td><td>0x7</td></tr></table>	Program Flash Size	Segment Size	Segment Size Encoding	256 KBytes	4 KBytes	0x4	512 KBytes	8 KBytes	0x5	768 KBytes	16 KBytes	0x6	1 MByte	16 KBytes	0x6	1.5 MBytes	32 KBytes	0x7	2 MBytes	32 KBytes	0x7
	Program Flash Size	Segment Size	Segment Size Encoding																			
	256 KBytes	4 KBytes	0x4																			
	512 KBytes	8 KBytes	0x5																			
	768 KBytes	16 KBytes	0x6																			
	1 MByte	16 KBytes	0x6																			
	1.5 MBytes	32 KBytes	0x7																			
2 MBytes	32 KBytes	0x7																				

33.3.3.10 Flash Access Segment Number Register (FTFE_FACSN)

The flash access segment number register provides the number of program flash segments that are available for XACC and SACC permissions.

All bits in the register are read-only.

The contents of this register are loaded during the reset sequence.

Functional Description

Address: 4002_0000h base + 2Bh offset = 4002_002Bh

* Notes:

- x = Undefined at reset.

FTFE_FACSN field descriptions

Field	Description
NUMSG	Number of Segments Indicator The NUMSG field indicates the number of equal-sized segments in the program flash. 0x30 Program flash memory is divided into 48 segments (768 Kbytes, 1.5 Mbytes) 0x40 Program flash memory is divided into 64 segments (256 Kbytes, 512 Kbytes, 1 Mbyte, 2 Mbytes)

33.4 Functional Description

The following sections describe functional details of the FTFE module.

33.4.1 Program flash memory swap

The user can configure the memory map of the program flash space such that either half of the program flash memory can exist at relative address 0x0000. This swap feature enables the lower half of the program flash space to be operational while the upper half is being updated for future use.

The Swap Control command handles swapping the two halves of program flash memory within the memory map. See [Swap Control command](#) for details.

33.4.2 Flash Protection

Individual regions within the flash memory can be protected from program and erase operations. Protection is controlled by the following registers:

- FPROT_n — Four registers protect 32 regions of the program flash memory as shown in the following figure

Figure 33-2. Program flash protection

NOTE

Flash protection features are discussed further in [AN4507: Using the Kinetis Security and Flash Protection Features](#). Some features described in the application note may not be available on this device.

33.4.3 Flash Access Protection

Individual segments within the program flash memory can be designated for restricted access. Specific flash commands (Program Check, Program Phrase, Erase Flash Block, Erase Flash Sector) monitor FXACC contents to protect flash memory but the FSACC contents do not impact flash command operation.

See [AN5112: Using the Kinetis Flash Execute-Only Access Control Feature](#) for further details.

Access is controlled by the following registers:

- FXACC —
 - For 2^n program flash sizes, eight registers control 64 segments of the program flash memory as shown in the following figure

Figure 33-3. Program flash execute-only access control (512KB, 1MB, or 2MB of program flash)

- FSACC —
 - For 2^n program flash sizes, eight registers control 64 segments of the program flash memory as shown in the following figure

Figure 33-4. Program flash supervisor access control (512KB, 1MB, or 2MB of program flash)

33.4.4 Interrupts

The FTFE module can generate interrupt requests to the MCU upon the occurrence of various FTFE events. These interrupt events and their associated status and control bits are shown in the following table.

Table 33-1. FTFE Interrupt Sources

FTFE Event	Readable Status Bit	Interrupt Enable Bit
FTFE Command Complete	FSTAT[CCIF]	FCNFG[CCIE]
FTFE Read Collision Error	FSTAT[RDCOLERR]	FCNFG[RDCOLLIE]

Note

Vector addresses and their relative interrupt priority are determined at the MCU level.

33.4.5 Flash Operation in Low-Power Modes

33.4.5.1 Wait Mode

When the MCU enters wait mode, the FTFE module is not affected. The FTFE module can recover the MCU from wait via the command complete interrupt (see [Interrupts](#)).

33.4.5.2 Stop Mode

When the MCU requests stop mode, if an FTFE command is active (CCIF = 0) the command execution completes before the MCU is allowed to enter stop mode.

CAUTION

The MCU should never enter stop mode while any FTFE command is running (CCIF = 0).

NOTE

While the MCU is in very-low-power modes (VLPR, VLPW, VLPS), the FTFE module does not accept flash commands.

33.4.6 Flash memory reads and ignored writes

The FTFE module requires only the flash address to execute a flash memory read. MCU read access is available to all flash memory.

The MCU must not read from the flash memory while commands are running (as evidenced by CCIF=0) on that block. Read data cannot be guaranteed from a flash block while any command is processing within that block. The block arbitration logic detects any simultaneous access and reports this as a read collision error (see the FSTAT[RDCOLERR] bit).

33.4.7 Read while write (RWW)

The following simultaneous accesses are allowed:

- The user may read from one program flash memory block while commands are active in the other program flash memory block.

Simultaneous operations are further discussed in [Allowed simultaneous flash operations](#).

33.4.8 Flash Program and Erase

All flash functions except read require the user to setup and launch an FTFE command through a series of peripheral bus writes. The user cannot initiate any further FTFE commands until notified that the current command has completed. The FTFE command structure and operation are detailed in [FTFE Command Operations](#).

33.4.9 FTFE Command Operations

FTFE command operations are typically used to modify flash memory contents. The next sections describe:

- The command write sequence used to set FTFE command parameters and launch execution
- A description of all FTFE commands available

33.4.9.1 Command Write Sequence

FTFE commands are specified using a command write sequence illustrated in [Figure 33-5](#). The FTFE module performs various checks on the command (FCCOB) content and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be zero and the CCIF flag must read 1 to verify that any previous command has completed. If CCIF is zero, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

Attempts to launch an FTFE command in VLP mode will be ignored. Attempts to launch an FTFE command in HSRUN mode will be trapped with the ACCERR flag being set.

33.4.9.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the desired FTFE command. The individual registers that make up the FCCOB data set can be written in any order.

33.4.9.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The CCIF flag remains zero until the FTFE command completes.

The FSTAT register contains a blocking mechanism, which prevents a new command from launching (can't clear CCIF) if the previous command resulted in an access error (FSTAT[ACCERR]=1) or a protection violation (FSTAT[FPVIOL]=1). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write clears the error flags, the second write clears CCIF.

33.4.9.1.3 Command Execution and Error Reporting

The command processing has several steps:

1. The FTFE reads the command code and performs a series of parameter checks and protection checks, if applicable, which are unique to each command.

If the parameter check fails, the FSTAT[ACCERR] (access error) flag is set. ACCERR reports invalid instruction codes and out-of bounds addresses. Usually, access errors suggest that the command was not set-up with valid parameters in the FCCOB register group.

Program and erase commands also check the address to determine if the operation is requested to execute on protected areas. If the protection check fails, the FSTAT[FPVIOL] (protection error) flag is set.

Command processing never proceeds to execution when the parameter or protection step fails. Instead, command processing is terminated after setting the FSTAT[CCIF] bit.

2. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to erase verify, may occur during the execution phase. Run-time errors are reported in the FSTAT[MGSTAT0] bit. A command may have access errors, protection errors, and run-time errors, but the run-time errors are not seen until all access and protection errors have been corrected.
3. Command execution results, if applicable, are reported back to the user via the FCCOB and FSTAT registers.
4. The FTFE sets the FSTAT[CCIF] bit signifying that the command has completed.

The flow for a generic command write sequence is illustrated in the following figure.

Figure 33-5. Generic Flash Command Write Sequence Flowchart

33.4.9.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

FCMD	Command	Program flash 0	Program flash 1	Program flash 2	Program flash 3	Function
0x00	Read 1s Block	x	x	x	x	Verify that a program flash block is erased.

Table continues on the next page...

Functional Description

FCMD	Command	Program flash 0	Program flash 1	Program flash 2	Program flash 3	Function
0x01	Read 1s Section	x	x	x	x	Verify that a given number of program flash locations from a starting address are erased.
0x02	Program Check	x	x	x	x	Tests previously-programmed phrases at margin read levels.
0x03	Read Resource	IFR,ID	IFR	IFR	IFR	Read 8 bytes from program flash IFR or version ID.
0x07	Program Phrase	x	x	x	x	Program 8 bytes in a program flash block.
0x08	Erase Flash Block	x	x	x	x	Erase a program flash block. An erase of any flash block is only possible when unprotected.
0x09	Erase Flash Sector	x	x	x	x	Erase all bytes in a program flash sector.
0x0B	Program Section	x	x	x	x	Program data from the Section Program Buffer to a program flash block.
0x40	Read 1s All Blocks	x	x	x	x	Verify that all program flash blocks are erased then release MCU security.
0x41	Read Once	IFR				Read 8 bytes of a dedicated 64 byte field in the program flash 0 IFR.
0x43	Program Once	IFR				One-time program of 8 bytes of a dedicated 64-

Table continues on the next page...

FCMD	Command	Program flash 0	Program flash 1	Program flash 2	Program flash 3	Function
						byte field in the program flash 0 IFR.
0x44	Erase All Blocks	x	x	x	x	Erase all program flash blocks, program flash swap IFR. Then, verify-erase and release MCU security. NOTE: An erase is only possible when all memory locations are unprotected.
0x45	Verify Backdoor Access Key	x		x		Release MCU security after comparing a set of user-supplied security keys to those stored in the program flash.
0x46	Swap Control	x	x	x	x	Handles swap-related activities.
0x49	Erase All Blocks Unsecure	x	x	x	x	Erase all program flash blocks, program flash swap IFR. Then, verify-erase, program the security byte to the unsecure state, and release MCU security.
0x4A	Read 1s All Execute-only Segments	x	x	x	x	Verify that all program flash execute-only (XA) segments are erased then release flash access control.
0x4B	Erase All Execute-only Segments	x	x	x	x	Erase all program flash execute-only (XA) segments then release flash access control.

33.4.9.3 Allowed simultaneous flash operations

Only the operations marked 'OK' in the following table are permitted to run simultaneously on the program flash memories. Some operations cannot be executed simultaneously because certain hardware resources are shared by the memories.

Table 33-2. Allowed Simultaneous Memory Operations

		Program flash X ¹			
		Read	Program Phrase	Erase Flash Sector	Erase Flash Block
Program flash Y ¹	Read		OK	OK	OK
	Program Phrase	OK			
	Erase Flash Sector	OK			
	Erase Flash Block	OK			

1. P-Flash X refers to any of the P-Flash blocks (0, 1, 2, 3) and P-Flash Y refers to any of the P-Flash blocks (0, 1, 2, 3), but not the same block. Thus, it is possible to read from any of the blocks while programming or erasing another.

33.4.10 Margin Read Commands

The Read-1s commands (Read 1s All Blocks, Read 1s Block, Read 1s Section, Read 1s All Execute-only Segments) and the Program Check command have a margin choice parameter that allows the user to apply non-standard read reference levels to the program flash array reads performed by these commands. Using the preset 'user' and 'factory' margin levels, these commands perform their associated read operations at tighter tolerances than a 'normal' read. These non-standard read levels are applied only during the command execution. All simple (uncommanded) flash array reads to the MCU always use the standard, un-margined, read reference level.

Only the 'normal' read level should be employed during normal flash usage. The non-standard, 'user' and 'factory' margin levels should be employed only in special cases. They can be used during special diagnostic routines to gain confidence that the device is not suffering from the end-of-life data loss customary of flash memory devices.

Erased ('1') and programmed ('0') bit states can degrade due to elapsed time and data cycling (number of times a bit is erased and re-programmed). The lifetime of the erased states is relative to the last erase operation. The lifetime of the programmed states is measured from the last program time.

The 'user' and 'factory' levels become, in effect, a minimum safety margin; i.e. if the reads pass at the tighter tolerances of the 'user' and 'factory' margins, then the 'normal' reads have at least this much safety margin before they experience data loss.

The 'user' margin is a small delta to the normal read reference level. 'User' margin levels can be employed to check that flash memory contents have adequate margin for normal level read operations. If unexpected read results are encountered when checking flash memory contents at the 'user' margin levels, loss of information might soon occur during 'normal' readout.

The 'factory' margin is a bigger deviation from the norm, a more stringent read criteria that should only be attempted immediately (or very soon) after completion of an erase or program command, early in the cycling life. 'Factory' margin levels can be used to check that flash memory contents have adequate margin for long-term data retention at the normal level setting. If unexpected results are encountered when checking flash memory contents at 'factory' margin levels, the flash memory contents should be erased and reprogrammed.

CAUTION

Factory margin levels must only be used during verify of the initial factory programming.

33.4.11 Flash command descriptions

This section describes all flash commands that can be launched by a command write sequence. The FTFE sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in a FCCOB field for the specific commands. Refer to the error handling table provided for each command.

Ensure that the ACCERR and FPVIOL bits in the FSTAT register are cleared prior to starting the command write sequence. As described in [Launch the Command by Clearing CCIF](#), a new command cannot be launched while these error flags are set.

Do not attempt to read a flash block while the FTFE is running a command (CCIF = 0) on that same block. The FTFE may return invalid data to the MCU with the collision error flag (FSTAT[RDCOLERR]) set.

CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

33.4.11.1 Read 1s Block command

The Read 1s Block command checks to see if an entire program flash block has been erased to the specified margin level. The FCCOB flash address bits determine which block is erase-verified.

Table 33-3. Read 1s Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x00 (RD1BLK)
1	Flash address [23:16] in the flash block to be verified
2	Flash address [15:8] in the flash block to be verified
3	Flash address [7:0] ¹ in the flash block to be verified
4	Read-1 Margin Choice

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

After clearing CCIF to launch the Read 1s Block command, the FTFE sets the read margin for 1s according to [Table 33-4](#) and then reads all locations within the selected program flash block.

Table 33-4. Margin Level Choices for Read 1s Block

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 33-5. Read 1s Block Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid margin choice is specified	FSTAT[ACCERR]
Program flash is selected and the address is out of program flash range	FSTAT[ACCERR]
Flash address is not 128-bit aligned	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

33.4.11.2 Read 1s Section command

The Read 1s Section command checks if a section of program flash memory is erased to the specified read margin level. The Read 1s Section command defines the starting address and the number of double-phrases to be verified.

Table 33-6. Read 1s Section Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x01 (RD1SEC)
1	Flash address [23:16] of the first double-phrase to be verified
2	Flash address [15:8] of the first double-phrase to be verified
3	Flash address [7:0] ¹ of the first double-phrase to be verified
4	Number of double-phrases to be verified [15:8]
5	Number of double-phrases to be verified [7:0]
6	Read-1 Margin Choice

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Read 1s Section command, the FTFE sets the read margin for 1s according to [Table 33-7](#) and then reads all locations within the specified section of flash memory.

If the FTFE fails to read all 1s (i.e. the flash section is not erased), the FSTAT(MGSTAT0) bit is set. The CCIF flag sets after the Read 1s Section operation completes.

Table 33-7. Margin Level Choices for Read 1s Section

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 33-8. Read 1s Section Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid margin code is supplied	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not 128-bit aligned	FSTAT[ACCERR]
The requested section crosses a flash block boundary	FSTAT[ACCERR]
The requested number of double-phrases is zero	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

33.4.11.3 Program Check command

The Program Check command tests a previously programmed program flash longword to see if it reads correctly at the specified margin level.

Table 33-9. Program Check Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x02 (PGMCHK)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Margin Choice
8	Byte 0 expected data
9	Byte 1 expected data
A	Byte 2 expected data
B	Byte 3 expected data

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Program Check command, the FTFE sets the read margin for 1s based on the provided margin choice according to [Table 33-10](#). The Program Check operation then reads the specified longword, and compares the actual read data to the expected data provided by the FCCOB. If the comparison at margin-1 fails, the MGSTAT0 bit is set.

The FTFE will then set the read margin for 0s based on the provided margin choice. The Program Check operation will then read the specified longword and compare the actual read data to the expected data provided by the FCCOB. If the comparison at margin-0 fails, the MGSTAT0 bit will be set. The CCIF flag will set after the Program Check operation has completed.

The starting address must be longword aligned (the lowest two bits of the byte address must be 00):

- Byte 0 data is expected at the supplied 32-bit aligned address,
- Byte 1 data is expected at byte address specified + 0b01,
- Byte 2 data is expected at byte address specified + 0b10, and
- Byte 3 data is expected at byte address specified + 0b11.

NOTE

See the description of margin reads, [Margin Read Commands](#)

Table 33-10. Margin Level Choices for Program Check

Read Margin Choice	Margin Level Description
0x01	Read at 'User' margin-1 and 'User' margin-0
0x02	Read at 'Factory' margin-1 and 'Factory' margin-0

Table 33-11. Program Check Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
An invalid margin choice is supplied	FSTAT[ACCERR]
Flash address is located in an XA controlled segment and the Erase All Blocks, Erase All Blocks Unsecure or the Read 1s All Blocks command has not successfully completed since the last reset	FSTAT[FPVIOL]
Either of the margin reads does not match the expected data	FSTAT[MGSTAT0]

33.4.11.4 Read Resource Command

The Read Resource command is provided for the user to read data from special-purpose memory resources located within the Flash module. The special-purpose memory resources available include program flash IFR space, and the Version ID field. The Version ID field contains an 8 byte code that indicates a specific FTFE implementation.

Table 33-12. Read Resource Command FCCOB Requirements

FCCOB Number	FCCOB contents [7:0]
0	0x03 (RDRSRC)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Resource select code (see Table 33-13)
Returned values	
4	Read Data [64:56]
5	Read Data [55:48]
6	Read Data [47:40]
7	Read Data [39:32]
8	Read Data [31:24]
9	Read Data [23:16]
A	Read Data [15:8]
B	Read Data [7:0]

1. Must be 64-bit aligned (Flash address [2:0] = 000).

Table 33-13. Read Resource Select Codes

Resource Select Code	Description	Resource Size	Local Address Range
0x00	Program Flash 0 IFR	1024 Bytes	0x00_0000 - 0x00_03FF
0x00	Program Flash Swap IFR	1024 Bytes	0x04_0000 - 0x04_03FF
0x01	Version ID	8 Bytes	0x00_0008 - 0x00_000F

After clearing CCIF to launch the Read Resource command, eight consecutive bytes are read from the selected resource at the provided relative address and stored in the FCCOB register. The CCIF flag will set after the Read Resource operation has completed. The Read Resource command exits with an access error if an invalid resource code is provided or if the address for the applicable area is out-of-range.

Table 33-14. Read Resource Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid resource code is entered	FSTAT[ACCERR]
Flash address is out-of-range for the targeted resource.	FSTAT[ACCERR]
Flash address is not 64-bit aligned	FSTAT[ACCERR]

33.4.11.5 Program Phrase command

The Program Phrase command programs eight previously-erased bytes in the program flash memory using an embedded algorithm.

CAUTION

A Flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a Flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

Table 33-15. Program Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x07 (PGM8)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹

Table continues on the next page...

Table 33-15. Program Phrase Command FCCOB Requirements (continued)

FCCOB Number	FCCOB Contents [7:0]
4	Byte 0 program value
5	Byte 1 program value
6	Byte 2 program value
7	Byte 3 program value
8	Byte 4 program value
9	Byte 5 program value
A	Byte 6 program value
B	Byte 7 program value

1. Must be 64-bit aligned (Flash address [2:0] = 000)

Upon clearing CCIF to launch the Program Phrase command, the FTFE programs the data bytes into the flash using the supplied address. The protection status is always checked. If the swap system is enabled, the double-phrase containing the swap indicator address in each half of the program flash space is implicitly protected from programming. The targeted flash locations must be currently unprotected (see the description of the FPROT registers) to permit execution of the Program Phrase operation.

The programming operation is unidirectional. It can only move NVM bits from the erased state ('1') to the programmed state ('0'). Erased bits that fail to program to the '0' state are flagged as errors in MGSTAT0. The CCIF flag is set after the Program Phrase operation completes.

The starting address must be 64-bit aligned (flash address [2:0] = 000):

- Byte 0 data is written to the starting address ('start'),
- Byte 1 data is programmed to byte address start+0b01,
- Byte 2 data is programmed to byte address start+0b10, and
- Byte 3 data is programmed to byte address start+0b11, etc.

Table 33-16. Program Phrase Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not 64-bit aligned	FSTAT[ACCERR]
Flash address points to a protected area	FSTAT[FPVIOL]
Flash address is located in an XA controlled segment and the Erase All Blocks, Erase All Blocks Unsecure or the Read 1s All Blocks command has not successfully completed since the last reset	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation.	FSTAT[MGSTAT0]

33.4.11.6 Erase Flash Block Command

The Erase Flash Block operation erases all addresses in a single program flash.

Table 33-17. Erase Flash Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x08 (ERSBLK)
1	Flash address [23:16] in the flash block to be erased
2	Flash address [15:8] in the flash block to be erased
3	Flash address [7:0] ¹ in the flash block to be erased

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Erase Flash Block command, the FTFE erases the main array of the selected flash block and verifies that it is erased. The Erase Flash Block command aborts and sets the FSTAT[FPVIOL] bit if any region within the block is protected (see the description of the program flash protection (FPROT) registers). If the swap system is enabled, the swap indicator address is implicitly protected from block erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the program flash block being erased is the non-active block that contains the swap indicator address. If the erase verify fails, the MGSTAT0 bit in FSTAT is set. The CCIF flag will set after the Erase Flash Block operation has completed.

Table 33-18. Erase Flash Block Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
Program flash is selected and the address is out of program flash range	FSTAT[ACCERR]
Flash address is not 128-bit aligned	FSTAT[ACCERR]
Any area of the selected flash block is protected	FSTAT[FPVIOL]
The selected program flash block contains an XA controlled segment and the Erase All Blocks, Erase All Blocks Unsecure or the Read 1s All Blocks command has not successfully completed since the last reset	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation ¹	FSTAT[MGSTAT0]

1. User margin read may be run using the Read 1s Block command to verify all bits are erased.

33.4.11.7 Erase Flash Sector command

The Erase Flash Sector operation erases all addresses in a flash sector.

Table 33-19. Erase Flash Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x09 (ERSSCR)
1	Flash address [23:16] in the flash sector to be erased
2	Flash address [15:8] in the flash sector to be erased
3	Flash address [7:0] ¹ in the flash sector to be erased

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

After clearing CCIF to launch the Erase Flash Sector command, the FTFE erases the selected program flash sector and then verifies that it is erased. The Erase Flash Sector command aborts if the selected sector is protected (see the description of the FPROT registers). If the swap system is enabled, the swap indicator address in each program flash block is implicitly protected from sector erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the program flash sector containing the swap indicator address being erased is in the non-active block. If the erase-verify fails the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase Flash Sector operation completes. The Erase Flash Sector command is suspendable (see the FCNFG[ERSSUSP] bit and [Figure 33-6](#)).

Table 33-20. Erase Flash Sector Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid Flash address is supplied	FSTAT[ACCERR]
Flash address is not 128-bit aligned	FSTAT[ACCERR]
The selected program flash sector is protected	FSTAT[FPVIOL]
The selected program flash sector is located in an XA controlled segment and the Erase All Blocks, Erase All Blocks Unsecure or the Read 1s All Blocks command has not successfully completed since the last reset	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation ¹	FSTAT[MGSTAT0]

1. User margin read may be run using the Read 1s Section command to verify all bits are erased.

33.4.11.7.1 Suspending an Erase Flash Sector Operation

To suspend an Erase Flash Sector operation set the FCNFG[ERSSUSP] bit when CCIF, ACCERR, and FPVIOL are clear and the CCOB command field holds the code for the Erase Flash Sector command. During the Erase Flash Sector operation (see [Erase Flash Sector command](#)), the flash samples the state of the ERSSUSP bit at convenient points. If the FTFE detects that the ERSSUSP bit is set, the Erase Flash Sector operation is suspended and the FTFE sets CCIF. While ERSSUSP is set, all writes to flash registers are ignored except for writes to the FSTAT and FCNFG registers.

If an Erase Flash Sector operation effectively completes before the FTFE detects that a suspend request has been made, the FTFE clears the ERSSUSP bit prior to setting CCIF. When an Erase Flash Sector operation has been successfully suspended, the FTFE sets CCIF and leaves the ERSSUSP bit set. While CCIF is set, the ERSSUSP bit can only be cleared to prevent the withdrawal of a suspend request before the FTFE has acknowledged it.

33.4.11.7.2 Resuming a Suspended Erase Flash Sector Operation

If the ERSSUSP bit is still set when CCIF is cleared to launch the next command, the previous Erase Flash Sector operation resumes. The FTFE acknowledges the request to resume a suspended operation by clearing the ERSSUSP bit. A new suspend request can then be made by setting ERSSUSP. A single Erase Flash Sector operation can be suspended and resumed multiple times.

There is a minimum elapsed time limit of 4.3 msec between the request to resume the Erase Flash Sector operation (CCIF is cleared) and the request to suspend the operation again (ERSSUSP is set). This minimum time period is required to ensure that the Erase Flash Sector operation will eventually complete. If the minimum period is continually violated, i.e. the suspend requests come repeatedly and too quickly, no forward progress is made by the Erase Flash Sector algorithm. The resume/suspend sequence runs indefinitely without completing the erase.

33.4.11.7.3 Aborting a Suspended Erase Flash Sector Operation

The user may choose to abort a suspended Erase Flash Sector operation by clearing the ERSSUSP bit prior to clearing CCIF for the next command launch. When a suspended operation is aborted, the FTFE starts the new command using the new FCCOB contents.

Note

Aborting the erase leaves the bitcells in an indeterminate, partially-erased state. Data in this sector is not reliable until a new erase command fully completes.

The following figure shows how to suspend and resume the Erase Flash Sector operation.

Figure 33-6. Suspend and Resume of Erase Flash Sector Operation

33.4.11.8 Program Section command

The Program Section operation programs the data found in the section program buffer to previously erased locations in the flash memory using an embedded algorithm. Data is preloaded into the section program buffer (see [Flash sector programming](#)).

The section program buffer is limited to the lower quarter of the programming acceleration RAM (relative byte addresses 0x0000-0x03FF - be sure to check your device specific memory map for the location of the programming acceleration RAM). Data written to the remainder of the programming acceleration RAM is ignored and may be overwritten during Program Section command execution.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

Table 33-21. Program Section Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x0B (PGMSEC)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Number of double-phrases to program [15:8]
5	Number of double-phrases to program [7:0]

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

After clearing CCIF to launch the Program Section command, the FTFE will block access to the programming acceleration RAM and program the data residing in the Section Program Buffer into the flash memory starting at the flash address provided.

The starting address must be unprotected (see the description of the FPROT registers) to permit execution of the Program Section operation. If the swap system is enabled, the double-phrase containing the swap indicator in each half of the program flash space is implicitly protected from programming. If the double-phrase containing the swap indicator address is encountered during the Program Section operation, it will be bypassed without setting FPVIOL and the contents will not be programmed. Programming, which is not allowed to cross a flash sector boundary, continues until all requested double-phrases have been programmed.

After the Program Section operation has completed, the CCIF flag will set. The contents of the Section Program Buffer are not changed by the Program Section operation unless the swap system is enabled and the Program Section operation is targeting the double-phrase containing the swap indicator in which case that double-phrase is changed to all ones.

Table 33-22. Program Section Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not 128-bit aligned	FSTAT[ACCERR]
The requested section crosses a program flash sector boundary	FSTAT[ACCERR]
The requested number of double-phrases is zero	FSTAT[ACCERR]
The space required to store data for the requested number of double-phrases is more than one quarter the size of the programming acceleration RAM	FSTAT[ACCERR]
The flash address falls in a protected area	FSTAT[FPVIOL]
The requested flash section is located in an XA controlled segment and the Erase All Blocks, Erase All Blocks Unsecure or the Read 1s All Blocks command has not successfully completed since the last reset	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

33.4.11.8.1 Flash sector programming

The process of programming an entire flash sector using the Program Section command is as follows:

1. Launch the Erase Flash Sector command to erase the flash sector to be programmed.
2. Beginning with the starting address of the programming acceleration RAM, sequentially write enough data to the RAM to fill an entire flash sector, or as much data is allowed due to RAM size versus flash sector size. This area of the RAM serves as the section program buffer. The section program buffer can be written to while the operation launched in step 1 is executing, i.e. while CCIF = 0.
3. Execute the Program Section command to program the contents of the section program buffer into the selected flash sector.
4. Repeat steps 2 through 3 to complete the entire flash sector, if necessary.
5. To program additional flash sectors, repeat steps 1 through 4.

33.4.11.9 Read 1s All Blocks Command

The Read 1s All Blocks command checks if the program flash blocks have been erased to the specified read margin level, if applicable, and releases security if the readout passes, i.e. all data reads as '1'.

Table 33-23. Read 1s All Blocks Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x40 (RD1ALL)
1	Read-1 Margin Choice

After clearing CCIF to launch the Read 1s All Blocks command, the FTFE :

- sets the read margin for 1s according to [Table 33-24](#),
- checks the contents of the program flash are in the erased state.

If the FTFE confirms that these memory resources are erased, access control is disabled and security is released by setting the FSEC[SEC] field to the unsecure state. The security byte in the flash configuration field (see [Flash configuration field description](#)) remains unaffected by the Read 1s All Blocks command. If the read fails, i.e. all flash memory resources are not in the fully erased state, the FSTAT[MGSTAT0] bit is set.

The EEERDY and RAMRDY bits are clear during the Read 1s All Blocks operation and are restored at the end of the Read 1s All Blocks operation.

The CCIF flag sets after the Read 1s All Blocks operation has completed.

Table 33-24. Margin Level Choices for Read 1s All Blocks

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 33-25. Read 1s All Blocks Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid margin choice is specified	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

33.4.11.10 Read Once Command

The Read Once command provides read access to a reserved 96-byte field located in the program flash 0 IFR (see [Program flash 0 IFR map](#) and [Program Once field](#)). Access to the Program Once field is via 12 records, each 8 bytes long. The Program Once field is programmed using the Program Once command described in [Program Once command](#).

Table 33-26. Read Once Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x41 (RDONCE)
1	Program Once record index (0x00 - 0x0B)
Returned Values	
4	Program Once byte 0 value
5	Program Once byte 1 value
6	Program Once byte 2 value
7	Program Once byte 3 value
8	Program Once byte 4 value
9	Program Once byte 5 value
A	Program Once byte 6 value
B	Program Once byte 7 value

After clearing CCIF to launch the Read Once command, an 8-byte Program Once record is read from the program flash IFR and stored in the FCCOB register. The CCIF flag is set after the Read Once operation completes. Valid record index values for the Read Once command range from 0x00 to 0x0B. During execution of the Read Once command, any attempt to read addresses within the program flash block containing this 96-byte field returns invalid data. The Read Once command can be executed any number of times.

Table 33-27. Read Once Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid record index is supplied	FSTAT[ACCERR]

33.4.11.11 Program Once command

The Program Once command enables programming to a reserved 96-byte field in the program flash 0 IFR (see [Program flash 0 IFR map](#) and [Program Once field](#)). Access to the Program Once field is via 12 records, each 8 bytes long. The Program Once field can

be read using the Read Once command (see [Read Once Command](#)) or using the Read Resource command (see [Read Resource Command](#)). Each Program Once record can be programmed only once since the program flash 0 IFR cannot be erased.

Table 33-28. Program Once Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x43 (PGMONCE)
1	Program Once record index (0x00 - 0x0B)
2	Not Used
3	Not Used
4	Program Once Byte 0 value
5	Program Once Byte 1 value
6	Program Once Byte 2 value
7	Program Once Byte 3 value
8	Program Once Byte 4 value
9	Program Once Byte 5 value
A	Program Once Byte 6 value
B	Program Once Byte 7 value

After clearing CCIF to launch the Program Once command, the FTFE first verifies that the selected record is erased. If erased, then the selected record is programmed using the values provided. The Program Once command also verifies that the programmed values read back correctly. The CCIF flag is set after the Program Once operation has completed.

The reserved program flash 0 IFR location accessed by the Program Once command cannot be erased and any attempt to program one of these records when the existing value is not Fs (erased) is not allowed. Valid record index values for the Program Once command range from 0x00 to 0x0B. During execution of the Program Once command, any attempt to read addresses within program flash 0 returns invalid data.

Table 33-29. Program Once Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid record index is supplied	FSTAT[ACCERR]
The requested record has already been programmed to a non-erased value ¹	FSTAT[ACCERR]
Any errors have been encountered during the verify operation.	FSTAT[MGSTAT0]

1. If a Program Once record is initially programmed to 0xFFFF_FFFF_FFFF_FFFF, the Program Once command is allowed to execute again on that same record.

33.4.11.12 Erase All Blocks Command

The Erase All Blocks operation erases all flash memory, verifies all memory contents, and releases MCU security.

Table 33-30. Erase All Blocks Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x44 (ERSALL)

After clearing CCIF to launch the Erase All Blocks command, the FTFE erases all program flash memory, program flash swap IFR space, then verifies that all are erased.

If the FTFE verifies that all flash memories were properly erased, access control is disabled and security is released by setting the FSEC[SEC] field to the unsecure state and the FCNFG[RAMRDY] bit is set. The Erase All Blocks command aborts if any flash region is protected. The swap indicator address in the program flash blocks are not implicitly protected from the erase operation. The security byte and all other contents of the flash configuration field (see [Flash configuration field description](#)) are erased by the Erase All Blocks command. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Blocks operation completes.

Access control determined by the contents of the FXACC registers will not block execution of the Erase All Blocks command. While most Flash memory will be erased, the program flash 0 IFR space containing the Program Once XACC and SACC fields will not be erased and, therefore, the contents of the Program Once XACC and SACC fields will not change. The contents of the FXACC and FSACC registers will not be impacted by the execution of the Erase All Blocks command. After completion of the Erase All Blocks command, access control is disabled until the next reset of the flash module or the Read 1s All Blocks command is executed and fails (FSTAT[MGSTAT0] is set).

Table 33-31. Erase All Blocks Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
Any region of the program flash memory is protected	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation ¹	FSTAT[MGSTAT0]

1. User margin read may be run using the Read 1s All Blocks command to verify all bits are erased.

33.4.11.12.1 Triggering an erase all external to the flash module

The functionality of the Erase All Blocks/Erase All Blocks Unsecure command is also available in an uncommanded fashion outside of the flash memory. Refer to the device's Chip Configuration details for information on this functionality.

Before invoking the external erase all function, the FCCOB0 register must not contain 0x44. When invoked, the erase-all function erases all program flash memory, program flash swap IFR space regardless of the state of the FSTAT[ACCERR and FPVIOL] flags or the protection settings or the state of the flash swap system. If the post-erase verify passes, access control determined by the contents of the FXACC registers is disabled and the routine releases security by setting the FSEC[SEC] field register to the unsecure state and the FCNFG[RAMRDY] bit sets. The security byte in the Flash Configuration Field is also programmed to the unsecure state. The status of the erase-all request is reflected in the FCNFG[ERSAREQ] bit. The FCNFG[ERSAREQ] bit is cleared once the operation completes and the normal FSTAT error reporting, except FPVIOL, is available as described in [Erase All Blocks Command/Erase All Blocks Unsecure Command](#).

CAUTION

Since the IFR Swap Field in the program flash swap IFR containing the swap indicator address is erased during the Erase All Blocks command operation, the swap system becomes uninitialized. The Swap Control command must be run with the initialization code to set the swap indicator address and initialize the swap system.

33.4.11.13 Verify Backdoor Access Key command

Execution of the Verify Backdoor Access Key command is qualified by the FSEC[KEYEN] bits. The Verify Backdoor Access Key command releases security if user-supplied keys in the FCCOB match those stored in the Backdoor Comparison Key bytes of the Flash Configuration Field. The column labeled Flash Configuration Field offset address shows the location of the matching byte in the Flash Configuration Field.

Table 33-32. Verify Backdoor Access Key Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]	Flash Configuration Field Offset Address
0	0x45 (VFYKEY)	
1-3	Not Used	
4	Key Byte 0	0x0_0003
5	Key Byte 1	0x0_0002
6	Key Byte 2	0x0_0001
7	Key Byte 3	0x0_0000
8	Key Byte 4	0x0_0007
9	Key Byte 5	0x0_0006
A	Key Byte 6	0x0_0005
B	Key Byte 7	0x0_0004

After clearing CCIF to launch the Verify Backdoor Access Key command, the FTFE checks the FSEC[KEYEN] bits to verify that this command is enabled. If not enabled, the FTFE sets the FSTAT[ACCERR] bit and terminates. If the command is enabled, the FTFE compares the key provided in FCCOB to the backdoor comparison key in the Flash Configuration Field. If the backdoor keys match, the FSEC[SEC] field is changed to the unsecure state and security is released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are immediately aborted and the FSTAT[ACCERR] bit is (again) set to 1 until a reset of the FTFE module occurs. If the entire 8-byte key is all zeros or all ones, the Verify Backdoor Access Key command fails with an access error. The CCIF flag is set after the Verify Backdoor Access Key operation completes.

Table 33-33. Verify Backdoor Access Key Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
The supplied key is all-0s or all-Fs	FSTAT[ACCERR]
An incorrect backdoor key is supplied	FSTAT[ACCERR]
Backdoor key access has not been enabled (see the description of the FSEC register)	FSTAT[ACCERR]
This command is launched and the backdoor key has mismatched since the last power down reset	FSTAT[ACCERR]

33.4.11.14 Swap Control command

The Swap Control command handles specific activities associated with swapping the two halves of program flash memory within the memory map.

Table 33-34. Swap Control Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x46 (SWAP)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Swap Control Code: 0x01 - Initialize Swap System 0x02 - Set Swap in Update State 0x04 - Set Swap in Complete State 0x08 - Report Swap Status 0x10 - Disable Swap System
Returned values	

Table continues on the next page...

Table 33-34. Swap Control Command FCCOB Requirements (continued)

FCCOB Number	FCCOB Contents [7:0]
5	Current Swap Mode: 0x00 - Uninitialized 0x01 - Ready 0x02 - Update 0x03 - Update-Erased 0x04 - Complete 0x05 - Disabled
6	Current Swap Block Status: 0x00 - Program flash block 0/1 at 0x0_0000 0x01 - Program flash block 2/3 at 0x0_0000
7	Next Swap Block Status (after any reset): 0x00 - Program flash block 0/1 at 0x0_0000 0x01 - Program flash block 2/3 at 0x0_0000

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Swap Control command, the FTFE will handle swap-related activities based on the Swap Control code provided in FCCOB4 as follows:

- 0x01 (Initialize Swap System to UPDATE-ERASED State) - After verifying that the current swap state is UNINITIALIZED, and that both phrases which will contain the swap indicators (located in each half of the Program flash memory within the relative double-phrase flash address provided) are erased, and that the flash address provided is in the lower half of Program flash memory but not in the Flash Configuration Field, the flash address provided (shifted with bits[3:0] removed) will be programmed into the IFR Swap Field found in the program flash swap IFR. After the swap indicator address has been programmed into the IFR Swap Field, the swap enable word will be programmed to 0x0000. After the swap enable word has been programmed, the swap indicator located in the lower half of the Program flash memory will be programmed to 0xFF00.
- 0x02 (Progress Swap to UPDATE State) - After verifying that the current swap state is READY and that the aligned flash address provided matches the one stored in the IFR Swap Field, the swap indicator located in the currently active program flash block will be programmed to 0xFF00.
- 0x04 (Progress Swap to COMPLETE State) - After verifying that the current swap state is UPDATE-ERASED and that the aligned flash address provided matches the one stored in the IFR Swap Field, the swap indicator located in the currently active program flash block will be programmed to 0x0000. Before executing with this Swap Control code, the user must erase the non-active swap indicator using the Erase Flash Block or Erase Flash Sector commands and update the application code or data as

needed. The non-active swap indicator will be checked at the erase verify level and if the check fails, the current swap state will be changed to UPDATE with ACCERR set.

- 0x08 (Report Swap Status) - After verifying that the aligned flash address provided is in the lower half of Program flash memory but not in the Flash Configuration Field, the status of the swap system will be reported as follows:
 - FCCOB5 (Current Swap State) - indicates the current swap state based on the status of the swap disable word, swap enable word and the swap indicators. If the MGSTAT0 flag is set after command completion, the swap state returned was not successfully transitioned from and the appropriate swap command code must be attempted again. If the current swap state is UPDATE and the non-active swap indicator is 0xFFFF, the current swap state is changed to UPDATE-ERASED.
 - FCCOB6 (Current Swap Block Status) - indicates which program flash block is currently located at relative flash address 0x0_0000.
 - FCCOB7 (Next Swap Block Status) - indicates which program flash block will be located at relative flash address 0x0_0000 after the next reset of the FTFE module.
- 0x10 (Disable Swap System) - After verifying that the current swap state is UNINITIALIZED and that the aligned flash address provided is not in the Flash Configuration Field, the swap disable word, located in the IFR Swap Field, is programmed to 0x0000 and the swap system changed to the DISABLED state with Program flash block 0 located at relative flash address 0x0_0000.

NOTE

It is recommended that the user execute the Swap Control command to report swap status (code 0x08) after any reset to determine if issues with the swap system were detected during the swap state determination procedure.

NOTE

It is recommended that the user write 0xFF to FCCOB5, FCCOB6, and FCCOB7 since the Swap Control command will not always return the swap state and status fields when an ACCERR is detected.

The CCIF flag is set after the Swap Control operation has completed.

The swap indicators are implicitly protected from being programmed during Program Phrase or Program Section command operations and are implicitly unprotected during Swap Control command operations. The swap indicators are implicitly protected from being erased during Erase Flash Block and Erase Flash Sector command operations unless the swap indicator being erased is in the non-active program flash block and the

swap system is in the UPDATE or UPDATE-ERASED state. The Erase All Blocks command or erase-all function can be used to place the swap system in the UNINITIALIZED state.

Table 33-35. Swap Control Command Error Handling

Error Condition	Swap Control Code	Error Bit
Command not available in current mode/security ¹	All	FSTAT[ACCERR]
Flash address is not in the lower half of program flash memory	All	FSTAT[ACCERR]
Flash address is in the Flash Configuration Field	1, 8, 10	FSTAT[ACCERR]
Flash address is not 128-bit aligned	All	FSTAT[ACCERR]
Swap system is in the disabled state	1, 2, 4, 10	FSTAT[ACCERR]
Flash address does not match the swap indicator address in the IFR	2, 4	FSTAT[ACCERR]
Swap initialize requested when phrase containing swap indicator (in each half of program flash memory) is not in the erased state	1	FSTAT[ACCERR]
Swap initialize requested when swap system is not in the uninitialized state	1	FSTAT[ACCERR]
Swap update requested when swap system is not in the ready state	2	FSTAT[ACCERR]
Swap complete requested when swap system is not in the update-erased state	4	FSTAT[ACCERR]
Swap disable requested when swap system is not in the uninitialized state	10	FSTAT[ACCERR]
An undefined swap control code is provided	-	FSTAT[ACCERR]
Any errors have been encountered during the swap determination and program-verify operations	1, 2, 4, 10	FSTAT[MGSTAT0]
Any brownouts were detected during the swap determination procedure	8	FSTAT[MGSTAT0]

1. Returned fields will not be updated, i.e. no swap state or status reporting

Figure 33-7. Valid Swap State Sequencing

Table 33-36. Swap State Report Mapping

Case	Swap Disable Word	Swap Enable Field ¹	Swap Indicator 0 ¹	Swap Indicator 1 ¹	Swap State ²	State Code	MGSTAT 0	Active Block
1	0xFFFF	0xFFFF	-	-	Uninitialized	0	0	0
2	0xFFFF	0x0000	0xFF00	0x0000	Update	2	0	0
3	0xFFFF	0x0000	0xFF00-	0xFFFF	Update-Erased	3	0	0
4	0xFFFF	0x0000	0x0000	0xFFFF ³	Complete ⁴	4	0	0
5	0xFFFF	0x0000	0x0000	0xFFFF	Ready ⁵	1	0	1
6	0xFFFF	0x0000	0x0000	0xFF00	Update	2	0	1
7	0xFFFF	0x0000	0xFFFF	0xFF00	Update-Erased	3	0	1
8	0xFFFF	0x0000	0xFFFF ³	0x0000	Complete ⁴	4	0	1
9	0xFFFF	0x0000	0xFFFF	0x0000	Ready ⁵	1	0	0
10	0x0000	-	-	-	Disabled	5	0	0
11	0xFFFF	0XXXX	-	-	Uninitialized	0	1	0
12	0xFFFF	0x0000	0xFFFF	0xFFFF	Uninitialized	0	1	0
13	0xFFFF	0x0000	0xFFXX	0xFFFF	Ready	1	1	0
14	0xFFFF	0x0000	0xFFXX	0x0000	Ready	1	1	0
15 ⁶	0xFFFF	0x0000	0XXXX	0x0000	Ready	1	1	0
16 ⁶	0xFFFF	0x0000	0xFFFF	0xFFXX	Ready	1	1	1
17	0xFFFF	0x0000	0x0000	0xFFXX	Ready	1	1	1
18 ⁶	0xFFFF	0x0000	0x0000	0XXXX	Ready	1	1	1
19	0xFFFF	0x0000	0xFF00	0xFFFF ⁷	Update	2	1	0
20	0xFFFF	0x0000	0xFF00	0XXXX	Update	2	1	0
21	0xFFFF	0x0000	0xFF(00)	0xFFXX	Update	2	1	0
22 ⁶	0xFFFF	0x0000	0x0000	0x0000	Update	2	1	0
23 ⁶	0xFFFF	0x0000	0XXXX	0XXXX	Update	2	1	0
24	0xFFFF	0x0000	0xFFFF ⁷	0xFF00	Update	2	1	1
25	0xFFFF	0x0000	0XXXX	0xFF00	Update	2	1	1
26	0xFFFF	0x0000	0xFFXX	0xFF(00)	Update	2	1	1
27	0xFFFF	0x0000	0XX00	0xFFFF	Update-Erased	3	1	0
28	0xFFFF	0x0000	0XXXX	0xFFFF	Update-Erased	3	1	0
29	0xFFFF	0x0000	0xFFFF	0XX00	Update-Erased	3	1	1
30	0xFFFF	0x0000	0xFFFF	0XXXX	Update-Erased	3	1	1
31	0XXXX	-	-	-	Disabled	5	0	0

1. 0XXXX, 0xFFXX, 0XX00 indicates a non-valid value was read; 0xFF(00) indicates more 0's than other indicator (if same number of 0's, then swap system defaults to block 0 active)
2. Cases 10-29 due to brownout (abort) detected during program or erase steps related to swap
3. Must read 0xFFFF with erase verify level before transition to Complete allowed
4. No reset since successful Swap Complete execution
5. Reset after successful Swap Complete execution
6. Not a valid case
7. Fails to read 0xFFFF at erase verify level

33.4.11.14.1 Swap state determination

During the reset sequence, the state of the swap system is determined by evaluating the IFR Swap Field in the program flash swap IFR and the swap indicators found within the double-phrase containing the relative swap indicator address in each half of the program flash memory.

Table 33-37. Program Flash Swap IFR Fields

Address Range	Size (Bytes)	Field Description
0x000 – 0x001	2	Swap Indicator Address
0x002 – 0x003	2	Swap Enable Word
0x004 – 0x009	6	Reserved
0x00A – 0x00B	2	Swap Disable Word
0x00C – 0x3FF	1012	Reserved

33.4.11.15 Erase All Blocks Unsecure Command

The Erase All Blocks Unsecure operation erases all flash memory, verifies all memory contents, programs the security byte in the Flash Configuration Field to the unsecure state, and releases MCU security.

Table 33-38. Erase All Blocks Unsecure Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x49 (ERSALLU)

After clearing CCIF to launch the Erase All Blocks Unsecure command, the FTFE erases all program flash memory, program flash swap IFR space, then verifies that all are erased.

If the FTFE verifies that all flash memories were properly erased, access control is disabled and security is released by setting the FSEC[SEC] field to the unsecure state, the security byte (see [Flash configuration field description](#)) is programmed to the unsecure state by the Erase All Blocks Unsecure command, and the FCNFG[RAMRDY] bit is set. The swap indicator address in the program flash blocks are not implicitly protected from the erase operation. If the erase or program verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Blocks Unsecure operation completes.

Access control determined by the contents of the FXACC registers will not block execution of the Erase All Blocks Unsecure command. While most Flash memory will be erased, the program flash 0 IFR space containing the Program Once XACC and SACC fields will not be erased and, therefore, the contents of the Program Once XACC and

SACC fields will not change. The contents of the FXACC and FSACC registers will not be impacted by the execution of the Erase All Blocks Unsecure command. After completion of the Erase All Blocks Unsecure command, access control is disabled until the next reset of the flash module or the Read 1s All Blocks command is executed and fails (FSTAT[MGSTAT0] is set).

Table 33-39. Erase All Blocks Unsecure Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
Any errors have been encountered during erase or program verify operations	FSTAT[MGSTAT0]

33.4.11.16 Read 1s All Execute-only Segments Command

The Read 1s All Execute-only Segments command checks if the program flash execute-only segments defined by the FXACC registers have been erased to the specified read margin level, if applicable, and releases flash access control if the readout passes, i.e. all data reads as '1'.

Table 33-40. Read 1s All Execute-only Segments Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x4A (RD1XA)
1	Read-1 Margin Choice

After clearing CCIF to launch the Read 1s All Execute-only Segments command, the flash memory module :

- sets the read margin for 1s according to [Table 33-41](#),
- checks the contents of the program flash execute-only segments are in the erased state.

If the flash memory module confirms that these segments are erased, flash access control is disabled until the next reset or, after programming any of the execute-only segments, the Read 1s All Execute-only Segments command is executed and fails with the FSTAT[MGSTAT0] bit set. If the read fails, i.e. all segments are not in the fully erased state, the FSTAT[MGSTAT0] bit is set.

The CCIF flag sets after the Read 1s All Execute-only Segments operation has completed.

Table 33-41. Margin Level Choices for Read 1s All Execute-only Segments

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 33-42. Read 1s All Execute-only Segments Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid margin choice is specified	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

33.4.11.17 Erase All Execute-only Segments Command

The Erase All Execute-only Segments operation erases all program flash execute-only segments defined by the FXACC registers, verifies all segments are erased, and releases flash access control.

Table 33-43. Erase All Execute-only Segments Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x4B (ERSXA)

After clearing CCIF to launch the Erase All Execute-only Segments command, the flash memory module erases all program flash execute-only segments, then verifies that all segments are erased.

If the flash memory module verifies that all segments were properly erased, flash access control is disabled until the next reset or, after programming any of the execute-only segments, the Read 1s All Execute-only Segments command is executed and fails with the FSTAT[MGSTAT0] bit set. The Erase All Execute-only Segments command aborts if any XA controlled segment is protected. If the swap system is enabled, the swap indicator address in each program flash block is implicitly protected from erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the program flash segment containing the swap indicator address being erased is in the non-active block. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Execute-only Segments operation completes.

Access control determined by the contents of the FXACC registers will not block execution of the Erase All Execute-only Segments command. While all XA controlled segments will be erased, the program flash IFR space containing the Program Once XACC fields will not be erased and, therefore, the contents of the Program Once XACC fields will not change. The contents of the FXACC registers will not be impacted by the execution of the Erase All Execute-only Segments command.

Table 33-44. Erase All Execute-only Segments Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
Any XA controlled segment in the program flash memory is protected	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

33.4.12 Security

The FTFE module provides security information to the MCU based on contents of the FSEC security register. The MCU then limits access to FTFE resources as defined in the device's Chip Configuration details. During reset, the FTFE module initializes the FSEC register using data read from the security byte of the Flash Configuration Field (see [Flash configuration field description](#)).

The following fields are available in the FSEC register. Details of the settings are described in the FSEC register description.

Flash security features are discussed further in [AN4507: Using the Kinetis Security and Flash Protection Features](#) . Some features described in the application note may not be available on this device.

Table 33-45. FSEC fields

FSEC field	Description
KEYEN	Backdoor Key Access
MEEN	Mass Erase Capability
FSLACC	Factory Security Level Access
SEC	MCU security

33.4.12.1 Changing the Security State

The security state out of reset can be permanently changed by programming the security byte of the flash configuration field. This assumes that you are starting from a mode where the necessary program flash erase and program commands are available and that the region of the program flash containing the flash configuration field is unprotected. If the flash security byte is successfully programmed, its new value takes effect after the next MCU reset.

33.4.12.1.1 Unsecuring the MCU Using Backdoor Key Access

The MCU can be unsecured by using the backdoor key access feature which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see [Flash configuration field description](#)). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see [Verify Backdoor Access Key command](#)) can be run which allows the user to present prospective keys for comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the MCU. The entire 8-byte key cannot be all 0s or all 1s, i.e. 0x0000_0000_0000_0000 and 0xFFFF_FFFF_FFFF_FFFF are not accepted by the Verify Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Verify Backdoor Access Key command](#)
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the MCU is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field ([Flash configuration field](#))

[description](#)). After the next reset of the MCU, the security state of the FTFE module reverts back to the Flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may erase the sector containing the Flash Configuration Field and reprogram the flash security byte to the unsecure state and change the backdoor keys to any desired value.

33.4.12.2 Unsecuring the MCU Using Backdoor Key Access

The MCU can be unsecured by using the backdoor key access feature which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see [Flash configuration field description](#)). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see [Verify Backdoor Access Key command](#)) can be run which allows the user to present prospective keys for comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the MCU. The entire 8-byte key cannot be all 0s or all 1s, i.e. 0x0000_0000_0000_0000 and 0xFFFF_FFFF_FFFF_FFFF are not accepted by the Verify Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Verify Backdoor Access Key command](#)
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the MCU is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field ([Flash configuration field description](#)). After the next reset of the MCU, the security state of the FTFE module reverts back to the Flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may erase the sector containing the Flash Configuration Field and reprogram the flash security byte to the unsecure state and change the backdoor keys to any desired value.

33.5 Reset Sequence

On each system reset the FTFE module executes a sequence which establishes initial values for the flash block configuration parameters, FPROT, FOPT, FSEC, FXACC, FSACC, and FACNFG registers and the FCNFG[SWAP, PFLSH, RAMRDY, EEERDY] bits.

CCIF is cleared throughout the reset sequence. The FTFE module holds off all CPU access for a portion of the reset sequence. Flash reads are possible when the hold is removed. Completion of the reset sequence is marked by setting CCIF which enables flash user commands.

If a reset occurs while any FTFE command is in progress, that command is immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed. Commands and operations do not automatically resume after exiting reset.

Chapter 34

Synchronous DRAM Controller Module (SDRAM)

34.1 Chip-specific SDRAM information

34.1.1 SDRAM clocking

The system provides a dedicated clock source (FlexBus clock to the SDRAM Controller module's CLKOUT input that is also used for FlexBus clocking. This clock source is divider controlled via SIM_CLKDIV1[OUTDIV3]. See [Clock Distribution](#) for more details.

34.1.2 SDRAM SDR signal multiplexing

The byte enable control signals of the SDRAM controller (SDRAM_DQMx) are multiplexed with the byte enable control signals of the FlexBus (FB_BE_xx_yy). The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals are available from the FlexBus module.

NOTE

In order to use the SDRAM simultaneously with the FlexBus, the FlexBus CSPMCR register must be configured to select the FlexBus byte enable signals (value of 0xX222_2000). Once this is configured and SDRAM module enabled, the device will automatically select the correct signal based on the transaction which is activated (FlexBus or SDRAM).

The control signals are illustrated in the [FlexBus signal multiplexing](#) section.

Therefore, use the CSPMCR and port control registers to configure which control signal is available on the external pin.

34.1.3 SDRAMC Security

When security is enabled on the device, SDRAM accesses may be restricted by configuring the SIM_SOPT2[FBSL] register. This is a shared control register between SDRAM and FlexBus. See [System Integration Module \(SIM\)](#) for details.

34.2 Introduction

This chapter describes configuration and operation of the synchronous DRAM (SDRAM) controller. It begins with a general description and brief glossary, and includes a description of signals involved in DRAM operations. The remainder of the chapter describes the programming model and signal timing, as well as the command set required for synchronous operations. It also includes extensive examples that the designer can follow to better understand how to configure the DRAM controller for synchronous operations.

34.3 Overview

The synchronous DRAM controller module provides glueless integration of SDRAM. The key features of the DRAM controller include the following:

- Support for two independent blocks of SDRAM
- Interface to standard SDRAM components
- Programmable $\overline{SRAS}$, $\overline{SCAS}$, and refresh timing
- Support for 8-, 16-, and 32-bit wide SDRAM blocks

34.3.1 Definitions

The following terminology is used in this chapter:

- SDRAM block: Any group of DRAM memories selected by one of the SDRAM_CS[1:0] signals. Thus, the controller can support two independent memory blocks. The base address of each block is programmed in the DRAM address and control registers (SDRAM_AC0 and SDRAM_AC1)

- SDRAM: RAMs that operate like asynchronous DRAMs but with a synchronous clock, a pipelined, multiple-bank architecture, and a faster speed
- SDRAM bank: An internal partition in an SDRAM device. For example, a 64-Mbit SDRAM component might be configured as four 512K x 32 banks. Banks are selected through the SDRAM component's bank select lines

34.3.2 Block Diagram and Major Components

The basic components of the SDRAM controller are shown in the figure below:

Figure 34-1. Block diagram

The DRAM controller's major components are as follows:

- DRAM address and control registers (SDRAM_AC0 and SDRAM_AC1)—The DRAM controller consists of two configuration register units, one for each supported memory block. SDRAM_AC0 is accessed at SDRAMC IPS Base Address + 0x048; SDRAM_AC1 is accessed at SDRAMC IPS Base Address + 0x050. The register information is passed on to the hit logic.
- Control logic and state machine—Generates all SDRAM signals, taking hit information and bus-cycle characteristic data from the block logic in order to generate SDRAM accesses. Handles refresh requests from the refresh counter

- DRAM control register (SDRAM_CTRL)—Contains data to control refresh operation of the DRAM controller. Both memory blocks are refreshed concurrently as controlled by SDRAM_CTRL[RC].
- Refresh counter—Determines when refresh should occur; controlled by the value of SDRAM_CTRL[RC]. It generates a refresh request to the control block.
- Hit logic—Compares address and attribute signals of a current SDRAM bus cycle to both SDRAM_ACn to determine if an SDRAM block is being accessed. Hits are passed to the control logic along with characteristics of the bus cycle to be generated
- Address multiplexing—Multiplexes addresses to allow column and row addresses to share pins. This allows glueless interface to SDRAMs
- Data Generation—Controls the data input and data output transmission between the on-platform and off-platform data buses.

34.4 SDRAM Controller Operation

By running synchronously with the system clock, SDRAM can (after an initial latency period) be accessed on every CLKOUT clock; 5-1-1-1 is a typical burst rate to the SDRAM. This controller does not have an independent SDRAM clock signal. The timing of the SDRAM controller is controlled by the CLKOUT signal. Note that because the controller cannot have more than one page open at a time, it does not support interleaving. SDRAM controllers send special commands for such functions as precharge, read, write, burst, auto-refresh, and various combinations of these functions. The following table lists common SDRAM commands.

Table 34-1. SDRAM Commands

Commands	Definitions
ACTV	Activate. Executed before read or write executes; SDRAM registers and decodes row address
MRS	Mode register set.
NOP	No-op. Does not affect SDRAM state machine; DRAM controller control signals negated; SDRAM_CS[1:0] asserted.
PALL	Precharge all. Precharges all internal banks of an SDRAM component; executed before new page is opened.
READ	Read access. SDRAM registers column address and decodes that a read access is occurring.
REF	Refresh. Refreshes internal bank rows of an SDRAM component.
SELF	Self refresh. Refreshes internal bank rows of an SDRAM component when it is in low-power mode.
SELFx	Exit self refresh. This command is sent to the DRAM controller when SDRAM_CTRL[IS] is cleared.
WRITE	Write access. SDRAM registers column address and decodes that a write access is occurring.

Commands are issued to memory using specific encodings on address and control pins. Soon after system reset, a command must be sent to the SDRAM mode register to configure SDRAM operating parameter

34.4.1 DRAM Controller Signals

The following table describes the behavior of DRAM signals in synchronous mode

Table 34-2. Synchronous DRAM Signal Connections

Signal	I/O	Description
SRAS	O	Synchronous row address strobe. Indicates a valid SDRAM row address is present and can be latched by the SDRAM. SRAS should be connected to the corresponding SDRAM $\overline{\text{SRAS}}$.
SCAS	O	Synchronous column address strobe. Indicates a valid column address is present and can be latched by the SDRAM. SCAS should be connected to the corresponding SDRAM $\overline{\text{SCAS}}$.
DRAMW	O	DRAM read/write. Asserted for write operations and negated for read operations.
SDRAM_CS[1:0]	O	Row address strobe. Select each memory block of SDRAMs connected to the controller. One SDRAM_CS signal selects one SDRAM block and connects to the corresponding CS signals.
SCKE	O	Synchronous DRAM clock enable. Connected directly to the CKE (clock enable) signal of SDRAMs. Enables and disables the clock internal to SDRAM. When CKE is low, memory can enter a power-down mode in which operations are suspended or capable of entering self-refresh mode.
BS[3:0]	O	SDRAM byte selects BS[3:0] function as byte enables to the SDRAMs. They connect to the DQM signals (or data qualifier masks) of the SDRAMs.
SDRAM_A [23:9]	O	SDRAM address bus output
SDRAM_D [31:0]	I/O	SDRAM data bus

34.4.2 Memory Map for SDRAMC Registers

The DRAM controller registers memory map is shown in the following table

SDRAM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4000_F042	Control Register (SDRAM_CTRL)	16	R/W	Undefined	34.4.2.1/ 804
4000_F048	Address and Control Register (SDRAM_AC0)	32	R/W	Undefined	34.4.2.2/ 806
4000_F04C	Control Mask (SDRAM_CM0)	32	R/W	Undefined	34.4.2.3/ 809
4000_F050	Address and Control Register (SDRAM_AC1)	32	R/W	Undefined	34.4.2.2/ 806
4000_F054	Control Mask (SDRAM_CM1)	32	R/W	Undefined	34.4.2.3/ 809

34.4.2.1 Control Register (SDRAM_CTRL)

SDRAM_CTRL register controls refresh logic

Address: 4000_F000h base + 42h offset = 4000_F042h

Bit	15	14	13	12	11	10	9	8
Read	Reserved		Reserved		IS	RTIM		RC
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*
Bit	7	6	5	4	3	2	1	0
Read	RC							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

SDRAM_CTRL field descriptions

Field	Description
15–14 Reserved	Reserved This field is reserved. Should be cleared
13 Reserved	Reserved This field is reserved. Should be cleared

Table continues on the next page...

SDRAM_CTRL field descriptions (continued)

Field	Description
12 Reserved	Reserved This field is reserved. Should be cleared
11 IS	Initiate self-refresh command. 0 Take no action or issue a selfx command to exit self refresh. 1 SDRAM controller sends a self command to both SDRAM blocks to put them in low-power, self-refresh state where they remain until IS is cleared. When IS is cleared, the controller sends a selfx command for the SDRAMs to exit self-refresh. The refresh counter is suspended while the SDRAMs are in self-refresh; the SDRAM controls the refresh period.
10–9 RTIM	Refresh timing Determines the timing operation of auto-refresh in the SDRAM controller. Specifically, it determines the number of bus clocks inserted between a ref command and the next possible actv command. This same timing is used for both memory blocks controlled by the SDRAM controller. This corresponds to t_{RC} in the SDRAM specifications 00 3 clocks 01 6 clocks 10 9 clocks 11 9 clocks
RC	Refresh count Controls refresh frequency. The number of bus clocks between refresh cycles is $(RC + 1) \times 16$. Refresh can range from 16–8192 bus clocks to accommodate both standard and low-power SDRAMs with bus clock operation from less than 2 MHz to greater than 50 MHz. The following example calculates RC for an auto-refresh period for 4096 rows to receive 64 ms of refresh every 15.625 μ s for each row (1031 bus clocks at 66 MHz). # of bus clocks = 1031 = $(RC \text{ field} + 1) \times 16$; $RC = (1031 \text{ bus clocks}/16) - 1 = 63.44$, which rounds to 63; therefore, $RC = 0x3F$.

34.4.2.2 Address and Control Register (SDRAM_ACn)

The SDRAM_ACn registers, contain the base address compare value and the control bits for memory blocks 0 and 1 of the SDRAM controller. Address and timing are also controlled by bits in SDRAM_ACn.

Address: 4000_F000h base + 48h offset + (8d × i), where i=0d to 1d

* Notes:

- x = Undefined at reset.

SDRAM_ACn field descriptions

Field	Description
31–18 BA	Base address register. With SDRAM_CM[BAM], determines the address range in which the associated DRAM block is located. Each BA bit is compared with the corresponding address of the current bus cycle. If all unmasked bits match, the address hits in the associated DRAM block. BA functions the same as in asynchronous operation.
17–16 Reserved	Should be cleared This field is reserved.
15 RE	Refresh enable Determines when the DRAM controller generates a refresh cycle to the DRAM block.

Table continues on the next page...

SDRAM_ACn field descriptions (continued)

Field	Description																																							
	0 Do not refresh associated DRAM block 1 Refresh associated DRAM block																																							
14 Reserved	Should be cleared This field is reserved.																																							
13–12 CASL	CAS Latency Affects the following SDRAM timing specifications. Timing nomenclature varies with manufacturers. Refer to the SDRAM specification for the appropriate timing nomenclature: <table><tr><th rowspan="2">Parameter</th><th colspan="4">Number of Bus Clocks</th></tr><tr><th>CASL=00</th><th>CASL=01</th><th>CASL=10</th><th>CASL=11</th></tr><tr><td>trcd—$\overline{SRAS}$ assertion to $\overline{SCAS}$ assertion</td><td>1</td><td>2</td><td>3</td><td>3</td></tr><tr><td>tcasl—$\overline{SCAS}$ assertion to data out</td><td>1</td><td>2</td><td>3</td><td>3</td></tr><tr><td>tras—actv command to precharge command</td><td>2</td><td>4</td><td>6</td><td>6</td></tr><tr><td>trp—Precharge command to actv command</td><td>1</td><td>2</td><td>3</td><td>3</td></tr><tr><td>trwl, trdl—Last data input to precharge command</td><td>1</td><td>1</td><td>1</td><td>1</td></tr><tr><td>tep—Last data out to precharge command</td><td>1</td><td>1</td><td>1</td><td>1</td></tr></table>	Parameter	Number of Bus Clocks				CASL=00	CASL=01	CASL=10	CASL=11	trcd— $\overline{SRAS}$ assertion to $\overline{SCAS}$ assertion	1	2	3	3	tcasl— $\overline{SCAS}$ assertion to data out	1	2	3	3	tras—actv command to precharge command	2	4	6	6	trp—Precharge command to actv command	1	2	3	3	trwl, trdl—Last data input to precharge command	1	1	1	1	tep—Last data out to precharge command	1	1	1	1

111	24	Not supported																																						
7 Reserved	Reserved This field is reserved.																																							

Table continues on the next page...

SDRAM_ACn field descriptions (continued)

Field	Description
	Should be cleared
6 IMRS	Initiate mode register set (mrs) command. Setting IMRS generates a mrs command to the associated SDRAMs. In initialization, IMRS should be set only after all DRAM controller registers are initialized and pall and refresh commands have been issued. After IMRS is set, the next access to an SDRAM block programs the SDRAM's mode register. Thus, the address of the access should be programmed to place the correct mode information on the SDRAM address pins. Because the SDRAM does not register this information, it doesn't matter if the IMRS access is a read or a write or what, if any, data is put onto the data bus. The DRAM controller clears IMRS after the mrs command finishes. 0 Take no action 1 Initiate mrs command
5-4 PS	Port size. Indicates the port size of the associated block of SDRAM, which allows for dynamic sizing of associated SDRAM accesses. PS functions the same in asynchronous operation. 00 32-bit port 01 8-bit port 10 16-bit port 11 16-bit port
3 IP	Initiate precharge all (pall) command. The DRAM controller clears IP after the pall command is finished. Accesses via IP should be no wider than the port size programmed in PS. 0 Take no action. 1 A pall command is sent to the associated SDRAM block. During initialization, this command is executed after all DRAM controller registers are programmed. After IP is set, the next write to an appropriate SDRAM address generates the pall command to the SDRAM block.
Reserved	Reserved. This field is reserved. Should be cleared

34.4.2.3 Control Mask (SDRAM_CMn)

The SDRAM_CMn, includes mask bits for the base address and for address attributes

Address: 4000_F000h base + 4Ch offset + (8d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BAM														Reserved	
W																
Reset	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*

R	Reserved							WP	Reserved							V
W																
Reset	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	0

* Notes:

- x = Undefined at reset.

SDRAM_CMn field descriptions

Field	Description
31–18 BAM	Base address mask. Masks the associated SDRAM_ACn[BA]. Lets the DRAM controller connect to various DRAM sizes. Mask bits need not be contiguous 0 The associated address bit is used in decoding the DRAM hit to a memory block 1 The associated address bit is not used in the DRAM hit decode
17–9 Reserved	Reserved This field is reserved. Should be cleared
8 WP	Write protect. Determines whether the associated block of DRAM is write protected. 0 Allow write accesses 1 Ignore write accesses. The DRAM controller ignores write accesses to the memory block and an address exception occurs. Write accesses to a write-protected DRAM region are compared in the chip select module for a hit. If no hit occurs, an external bus cycle is generated. If this external bus cycle is not acknowledged, an access exception occurs.
7–1 Reserved	Reserved This field is reserved. Should be cleared
0 V	Valid. Cleared at reset to ensure that the DRAM block is not erroneously decoded 0 Do not decode DRAM accesses. 1 Registers controlling the DRAM block are initialized; DRAM accesses can be decoded

34.5 General Synchronous Operation Guidelines

To reduce system logic and to support a variety of SDRAM sizes, the DRAM controller provides SDRAM control signals as well as a multiplexed row address and column address to the SDRAM.

34.5.1 Address Multiplexing

The following table shows the generic address multiplexing scheme for SDRAM configurations. All possible address connection configurations can be derived from this table.

NOTE

The maximum SDRAM address size is 128 Mbits.

Table 34-3. Generic Address Multiplexing Scheme

Address Pins	Row Address	Column Address	Notes Relating to Port Sizes
17	17	0	8-bit port only
16	16	1	8- and 16-bit ports only
15	15	2	
14	14	3	
13	13	4	
12	12	5	
11	11	6	
10	10	7	
9	9	8	
17	17	16	32-bit port only
18	18	17	16-bit port only or 32-bit port with only 8 column address lines
19	19	18	16-bit port only when at least 9 column address lines are used
20	20	19	
21	21	20	
22	22	21	
23	23	22	

The following tables provide a more comprehensive, step-by-step way to determine the correct address line connections for interfacing the SDRAM. To use the tables, find the one that corresponds to the number of column address lines on the SDRAM and to the port size as seen by the controller, which is not necessarily the SDRAM port size. For example, if two 1M x 16-bit SDRAMs together form a 1M x 32-bit memory, the port size

is 32 bits. The tables below assume that the SDRAM's A10 signal is used for command. If using a memory where command is on a different address signal modifications to the connections shown might be needed. Most SDRAMs likely have fewer address lines than are shown in the tables, so follow only the connections shown until all SDRAM address lines are connected.

Table 34-4. SDRAM Controller to SDRAM Interface (8-Bit Port, 9-Column Address Lines)

34.5.4 Burst Page Mode

SDRAM can efficiently provide data when an SDRAM page is opened. As soon as $\overline{SCAS}$ is issued, the SDRAM accepts a new address and asserts $\overline{SCAS}$ every CLKOUT for as long as accesses occur in that page. In burst page mode, there are multiple read or write operations for every ACTV command in the SDRAM if the requested transfer size exceeds the port size of the associated SDRAM. The primary cycle of the transfer generates the ACTV and READ or WRITE commands; secondary cycles generate only READ or WRITE commands. As soon as the transfer completes, the PALL command is generated to prepare for the next access.

Note that in synchronous operation, burst mode and address incrementing during burst cycles are controlled by the DRAM controller. Thus, instead of the SDRAM enabling its internal burst incrementing capability, the SDRAM Controller controls this function. This means that the burst function that is enabled in the mode register of SDRAMs must be disabled when interfacing to the SDRAM Controller.

Figure 34-3 figure shows a burst read operation. In this example, $\text{SDRAM\_AC}[\text{CASL}] = 01$ for an $\overline{\text{SRAS}}$ -to- $\overline{\text{SCAS}}$ delay (t_{RCD}) of 2 system clock cycles. Because t_{RCD} is equal to the read CAS latency ($\overline{\text{SCAS}}$ assertion to data out), this value is also 2 system clock cycles. Notice that NOPs are executed until the last data is read. A PALL command is executed one cycle after the last data transfer.

Figure 34-3. Burst Read SDRAM Access

Figure 34-4 figure shows the burst write operation. In this example, $\text{SDRAM\_AC}[\text{CASL}] = 01$, which creates an $\overline{\text{SRAS}}$ -to- $\overline{\text{SCAS}}$ delay (t_{RCD}) of 2 system clock cycles. Note that data is available upon $\overline{\text{SCAS}}$ assertion and a burst write cycle completes two cycles sooner than a burst read cycle with the same t_{RCD} . The next bus cycle is initiated sooner, but cannot begin an SDRAM cycle until the precharge-to-ACTV delay completes.

Figure 34-4. Burst Write SDRAM Access

Accesses in synchronous burst page mode always cause the following sequence

- ACTV command
- NOP commands to assure $\overline{\text{SRAS}}$ -to- $\overline{\text{SCAS}}$ delay (if CAS latency is 1, there are no NOP commands).
- Required number of READ or WRITE commands to service the transfer size with the given port size.
- Some transfers need more NOP commands to assure the ACTV-to-precharge delay.
- PALL command
- Required number of idle clocks inserted to assure precharge-to-ACTV delay.

34.5.5 Auto-Refresh Operation

The DRAM controller is equipped with a refresh counter and control. This logic is responsible for providing timing and control to refresh the SDRAM without user interaction. Once the refresh counter is set, and refresh is enabled, the counter counts to zero. At this time, an internal refresh request flag is set and the counter begins counting down again. The DRAM controller completes any active burst operation and then performs a PALL operation. The DRAM controller then initiates a refresh cycle and clears the refresh request flag. This refresh cycle includes a delay from any precharge to

the auto-refresh command, the auto-refresh command, and then a delay until any ACTV command is allowed. Any SDRAM access initiated during the auto-refresh cycle is delayed until the cycle is completed.

Figure 34-5 shows the auto-refresh timing. In this case, there is an SDRAM access when the refresh request becomes active. The request is delayed by the precharge to ACTV delay programmed into the active SDRAM bank by the CAS bits. The REF command is then generated and the delay required by SDRAM_CTRL[RTIM] is inserted before the next ACTV command is generated. In this example, the next bus cycle is initiated, but does not generate an SDRAM access until TRC is finished. Because both chip selects are active during the REF command, it is passed to both blocks of external SDRAM.

Figure 34-5. Auto-Refresh Operation

34.5.6 Self-Refresh Operation

Self-refresh is a method of allowing the SDRAM to enter into a low-power state, while at the same time to perform an internal refresh operation and to maintain the integrity of the data stored in the SDRAM. The DRAM controller supports self-refresh with SDRAM_CTRL[IS]. When IS is set, the SELF command is sent to the SDRAM. When IS is cleared, the SELF command is sent to the DRAM controller. Figure 34-6 diagram shows the self-refresh operation.

Figure 34-6. Self-Refresh Operation

34.6 Initialization Sequence

Synchronous DRAMs have a prescribed initialization sequence. The DRAM controller supports this sequence with the following procedure:

- SDRAM control signals are reset to idle state. Wait the prescribed period after reset before any action is taken on the SDRAMs. This is normally around 100 μ s.
- Initialize the CTRL, AC, and CM registers in their operational configuration. Do not yet enable PALL or REF commands.
- Issue a PALL command to the SDRAMs by setting SDRAM_AC[IP] and accessing a SDRAM location with the size equal the SDRAM port size. Wait the time (determined by t_{RP}) before any other execution.
- Enable refresh (set SDRAM_AC[RE]) and wait for at least 8 refreshes to occur.
- Before issuing the MRS command, determine if the mask bits of CM register need to be modified to allow the MRS to execute properly
- Issue the MRS command by setting SDRAM_AC[IMRS] and accessing a location in the SDRAM with the size equal the SDRAM port size. Note that mode register settings are driven on the SDRAM address bus, so care must be taken to change SDRAM_CM[BAM] if the mode register configuration does not fall in the address range determined by the address mask bits. After the mode register is set, mask bits of CM register can be restored to their desired configuration.

34.6.1 Mode Register Settings

It is possible to configure the operation of SDRAMs, namely their burst operation and CAS latency, through the SDRAM component's mode register. CAS latency is a function of the speed of the SDRAM and the bus clock of the DRAM controller. The DRAM controller operates at a CAS latency of 1, 2, or 3.

Although the DRAM controller supports bursting operations, it does not use the bursting features of the SDRAMs. Because the SDRAM Controller can burst operand sizes of 1, 2, 4, or 16 bytes long, the concept of a fixed burst length in the SDRAMs mode register becomes problematic. Therefore, the SDRAM controller generates the burst cycles rather than the SDRAM device. Because the SDRAM Controller generates a new address and a READ or WRITE command for each transfer within the burst, the SDRAM mode register should be set either not to burst or to a burst length of one. This allows bursting to be controlled by the SDRAM controller.

The SDRAM mode register is written by setting the associated block's SDRAM_AC[IMRS]. First, the base address and mask registers must be set to the appropriate configuration to allow the mode register to be set. Note that improperly set mask bits of CM register may prevent access to the mode register address. Thus, the user should determine the mapping of the mode register address to the processor address bits to find out if an access is blocked. If the CM register setting prohibits mode register access, then it should be reconfigured to enable the access and then set to its necessary configuration after the MRS command executes.

After SDRAM_AC[IMRS] is set, the next access to the SDRAM address space generates the MRS command to that SDRAM. The address of the access should be selected to place the correct mode information on the SDRAM address pins. The address is not multiplexed for the MRS command. The MRS access can be a read or write and should be equal the SDRAM port size. The important thing is that the address output of that access needs the correct mode programming information on the correct address bits.

[Figure 34-7](#) shows the MRS command, which occurs in the first clock of the bus cycle.

Figure 34-7. Mode Register Set (MRS) Command

34.7 SDRAM Example

This example interfaces a 512K x 32-bit x 4 bank SDRAM component operating at 40 MHz. [Table 34-15](#) table lists design specifications for this example.

Table 34-15. SDRAM Example Specifications

Parameter	Specification
Speed grade (-8E)	40 MHz (25-ns period)
10 rows, 8 columns	
Two bank-select lines to access four internal banks	
ACTV-to-read/write delay (t_{RCD})	20ns(min)
Period between auto-refresh and ACTV command (t_{RC})	70 ns
ACTV command to precharge command (t_{RAS})	48 ns (min)
ACTV command to precharge command (t_{RAS}) 48 ns (min.) Precharge command to ACTV command (t_{RP})	20ns (min)
Last data input to PALL command (t_{RWL})	1 bus clock (25ns)
Auto-refresh period for 4096 rows (t_{REF})	64ms

34.7.1 SDRAM Interface Configuration

To interface this component to the DRAM controller, use the connection table that corresponds to a 32-bit port size with 8 columns. Two pins select one of four banks when the part is functional. The following table shows the proper hardware connections

Table 34-16. SDRAM Hardware Connections

SDRAM Controller Pins	A15	A14	A13	A12	A11	A10	A9	A17	A18	A19	A20	A21	A22
SDRAM Pins	A0	A1	A2	A3	A4	A5	A6	A7	A8	A9	A10=CMD	BA0	BA1

34.7.2 SDRAM_CTRL Register Initialization

At power-up, the SDRAM_CTRL register has the following configuration if synchronous operation and SDRAM address multiplexing are desired.

	15	14	13	12	11	10	9	8	0	
Field	—	—	—	—	IS	RTIM		RC		
Setting	0000_0000_0010_0110									
(hex)	0026									

Figure 34-8. Initialization Values for SDRAM_CTRL Register

This configuration results in a value of 0x0026 for SDRAM_CTRL register, as shown in the following table

Table 34-17. DCR Initialization Values

Bits	Name	Setting	Description
15	—	0	Reserved
14	—	0	Reserved
13	-	0	Reserved
12	-	0	Reserved
11	IS	0	At power-up, allowing power self-refresh state is not appropriate because registers are being set up.
10-9	RTIM	00	Because t_{RC} value is 70 ns, indicating a 3-clock refresh-to-ACTV timing.
8-0	RC	0x26	Specification indicates auto-refresh period for 4096 rows to be 64 mS or refresh every 15.625 μ s for each

Table 34-17. DCR Initialization Values

Bits	Name	Setting	Description
			row, or 625 bus clocks at 40 MHz. Because SDRAM_CTRL[RC] is incremented by 1 and multiplied by 16, RC = (625 bus clocks/16) - 1 = 38.06 = 38

34.7.3 SDRAM_AC Register Initialization

The starting address of the SDRAM is 0x7000_0000. Continuous page mode feature is used.

The SDRAM_AC registers should be programmed as shown in [Figure 34-9](#) figure.

	31															18			17		16											
Field	BA																	—														
Setting	0111_0000_0000_00xx																															
(hex)	7					0					0					0																
	15		14		13		12		11		10		9		8		7		6		5		4		3		2		1		0	
Field	RE	—	CASL		—		CBM					—		IMRS		PS		IP		—												
Setting	0000_x011_x000_0000																															
(hex)	0300																															

Figure 34-9. SDRAM_AC Register Configuration

This configuration results in a value of SDRAM_AC0 = 0x7000_0300, as described in the following table. SDRAM_AC1 initialization is not needed because there is only one block. Subsequently, SDRAM_AC1[RE,IMRS,IP] should be cleared; everything else is a don't care.

Table 34-18. DACR Initialization Values

Bits	Name	Setting	Description
31–18	BA	0111_0000_0000_00	Base address. So SDRAM_AC0[31–16] = 0x7000, placing the starting address of the SDRAM accessible

Table continues on the next page...

Table 34-18. DACR Initialization Values (continued)

Bits	Name	Setting	Description
			memory at 0x7000_0000.
17-16	–		Reserved. Don't Care.
15	RE	0	Keeps auto-refresh disabled because registers are being set up at this time.
14	–		Reserved. Don't Care.
13-12	CASL	00	Indicates a delay of data 1 cycle after SCAS is asserted
11	–		Reserved. Don't Care.
10-8	CBM	011	Command bit is pin 20 and bank selects are 21 and up.
7	–		Reserved. Don't Care.
6	IMRS	0	Indicates MRS command has not been initiated.
5-4	PS	00	32-bit port
3	IP	0	Indicates precharge has not been initiated.
2-0	–		Reserved. Don't Care.

34.7.4 SDRAM_CM Register Initialization

The SDRAM_CM registers have the following configuration.

	31															18	17	16
Field	BAM																—	
Setting	0000_0000_0111_11xx																	
(hex)	007C																	

	15			9	8	7	6	5	4	3	2	1	0
Field	—				WP	—	C/I	AM	SC	SD	UC	UD	V
Setting	xxxx_xxx0_xxxx_xxx1												
(hex)	0001												

Figure 34-10. SDRAM_CM0 Register

With this configuration, the SDRAM_CM0 = 0x007C_0001, as described in the following table.

Table 34-19. SDRAM_CM0 Initialization Values

Bits	Name	Setting	Description
31–18	BAM		With bits 17 and 16 as don't cares, BAM = 0x007C, which creates 8 MByte block of memory.
17-16	—		Reserved. Don't Care.
15-1	—		Reserved. Don't Care.
0	V	1	Enable accesses.

34.7.5 Mode Register Initialization

When SDRAM_AC[IMRS] is set, a bus cycle initializes the mode register. If the mode register setting is read on A[10:0] of the SDRAM on the first bus cycle, the bit settings on the corresponding processor address pins must be determined while being aware of masking requirements

The following table lists the desired initialization setting:

Table 34-20. Mode Register Initialization

SDRAM Controller Pins	SDRAM Pins	Mode Register Initialization	
A20	A10	Reserved	X
A19	A9	WB	0
A18	A8	Opmode	0

Table continues on the next page...

Table 34-20. Mode Register Initialization (continued)

SDRAM Controller Pins	SDRAM Pins	Mode Register Initialization	
A17	A7	Opmode	0
A9	A6	CASL	0
A10	A5	CASL	0
A11	A4	CASL	1
A12	A3	BT	0
A13	A2	BL	0
A14	A1	BL	0
A15	A0	BL	0

Next, this information is mapped to an address to determine the hexadecimal value.

Quad Serial Peripheral Interface (QuadSPI)

35.1 Chip-specific QuadSPI information

35.1.1 QuadSPI Module Instantiations

This device contains one QuadSPI module . This device contains a single dual-QUADSPI module with upto 8 data lines for XiP functionality. The controller supports singles,dual, quad or octal data lines in single (SDR) or double (DDR) data rate configurations. SDR mode supports upto 100 MHz and DDR mode supports up to 75MHz. Several QuadSPI configurations are possible depending on QuadSPI memory selected. See [QSPI Modes of Interfacing](#) for more details.

35.1.2 QuadSPI Modes of Interfacing

QuadSPI Mode Support by Package								

35.1.2.1 QuadSPI Pin Muxing

Figure 35-1. QuadSPI Interface to 2 Separate QuadSPI in SDR mode

35.1.3 QuadSPI clocking

Details on the QuadSPI module can be found in [QuadSPI clocking](#).

35.1.4 QuadSPI Advanced Configuration

35.1.4.1 QuadSPI Clock Configuration

- Clock source selection for the clock divider is controlled by QuadSPI_SOCCR[2:0]

Field	Description
2 – 0 QSPISRC	QSPI clock source select • 000 Core/system clock • 001 MCGFLL clock • 010 MCGPLL clock • 011 MCGPLL 2x clock • 100 IRC48M clock. • 101 OSCERCLK clock • 110 MCGIRCLK clock. • 111 USB1PFDCLK

- Clock divider is configured by QuadSPI_MCR[27:24]

Field	Description
27 – 24 SCLKCFG	Serial clock divider • 0000 Divide by 1 • 0001 Divide by 2 • 0010 Divide by 3 • 0011 Divide by 4 • • 1111 Divide by 16

35.1.4.2 QSPI Octal Flash Pinmux Configuration

- Octal flash pinmux is configured by QuadSPI_SOCCR[15:13] in addition to the Port Control module.

Field	Description
15 OCTEN	Octal data pins enable When this bit is set QSPI0B_DATAx pins are switched to QSPI Port A to composite eight bit data bus 0 QSPI0B_DATAx pins are assigned to QSPI Port B 1 QSPI0B_DATAx pins are assigned to QSPI Port A NOTE: Here 'x'=0,1,2,3.
14	Differential flash clock pins enable

Table continues on the next page...

Chip-specific QuadSPI information

Field	Description
DIFFCKEN	When this bit is set QSPI0B_SCLK pin serves as an inverse QSPI0A_SCLK, QSPI0B_SS1_B pin serves as an inverse CK2 clock if CK2EN bit is set as well. 0 Differential flash clock is disabled. 1 Differential flash clock is enabled.
13 CK2EN	Flash CK2 clock pin enable When this bit is set QSPI0B_DQS pin serves as flash CK2 clock, QSPI0B_SS1_B pin serves as an inverse CK2 clock if DIFFCKEN bit is set as well. CK2 and inverse CK2 are only available in 144 pin packages 0 CK2 flash clock is disabled 1 CK2 flash clock is enabled

- After configuring the Alt selection and QuadSPI_SOCCR[15:13], QSPI Port A can operate in octal mode.

Pin Name	Alt Selection	Alt Function	QSPI_SOCCR	Octal Flash Pin
PTE0	ALT5	QSPI0A_DATA3	–	DQ3

35.1.4.3 QuadSPI DQS Configuration

- To support high flash clock frequency DQS function need be enabled. Besides the QuadSPI_MCR[DQS_EN] and QuadSPI_MCR[DQS_LAT_EN], there are other control bits in QuadSPI_SOCCR register as below.

Field	Description
29 – 24 DLYTAPSELB	Delay chain tap number selection for QSPI Port B DQS 000000 Select 1 delay chain tap

Table continues on the next page...

Field	Description
	000001 Select 2 delay chain taps 000010 Select 3 delay chain taps 111111 Select 64 delay chain tap
21 – 16 DLYTAPSELA	Delay chain tap number selection for QSPI Port A DQS 000000 Select 1 delay chain tap 000001 Select 2 delay chain taps 000010 Select 3 delay chain taps 111111 Select 64 delay chain tap
12 DQSINVSEL	Select clock source for internal DQS generation 0 Use 1x internal reference clock for the DQS generation 1 Use inverse 1x internal reference clock for the DQS generation
11 – 10 DQSPHASEL	Select phase shift for internal DQS generation. These bits are always zero in SDR mode. 00 No phase shift 01 Select 45 degree phase shift 10 Select 90 degree phase shift 11 Select 135 degree phase shift
9 DQSPADLPEN	When this bit is set the internal generated DQS will be sent to the DQS pad first and then looped back to QuadSPI. DQSLPEN should be cleared when this bit is set. 0 DQS loop back from DQS pad is disabled 1 DQS loop back from DQS pad is enabled
8 DQSLPEN	When this bit is set the internal generated DQS is selected and looped back to QuadSPI, without going to DQS pad. DQSPADLPEN should be cleared when this bit is set. 0 DQS loop back is disabled 1 DQS loop back is enabled

35.1.5 QuadSPI_MCR[SCLKCFG] implementation

The following table shows the serial clock configuration for this chip.

Table 35-2. QuadSPI_MCR[SCLKCFG] field description

Field	Description
31-24 SCLKCFG	Serial Clock Configuration. Used for dividing clocks. 0x00: Divide by 1 0x01: Divide by 2 0x02: Divide by 3 0x04: Divide by 4

Table 35-2. QuadSPI_MCR[SCLKCFG] field description

Field	Description
	...
	0x0F: Divide by 16
	All others: reserved

35.1.6 QuadSPI register reset values

All reset values for the QuadSPI registers that are device specific are shown in the following tables. All other register reset values are shown in the module memory map.

Table 35-3. QuadSPI Module Configuration Register Reset Values

Register	Reset Value
Module Configuration Register (QuadSPI_MCR)	000F_400Ch

Table 35-4. QuadSPI Buffer Configuration Register Reset Values

Register	Reset Value
Buffer0 Configuration Register (QuadSPI_BUF0CR)	0000_0002h
Buffer1 Configuration Register (QuadSPI_BUF1CR)	0000_0003h
Buffer2 Configuration Register (QuadSPI_BUF2CR)	0000_0004h
Buffer3 Configuration Register (QuadSPI_BUF3CR)	8000_0000h

Table 35-5. Serial Flash A1 Top Address Reset Values

Register	Reset Value
QuadSPI0_SFA1AD	6fff_fc00h

Table 35-6. Serial Flash A2 Top Address Reset Values

Register	Reset Value
QuadSPI0_SFA2AD	6fff_fc00h

Table 35-7. Serial Flash B1 Top Address Reset Values

Register	Reset Value
QuadSPI0_SFB1AD	6fff_fc00h

Table 35-8. Serial Flash B2 Top Address Reset Values

Register	Reset Value
QuadSPI0_SFB2AD	6fff_fc00h

35.1.7 QuadSPI AHB flexible buffer size

For this chip, the size of the complete buffer mentioned is 512 bytes.

35.1.8 QuadSPI signal assignment

Table 35-9. QuadSPI signal assignment on K27F

QuadSPI signal name	Pin Name	Alt Selection	Pin Name	Alt Selection
QSPI0A_SCLK	PTE1/LLWU_P0	ALT5	PTC25	ALT7
QSPI0A_DATA0	PTE2/LLWU_P1	ALT5	PTC26	ALT7
QSPI0A_DATA1	PTE4/LLWU_P2	ALT5	PTC28	ALT7
QSPI0A_DATA2	PTE3	ALT5	PTC27	ALT7
QSPI0A_DATA3	PTE0	ALT5	PTC24	ALT7
QSPI0A_SS0_B	PTE5	ALT5	PTC29	ALT7
QSPI0A_SS1_B	PTE7	ALT7	PTC19	ALT7
QSPI0A_DQS	PTE11	ALT7		
QSPI0B_SCLK	PTE7	ALT5		
QSPI0B_DATA0	PTE8	ALT5		
QSPI0B_DATA1	PTE10/LLWU_P18	ALT5		
QSPI0B_DATA2	PTE9/LLWU_P17	ALT5		
QSPI0B_DATA3	PTE6/LLWU_P16	ALT5		
QSPI0B_SS0_B	PTE11	ALT5		
QSPI0B_SS1_B	PTE13	ALT5		
QSPI0B_DQS	PTE12	ALT5		

QuadSPI signals are shared with PortE pins and PortC pins. PortE QuadSPI signals will be powered via the VDDIO_E supply. PortC QuadSPI signals will be powered via the VDD supply. PortC only provide nibble support of "QuadSPI portA". See K27F pinout for pin position for specific supported packages.

35.2 Introduction

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to a single or two external serial flash devices, each with up to eight bidirectional data lines.

35.2.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices. As there is no specific standard, the module supports various kind of flashes from different vendors. Refer [Serial Flash Devices](#) for example sequences.
- Single, dual, quad and octal modes of operation.
- Double data rate (DDR)/Double transfer rate (DTR) mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and Single data rate (SDR) mode.
- Support for parallel writes via register mapped interface in single I/O mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- AHB master to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access) and fill TX Buffer via IPS register space (32-bit access).
 - AHB master can be a DMA with configurable inner loop size.
- Multimaster accesses with priority
 - Flexible and configurable buffer for each master
- Multiple interrupt conditions (see [Table 35-19](#))
- All AHB accesses to flash devices are directly memory mapped to the chip system memory.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations. Software needs to select the corresponding sequence according to the connected flash device.
 - Supports all types of addressing.

35.2.2 Block Diagram

The following figure is a block diagram of the Quad Serial Peripheral Interface (QuadSPI) module.

Figure 35-2. QuadSPI Block Diagram

35.2.3 QuadSPI Modes of Operation

For power management through IPS interface access and correct config register programming sequences, QuadSPI supports three modes: normal, module disable and stop mode.

- Normal Mode can be used for write or read accesses to an external serial flash device.
 - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to [Flash Programming](#) for further details.
 - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see [Flash Read](#).
- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

35.2.4 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 35-10. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select
DMA	Direct Memory Access
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a 1 to this field resets the flag
I/O	Input output. In this document, I/O lines are also referred as pads .

35.2.5 Glossary for QuadSPI module

Table 35-11. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 35-16 . Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
QSPI_AMBA_BASE	The first address of the serial flash device as presented to the QuadSPI controller. This may be the base of the serial flash in the system address map or it may be a remapping, for instance to 0x0, done by the system. Refer to the system address map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 35-30 for details on errors.
Single/Dual/Quad/Octal Instructions	Depending on the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. Single pad: Single line I/O with one data out and one data in line to/from the serial flash device.

Table continues on the next page...

Table 35-11. Glossary (continued)

Term	Definition
	- Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module - Quad pad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI - Octal pad: Octal line I/O with 8 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode-and/or dummy bytes, transmit and/or receive data.
LUT	Look-up table.

35.3 External Signal Description

This section provides the external signal information of the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

Table 35-12. Signal Properties

Signal Name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash A1	O	This signal is the chip select for the serial flash device A1. A1 represents the first device in a dual-die package flash A or the first of the two flash devices that share IOFA. Refer to Dual Die Flashes for more details.
PCSFA2	Peripheral Chip Select Flash A2	O	This signal is the chip select for the serial flash device A2. A2 represents the second device in a dual-die package flash A or the second of the two flash devices that share IOFA. Refer to Dual Die Flashes for more details.
PCSFB1	Peripheral Chip Select Flash B1	O	This signal is the chip select for the serial flash device B1. B1 represents the first device in a dual-die package flash B or the first of the two flash devices that share IOFB. Refer to Dual Die Flashes for more details.
PCSFB2	Peripheral Chip Select Flash B2	O	This signal is the chip select for the serial flash device B2. B2 represents the second device in a dual-die package flash B or the second of the two flash devices that share IOFB. Refer to Dual Die Flashes for more details.
SCKFA	Serial Clock Flash A	O	This signal is the serial clock output to the serial flash device A.
SCKFB	Serial Clock Flash B	O	This signal is the serial clock output to the serial flash device B.
IOFA[7:0]	Serial I/O Flash A	I/O	These signals are the data I/O lines to/from the serial flash device A. Refer to Driving External Signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as control inputs when Single and Dual Instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1].

Table continues on the next page...

Table 35-12. Signal Properties (continued)

Signal Name	Function	Direction	Description
IOFB[7:0]	Serial I/O Flash B	I/O	These signals are the data I/O lines to/from the serial flash device B. Refer to Driving External Signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as control inputs when Single and Dual Instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFB[0] and expects data on IOFB[1].
DQSFA	Data Strobe signal Flash A	I	Data strobe signal for port A. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.
DQSFB	Data Strobe signal Flash B	I	Data strobe signal for port B. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.

35.3.1 Driving External Signals

The different phases of the serial flash access scheme are shown in the following figure.

Figure 35-3. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- **IDLE**: Serial flash device not selected. No interaction with the serial flash device. All IOFx signals driven.
- **INSTRUCTION**: Serial flash device selected. The instruction is sent to the serial flash device. All IOFx signals are driven.

- **ADDRESS:** Serial Flash Address is sent to the device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- **MODE:** Mode bytes are sent to the serial flash device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- **DUMMY:** Dummy clocks are provided to the serial flash device. Refer to the [Figure 35-3](#) for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- **DATA:** Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device. In Parallel Flash Mode this applies to both serial flash devices simultaneously.

35.4 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

35.4.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 35-13. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if <i>QSPI_MCR[MDIS] = 1</i> .
Normal Mode	Write access only if the module is in <i>Normal Mode</i> .

- Register Write Access Requirements**

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

35.4.2 Peripheral Bus Register Descriptions

This section provides the memory map and register definitions of the QuadSPI module.

NOTE

Access to location 0x4 does not give transfer error.

QuadSPIx_MCR field descriptions

Field	Description
31–24 SCLKCFG	Serial Clock Configuration. This field configuration is chip specific. For details, refer to chip-specific QuadSPI information. It may be used for dividing clocks.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
23–20 Reserved	This field is reserved.
19 ISD3FB	Idle Signal Drive IOFB[3] Flash B. This bit determines the logic level the IOFB[3] output of the QuadSPI module is driven to in the inactive state. Refer to Driving Flash Control Signals in Single and Dual Mode . 0 IOFB[3] is driven to logic L 1 IOFB[3] is driven to logic H
18 ISD2FB	Idle Signal Drive IOFB[2] Flash B. This bit determines the logic level the IOFB[2] output of the QuadSPI module is driven to in the inactive state. Refer to Driving Flash Control Signals in Single and Dual Mode . 0 IOFB[2] is driven to logic L 1 IOFB[2] is driven to logic H
17 ISD3FA	Idle Signal Drive IOFA[3] Flash A. This bit determines the logic level the IOFA[3] output of the QuadSPI module is driven to in the inactive state. Refer to Driving Flash Control Signals in Single and Dual Mode . 0 IOFA[3] is driven to logic L 1 IOFA[3] is driven to logic H
16 ISD2FA	Idle Signal Drive IOFA[2] Flash A. This bit determines the logic level the IOFA[2] output of the QuadSPI module is driven to in the inactive state. Refer to Driving Flash Control Signals in Single and Dual Mode . 0 IOFA[2] is driven to logic L 1 IOFA[2] is driven to logic H
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidates the TX Buffer content. This is a self-clearing field. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSTR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidates the RX Buffer. This is a self-clearing field. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9 Reserved	This field is reserved.
8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
	0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable. This field is valid for both SDR and DDR mode. For more details, refer to Data Strobe (DQS) sampling method . 0 DQS disabled. 1 DQS enabled. When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5 DQS_LAT_EN	DQS Latency Enable. This field is valid when latency is included in between read access from flash memory in cases when QSPI_MCR[DQS_EN] is 1. For more details, refer to Data Strobe (DQS) sampling method . 0 DQS Latency disabled 1 DQS feature with latency included enabled
4 Reserved	This field is reserved.
3–2 END_CFG	Defines the endianness of the QuadSPI module. For more details refer to Byte Ordering Endianness
1 SWRSTHD	Software reset for AHB domain 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects. NOTE: The software resets need the clock to be running to propagate to the design. The MCR[MDIS] should therefore be set to 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTHD] to 0), it is recommended to set the MCR[MDIS] bit to 1. Once the software resets have been deasserted, the normal operation can be started by setting the MCR[MDIS] bit to 0.
0 SWRSTSD	Software reset for serial flash domain 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects. NOTE: The software resets need the clock to be running to propagate to the design. The MCR[MDIS] should therefore be set to 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTSD] to 0), it is recommended to set the MCR[MDIS] bit to 1. Once the software resets have been deasserted, the normal operation can be started by setting the MCR[MDIS] bit to 0.

35.4.2.2 IP Configuration Register (QuadSPIx_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to [Normal Mode](#), for details about the command triggering and command execution.

Write:

- $QSPI\_SR[IP\_ACC]=0$

Address: 400D_A000h base + 8h offset = 400D_A008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	Reserved				SEQID				Reserved								PAR_EN
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	IDATSZ																
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

QuadSPIx_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up table. This field defines bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
IDATSZ	IP data transfer size. Defines the data transfer size in bytes of the IP command.

35.4.2.3 Flash Configuration Register (QuadSPIx_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$
- $QSPI\_SR[IP\_ACC] = 0$

Address: 400D_A000h base + Ch offset = 400D_A00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	Reserved															TDH		Reserved				TCSH				Reserved				TCSS			
W																																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1		

QuadSPIx_FLSHCR field descriptions

Field	Description
31–18 Reserved	This field is reserved.
17–16 TDH	Serial flash data in hold time. This helps in meeting the Data In Hold time requirement of a flash. This is valid only in DDR mode. NOTE: This field should be set to 0x00 in SDR mode (QuadSPI_MCR[DDR_EN]=0). Refer to Data input hold requirement of Flash for details. The valid TDH programming options are shown below. Other combinations are invalid. 00 Data aligned with the posedge of Internal reference clock of QuadSPI 01 Data aligned with 2x serial flash half clock 10 Data aligned with 4x serial flash half clock
15–12 Reserved	This field is reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles. NOTE: The actual delay between chip select and clock is defined as: • $TCSH = 1 \text{ SCK clk}$ if $N = 0/1$ else, $N \text{ SCK clk}$ if $N > 1$, where N is the setting of TCSH
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles. NOTE: 1. The actual delay between chip select and clock is defined as: • $TCSS = 0.5 \text{ SCK clk}$ if $N = 0/1$ else, $N + 0.5 \text{ SCK clk}$ if $N > 1$, where N is the setting of TCSS. 2. Any update to the TCSS register bits is visible on the flash interface only from the second transaction following the update.

35.4.2.4 Buffer0 Configuration Register (QuadSPIx_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 10h offset = 400D_A010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	HP_EN	Reserved														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved	ADATSZ							Reserved				MSTRID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*	*

* Notes:

- MSTRID field: See the module configuration for reset value.

QuadSPIx_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable. When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

35.4.2.5 Buffer1 Configuration Register (QuadSPIx_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 14h offset = 400D_A014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

35.4.2.6 Buffer2 Configuration Register (QuadSPIx_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 18h offset = 400D_A018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

* Notes:

- MSTRID field: See the module configuration for the device specific reset value.

QuadSPIx_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

35.4.2.7 Buffer3 Configuration Register (QuadSPIx_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 1Ch offset = 400D_A01Ch

* Notes:

- MSTRID field: See the module configuration for the device specific reset value.

QuadSPIx_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable. When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

35.4.2.8 Buffer Generic Configuration Register (QuadSPIx_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Memory Map and Register Definition

Address: 400D_A000h base + 20h offset = 400D_A020h

QuadSPIx_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table . NOTE: If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

35.4.2.9 SOC Configuration Register (QuadSPIx_SOCCR)

This register is programmed at chip level for QuadSPI delay chain configuration. For details, refer to chip-specific QuadSPI information.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 24h offset = 400D_A024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_SOCCR field descriptions (continued)

Field	Description
	For details, refer to chip-specific QuadSPI information.

35.4.2.10 Buffer0 Top Index Register (QuadSPIx_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned, as each buffer entry is 64 bits long.

The register value should be set to the desired number of bytes. For example, setting BUF0IND[31:3] to 0 gives 0 bytes, 1 gives 8 bytes etc.

The size of buffer0 is the difference between BUF0IND and 0.

Software should ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 30h offset = 400D_A030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

35.4.2.11 Buffer1 Top Index Register (QuadSPIx_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned as each buffer entry is 64 bits long.

The size of buffer1 is the difference between BUF1IND and BUF0IND. The register value should be entered in bytes. For example, If BUF0IND = 0x100 then setting BUF1IND = 0x130 will set buffer1 size to 0x30 bytes.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 34h offset = 400D_A034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF1IND field descriptions

Field	Description
31–3 TPINDEX1	Top index of buffer 1.
Reserved	This field is reserved.

35.4.2.12 Buffer2 Top Index Register (QuadSPIx_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned as each buffer entry is 64 bits long.

The size of buffer2 is the difference between the BUF2IND and BUF1IND. The register value should be entered in bytes. For example, if BUF1IND = 0x130 then setting BUF2IND = 0x180 will set buffer2 size to 0x50 bytes.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 38h offset = 400D_A038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–3 TPINDEX2	Top index of buffer 2.
Reserved	This field is reserved.

35.4.2.13 Serial Flash Address Register (QuadSPIx_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24-bit mode, only bits 23-0 are sent to the flash. In 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 when QSPI_SFACR[CAS] is set to 0. Say, if QSPI_SFACR[CAS] is 3 then bits 26-3 are sent to flash as it page address in case flash is operating in 24-bit mode. Total number of address bits request by flash as it page and column address must not be more than 32 bit. Refer to [Table 35-14](#) for the mapping between the access mode and the QSPI_SFAR content and to [Normal Mode](#) for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in [Table 35-14](#).

Write:

- $QSPI\_SR[IP\_ACC] = 0$

Address: 400D_A000h base + 100h offset = 400D_A100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_SFAR field descriptions

Field	Description
SFADR	Serial Flash Address. The register content is used as byte address for all following IP Commands.

35.4.2.14 Serial Flash Address Configuration Register (QuadSPIx_SFACR)

This register contains the serial flash specific address requirements that must be configured according to the flash connected, for the controller to function properly. The module automatically translates the address QSPI_SFAR on the memory map or the incoming address on the AHB bus to the column address on the flash itself. Say, a flash needs 3 bits as its column address than only the lower 3 bits of QSPI_SFAR/AHB address are send to flash as its column address. The software should ensure that the serial flash address provided in the QSPI_SFAR register or the incoming AHB address lies in the valid flash address range.

Write:

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 104h offset = 400D_A104h

W																CAS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_SFACR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 WA	Word Addressable Defines whether the serial flash is a byte addressable flash or a word addressable flash. According to this bit configuration the address is re-mapped to the flash interface. Refer to Address scheme for details. 0 Byte addressable serial flash mode. 1 Word (2 byte) addressable serial flash mode.
15–4 Reserved	This field is reserved.
CAS	Column Address Space Defines the width of the column address. If the coulmn address is say [2:0] of QSPI_SFAR/AHB address, then CAS must be 3. If there is no column address separation in any serial flash this bit must be programmed to 0.

35.4.2.15 Sampling Register (QuadSPIx_SMPR)

The Sampling Register allows configuration of how the incoming data from the external serial flash devices are sampled in the QuadSPI module.

Write: Disabled Mode

Address: 400D_A000h base + 108h offset = 400D_A108h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_SMPR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 DDRSMP	DDR Sampling point Select the sampling point for incoming data when serial flash is executing a DDR instruction. Refer to Figure 35-13 for details on the sampling points.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FSDLY	Full Speed Delay selection for SDR instructions. Select the delay with respect to the reference edge for the sample point valid for full speed commands. 0 One clock cycle delay 1 Two clock cycles delay. NOTE: Please refer to Supported read modes for its usage. It is ignored when using non-DQS DDR instructions.
5 FSPHS	Full Speed Phase selection for SDR instructions. Select the edge of the sampling clock valid for full speed commands. 0 Select sampling at non-inverted clock 1 Select sampling at inverted clock. NOTE: Please refer to Supported read modes for its usage. FSPHS programming is only supported with internal non-DQS SDR sampling. It must be '0' in other sampling modes.

Table continues on the next page...

QuadSP1x_SMPR field descriptions (continued)

Field	Description
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 HSDLY	Half Speed Delay selection for SDR instructions. Only relevant when HSENA bit is set. Select the delay with respect to the reference edge for the sample point valid for half speed commands. 0 One clock cycle delay 1 Two clock cycle delay
1 HSPHS	Half Speed Phase selection for SDR instructions. Only relevant when HSENA bit is set. Select the delay with respect to the reference edge for the sample point valid for half speed commands. 0 Select sampling at non-inverted clock 1 Select sampling at inverted clock
0 HSENA	Half Speed serial flash clock Enable This bit enables the divide by 2 of the clock to the external serial flash device for all commands, only in SDR. Refer to Serial Flash Clock Frequency Limitations for details. 0 Disable divide by 2 of serial flash clock for half speed commands 1 Enable divide by 2 of serial flash clock for half speed commands

35.4.2.16 RX Buffer Status Register (QuadSPIx_RBSR)

This register contains information related to the receive data buffer.

Address: 400D_A000h base + 10Ch offset = 400D_A10Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter. Indicates how many entries of 4 bytes have been removed from the RX Buffer. For example, a value of 0x2 would indicate 8 bytes have been removed. It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDP]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details, refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15) and "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read .
15–14 Reserved	This field is reserved.
13 Reserved	This field is reserved.
12–8 RDBFL	RX Buffer Fill Level. Indicates how many entries of 4 bytes are still available in the RX Buffer. For example, a value of 0x2 would indicate 8 bytes are available.
Reserved	This field is reserved.

35.4.2.17 RX Buffer Control Register (QuadSPIx_RBCT)

This register contains control data related to the receive data buffer.

Write:

- $QSPI\_SR[IP\_ACC] = 0$

Address: 400D_A000h base + 110h offset = 400D_A110h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout. This field specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB15 . For details, refer to Exclusive Access to Serial Flash for AHB Commands . 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR15 .
7–5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
WMRK	RX Buffer Watermark. This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted. The value should be entered as the number of 4-byte entries minus 1. For example, a value of 0x0 would set the watermark to 4 bytes, 1 to 8 bytes, 2 to 12 bytes, and so on. For details, refer to DMA Usage .

35.4.2.18 TX Buffer Status Register (QuadSPIx_TBSR)

This register contains information related to the transmit data buffer.

Address: 400D_A000h base + 150h offset = 400D_A150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TRCTR																Reserved		TRBFL				Reserved									
W																	Reserved						Reserved									
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

QuadSPIx_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written to QSPI_MCR[CLR_TXF]. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

35.4.2.19 TX Buffer Data Register (QuadSP1x_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 64 bytes . This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to [Table 35-23](#) for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- $QSPI\_SR[TXFULL] = 0$

32-bit write access required

Address: 400D A000h base + 154h offset = 400D A154h

QuadSPiX_TBDR field descriptions

Field	Description
TXDATA	TX Data On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly. On a read access, the last data written to the register is returned.

35.4.2.20 Tx Buffer Control Register (QuadSPIx_TBCT)

This register contains control information for transmit data buffer.

Address: 400D_A000h base + 158h offset = 400D_A158h

QuadSPIx_TBCT field descriptions

Field	Description
31–5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
WMRK	Determines the watermark for the TX Buffer. When the number of available space in TX Buffer is greater than the number given by (WMRK+1), QSPI_SR[TXWA] is asserted. The values should be entered as the number of 4Bytes entries minus 1. For example, a value of 0x0 would set the watermark to 4 bytes, 1 to 8 bytes, 2 to 12 Bytes, and so on.For details, refer to DMA Usage .

35.4.2.21 Status Register (QuadSPIx_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer, TX Buffer, and the AHB Buffer.

Address: 400D_A000h base + 15Ch offset = 400D_A15Ch

QuadSPIx_SR field descriptions

Field	Description
31–29 DLPSMP	Data learning pattern sampling point. The sampling point found by the controller with the data learning pattern. - This is used for DDR only. - If the learning fails, this field will return garbage and DLPFF bit will be set. - In case of Data learning with DQS this field will return the reset value as sampling point match is not found in case of DQS. For details, refer to Data Learning.
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full. Asserted when no more data can be stored.
26 TXDMA	TXDMA Asserted when TXFIFO fill via DMA is active i.e. DMA is requested or running
25 TXWA	TX Buffer watermark Available Asserted when the number of available spaces in TX buffer is greater than or equal to the value give by QSPI_TBCT[WMRK].

Table continues on the next page...

QuadSPIx_SR field descriptions (continued)

Field	Description
24 TXEDA	Tx Buffer Enough Data Available Asserted when TX Buffer contains enough data for any pop operation to take place. There must be at least 128 bit data available in TX FIFO for any pop operation; otherwise, QSPI_FR[TBUF] will be set.
23 RXDMA	RX Buffer DMA. Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full. Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded. Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full. Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full. Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full. Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full. Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty. Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty. Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty. Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty. Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending. Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration .
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access. Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access. Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy. Asserted when module is currently busy handling a transaction to an external flash device.

35.4.2.22 Flag Register (QuadSPIx_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write: Enabled Mode

Address: 400D_A000h base + 160h offset = 400D_A160h

QuadSP1x_FR field descriptions

Field	Description
31 DLPFF	Data Learning Pattern Failure Flag. Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern in case only 8 bit data learning is requested for non DQS mode. The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP]. If more than 8 bits data learning are requested with QSPI_MCR[DQS_EN] set to 0, and the sampling point found after first 8 bit match doesn't remain the same for the whole instruction duration, this flag is set. In case of Data learn with DQS this flag is set whenever the incoming data from flash on DQS edges doesn't match the pattern in QSPI_DLPR. For details, refer to Data Learning .
30–29 RESERVED	This field is reserved.
28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag. Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag. Set when the module tried to pull data although TX Buffer was empty or the buffer contains less than 128 bits of data. The application must ensure that the buffer never goes empty during a transaction except for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid TX underrun). The application must clear the TX Buffer in response to this event by writing a 1 to the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag. Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 35-21 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag. Set when not all the data read from the serial flash device could be pushed into the RX Buffer.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
	The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device. The content of the RX Buffer is not changed.
16 RBDF	RX Buffer Drain Flag. Will be set if the QuadSPI_SR[RXWE] status bit is asserted. Writing 1 into this bit triggers one of the following actions: • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.
15 ABSEF	AHB Sequence Error Flag. Set when the execution of an AHB Command is started with a WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register. (QSPI_BUFxCR implies any one of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR.) Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module. The AHB bus request which triggered this command is answered with an ERROR response.
14 AITEF	AHB Illegal transaction error flag. Set whenever there is no response generated from QSPI to AHB bus in case of illegal transaction and the watchdog timer expires. The timer value is taken as parameter.
13 AIBSEF	AHB Illegal Burst Size Error Flag. Set whenever the total burst size (size x beat) of an AHB transaction is greater than the prefetch data size. The prefetch data size is defined by QSPI_BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field in case ADATSZ = 0. Refer to HBURST Support for more details on HBURST feature.
12 ABOF	AHB Buffer Overflow Flag. Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly. The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device. The content of the AHB Buffer is not changed.
11 IUEF	IP Command Usage Error Flag. Set when in parallel flash mode the execution of an IP Command is started with more than one pad enabled and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 35-21 table for the related commands. Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.
10–8 Reserved	This field is reserved.
7 IPAIEF	IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAIEF flag is ignored.
6 IPIEF	IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
	- Write access to the QSPI_SFAR register. - Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.
4 IPGEF	IP Command Trigger during AHB Grant Error Flag. Set when the following condition occurs: A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag. Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

35.4.2.23 Interrupt and DMA Request Select and Enable Register (QuadSPIx_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

Write: Anytime

Address: 400D_A000h base + 164h offset = 400D_A164h

35.4.2.24 Sequence Suspend Status Register (QuadSPIx_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: 400D_A000h base + 168h offset = 400D_A168h

QuadSPIx_SPNDST field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15 Reserved	This field is reserved.
14–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

35.4.2.25 Sequence Pointer Clear Register (QuadSPIx_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: 400D_A000h base + 16Ch offset = 400D_A16Ch

8 IPTRC	IP Pointer Clear: 1: Clears the sequence pointer for IP accesses as defined in QuadSPI_IPCR This is a self-clearing field.
7–1 Reserved	This field is reserved. Reserved.
0 BPTRC	Buffer Pointer Clear: 1: Clears the sequence pointer for AHB accesses as defined in QuadSPI_BFGENCR. This is a self-clearing field.

35.4.2.26 Serial Flash A1 Top Address (QuadSPIx_SFA1AD)

The QSPI_SFA1AD register provides the address mapping for the serial flash A1. The difference between QSPI_SFA1AD[TPADA1] and QSPI_AMBA_BASE defines the size of the memory map for serial flash A1.

Write:

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 180h offset = 400D_A180h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–10 TPADB2	Top address for Serial Flash B2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

35.4.2.30 Data Learn Pattern Register (QuadSPIx_DLPR)

The QSPI_DLPR register contains the information of the data to be used for Data Learning.

Write:

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: 400D_A000h base + 190h offset = 400D_A190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_DLPR field descriptions

Field	Description
DLPV	Data Learning Pattern Value: This value is used for data learning in DDR and DQS mode. If programmer wants to do data learn for more than 32 bit than the same value in the register is repeated. Say if 64 bit data learning is requested by any flash and the value of DLPR is aa55_3443 then the 64 bit value will be aa55_3443_aa55_3443. If 8 bit data learning was enabled by programming in seq_operand fields of DATA_LEARN instruction to 1, the bits [7:0] are used as data_learning pattern. For details, refer to Data Learning

35.4.2.31 RX Buffer Data Register (QuadSPIx_RBDR)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to [Table 35-23](#) for the byte ordering scheme.

QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 16 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR15 .

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: 400D_A000h base + 200h offset + (4d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

35.4.2.33 LUT Lock Configuration Register (QuadSPIx_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to [Look-up Table](#) for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write: Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: 400D_A000h base + 304h offset = 400D_A304h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

QuadSPIx_LCKCR field descriptions

Field	Description
31–2 Reserved	This field is reserved.
1 UNLOCK	Unlocks the LUT when the following two conditions are met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

35.4.2.34 Look-up Table register (QuadSPiX_LUTn)

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed by [Program Sequence Engine](#) in the LUT is referred to by its index. The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT63. A maximum of 16 sequences can be defined at one time. [Look-up Table](#) describes the LUT registers in detail.

NOTE

The reset values for LUT0 and LUT1 are 0818_0403h and 2400_1C08h, respectively.

Write: Once the LUT is unlocked

Address: 400D_A000h base + 310h offset + (4d × i), where i=0d to 63d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPiX_LUTn field descriptions

Field	Description
31–26 INSTR1	Instruction 1
25–24 PAD1	Pad information for INSTR1. 00 1 Pad 01 2 Pads 10 4 Pads 11 8 Pads

Table continues on the next page...

QuadSPIx_LUTn field descriptions (continued)

Field	Description
23–16 OPRND1	Operand for INSTR1.
15–10 INSTR0	Instruction 0
9–8 PAD0	Pad information for INSTR0. 00 1 Pad 01 2 Pads 10 4 Pads 11 8 Pads
OPRND0	Operand for INSTR0.

35.4.3 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into [Serial Flash A1 Top Address \(QuadSPI_SFA1AD\)](#) and [Serial Flash A2 Top Address \(QuadSPI_SFA2AD\)](#) for device A and into [Serial Flash B1 Top Address \(QuadSPI_SFB1AD\)](#) and [Serial Flash B2 Top Address \(QuadSPI_SFB2AD\)](#) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 35-14. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(T PADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to Serial Flash A1
TOP_ADDR_MEMA2(T PADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to Serial Flash A2
TOP_ADDR_MEMB1(T PADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to Serial Flash B1
TOP_ADDR_MEMB2(T PADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to Serial Flash A2

35.5 Flash memory mapped AMBA bus

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash in the system. Refer to the system address map. Note that this may be a remapping of the physical address of the serial flash in the system. Refer to the system address map.

Table 35-15. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 35-23 and Table 35-28 for information about the byte ordering.
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B for details and to Table 35-23 and Table 35-28 for information about the byte ordering.
Parallel Flash Mode	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to Parallel Flash Mode for details and to Table 35-27 and Table 35-28 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15)	
QSPI_ARDB_BASE to... (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15) Refer to Table 35-23 and Table 35-25 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In case of single-die flash devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1 respectively (in effect, setting the size of these devices to 0). This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read and data write in single io mode from the serial flash. The first device of flash A has to be paired with the first device of

flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the `QSPI_BFGENCR[PAR_EN]` bit for all masters in AHB driven mode and via the `QSPI_IPCR[PAR_EN]` in IP driven mode. In parallel mode, the incoming address (SFAR address in case of IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read and write (through one pad) in Parallel Flash Mode will result in the assertion of the `QSPI_FR[IUEF]` flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the `QSPI_FR[ABSEF]` flag.

In 'Individual Flash Modes', the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by `SFADR [23:0]` or `SFADR [31:0]` as given in the table above.

In 'Parallel Flash Mode', both flashes are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from `SFADR [24:1]` or `SFADR [31:1]` as given in the table above. The LSB of the `SFADR` field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

35.5.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore, the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus.

- At present, the QuadSPI does not support AHB writes so any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the `QSPI_FR[ABSEF]` flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.

- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

35.5.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI_AMBA_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI_AMBA_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 35-23](#) and for 64 bit read access the byte ordering is given in [Table 35-28](#).

Table 35-16. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
QSPI_AMBA_BASE + 0x00	QSPI_AMBA_BASE + 0x00	0x00_0000 to 0x00_0003	A1
QSPI_AMBA_BASE + 0x04		0x00_0004 to 0x00_0007	
...	...	...	
TOP_ADDR_MEMA1 - 0x08	TOP_ADDR_MEMA1 - 0x08	(TOP_ADDR_MEMA1 - 0x08) to (TOP_ADDR_MEMA1 - 0x04 - 0x01)	
TOP_ADDR_MEMA1 - 0x04		(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)	
TOP_ADDR_MEMA1 + 0x00	TOP_ADDR_MEMA1 + 0x00_0000	0x00_0000 to 0x00_0003	A2
TOP_ADDR_MEMA1 + 0x04		0x00_0004 to 0x00_0007	
.....	...	...	
TOP_ADDR_MEMA2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMA2 - 0x04		(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

35.5.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP_ADDR_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP_ADDR_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 35-23](#) and for 64 bit read access the byte ordering is given in [Table 35-28](#).

Table 35-17. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
...		...	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 - 0x01)	B1
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
.....	...	...	B2
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

35.5.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 35-25](#) and for 64 bit read access the byte ordering is given in [Table 35-28](#).

Table 35-18. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes .	0x00_0000	0x00_0000
		-	-
		0x00_0001	0x00_0001
		0x00_0002	0x00_0002
QSPI_AMBA_BASE + 0x0000_0004	QSPI_AMBA_BASE + 0x08	-	-
		0x00_0003	0x00_0003
		0x00_0004	0x00_0004
		-	-
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0005	0x00_0005
		0x00_0006	0x00_0006
		-	-
		0x00_0007	0x00_0007
QSPI_AMBA_BASE + 0x0000_000C	QSPI_AMBA_BASE + 0x08	-	-
		0x00_0007	0x00_0007
...	...	...	...
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

35.5.5 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15)

NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	AHB RX Data Buffer register (ARDB0)	32	R/W	0000_0000h	35.5.5.1/893
4	AHB RX Data Buffer register (ARDB1)	32	R/W	0000_0000h	35.5.5.1/893
8	AHB RX Data Buffer register (ARDB2)	32	R/W	0000_0000h	35.5.5.1/893

24	AHB RX Data Buffer register (ARDB9)	32	R/W	0000_0000h	35.5.5.1/893
28	AHB RX Data Buffer register (ARDB10)	32	R/W	0000_0000h	35.5.5.1/893
2C	AHB RX Data Buffer register (ARDB11)	32	R/W	0000_0000h	35.5.5.1/893
30	AHB RX Data Buffer register (ARDB12)	32	R/W	0000_0000h	35.5.5.1/893
34	AHB RX Data Buffer register (ARDB13)	32	R/W	0000_0000h	35.5.5.1/893
38	AHB RX Data Buffer register (ARDB14)	32	R/W	0000_0000h	35.5.5.1/893
3C	AHB RX Data Buffer register (ARDB15)	32	R/W	0000_0000h	35.5.5.1/893

35.5.5.1 AHB RX Data Buffer register (ARDB)

The AHB RX Data Buffer register 0 to 15 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in [Flash Read](#) section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to [Byte Ordering of Serial Flash Read Data](#) for the byte ordering scheme.

Interrupt Signals

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 16 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB15.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ARDBn field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

35.6 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 35-19. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overn		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error

Table continues on the next page...

Table 35-19. Assignment of Interrupt Request Lines (continued)

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_ored	DLFFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, , AITEF, AIBSEF	Logical OR from all the QSPI_FR flags mentioned

35.7 Functional Description

This section provides the functional information of the QuadSPI module.

35.7.1 Serial Flash Access Schemes

The following access schemes are possible, depending on the serial flash devices attached to the QuadSPI module.

Table 35-20. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	Yes	N/a	Yes
Individual Flash Mode: Access to Flash B	N/a	Yes	Yes
Parallel Flash Mode: Read from Flash A and Flash B	N/a	N/a	Yes

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands and write command (in x1 mode) are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

35.7.2 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

35.7.2.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 35-21. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2,3}	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2	2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions , if QSPI_SFACR[CAS] is set to 0, else the actual address will take CAS into consideration.

Table continues on the next page...

Table 35-21. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
DUMMY	6'd3		Number of dummy clock cycles (should be ≤ 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	$N=2^d\{0,1\}$	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads ¹ specified
MODE4	6'd6	$N=2^d\{0,1,2\}$	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads ² specified
READ	6'd7	$N=2^d\{0,1,2,3\}$ 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Read data size in bytes (the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads specified. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
JMP_ON_CS	6'd9	NA	Instruction number	Every time the chip select (CS) is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	$N=2^d\{0,1,2,3\}$ 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Number of address bits to be sent (for example, 8'd24 $\Rightarrow$ 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions, if QSPI_SFACR[CAS] is set to 0, else the actual address will take CAS into consideration.
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	$N=2^d\{0\}$	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash ³
MODE4_DDR	6'd13	$N=2^d\{0,1\}$	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash ⁴ .
READ_DDR	6'd14	$N=2^d\{0,1,2,3\}$ 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions

Table continues on the next page...

Table 35-21. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
WRITE_DDR	6'd15	2'd3- Eight pads	Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
DATA_LEARN	6'd16		Number of data in bytes to be used for data learning. Say if operand is 1 than 8 bit data_learning is enabled.	Finds the correct sampling point in case of only DDR operations. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by data learning. But this feature of sampling point is valid for only DDR modes. If DQS mode is enabled, then data learn instruction just matches the incoming data from flash and if it does not matches the QSPI_DLPV then Flag in QSPI_FR[DLPFF] is set.
CMD_DDR	6'd17	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	8 bit command value	Provide the serial flash with the operand with number of pads specified at each clock edge of the serial flash
CADDR	6'd18		Number of Column address bits to be sent(8'd8 means 8 bits of column address is to be sent)	Provide the serial flash with column address cycles according to the operand on the number of pads specified. The actual address to be provided to flash will depend on value of QSPI_SFACR[CAS]. For example, if QSPI_SFACR[CAS] is 3, then the address to flash will be [2:0] of incoming address in case of AHB and the value of QSPI_SFAR in case of IP. This will be appended with zero if QSPI_SFACR[CAS] is less than number of pads for a Flash.
CADDR_DDR	6'd19		Number of Column address bits to be sent(8'd8 means 8 bits of column address is to be sent)	Provide the serial flash with column address cycles according to the operand on the number of pads specified at each clock edge of the serial flash. The actual address to be provided to flash will depend on value of QSPI_SFACR[CAS]. For example, if CAS is 3, then the address to flash will be [2:0] of incoming address in case of AHB and the value of QSPI_SFAR in case of IP. This will be appended with zero if CAS is less than number of pads for a Flash.
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

35.7.2.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated. The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash. As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. [Figure 35-4](#) shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to [Look-up Table](#) for details.

Figure 35-4. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from [Sequence Suspend Status Register \(QuadSPI_SPNDST\)](#).

35.7.2.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

35.7.2.4 HBURST Support

QuadSPI controller supports HBURST and HSIZE on the AHB interface. HBURST indicates if the transfer forms part of a burst. Four, eight and sixteen beat bursts are supported and the burst may be either incrementing or wrapping. HSIZE indicates the size of the transfer. 8, 16, 32 and 64 bit data size are supported. In case of WRAP accesses, QuadSPI generates aligned accesses to Serial Flash if there is no buffer hit for any incoming non-sequential AHB access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size an error response is generated and QSPI_FR[AIBSEF] is set. The data prefetch size can be defined by QSPI_BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as zero. A few examples are shown in the figure below:

HADDR = 0x38 HBURST = WRAP4 HSIZE = 64 bits Flash xsaction start = 0x20 Incoming AHB access= 0x38, 0x20, 0x28, 0x30	HADDR = 0x38 HBURST = INCR4 HSIZE = 64 bits Flash xsaction start = 0x38 Incoming AHB access= 0x38, 0x40, 0x48, 0x50
HADDR = 0x50 HBURST = WRAP8 HSIZE = 64 bits Flash xsaction start = 0x40 Incoming AHB access= 0x50, 0x58, 0x60, 0x68, 0x70, 0x78, 0x40, 0x48	
HADDR = 0xD0 HBURST = WRAP16 HSIZE = 64 bits Flash xsaction start = 0x80 Incoming AHB access= 0xD0, 0xD8, 0xE0, ...0xF8, 0x80, 0x88, ... 0xC8	
HADDR = 0xD4 HBURST = WRAP8 HSIZE = 32bits Flash xsaction start = 0xC0 Incoming AHB access= 0xD4, 0xD8, 0xDC, 0xC0, 0xC4, 0xC8, 0xCC, 0xD0	
HADDR = 0x54 HBURST = INCR8 HSIZE = 32bits Flash xsaction start = 0x54 Incoming AHB access= 0x54, 0x58, 0x5C, 0x60, 0x64, 0x68, 0x6C, 0x70	

Figure 35-5. QuadSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

35.7.2.5 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

Figure 35-6. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in [Table 35-22](#). After reset the complete LUT may be reprogrammed according to the device connected on board. In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key (**0x5AF05AF0**) in to the **LUT Key Register (QuadSPI_LUTKEY)**.
2. Write 0b01 to the **LUT Lock Configuration Register (QuadSPI_LCKCR)**. Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key (**0x5AF05AF0**) into the **LUT Key Register (QuadSPI_LUTKEY)**.
2. Write 0b10 to the **LUT Lock Configuration Register (QuadSPI_LCKCR)**. Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from QSPI_LCKCR[UNLOCK] and QSPI_LCKCR[LOCK] bit.

Some example sequences are defined in [Example Sequences](#). The reset sequence at LUT index 0 is given in the following table.

Table 35-22. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

35.7.2.6 Issuing Serial Flash Memory (SFM) Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.

4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in [Flash Programming](#) and [Flash Read](#).

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

For IP Commands the required components need to be written into the following registers:

- Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to [Serial Flash Address Register \(QSPI_SFAR\)](#). For IP Commands not related to specific addresses, the base address of the related flash need to be programmed. For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.
- Write the sequence ID and data size details in the [IP Configuration Register \(QSPI_IPCR\)](#).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to [IP Configuration Register \(QSPI_IPCR\)](#) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in [Command Arbitration](#).

- **Using AHB commands**

Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in [Flexible AHB buffers](#).

An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#) and [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#).

Again the possible error conditions are described in [Command Arbitration](#).

35.7.2.7 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check QuadSPI_SR[BUSY] is de-asserted or '0'. Check that the TX buffer is empty. If it is required to discard the data present in the TX buffer (QSPI_SR[TXEDA]) bit is set, then the TX buffer must be cleared by writing '1' into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register. Program the QSPI_SFACR[CAS] if required to desired value else to 0. Program the QSPI_SFACR[WA] to 1 if the serial flash is a word addressable flash else to 0 in case serial flash is byte addressable.
3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR) . At least four word of data must be written into the TX Buffer up to a maximum of 16.
4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed. The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register. The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **16** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

35.7.2.8 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. Reading Serial Flash Data into the QuadSPI Module Internal Buffers

A read access to the external serial flash device can be triggered in two different ways:

- **IP Command Read:** For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI_SFAR) , QSPI_SFACR[CAS] and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI_MCR[CLR_RXF] field.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command, the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBSR[RDBFL].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

- **AHB Command Read:** For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should program the QSPI_SFACR[CAS], if required, to desired value else to 0. The user should also program the buffer registers corresponding to the AHB master initiating the request, this depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address

accessed in the AHB address space associated to the QuadSPI module (refer to [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#), [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#) and [Parallel Flash Mode](#)).

On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the `QSPI_BUFxCR[ADATSZ]` field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the `QSPI_SR[AHB_ACC]` status bit is set driving in turn the `QSPI_SR[BUSY]` bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. Data Transfer from the QuadSPI Module Internal Buffers

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to [Block Diagram](#) for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

Figure 35-7. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 16 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR15

In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB15. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how

many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in [RX Buffer Data Register \(QuadSPI_RBDR\)](#) and in [AHB RX Data Buffer \(QSPI_ARDB0 to QSPI_ARDB15\)](#).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDRn) or the AHB address space (QSPI_ARDBn). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module. The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in [DMA Usage](#).

DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDRn or QSPI_ARDBn related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in [Table 35-15](#) table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress*. If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data.

Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the

access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

35.7.2.9 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

- Flash A or Flash B in Individual Flash Mode
- All AHB data read commands with access size of 32 bit

Table 35-23. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• Byte Ordering in Parallel Flash Mode

In Parallel Flash Mode each byte is combined out of 2 half bytes which are read or written in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 35-24. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbI0
1	fah1	fal1	fbh1	fbI1
2	fah2	fal2	fbh2	fbI2
3	fah3	fal3	fbh3	fbI3
4	fah4	fal4	fbh4	fbI4
5	fah5	fal5	fbh5	fbI5
6	fah6	fal6	fbh6	fbI6
7	fah7	fal7	fbh7	fbI7
8	fah8	fal8	fbh8	fbI8

The table entry naming reflects the half byte positioning in the serial flash devices:

- <fa>h0 means **Flash A**, <fb>h0 means Flash B.
- fa<h>0 means half byte in **high position**, fa<l>0 means half byte in low position.
- fah<0> means **physical byte address 0** in the serial flash device, fal<1> means physical byte address 1 in the serial flash device.

Table 35-25. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000

Table continues on the next page...

**Table 35-25. Byte Ordering in Parallel Flash Mode - RX Buffer
(continued)**

QSPI_RBDR0 QSPI_ARDB0	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_RBDR1 QSPI_ARDB1	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 QSPI_ARDB0	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
QSPI_RBDR1 QSPI_ARDB1	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

Table 35-26. Byte Ordering in Parallel Flash Mode - TX Buffer*

QSPI_SFAR[SFADR] set to 0x000_0000								
QSPI_TBDR0	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_TBDR1	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

* Applicable only for single I/O mode.

Table 35-27. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address (32 Bit Access)	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
AHB Address 0x800_0004 (32 Bit Access)	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• Buffer Entry Ordering for 64 Bit Read Access

For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 35-28. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

35.7.2.10 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the [Flag Register \(QSPI_FR\)](#).

Table 35-29. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn pattern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
AHB Illegal Transaction Error	AITEF	-
AHB Illegal Burst Size Error	AIBSEF	-
IP Command Usage Error	IUEF	-

Table continues on the next page...

Table 35-29. Interrupt and DMA Request Conditions (continued)

Condition	Flag(QSPI_FR)	DMA
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the [Flag Register \(QSPI_FR\)](#) and a Request Enable bit in the [DMA Request Select and Enable Register \(QSPI_RSER\)](#). The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the device's Interrupt Vector Table for more details.

- **Transmit Buffer Fill Interrupt Request:**

The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSPI_RSER[TBFIE]) is set. Refer to [TX Buffer Operation](#), for details about the assertion of the QSPI_FR[TBFF] flag.

Aside from IRQ it is possible to handle TX Buffer fill by DMA. If the QSPI_RSER[TBFDE] bit is set, a DMA request will be triggered when the number of available space in the TX Buffer is more than the QSPI_TBCT[WMRK] valid entries and QSPI_SR[TXWA] is set. The application must set the environment appropriately (eg. the DMA controller) for the DMA transfer.

- **Receive Buffer Drain Interrupt or DMA Request:**

The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- **Buffer Overflow/Underrun Interrupt Request:**

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TBUIE] bit is set.

The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

The IP Command Transaction Finished IRQ indicates the completion of the current IP Command. It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

35.7.2.11 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag. The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from failure point will serve the purpose. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to [TX Buffer Status Register \(QuadSPI_TBSR\)](#) and [Flag Register \(QuadSPI_FR\)](#) for details about the TX Buffer related registers.

35.7.2.12 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode. It also supports segregation of address programmed, into Row address and Column address of the Flash, as per requirement.

- **Extended Address Mode**

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8'd32 as the operand value with QSPI_SFACR[CAS] programmed to 0. If a flash needs some bits of the address as its column address, then it must always be considered that the total bits required by the Flash should not exceed 32, as maximum address supported by QuadSPI is 32 bits. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

- **Separation of address into row and column address**

This mode has been introduced for flashes which needs addresses segregated into Row and Column. The value in QSPI_SFACR[CAS] defines the width of the column address required by a flash. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions, if QSPI_SFACR[CAS] is set to 0, else the actual address will take CAS into consideration. If QSPI_SFACR[CAS] is 3 then bits 26-3 of the address programmed are sent to flash as it page address in case flash is operating in 24bit mode and bits 2-0 are sent as its column address. If a flash requirement for column address is less than the number of pads in which address has to be sent than the remaining bits are appended with 0 by QuadSPI. The user must program the operand value in CADDR and CADDR_DDR command accordingly. It must be ensured that the total number of address bits request by flash as its page and column address must not be more than 32 bits.

- **Word addressable mode for Flash**

This mode has been introduced for flashes which has word addressable memory i.e. each address of the flash contains one word (two bytes) of data. The QSPI_SFACR [WA] is set to 1 to enter this mode. QuadSPI internally divides the incoming address in the AHB bus or the address in the QSPI_SFAR to map it to a valid flash location. For example, if the incoming address is 0x2004, the controller re-maps this address to access the flash location 0x1002. If not in this mode, the incoming address 0x2004 will be mapped to flash location 0x2004.

35.8 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

35.8.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

35.8.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

35.8.2.1 IP Commands

Refer to [IP Configuration Register \(QuadSPI_IPCR\)](#) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

Refer to [Table 35-30](#) below.

35.8.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in [Flash Read](#) for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

Refer to [Table 35-30](#) below.

35.8.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 35-30. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flag	ABSEF	Flash transaction is aborted	AHB sequence contains • WRITE instruction • WRITE_DDR instruction
AHB Error Flag	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
AHB Error Flag	AIBSEF	Flash transaction is aborted	Total burst size of AHB transaction is greater than prefetch data size
AHB Error Flag	AITEF	Flash transaction is aborted	No response generated from QSPI to AHB bus in case of illegal transaction and the watchdog timer expires
Miscellaneous Error Flag	DLPPF	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.

Table continues on the next page...

Table 35-30. Overview of QSPI_FR Error Flags (continued)

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Miscellaneous Error Flag	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Error	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
Command Arbitration Error	IPAEF		• AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
Command Arbitration Error	IPGEF		• Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF	—	• IP Command Usage Error
Buffer Related Error	RBOF	TFF is asserted on completion	• RX Buffer Overrun
Buffer Related Error	TBUF		• TX Buffer Underrun

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

35.8.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for a description of the flags and [Command Arbitration](#), for details about possible command collisions.

35.8.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR n register) and the other masters by triggering AHB Commands (via ARDB n Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer. Refer to [Figure 35-7](#) To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

35.8.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

35.8.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR15.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0), allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

35.8.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in [Exclusive Access to Serial Flash for AHB Commands](#) is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[PIEF] flag is asserted when the host tries to write into the QSPI_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to [Flag Register \(QuadSPI_FR\)](#) for the description of these flags.

When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

35.8.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to [Serial Flash Address Register \(QuadSPI_SFAR\)](#) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to [Flash memory mapped AMBA bus](#) for details.

35.8.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

35.8.6.1 DMA Usage in Normal Mode

35.8.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read/write data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading/writing data from/to the RX/TX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result. Similarly, the data consumed by the serial flash device must not exceed the average TX buffer fill rate. If this persists, it would eventually lead to an underrun.

AHB Bus Side (data read):

The following table gives some examples for typical use cases:

Case 1: DMA need to read 4 bytes from SRAM and provide to QuadSPI. It costs total 4 BUS clock cycles. Then DMA handshake added additional 6 BUS clock cycles. Total $[6 + 4 * (32/4) = 38]$ BUS clock cycles.

Table 35-31. Access Duration Examples - Bus Clock Side

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 60Mhz Bus clock Frequency
3	16	$6 + (16/4) * 4 = 22$	~366ns
7	32	$6 + (32/4) * 4 = 38$	~633ns
11	48	$6 + (48/4) * 4 = 54$	~900ns
15	64	$6 + (64/4) * 4 = 70$	~1166ns

Case2: DMA need to read 32 bytes from SRAM and provide to QuadSPI DMA handshake takes additional 6 BUS cycles, with 32byte DMA read from SRAM costs $(8 + 3)$ CORE clock cycles. DMA write 32 byte to QSPI takes $2 * (32/4) = 16$ BUS cycles with one additional CPU access to QuadSPI, costing 2 BUS clock cycles. Total $6 + (8+3)/2 + 2 * (32/4) + 2 = 30$ BUS clock cycles.

Table 35-32. Access Duration Examples - Bus Clock Side

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop >	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 80Mhz Bus clock Frequency
3	16	$6 + (4+3) / 2 + (16/4) * 2 + 2 = 20$	~333ns
7	32	$6 + (8+3) / 2 + (32/4) * 2 + 2 = 30$	~500ns
11	48	$6 + (4+3)/2 * 3 + (48/4) * 2 + 2 = 44$	~733ns
15	64	$6 + (8+3) + (64/4) * 2 + 2 = 51$	~810ns

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad

DDR mode instructions in Parallel Flash Mode, 2 cycles for Octal DDR mode (Hyperflash) in individual flash mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode, or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.

- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 35-33. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop ¹	Num SCKF _x for 80MHz SCKF _x			Time duration of Flash data readout for 80MHz SCKF _x (~12.5ns period)		
		IFM ² Quad	IFM Quad DDR	PFM ³ Quad DDR/ IFM Octal DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	8	4	2	~100ns	~50ns	~25ns
1	8	16	8	4	~200ns	~100ns	~50ns
3	16	32	16	8	~400ns	~200ns	~100ns
7	32	64	32	16	~800ns	~400ns	~200ns
11	48	96	48	24	~1200ns	~600ns	~300ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.

2. Individual flash mode.

3. Parallel flash mode.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

IPS Bus Side (data write):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 16 bytes (128 bit write size): Assume 4 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_TBCT[WMRK] field, therefore the overhead given above distributes among (QSPI_TBCT[WMRK]+1) write accesses of 32 bit each.

The following table gives some examples for typical use cases:

Table 35-34. Access Duration Examples - Bus Clock Side

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop ¹	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 80Mhz Bus clock Frequency
3	16	12+4 = 16	~200ns
7	32	12+8 = 20	~250ns
11	48	12+12 = 24	~300ns
15	64	12+16 = 28	~350ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data write):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to write 16 bytes, corresponding to four TX Buffer entry(setup of command and address not considered): 8 cycles for Octal DDR mode (Hyperflash) instructions in Individual Flash Mode, 32 cycles for Quad SDR writes in individual flash mode, 64 cycles in single io SDR writes in parallel flash mode.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_TBCT[WMRK] field:

Table 35-35. Access Duration Examples - Serial Flash side

QSPI_TBCT[WMRK] setting	Num Bytes per DMA Loop ¹	Num SCKFx			Time duration for consuming data at Flash interface 100MHz SCKFx (10ns period) ²			Time for fifo to get empty ³		
		IFM ⁴ Quad	IFM Octal DDR	⁵ Single IO SDR Mode	IFM Quad	IFM Octal DDR	PFM Single IO SDR	IFM Quad	IFM Octal DDR	PFM Single IO SDR
3	16	32	8	64	320ns	80ns	640ns	2240ns	560ns	4480ns
7	32	64	16	128	640ns	160ns	1280ns	1920ns	480ns	3840ns
15	64	128	32	256	1280ns	320ns	2560ns	1280ns	320ns	2560ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Not all flash devices support writes at 100Mhz. Please refer to the flash datasheet for the actual page program frequency supported.
3. The assumption for these timings is that the TX Fifo was full when the transaction was initiated
4. Individual flash mode.
5. Parallel flash mode.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

From the examples given in the two tables above for TX fifo, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash consumes data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation will occur. To avoid TX Buffer underrun, the data transaction size should be large enough.

35.8.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Only read operations and x1 mode write are allowed in parallel mode. In case a write transaction is initiated in with mode than one pad in parallel mode, QSPI_FR[IUEF] is set. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

Figure 35-8. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

$$\text{Flash Address} = (\text{Memory mapped address} - \text{QSPI\_AMBA\_BASE})/2$$

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

$$\text{Flash Address} = (\text{Memory mapped address} - \text{SFA2AD})/2$$

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

Figure 35-9. Memory map - Serial and Parallel

35.9 Byte Ordering - Endianness

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64 bit LE format on the AHB bus and 32 bit LE format on the IPS interface when read via the RX buffer and written in 32 bit LE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions. Refer to figure [Figure 35-7](#)

Table 35-36. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 35-37. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 35-38. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

35.9.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 35-39. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01...02...03...04...05...06...07...08

35.9.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the RX Buffer filled with:

Table 35-40. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

35.9.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the Peripheral bus interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

35.9.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04
- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

35.9.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the AHB Buffer filled with:

Table 35-41. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

35.9.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04
- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

35.10 Driving Flash Control Signals in Single and Dual Mode

In single and dual mode the serial flash devices which can connect to the QuadSPI module expect additional control signals on the inputs which are connected to IOFA[3], IOFA[2], IOFB[3] and IOFB[2] in quad mode. For easy interfacing the outputs IOFA[3:2] for Flash A and the IOFB[3:2] for Flash B are driven to the logic state given by the configuration bits QSPI_MCR[ISD3FA], QSPI_MCR[ISD2FA], QSPI_MCR[ISD3FB] and QSPI_MCR[ISD2FB].

These outputs are driven all the time to the logic level programmed in the QSPI_MCR register except the time when quad commands of the serial flash are executed. Refer to the specification of the related serial flash device for details about the inactive level.

35.11 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

35.11.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 35-42. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

35.11.1.1 Read Command (Spansion Hyperflash)

This section provides the read command sequences (Spansion Hyperflash) of the QuadSPI module.

Table 35-43. Read Command (Spansion Hyperflash)

INSTR	PAD	OPERAND	COMMENT
CMD_DDR	0x3	0xA0	Read command with continuous burst type
ADDR_DDR	0x3	0x18	24 bit row address

Table continues on the next page...

Table 35-43. Read Command (Spansion Hyperflash) (continued)

CADDR_DDR	0x3	0x10	16 bit column address with lower 3 bits valid rest 0
DUMMY	0x3	0x0F	15 dummy cycles
READ_DDR	0x3	0x4	32 bit data read on 8 pads
STOP	0x3	0x00	STOP, Instruction over

Hyperflash is a word addressable flash i.e. each address accesses a word wide (2 bytes) data value, the software should ensure that when Hyperflash is connected to the controller, the QSPI_SFACR [WA] bit must be set. If this bit is set the controller remaps a byte addressable access to a word addressable access.

35.11.1.2 Read Status Register(Spansion Hyperflash)

This section provides the read status register of the QuadSPI module.

Table 35-44. Read Status register (Spansion Hyperflash)

INSTR	INSTR SEQUENCE	PAD	OPERAND	COMMENT
CMD_DDR	Read Pre Comman	0x3	0x00	Write command with wrapped burst type.
ADDR_DDR		0x3	0x18	24 bit row address(0000AAh)
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0005h),treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x70	Write data to be sent to flash as pre-command
CMD_DDR	Command phase (fourth/final chip select phase)	0x3	0xA0	Read command with continuous burst type
ADDR_DDR		0x3	0x18	24 bit row address
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0
DUMMY		0x3	0x0F	15 dummy cycles
READ_DDR		0x3	0x4	32 bit data read on 8 pads
STOP		0x3	0x00	STOP, Instruction over

35.11.1.3 Word Program (Spanion Hyperflash)

This section provides the Word Program (Spanion Hyperflash) of the QuadSPI module.

Table 35-45. Word Program (Spanion Hyperflash)

INSTR	INSTR SEQUENCE	PAD	OPERAND	COMMENT
CMD_DDR	Unlock Sequence 1 (first chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0xAA	8 bit address AAh treated as command
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0005h), treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type.
CMD_DDR		0x3	0xAA	Write data to be sent to flash as pre-command.
CMD_DDR	Unlock Sequence 2 (second chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x55	8 bit address 55h treated as command
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0002h), treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x55	Write data to be sent to flash as pre-command
CMD_DDR	Program setup phase (third chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0xAA	8 bit address AAh treated as command
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0005h), treated as command

Table continues on the next page...

Table 35-45. Word Program (Spansion Hyperflash) (continued)

CMD_DDR	Command phase (fourth/final chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0xA0	Write data to be sent to flash as pre-command
CMD_DDR		0x3	0x00	Write command with wrapped burst type
ADDR_DDR		0x3	0x18	24 bit row address
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0
WRITE_DDR		0x3	0x2	2 bytes data written on 8 pads (D1D2)
STOP		0x3	0x00	STOP, Instruction over

35.11.1.4 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

Table 35-46. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

35.11.1.5 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 35-47. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.

Table continues on the next page...

Table 35-47. Fast Dual I/O DT Read sequence (continued)

Instruction	Pad	Operand	Comment
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

35.11.1.6 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 35-48. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

35.11.1.7 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 35-49. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

35.11.1.8 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 35-50. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

35.11.1.9 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 35-51. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

35.11.1.10 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

Table 35-52. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

35.11.1.11 Data Learn Instruction Sequence

The following table shows the data learn sequence for 4 I/O flash.

Table 35-53. Data learn Instruction sequence (4 I/O)

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast Read Quad command = 0x6B
ADDR_DDR	0x2	0x18	24 address bits in DDR mode to be sent on four pads
DUMMY	0x2	0x08	8 Dummy cycle
DATA_LEARN	0x2	0x01	1 Byte data learn
READ_DDR	0x2	0x06	Read 6 bytes in 4 pads
JMP_ON_CS	0x0	0x00	Jump to Inst 0 (CMD)

The following table shows the data learn sequence for 8 I/O (Spansion Hyperflash) flash.

Table 35-54. Data learn Instruction sequence (8 I/O)

Instruction	Pad	Operand	Comment
CMD_DDR	0x3	0xA0	Read command for Hyperflash
ADDR_DDR	0x3	0x18	24 bit row address ¹
CADDR_DDR	0x3	0x10	16 bit column address
DUMMY	0x3	0x0F	15 cycle dummy
DATA_LEARN	0x3	0x01	1 byte data learn
READ_DDR	0x3	0x08	Read 8 bytes in 8 pads
STOP	0x3	0x00	STOP, instruction over

1. Address needs to be aligned i.e. No latency should be there between the RWDS edges.

35.11.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

Figure 35-10. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

35.11.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.
- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
 - The total sizes of all the flashes connected on board
 - Whether DDR mode supported
 - Frequency of DDR operation

- Continuous mode entry sequence
- 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
 - Quad Mode enabled
 - Dummy reads to enter into XIP
- QuadSPI is configured
 - Parallel enable set
 - LUT configured for highest performance reads
 - DDR mode enabled (if applicable)
 - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

35.11.4 Serial Flash Clock Frequency Limitations

Certain commands of some serial flash devices are limited in the frequency applied to the serial flash device on command execution. In order to support these commands without having to recalibrate the module clocks, the the serial flash device clock can be divided by 2 (half speed) by setting the QSPI_SMPR[HSENA] bit. The SCLK will return to full speed once the the QSPI_SMPR[HSENA] bit is cleared.

35.12 Sampling of Serial Flash Input Data

35.12.1 Basic Description

QuadSPI is used to read data from the serial flash device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

Figure 35-11. Serial Flash Sampling Clock Overview

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrives at the internal sampling stage of the QuadSPI module. According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Device delay corresponding to the input data

NOTE

The amount of total delay $t_{Del,total}$ is specific to the characteristics of the actual implementation. Also, the serial flash device clock (SCK) is inverted with respect to the QuadSPI internal reference clock.

35.12.2 Supported read modes

The table below provides an overview of QuadSPI read modes.

Table 35-55. QuadSPI read modes

Read modes			QuadSPI_MC R[DDR_EN]	QuadSPI_MC R[DQS_EN]	Data learning support	For more information
SDR mode	Internal sampling (N/1, I/1)		0	0	No	Internal sampling
	DQS sampling method	Internally generated DQS	0	1	No	Internally generated DQS
		External DQS	0	1	No	External DQS
DDR mode	Internal sampling (4x method)		1	0	Yes	Internal sampling (4x sampling method)
	DQS sampling method	Internally generated DQS	1	1	Yes	Internally generated DQS
		External DQS	1	1	Yes	External DQS

35.12.2.1 SDR mode

Most flash memories operate in single data rate (SDR) mode. In SDR mode, the data is transferred only on one edge of the clock signal. The SDR serial flash memories sample the incoming data on the rising edge of serial flash clock and drive the output data on the falling edge of the serial flash clock.

35.12.2.1.1 Internal sampling

QuadSPI uses different edges of the internal reference clock for sampling the input data in SDR mode.

Figure 35-12. Internal sampling in SDR mode

The possible points in time for sampling incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register. Refer to [Sampling Register \(QuadSPI_SMPR\)](#) for details. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 35-56. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting ¹
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending on the actual delay and the serial flash clock frequency, the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be two settings possible to capture the correct data, since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.

- Depending on the timing uncertainties, it may turn out in actual applications that only one possible sample position remains. This is subject to careful consideration depending on the actual implementation.
- The delay $t_{\text{Del, total}}$ is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SMPR register.

35.12.2.1.2 DQS sampling method

Data sampling in SDR mode can be supported using the DQS sampling method. Refer to [Data Strobe \(DQS\) sampling method](#) for more details.

35.12.2.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

35.12.2.2.1 Internal sampling (4x sampling method)

When the serial flash memories function in DDR mode, the data is valid for only half a clock cycle. This, along with the fact that the time for which the data is actually valid is smaller than half a clock cycle, requires that we provide closely spaced sampling points. The QuadSPI module provides a mechanism to sample the incoming data at multiple sampling points provided by a 4x serial flash clock in DDR mode. The figure below shows the different sampling points as configured by QuadSPI_SMPR[DDRSMP]. The FSDLY/FSPHS and HSDLY/HSPHS bits are ignored for DDR instructions.

Figure 35-13. 4x sampling edges in DDR mode

Software should ensure that the correct sampling value is configured in the QuadSPI_SMPR[DDRSMP] register.

NOTE

Higher frequency can be achieved using data learning. For details, refer to [Data Learning](#).

35.12.2.2.2 DQS sampling method

Data sampling in DDR mode can be supported using DQS method. Refer to [Data Strobe \(DQS\) sampling method](#) for more details.

A higher frequency can be achieved using Data learning. For details refer to [Data Learning](#).

35.12.3 Data Strobe (DQS) sampling method

35.12.3.1 Basic Description

In DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash move in the same direction, so it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on rising edge of the strobe signal. FSPHS=0 only.

The figure below shows sampling read data in SDR mode using DQS.

Figure 35-14. Data Strobe functionality in SDR mode

When using DQS for DDR reads, QuadSPI internally samples the incoming data on both the edges of the strobe signal. Refer to the figure below for more detail.

Figure 35-15. Data Strobe functionality in DDR mode

35.12.3.2 Internally generated DQS

In this mode, the internal reference clock is fed as a strobe to QuadSPI for read data sampling. The data strobe must be generated in a way such that the data is correctly sampled by the QuadSPI module. This internally generated data strobe signal can be used by QuadSPI to capture the data in:

- SDR mode
- DDR mode

Refer to QuadSPI chip-specific information for additional details about internally generated DQS.

35.12.3.3 External DQS

In serial flash memories supporting DQS, the data strobe signal is an output from the flash device that indicates when data is being transferred from the flash to the host controller. The data is then captured by the controller on:

- Only one edge (either rising or falling edge) of DQS signal in SDR mode
- Both rising/falling edge of the DQS signal in DDR mode

Some serial flash memories (for example, HyperFlash) provide the data strobe output (RWDS) with latency cycles included in between the ongoing read transaction. The data is sampled on both the edges of this signal taking into consideration that when no signal is provided by flash between ongoing transaction, data is not sampled then and at the end of transaction the required number of data to be fetched remains the same. Refer to the figure below for more detail.

Figure 35-16. Data Strobe functionality with latency included

35.12.3.3.1 External Center Aligned Read Strobe

The QuadSPI supports serial flash memories using the Center Aligned Read Strobe (CRS) protocol. By virtue of this protocol, in addition to the SCK, the host controller provides a 90° phase shifted SCK that allows the flash memory to generate valid data timed off SCK edges and a Data Read Strobe (DQS) signal output that is timed off the 90° phase shifted SCK edges that is centered within the valid read data window. This allows the host controller to easily capture read data from the flash by using the data read strobe transitions and thereby allows for higher performance operation. Since the flash memory is the originator of the center aligned data read strobe as well as the read data, the temporal timing phase alignment between these signals is easier to guarantee across PVT (Process, Voltage and Temperature) corners.

The figure below shows data strobe functionality using CRS protocol.

Figure 35-17. Data Strobe functionality using CRS protocol

35.12.4 Data Learning

35.12.4.1 Basic description

“Data learning” is used to manage varying data valid windows from flash memory as well as any variations in the chip based on PVT conditions in DDR mode. QuadSPI provides this feature via the `DATA_LEARN` instruction for all flash memories, irrespective of whether the flash supports it. The `DATA_LEARN` instruction accepts an operand that defines the number of bits of the known pattern for which the data learning has to be done. The known pattern is provided in the `QSPI_DLPR` register.

QuadSPI supports the data learning methods below:

- 4x sampling method
- Data Strobe (DQS) sampling method

The following sections explain data learning in greater detail.

35.12.4.2 4x sampling method

Automatic data learning is supported in 4x sampling mode. To start data learning:

1. Certain flash memories provide data learning as a feature for DDR data reads.

For flash memories that support data learning, configure a known pattern in the Data Learn register inside flash. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash will itself return the data learning pattern in between dummy cycles in every read command. Each I/O will output the same DLP value for every clock edge.

For flash memories that *do not* support data learning, configure a known location in flash memory with a known pattern. The pattern should not have 0x00 or 0xFF in it. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The address in the QuadSPI_SFAR register should point to the known location with the pattern. Configure the known pattern in the QuadSPI_DLPR [DLPV] field. Refer to [Table 35-57](#) for details on how the data has to be ordered in memory for correct operation.

2. Select a sampling point using QuadSPI_SMPR[DDRSMP].
3. Initiate the read via a peripheral transaction.
4. QuadSPI reads the data from the flash. It then encounters the DATA_LEARN instruction and samples the incoming data on all 8 possible sampling points for all the data bus bits.
5. The sample point at which data matches the known pattern is reported in QuadSPI_SR[DLPSMP].
6. If data doesn't match at any sample point, QuadSPI_FR[DLPFF] is set.
7. If the correct sampling point is located, QuadSPI uses the new sampling point to sample the read data following the DATA_LEARN instruction.

This feature may be used to auto-calibrate the sampling point for DDR reads. This auto-calibration may be triggered at fixed intervals, or depending on a change in PVT conditions.

The following figure shows data learning with 4x DDR sampling:

Figure 35-18. Data learning with 4x sampling method

35.12.4.3 Data Strobe (DQS) sampling method

Semi-automatic data learning is supported in DQS sampling method. To start data learning:

1. Certain flash memories provide data learning as a feature for DDR data reads.

For flash memories that support data learning, configure a known pattern in the Data Learn register inside flash. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash will itself return the data learning pattern in between dummy cycles in every read command. Each I/O will output the same DLP value for every clock edge.

For flash memories that *do not* support data learning, configure a known location in flash memory with a known pattern. The pattern should not have 0x00 or 0xFF in it. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The address in the QSPI_SFAR register should point to the known location with the pattern. Configure the known pattern in the QSPI_DLPR[DLPV] field. Refer to [Table 35-57](#) for details on how the data has to be ordered in memory for correct operation.

2. Select a sampling point. See chip-specific QuadSPI information for selection of the sampling point.
3. Initiate the read via a peripheral transaction.
4. QuadSPI reads the data from the flash. It then encounters the DATA_LEARN instruction and samples the incoming data on both edges (rising and falling) of the DQS.
5. If the data from the flash doesn't match the data learning pattern, the QuadSPI_FR[DLPFF] flag is set.
6. No sampling point is reported automatically by the QuadSPI module.
7. These steps (2-7) are repeated with varying VT conditions for a particular process until the QuadSPI_FR[DLPFF] is set. The sampling points where no QuadSPI_FR[DLPFF] is set signify valid setting.
8. In the case of multiple valid settings, software should choose the middle point.
9. The sampling point should be fixed with the above chosen point for the next READ transactions.

NOTE

It must be ensured that QuadSPI is not accessed during calibration.

NOTE

Ensure that there is no latency in between DQS edges while doing data learning using DQS sampling method.

This feature may be used to auto-calibrate the sampling point for DDR reads. This auto-calibration may be triggered at fixed intervals, or depending on a change in PVT conditions.

The following figure shows data learning in DQS mode:

Figure 35-19. Data learning with DQS sampling method

35.12.4.4 Example: programming the data learning pattern in flash memory

If QSPI_DLPR[DLPV] is set to 0x43, QuadSPI tries to match this sample on every incoming data line for single, dual, quad, or octal configurations. The table below shows the data programmed in flash with endianness taken into consideration.

Table 35-57. Programming the Data Learning Pattern in flash memory

Endianness	Single IO	Dual IO	Quad IO	Octal IO
BE	0x43	0x300F	0x0F0000FF	0x00FF00000000FFFF
LE	0x43	0X0F30	0XFF00000F	0XFFFF0000000000FF

35.13 Data Input Hold Requirement of Flash

In DDR mode, the data is valid only for half clock cycle. It is difficult to meet the data input hold time requirement of flash. QuadSPI internally delays the data sent to flash so that it will be easy to meet the hold requirement. The QSPI_FLSHCR[TDH] is used for this purpose. If QSPI_FLSHCR[TDH] is configured to 0, the data sent to flash is aligned

with the internal reference clock of QuadSPI, if it is 1, then, the data is aligned to 2x internal reference half clock, if it is 2, then, the data is aligned to 4x internal reference half clock.

Figure 35-20. Data Hold

Chapter 36

External Bus Interface (FlexBus)

36.1 Chip-specific Flexbus information

36.1.1 FlexBus clocking

The system provides a dedicated clock source to the FlexBus module's external CLKOUT. Its clock frequency is derived from a divider of the MCGOUTCLK. See [Clock Distribution](#) for more details.

36.1.2 FlexBus signal multiplexing

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals are controlled by the port control and FlexBus modules. The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals and/or SDRAM_DQMx signals are available from the modules. The control signals are grouped as illustrated:

Figure 36-1. FlexBus control signal multiplexing

Therefore, use the CPMCR and port control registers to configure which control signal is available on the external pin. All control signals, except for **FB_TA**, are assigned to the ALT5 function in the port control module. Since, unlike the other control signals, **FB_TA** is an input signal, it is assigned to the ALT6 function.

36.1.3 FlexBus CSCR0 reset value

On this device the CSCR0 resets to 0x003F_FC00. Configure this register as needed before performing any FlexBus access.

36.1.4 FlexBus Security

When security is enabled on the device, FlexBus accesses may be restricted by configuring SIM_SOPT2[FBSL]. See [System Integration Module \(SIM\)](#) for details.

36.1.5 FlexBus line transfers

Line transfers are not possible from the ARM Cortex-M4 core. Ignore any references to line transfers in the FlexBus chapter.

36.2 Introduction

This chapter describes external bus data transfer operations and error conditions. It describes transfers initiated by the core processor (or any other bus master) and includes detailed timing diagrams showing the interaction of signals in supported bus operations.

36.2.1 Definition

The FlexBus multifunction external bus interface controller is a hardware module that:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Can be directly connected to the following asynchronous or synchronous slave-only devices with little or no additional circuitry:
 - External ROMs
 - Flash memories

- Programmable logic devices
- Other simple target (slave) devices

36.2.2 Features

FlexBus offers the following features:

- Six independent, user-programmable chip-select signals ($\overline{\text{FB\_CS5}}$ – $\overline{\text{FB\_CS0}}$)
- 8-bit, 16-bit, and 32-bit transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with respect to the assertion of a chip-select
- Programmable address-hold time with respect to the deassertion of a chip-select and transfer direction
- Extended address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

36.3 Signal descriptions

This table describes the external signals involved in data-transfer operations.

NOTE

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

Table 36-1. FlexBus signal descriptions

Signal	I/O	Function
FB_AD31 - FB_AD0	I/O	This is the address and data bus, FB_AD. The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select. The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0.
FB_CS5–FB_CS0	O	General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].

Table continues on the next page...

Table 36-1. FlexBus signal descriptions (continued)

Signal	I/O	Function
$\overline{\text{FB\_BE}}_{31\_24}$ $\overline{\text{FB\_BE}}_{23\_16}$ $\overline{\text{FB\_BE}}_{15\_8}$ $\overline{\text{FB\_BE}}_{7\_0}$	O	Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only. For external SRAM or flash devices, the $\overline{\text{FB\_BE}}$ outputs should be connected to individual byte strobe signals.
FB_OE	O	Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.
FB_R/W	O	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W high) or a write operation (FB_R/W low).
$\overline{\text{FB\_TS}}$	O	Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. An inverted $\overline{\text{FB\_TS}}$ is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus. $\overline{\text{FB\_TS}}$/FB_ALE is asserted for one bus clock cycle. The chip can extend this signal until the first positive clock edge after $\overline{\text{FB\_CS}}$ asserts. See CSCR[EXTS] and Extended Transfer Start/Address Latch Enable.
FB_ALE	O	Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of $\overline{\text{FB\_TS}}$).
FB_TSIZ1–FB_TSIZ0	O	Transfer Size—Indicates (along with $\overline{\text{FB\_TBST}}$) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports. • 00b = 4 bytes • 01b = 1 byte • 10b = 2 bytes • 11b = 16 bytes (line) For misaligned transfers, FB_TSIZ1–FB_TSIZ0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZ1–FB_TSIZ0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZ1–FB_TSIZ0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZ1–FB_TSIZ0 = 01b). For aligned transfers larger than the port size, FB_TSIZ1–FB_TSIZ0 behave as follows: • If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size. • If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size. For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each $\overline{\text{FB\_TS}}$ assertion to reflect the next transfer size. For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.

Table continues on the next page...

Table 36-1. FlexBus signal descriptions (continued)

Signal	I/O	Function
FB_TBST	O	Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size. Note: When a burst transfer is in progress ($\overline{\text{FB\_TBST}} = 0\text{b}$), the transfer size is 16 bytes ($\text{FB\_TSIZ1} - \text{FB\_TSIZ0} = 11\text{b}$), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.
FB_TA	I	Transfer Acknowledge—Indicates that the external data transfer is complete. When $\overline{\text{FB\_TA}}$ is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When $\overline{\text{FB\_TA}}$ is asserted during a write transfer, the transfer is terminated. If auto-acknowledge is disabled ($\text{CSCR}[\text{AA}] = 0$), the external memory or peripheral drives $\overline{\text{FB\_TA}}$ to terminate the transfer. If auto-acknowledge is enabled ($\text{CSCR}[\text{AA}] = 1$), $\overline{\text{FB\_TA}}$ is generated internally after a specified number of wait states, or the external memory or peripheral may assert external $\overline{\text{FB\_TA}}$ before the wait-state countdown to terminate the transfer early. The chip deasserts $\overline{\text{FB\_CS}}$ one cycle after the last $\overline{\text{FB\_TA}}$ is asserted. During read transfers, the external memory or peripheral must continue to drive data until $\overline{\text{FB\_TA}}$ is recognized. For write transfers, the chip continues driving data one clock cycle after $\overline{\text{FB\_CS}}$ is deasserted. The number of wait states is determined by CSCR or the external $\overline{\text{FB\_TA}}$ input. If the external $\overline{\text{FB\_TA}}$ is used, the external memory or peripheral has complete control of the number of wait states. Note: External memory or peripherals should assert $\overline{\text{FB\_TA}}$ only while the $\overline{\text{FB\_CS}}$ signal to the external memory or peripheral is asserted. The CSPMCR register controls muxing of $\overline{\text{FB\_TA}}$ with other signals. When the CSPMCR register does not allow fb_ta control, auto-acknowledge must be used ($\text{CSCR}[\text{AA}] = 1'b1$); otherwise the bus may hang.
FB_CLK	O	FlexBus Clock Output

36.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations.

FB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4000_C000	Chip Select Address Register (FB_CSAR0)	32	R/W	0000_0000h	36.4.1/963

36.4.1 Chip Select Address Register (FB_CSAR_n)

Specifies the associated chip-select's base address.

Address: 4000_C000h base + 0h offset + (12d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BA																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

FB_CSAR_n field descriptions

Field	Description
31–16 BA	Base Address Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed.

Table continues on the next page...

FB_CSAR_n field descriptions (continued)

Field	Description
	NOTE: Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. See the chip memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSAR _n and CSMR _n registers appropriately before accessing this region.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

36.4.2 Chip Select Mask Register (FB_CSMR_n)

Specifies the address mask and allowable access types for the associated chip-select.

Address: 4000_C000h base + 4h offset + (12d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BAM															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FB_CSMR_n field descriptions

Field	Description
31–16 BAM	Base Address Mask Defines the associated chip-select's block size by masking address bits. 0 The corresponding address bit in CSAR is used in the chip-select decode. 1 The corresponding address bit in CSAR is a don't care in the chip-select decode.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 WP	Write Protect Controls write accesses to the address range in the corresponding CSAR. 0 Write accesses are allowed. 1 Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 V	Valid Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0, which acts as the global chip-select).

Table continues on the next page...

FB_CSMR_n field descriptions (continued)

Field	Description
	NOTE: At reset, FB_CS0 will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.
0	Chip-select is invalid.
1	Chip-select is valid.

36.4.3 Chip Select Control Register (FB_CSCR_n)

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

NOTE

To support the global chip-select (FB_CS0), the CSCR0 reset values differ from the other CSCRs. The reset value of CSCR0 is as follows:

- Bits 31–24 are 0b
- Bit 23–3 are chip-dependent
- Bits 3–0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

Address: 4000_C000h base + 8h offset + (12d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

* Notes:

- x = Undefined at reset.

FB_CSCR_n field descriptions

Field	Description
31–26 SWS	Secondary Wait States Used only when the SWSEN bit is 1b. Specifies the number of wait states inserted before an internal transfer acknowledge is generated for a burst transfer (except for the first termination, which is controlled by WS).
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SWSEN	Secondary Wait State Enable 0 Disabled. A number of wait states (specified by WS) are inserted before an internal transfer acknowledge is generated for all transfers. 1 Enabled. A number of wait states (specified by SWS) are inserted before an internal transfer acknowledge is generated for burst transfer secondary terminations.
22 EXTS	Extended Transfer Start/Extended Address Latch Enable Controls how long $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ is asserted. 0 Disabled. $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ asserts for one bus clock cycle. 1 Enabled. $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ remains asserted until the first positive clock edge after $\overline{\text{FB\_CSn}}$ asserts.
21–20 ASET	Address Setup Controls when the chip-select is asserted with respect to assertion of a valid address and attributes. 00 Assert $\overline{\text{FB\_CSn}}$ on the first rising clock edge after the address is asserted (default for all but $\overline{\text{FB\_CS0}}$). 01 Assert $\overline{\text{FB\_CSn}}$ on the second rising clock edge after the address is asserted. 10 Assert $\overline{\text{FB\_CSn}}$ on the third rising clock edge after the address is asserted. 11 Assert $\overline{\text{FB\_CSn}}$ on the fourth rising clock edge after the address is asserted (default for $\overline{\text{FB\_CS0}}$).
19–18 RDAH	Read Address Hold or Deselect Controls the address and attribute hold time after the termination during a read cycle that hits in the associated chip-select's address space. NOTE: - The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. - The number of cycles the address and attributes are held after $\overline{\text{FB\_CSn}}$ deassertion depends on the value of the AA bit. 00 When AA is 1b, 1 cycle. When AA is 0b, 0 cycles. 01 When AA is 1b, 2 cycles. When AA is 0b, 1 cycle. 10 When AA is 1b, 3 cycles. When AA is 0b, 2 cycles. 11 When AA is 1b, 4 cycles. When AA is 0b, 3 cycles.
17–16 WRAH	Write Address Hold or Deselect Controls the address, data, and attribute hold time after the termination of a write cycle that hits in the associated chip-select's address space. NOTE: The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. 00 1 cycle (default for all but $\overline{\text{FB\_CS0}}$) 01 2 cycles

Table continues on the next page...

FB_CSCR_n field descriptions (continued)

Field	Description
	10 3 cycles 11 4 cycles (default for <code>FB_CS0</code>)
15–10 WS	Wait States Specifies the number of wait states inserted after FlexBus asserts the associated chip-select and before an internal transfer acknowledge is generated (WS = 00h inserts 0 wait states, ..., WS = 3Fh inserts 63 wait states).
9 BLS	Byte-Lane Shift Specifies if data on <code>FB_AD</code> appears left-aligned or right-aligned during the data phase of a FlexBus access. 0 Not shifted. Data is left-aligned on <code>FB_AD</code> . 1 Shifted. Data is right-aligned on <code>FB_AD</code> .
8 AA	Auto-Acknowledge Enable Asserts the internal transfer acknowledge for accesses specified by the chip-select address. NOTE: If AA is 1b for a corresponding <code>FB_CS_n</code> and the external system asserts an external <code>FB_TA</code> before the wait-state countdown asserts the internal <code>FB_TA</code> , the cycle is terminated. Burst cycles increment the address bus between each internal termination. NOTE: This field must be 1b if <code>CSPMCR</code> disables <code>FB_TA</code> . 0 Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally. 1 Enabled. Internal transfer acknowledge is asserted as specified by WS.
7–6 PS	Port Size Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles. 00 32-bit port size. Valid data is sampled and driven on <code>FB_D[31:0]</code> . 01 8-bit port size. Valid data is sampled and driven on <code>FB_D[31:24]</code> when BLS is 0b, or <code>FB_D[7:0]</code> when BLS is 1b. 1X 16-bit port size. Valid data is sampled and driven on <code>FB_D[31:16]</code> when BLS is 0b, or <code>FB_D[15:0]</code> when BLS is 1b.
5 BEM	Byte-Enable Mode Specifies whether the corresponding <code>FB_BE</code> is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs. 0 <code>FB_BE</code> is asserted for data write only. 1 <code>FB_BE</code> is asserted for data read and write accesses.
4 BSTR	Burst-Read Enable Specifies whether burst reads are enabled for memory associated with each chip select. 0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads. 1 Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports.

Table continues on the next page...

FB_CSCR_n field descriptions (continued)

Field	Description
3 BSTW	Burst-Write Enable Specifies whether burst writes are enabled for memory associated with each chip select. 0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes. 1 Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

36.4.4 Chip Select port Multiplexing Control Register (FB_CSPMCR)

Controls the multiplexing of the FlexBus signals.

NOTE

A bus error occurs when you do any of the following:

- Write to a reserved address
- Write to a reserved field in this register, or
- Access this register using a size other than 32 bits.

Address: 4000_C000h base + 60h offset = 4000_C060h

Field	Description
23–20 GROUP3	FlexBus Signal Group 3 Multiplex control Controls the multiplexing of the $\overline{\text{FB\_CS5}}$, $\overline{\text{FB\_TSIZ1}}$, and $\overline{\text{FB\_BE\_23\_16}}$ signals. 0000 $\overline{\text{FB\_CS5}}$ 0001 $\overline{\text{FB\_TSIZ1}}$ 0010 $\overline{\text{FB\_BE\_23\_16}}$ Any other value Reserved
19–16 GROUP4	FlexBus Signal Group 4 Multiplex control Controls the multiplexing of the $\overline{\text{FB\_TBST}}$, $\overline{\text{FB\_CS2}}$, and $\overline{\text{FB\_BE\_15\_8}}$ signals. 0000 $\overline{\text{FB\_TBST}}$ 0001 $\overline{\text{FB\_CS2}}$ 0010 $\overline{\text{FB\_BE\_15\_8}}$ Any other value Reserved
15–12 GROUP5	FlexBus Signal Group 5 Multiplex control Controls the multiplexing of the $\overline{\text{FB\_TA}}$, $\overline{\text{FB\_CS3}}$, and $\overline{\text{FB\_BE\_7\_0}}$ signals. NOTE: When GROUP5 is not 0000b, you must write 1b to the CSCR[AA] bit. Otherwise, the bus hangs during a transfer. 0000 $\overline{\text{FB\_TA}}$ 0001 $\overline{\text{FB\_CS3}}$. You must also write 1b to CSCR[AA]. 0010 $\overline{\text{FB\_BE\_7\_0}}$. You must also write 1b to CSCR[AA]. Any other value Reserved
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

36.5 Functional description

36.5.1 Use cases

In general, FlexBus supports the following use cases, but note that your device may not support all of these use cases, because of limitations imposed by your specific package's pinouts:

- Multiplexed 32-bit address and 32-bit data
- Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)

- Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)
- Non-multiplexed 32-bit address and 32-bit data busses

NOTE

All use cases require signals to actually be available on the pins of your specific device package. Refer to your specific device's signal multiplexing table to verify the availability of specific signals for your device package.

36.5.2 Address comparison

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

When the transfer address	Then FlexBus
Matches one address register configuration	Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR. If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle.
Does not match an address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.
Matches more than one address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.

36.5.3 Address driven on address bus

FlexBus always drives a 32-bit address on the FB_AD bus regardless of the external memory's or peripheral's address size.

36.5.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
 - FB_AD from FB_AD0 upward
- Data lines

- If CSCR[BLS] = 0, FB_AD from FB_AD31 downward
- If CSCR[BLS] = 1, FB_AD from FB_AD0 upward

36.5.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB_AD16–FB_AD1 and data15–data0 to FB_AD31–FB_AD16. See [Data-byte alignment and physical connections](#) for a graphical connection.

36.5.6 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB_AD31–FB_AD0)
- Control signals ($\overline{\text{FB\_TS}}/\text{FB\_ALE}$, $\overline{\text{FB\_TA}}$, $\overline{\text{FB\_CSn}}$, $\overline{\text{FB\_OE}}$, $\text{FB\_R}/\overline{\text{W}}$, $\overline{\text{FB\_BEn}}$)
- Attribute signals ($\overline{\text{FB\_TBST}}$, FB_TSI1–FB_TSI0)

36.5.7 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB_CLK):

- Address
- Write data
- $\overline{\text{FB\_TS}}/\text{FB\_ALE}$
- $\overline{\text{FB\_CSn}}$
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

36.5.8 Data-byte alignment and physical connections

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane

Functional description

FB_AD31–FB_AD24 ($\overline{\text{FB\_BE\_31\_24}}$). A 32-bit transfer through this 8-bit port takes four transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each four-byte lane.

Figure 36-2. Connections for external memory port sizes (CSCRn[BLS] = 0)

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

In BLS=1 mode, the byte enable that corresponds to a given byte lane, depends on the port size that you are using.

Figure 36-3. Connections for external memory port sizes (CSCRn[BLS] = 1)

36.5.9 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB_AD31–FB_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB_AD31–FB_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB_AD31–FB_AD0 lines not used for data.

36.5.9.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
32-bit	Address phase	Address			
	Data phase	Data			
16-bit	Address phase	Address			
	Data phase	Data		Address	

Table continues on the next page...

Functional description

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
8-bit	Address phase	Address			
	Data phase	Data	Address		

36.5.9.2 FlexBus multiplexed operating modes for CSCRn[BLS]=1

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 1b.

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
32-bit	Address phase	Address			
	Data phase	Data			
16-bit	Address phase	Address			
	Data phase	Address		Data	
8-bit	Address phase	Address			
	Data phase	Address			Data

36.5.10 Data transfer states

Basic data transfers occur in four clocks or states. (See [Figure 36-5](#) and [Figure 36-7](#) for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

The states are described in this table.

State	Cycle	Description
S0	All	The read or write cycle is initiated. On the rising clock edge, FlexBus: - Places a valid address on FB_ADn - Asserts FB_TS/FB_ALE - Drives FB_R/$\overline{W}$ high for a read and low for a write
S1	All	FlexBus: - Negates $\overline{FB\_TS}$/FB_ALE on the rising edge of FB_CLK - Asserts FB_CSn - Drives the data on FB_AD31–FB_ADX for writes - Tristates FB_AD31–FB_ADX for reads - Continues to drive the address on FB_AD pins that are unused for data If the external memory or peripheral asserts $\overline{FB\_TA}$, then the process moves to S2. If $\overline{FB\_TA}$ is not asserted internally or externally, then S1 repeats.
	Read	The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with $\overline{FB\_TA}$ asserted.
S2	All	For internal termination, FlexBus negates $\overline{FB\_CSn}$ and the transfer is complete. For external termination, the external memory or peripheral negates $\overline{FB\_TA}$, and FlexBus negates $\overline{FB\_CSn}$ after the rising edge of FB_CLK at the end of S2.
	Read	FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge or continue to drive the data until the end of S3 or through any additional address hold cycles.
S3	All	FlexBus invalidates the address, data, and FB_R/ $\overline{W}$ on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.

36.5.11 FlexBus Timing Examples

Note

The timing diagrams throughout this section use signal names that may not be included on your particular device. Ignore these extraneous signals.

Note

Throughout this section:

- FB_D[X] indicates a 32-, 16-, or 8-bit wide data bus
- FB_A[Y] indicates an address bus that can be 32, 24, or 16 bits wide.

36.5.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device. The following figure shows a read cycle flowchart.

Figure 36-4. Read Cycle Flowchart

The read cycle timing diagram is shown in the following figure.

Note

FB_TĀ does not have to be driven by the external device for internally-terminated bus cycles.

Note

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

Figure 36-5. Basic Read-Bus Cycle

36.5.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device. The following figure shows the write cycle flowchart.

Figure 36-6. Write-Cycle Flowchart

The following figure shows the write cycle timing diagram.

Note

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

Figure 36-7. Basic Write-Bus Cycle

36.5.11.3 Bus Cycle Sizing

This section shows timing diagrams for various port size scenarios.

36.5.11.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The following figure illustrates the basic byte read transfer to an 8-bit device with no wait states:

- The address is driven on the full FB_AD[31:0] bus in the first clock.

Functional description

- The device tristates FB_AD[31:24] on the second clock and continues to drive address on FB_AD[23:0] throughout the bus cycle.
- The external device returns the read data on FB_AD[31:24] and may tristate the data line or continue driving the data one clock after FB_TA is sampled asserted.

Figure 36-8. Single Byte-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB_AD[31:24].

Figure 36-9. Single Byte-Write Transfer

36.5.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The following figure illustrates the basic word read transfer to a 16-bit device with no wait states.

- The address is driven on the full FB_AD[31:8] bus in the first clock.
- The device tristates FB_AD[31:16] on the second clock and continues to drive address on FB_AD[15:0] throughout the bus cycle.
- The external device returns the read data on FB_AD[31:16] and may tristate the data line or continue driving the data one clock after FB_TA is sampled asserted.

Figure 36-10. Single Word-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB_AD[31:16].

Figure 36-11. Single Word-Write Transfer

36.5.11.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The following figure depicts a longword read from a 32-bit device.

Figure 36-12. Longword-Read Transfer

The following figure illustrates the longword write to a 32-bit device.

Figure 36-13. Longword-Write Transfer

36.5.11.4 Timing Variations

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

36.5.11.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the $CSCR_n$ registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in [Figure 36-5](#) and [Figure 36-10](#)) with the default of no wait states respectively.

Figure 36-14. Basic Read-Bus Cycle (No Wait States)

Figure 36-15. Basic Write-Bus Cycle (No Wait States)

If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external $\overline{\text{FB\_TA}}$ is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.

Figure 36-16. Read-Bus Cycle (One Wait State)

Figure 36-17. Write-Bus Cycle (One Wait State)

36.5.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable ($\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

Figure 36-18. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)

Figure 36-19. Write-Bus Cycle with Two Clock Address Setup (No Wait States)

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

Figure 36-20. Read Cycle with Two-Clock Address Hold (No Wait States)

Figure 36-21. Write Cycle with Two-Clock Address Hold (No Wait States)

The following figure shows a bus cycle using address setup, wait states, and address hold.

Figure 36-22. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)

36.5.12 Burst cycles

The chip can be programmed to initiate burst cycles if its transfer size exceeds the port size of the selected destination. The initiation of a burst cycle is encoded on the transfer size pins (FB_TSI[1:0]). For burst transfers to smaller port sizes, FB_TSI[1:0] indicates the size of the entire transfer. For example, with bursting enabled, a 16-bit transfer to an 8-bit port takes two beats (two byte-sized transfers), for which FB_TSI[1:0] equals 10b throughout. A 32-bit transfer to an 8-bit port takes four beats (four byte-sized transfers), for which FB_TSI[1:0] equals 00b throughout.

36.5.12.1 Enabling and inhibiting burst

The CSCRn registers enable bursting for reads, writes, or both.

Memory spaces can be declared burst-inhibited for reads and writes by writing 0b to the appropriate CSCRn[BSTR] and CSCRn[BSTW] fields.

36.5.12.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

Port size PS[1:0]	Transfer size FB_TSIZ[1:0]	Burst-inhibited: Number of transfers Burst enabled: Number of beats
01b (8 bit)	10b (16 bits)	2
	00b (32 bits)	4
	11b (16 bytes)	16
1Xb (16 bit)	00b (32 bits)	2
	11b (16 bytes)	8
00b (32 bit)	11b (line)	4

The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

36.5.12.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

Note

- In **non-multiplexed address/data mode**: the address on FB_A increments only during internally-terminated burst

cycles. The first address is driven throughout the entire burst for externally-terminated cycles.

- In **multiplexed address/data mode**: the address is driven on FB_AD only during the first cycle for all terminated cycles. In other words, the lower address lines only increment during internally-terminated burst cycles (assuming that the lower address lines are being driven with the address during the data phase).

Figure 36-23. 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

36.5.12.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

Note

The first beat of any write burst cycle has at least one wait state. If the bus cycle is programmed for zero wait states (CSCRN[WS] = 0b), one wait state is added. Otherwise, the programmed number of wait states are used.

Figure 36-24. 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

36.5.12.5 32-bit-read burst-inhibited from 8-bit port (no wait states)

The following figure shows a 32-bit read from an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

Note

There is an extra clock of address setup (AS) for each burst-inhibited transfer between states S0 and S1.

36.5.12.6 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

Figure 36-25. 32-bit-write burst-inhibited to 8-bit port (no wait states)

36.5.12.7 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSSEN] = 1b) determines the number of wait states.

Figure 36-26. 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

36.5.12.8 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.

Figure 36-27. 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

36.5.12.9 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

Note

In non-multiplexed address/data mode, the address on FB_A increments only during internally-terminated burst cycles (CSCRN[AA] = 1b). The attached device must be able to

account for this, or a wait state must be added. The first address is driven throughout the entire burst for externally-terminated cycles.

In multiplexed address/data mode, the address is driven on FB_AD only during the first cycle for internally- and externally-terminated cycles.

Figure 36-28. 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

36.5.12.10 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.

Figure 36-29. 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

36.5.13 Extended Transfer Start/Address Latch Enable

The $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ signal asserts for a single bus clock cycle. When $\text{CSCR}_n[\text{EXTS}]$ is set, the $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ signal asserts and remain asserted until the first positive clock edge after $\overline{\text{FB\_CS}}_n$ asserts. See the following figure.

NOTE

When EXTS is set, $\text{CSCR}_n[\text{WS}]$ must be programmed to have at least one primary wait state.

Figure 36-30. Read-Bus Cycle with CSCRn[EXTS] = 1 (One Wait State)

36.5.14 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, then the transfer can be terminated by asserting $\overline{\text{FB\_TA}}$. If the processor must manage a bus error differently, then asserting an interrupt to the core along with $\overline{\text{FB\_TA}}$ when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for $\overline{\text{FB\_TA}}$.

36.6 Initialization/Application Information

36.6.1 Initializing a chip-select

Before using any other chip select to take it out of global chip select mode, you must initialize CS0.

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

36.6.2 Reconfiguring a chip-select

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

Chapter 37

Cyclic Redundancy Check (CRC)

37.1 Introduction

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

37.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or byte-wise.
This option is required for certain CRC standards. A byte-wise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the byte-wise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

37.1.2 Block diagram

The following is a block diagram of the CRC.

Figure 37-1. Programmable cyclic redundancy check (CRC) block diagram

37.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

37.1.3.1 Run mode

This is the basic mode of operation.

37.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

37.2 Memory map and register descriptions

CRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_2000	CRC Data register (CRC_DATA)	32	R/W	FFFF_FFFFh	37.2.1/1009
4003_2004	CRC Polynomial register (CRC_GPOLY)	32	R/W	0000_1021h	37.2.2/1010
4003_2008	CRC Control register (CRC_CTRL)	32	R/W	0000_0000h	37.2.3/1010

37.2.1 CRC Data register (CRC_DATA)

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: 4003_2000h base + 0h offset = 4003_2000h

CRC_DATA field descriptions

Field	Description
31–24 HU	CRC High Upper Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23–16 HL	CRC High Lower Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15–8 LU	CRC Low Upper Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
LL	CRC Low Lower Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

37.2.2 CRC Polynomial register (CRC_GPOLY)

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 4003_2000h base + 4h offset = 4003_2004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HIGH																LOW															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	0	1

CRC_GPOLY field descriptions

Field	Description
31–16 HIGH	High Polynomial Half-word Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0).
LOW	Low Polynomial Half-word Writable and readable in both 32-bit and 16-bit CRC modes.

37.2.3 CRC Control register (CRC_CTRL)

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

Address: 4003_2000h base + 8h offset = 4003_2008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TOT		TOTR		0	FXOR	WAS	TCRC	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CRC_CTRL field descriptions

Field	Description
31–30 TOT	Type Of Transpose For Writes Defines the transpose configuration of the data written to the CRC data register. See the description of the transpose feature for the available transpose options. 00 No transposition. 01 Bits in bytes are transposed; bytes are not transposed. 10 Both bits in bytes and bytes are transposed. 11 Only bytes are transposed; no bits in a byte are transposed.
29–28 TOTR	Type Of Transpose For Read Identifies the transpose configuration of the value read from the CRC Data register. See the description of the transpose feature for the available transpose options. 00 No transposition. 01 Bits in bytes are transposed; bytes are not transposed. 10 Both bits in bytes and bytes are transposed. 11 Only bytes are transposed; no bits in a byte are transposed.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FXOR	Complement Read Of CRC Data Register Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on the fly complementing of read data. 0 No XOR on reading. 1 Invert or complement the read value of the CRC Data register.
25 WAS	Write CRC Data Register As Seed When asserted, a value written to the CRC data register is considered a seed value. When deasserted, a value written to the CRC data register is taken as data for CRC computation. 0 Writes to the CRC data register are data values. 1 Writes to the CRC data register are seed values.
24 TCRC	Width of CRC protocol. 0 16-bit CRC protocol. 1 32-bit CRC protocol.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

37.3 Functional description

37.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program `CRC_CTRL[WAS]`, `CRC_GPOLY`, necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting `CRC_CTRL[WAS]` enables the programming of the seed value into the `CRC_DATA` register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting `CRC_CTRL[WAS]` and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

37.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

37.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear `CRC_CTRL[TCRC]` to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 16-bit polynomial to the `CRC_GPOLY[LOW]` field. The `CRC_GPOLY[HIGH]` field is not usable in 16-bit CRC mode.
4. Set `CRC_CTRL[WAS]` to program the seed value.
5. Write a 16-bit seed to `CRC_DATA[LU:LL]`. `CRC_DATA[HU:HL]` are not used.
6. Clear `CRC_CTRL[WAS]` to start writing data values.
7. Write data values into `CRC_DATA[HU:HL:LU:LL]`. A CRC is computed on every data value write, and the intermediate CRC result is stored back into `CRC_DATA[LU:LL]`.
8. When all values have been written, read the final CRC result from `CRC_DATA[LU:LL]`.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

37.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 32-bit polynomial to CRC_GPOLY[HIGH:LOW].
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC_DATA[HU:HL:LU:LL].
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[HU:HL:LU:LL]. The CRC is calculated byte-wise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

37.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

37.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. CTRL[TOT] or CTRL[TOTR] is 00.

No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 01

Bits in a byte are transposed, while bytes are not transposed.

reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

Figure 37-2. Transpose type 01

3. CTRL[TOT] or CTRL[TOTR] is 10.

Both bits in bytes and bytes are transposed.

reg[31:0] becomes = {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}

Figure 37-3. Transpose type 10

4. CTRL[TOT] or CTRL[TOTR] is 11.

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

Figure 37-4. Transpose type 11

NOTE

- For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only.
- When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[**HU:HL**] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

37.3.4 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

Chapter 38

Memory-Mapped Cryptographic Acceleration Unit (MMCAU)

38.1 Overview

The set of implemented algorithms provides excellent support for network security standards, such as SSL and IPsec. Additionally, using the CAU efficiently permits the implementation of any higher level functions or modes of operation, such as HMAC, CBC, and so on based on the supported algorithms.

The cryptographic algorithms are implemented partially in software with only functions critical to increasing performance implemented in hardware. The CAU allows for efficient, fine-grained partitioning of functions between hardware and software:

- Implement the innermost security kernel functions using the coprocessor instructions.
- Implement higher level functions in software by using the standard processor instructions.

This partitioning of functions is key to minimizing size of the CAU while maintaining a high level of throughput. Using software for some functions also simplifies the CAU design. The CAU implements a set of coprocessor commands that operate on a register file of 32-bit registers.

38.2 Features

The CAU includes the following distinctive features:

- Supports DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms
- Simple, flexible programming model

38.3 Register definition

The CAU contains multiple registers used by each of the supported algorithms. The following table shows registers that are applicable to each supported algorithm and indicates the corresponding letter designations for each algorithm.

For more information on these letter designations, see the supported algorithm specifications.

Code	Register	DES	AES	MD5	SHA-1	SHA-256
0	CAU Status Register (CASR)	—	—	—	—	—
1	CAU Accumulator (CAA)	—	—	a	T	T
2	General-Purpose Register 0 (CA0)	C	W0	—	A	A
3	General-Purpose Register 1 (CA1)	D	W1	b	B	B
4	General-Purpose Register 2 (CA2)	L	W2	c	C	C
5	General-Purpose Register 3 (CA3)	R	W3	d	D	D
6	General-Purpose Register 4 (CA4)	—	—	—	E	E
7	General-Purpose Register 5 (CA5)	—	—	—	W	F
8	General-Purpose Register 6 (CA6)	—	—	—	—	G
9	General-Purpose Register 7 (CA7)	—	—	—	—	H

Table continues on the next page...

Code	Register	DES	AES	MD5	SHA-1	SHA-256
10	General-Purpose Register 8 (CA8)	—	—	—	—	W/T ₁

The CAU supports only 32-bit operations and register accesses. All registers support read, write, and ALU operations. However, only bits 1–0 of the CASR are writeable. Bits 31–2 of the CASR must be written as 0 for compatibility with future versions of the CAU.

NOTE

In the following table, the "address" or "offset" refers to the command code value for the CAU registers.

CAU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
E008_1000	Status Register (CAU_CASR)	32	R/W	2000_0000h	38.3.1/1020
E008_1001	Accumulator (CAU_CAA)	32	R/W	0000_0000h	38.3.2/1021
E008_1002	General Purpose Register (CAU_CA0)	32	R/W	0000_0000h	38.3.3/1021
E008_1003	General Purpose Register (CAU_CA1)	32	R/W	0000_0000h	38.3.3/1021
E008_1004	General Purpose Register (CAU_CA2)	32	R/W	0000_0000h	38.3.3/1021
E008_1005	General Purpose Register (CAU_CA3)	32	R/W	0000_0000h	38.3.3/1021
E008_1006	General Purpose Register (CAU_CA4)	32	R/W	0000_0000h	38.3.3/1021
E008_1007	General Purpose Register (CAU_CA5)	32	R/W	0000_0000h	38.3.3/1021
E008_1008	General Purpose Register (CAU_CA6)	32	R/W	0000_0000h	38.3.3/1021
E008_1009	General Purpose Register (CAU_CA7)	32	R/W	0000_0000h	38.3.3/1021
E008_100A	General Purpose Register (CAU_CA8)	32	R/W	0000_0000h	38.3.3/1021

38.3.1 Status Register (CAU_CASR)

CASR contains the status and configuration for the CAU.

Address: E008_1000h base + 0h offset = E008_1000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	VER				0											
W																
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0														DPE	IC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAU_CASR field descriptions

Field	Description
31–28 VER	CAU Version Indicates CAU version. 0x1 Initial CAU version. 0x2 Second version, added support for SHA-256 algorithm (This is the value on this device).
27–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DPE	DES Parity Error Indicates whether the DES parity error is detected. 0 No error detected. 1 DES key parity error detected.
0 IC	Illegal Command Indicates an illegal instruction has been executed. 0 No illegal commands issued. 1 Illegal command issued.

38.3.2 Accumulator (CAU_CAA)

Commands use the CAU accumulator for storage of results and as an operand for the cryptographic algorithms.

Address: E008_1000h base + 1h offset = E008_1001h

CAU_CAA field descriptions

Field	Description
ACC	Accumulator Stores results of various CAU commands.

38.3.3 General Purpose Register (CAU_CAn)

The General Purpose Register is used in the CAU commands for storage of results and as operands for various cryptographic algorithms.

Address: E008_1000h base + 2h offset + (1d × i), where i=0d to 8d

CAU_CAn field descriptions

Field	Description
CAn	General Purpose Registers Used by the CAU commands. Some cryptographic operations work with specific registers.

38.4 Functional description

This section discusses the programming model and operation of the CAU.

38.4.1 CAU commands

The CAU supports the commands shown in the following table. All other encodings are reserved. The CASR[IC] bit is set if an undefined command is issued. A specific illegal command (ILL) is defined to allow software self-checking. Reserved commands must not be issued so as to ensure compatibility with future implementations.

The CMD field specifies the 9-bit CAU opcode for the operation command.

See [Assembler equate values](#) for a set of assembly constants used in the command descriptions here. If supported by the assembler, macros can also be created for each instruction. The value CAx should be interpreted as any CAU register (CASR, CAA, and CAn)

Table 38-1. CAU commands

Type	Command name	Description	CMD									Operation
			8	7	6	5	4	3	2	1	0	
	CNOP	No Operation	0x000									—
	LDR	Load Reg	0x01				CAx				Op1 → CAx	
	STR	Store Reg	0x02				CAx				CAx → Result	
	ADR	Add	0x03				CAx				CAx + Op1 → CAx	
	RADR	Reverse and Add	0x04				CAx				CAx + ByteRev(Op1) → CAx	
	ADRA	Add Reg to Acc	0x05				CAx				CAx + CAA → CAA	
	XOR	Exclusive Or	0x06				CAx				CAx ^ Op1 → CAx	
	ROTL	Rotate Left	0x07				CAx				(CAx <<< (Op1 % 32)) (CAx >>> (32 - (Op1 % 32))) → CAx	
	MVRA	Move Reg to Acc	0x08				CAx				CAx → CAA	
	MVAR	Move Acc to Reg	0x09				CAx				CAA → CAx	
	AESS	AES Sub Bytes	0x0A				CAx				SubBytes(CAx) → CAx	
	AESIS	AES Inv Sub Bytes	0x0B				CAx				InvSubBytes(CAx) → CAx	
	AESC	AES Column Op	0x0C				CAx				MixColumns(CAx)^Op1→CAx	
	AESIC	AES Inv Column Op	0x0D				CAx				InvMixColumns(CAx^Op1) → CAx	
	AESR	AES Shift Rows	0x0E0									ShiftRows(CA0-CA3) → CA0-CA3
	AESIR	AES Inv Shift Rows	0x0F0									InvShiftRows(CA0-CA3)→CA0-CA3
	DESR	DES Round	0x10				IP	FP	KS[1:0]		DES Round(CA0-CA3)→CA0-CA3	
	DESK	DES Key Setup	0x11				0	0	CP	DC	DES Key Op(CA0-CA1)→CA0-CA1 Key Parity Error & CP → CASR[1]	

Table continues on the next page...

Table 38-1. CAU commands (continued)

Type	Command name	Description	CMD								Operation
			8	7	6	5	4	3	2	1	
	HASH	Hash Function	0x12					0	HF[2:0]		Hash Func(CA1-CA3)+CAA→ CAA
	SHS	Secure Hash Shift	0x130								CAA <<< 5→ CAA, CAA→CA0, CA0→CA1, CA1 <<< 30 → CA2, CA2→CA3, CA3→CA4
	MDS	Message Digest Shift	0x140								CA3→CAA, CAA→CA1, CA1→CA2, CA2→CA3,
	SHS2	Secure Hash Shift 2	0x150								CAA→CA0, CA0→CA1, CA1 → CA2, CA2→CA3, CA3 + CA8 →CA4, CA4 → CA5, CA5 → CA6, CA6 → CA7
	ILL	Illegal Command	0x1F0								0x1→CASR[IC]

38.4.1.1 Coprocessor No Operation (CNOP)

The CNOP command is the coprocessor no-op

38.4.1.2 Load Register (LDR)

The LDR command loads CAX with the source data specified by .

38.4.1.3 Store Register (STR)

The STR command returns the value of CAX to the destination specified .

38.4.1.4 Add to Register (ADR)

The ADR command adds the source operand specified by to CAX and stores the result in CAX.

38.4.1.5 Reverse and Add to Register (RADR)

The RADR command performs a byte reverse on the source operand specified by , adds that value to CAX, and stores the result in CAX. The table below shows an example.

Table 38-2. RADR command example

Operand	CAX before	CAX after
0x0102_0304	0xA0B0_C0D0	0xA4B3_C2D1

38.4.1.6 Add Register to Accumulator (ADRA)

The ADRA command adds CAX to CAA and stores the result in CAA.

38.4.1.7 Exclusive Or (XOR)

The XOR command performs an exclusive-or of the source operand specified by with CAX and stores the result in CAX.

38.4.1.8 Rotate Left (ROTL)

ROTL rotates the CAX bits to the left with the result stored back to CAX. The number of bits to rotate is the value specified by modulo 32.

38.4.1.9 Move Register to Accumulator (MVRA)

The MVRA command moves the value from the source register CAX to the destination register CAA.

38.4.1.10 Move Accumulator to Register (MVAR)

The MVAR command moves the value from source register CAA to the destination register CAX.

38.4.1.11 AES Substitution (AESS)

The AESS command performs the AES byte substitution operation on CAx and stores the result back to CAx.

38.4.1.12 AES Inverse Substitution (AESIS)

The AESIS command performs the AES inverse byte substitution operation on CAx and stores the result back to CAx.

38.4.1.13 AES Column Operation (AESC)

The AESC command performs the AES column operation on the contents of CAx. It then performs an exclusive-or of that result with the source operand specified by and stores the result in CAx.

38.4.1.14 AES Inverse Column Operation (AESIC)

The AESIC command performs an exclusive-or operation of the source operand specified by on the contents of CAx followed by the AES inverse mix column operation on that result and stores the result back in CAx.

38.4.1.15 AES Shift Rows (AESR)

The AESR command performs the AES shift rows operation on registers CA0, CA1, CA2, and CA3. The table below shows an example.

Table 38-3. AESR command example

Register	Before	After
CA0	0x0102_0304	0x0106_0B00
CA1	0x0506_0708	0x050A_0F04
CA2	0x090A_0B0C	0x090E_0308
CA3	0x0D0E_0F00	0x0D02_070C

Where:

- row 1 = CA0[31:24], CA1[31:24], CA2[31:24], CA3[31:24]
- row 2 = CA0[23:16], CA1[23:16], CA2[23:16], CA3[23:16]

- row 3 = CA0[15:8], CA1[15:8], CA2[15:8], CA3[15:8]
- row 4 = CA0[7:0], CA1[7:0], CA2[7:0], CA3[7:0]

38.4.1.16 AES Inverse Shift Rows (AESIR)

The AESIR command performs the AES inverse shift rows operation on registers CA0, CA1, CA2, and CA3. The table below shows an example.

Table 38-4. AESIR command example

Register	Before	After
CA0	0x0106_0B00	0x0102_0304
CA1	0x050A_0F04	0x0506_0708
CA2	0x090E_0308	0x090A_0B0C
CA3	0x0D02_070C	0x0D0E_0F00

Where:

- row 1 = CA0[31:24], CA1[31:24], CA2[31:24], CA3[31:24]
- row 2 = CA0[23:16], CA1[23:16], CA2[23:16], CA3[23:16]
- row 3 = CA0[15:8], CA1[15:8], CA2[15:8], CA3[15:8]
- row 4 = CA0[7:0], CA1[7:0], CA2[7:0], CA3[7:0]

38.4.1.17 DES Round (DESR)

The DESR command performs a round of the DES algorithm and a key schedule update with the following source and destination designations: CA0=C, CA1=D, CA2=L, CA3=R. If the IP bit is set, DES initial permutation performs on CA2 and CA3 before the round operation. If the FP bit is set, DES final permutation, that is, inverse initial permutation, performs on CA2 and CA3 after the round operation. The round operation uses the source values from registers CA0 and CA1 for the key addition operation. The KSx field specifies the shift for the key schedule operation to update the values in CA0 and CA1. The following table defines the specific shift function performed based on the KSx field.

Table 38-5. Key shift function codes

KSx code	KSx define	Shift function
0	KSL1	Left 1
1	KSL2	Left 2
2	KSR1	Right 1
3	KSR2	Right 2

38.4.1.18 DES Key setup (DESK)

The DESK command performs the initial key transformation, permuted choice 1, defined by the DES algorithm on CA0 and CA1 with CA0 containing bits 1–32 of the key and CA1 containing bits 33–64 of the key¹. If the DC bit is set, no shift operation performs and the values C₀ and D₀ store back to CA0 and CA1, respectively. The DC bit must be set for decrypt operations. If the DC bit is not set, a left shift by one also occurs and the values C₁ and D₁ store back to CA0 and CA1, respectively. The DC bit should be cleared for encrypt operations. If the CP bit is set and a key parity error is detected, CASR[DPE] bit is set; otherwise, it is cleared.

38.4.1.19 Hash Function (HASH)

The HASH command performs a hashing operation on a set of registers and adds that result to the value in CAA and stores the result in CAA. The specific hash function performed is based on the HFX field as defined in the table below.

This table uses the following terms:

- ROTRⁿ(CA_x): rotate CA_x register right *n* times
- SHRⁿ(CA_x): shift CA_x register right *n* times

Table 38-6. Hash Function codes

HFX code	HFX define	Hash Function	Hash logic
0	HFF	MD5 F()	$(CA1 \& CA2) \mid (\overline{CA1} \& CA3)$
1	HFG	MD5 G()	$(CA1 \& CA3) \mid (CA2 \& \overline{CA3})$
2	HFH	MD5 H(), SHA Parity()	$CA1 \wedge CA2 \wedge CA3$
3	HFI	MD5 I()	$CA2 \wedge (CA1 \mid \overline{CA3})$
4	HFC	SHA Ch()	$(CA1 \& CA2) \wedge (\overline{CA1} \& CA3)$
5	HFM	SHA Maj()	$(CA1 \& CA2) \wedge (CA1 \& CA3) \wedge (CA2 \& CA3)$
6	HF2C	SHA-256 Ch()	$(CA4 \& CA5) \wedge (\overline{CA1} \& CA6)$
7	HF2M	SHA-256 Maj()	$(CA0 \& CA1) \wedge (CA0 \& CA2) \wedge (CA1 \& CA2)$
8	HF2S	SHA-256 Sigma 0	$ROTR^2(CA0) \wedge ROTR^{13}(CA0) \wedge ROTR^{22}(CA0)$
9	HF2T	SHA-256 Sigma 1	$ROTR^6(CA4) \wedge ROTR^{11}(CA4) \wedge ROTR^{25}(CA4)$
A	HF2U	SHA-256 Sigma 0	$ROTR^7(CA8) \wedge ROTR^{18}(CA8) \wedge SHR^3(CA8)$
B	HF2V	SHA-256 Sigma 1	$ROTR^{17}(CA8) \wedge ROTR^{19}(CA8) \wedge SHR^{10}(CA8)$

1. The DES algorithm numbers the most significant bit of a block as bit 1 and the least significant as bit 64.

38.4.1.20 Secure Hash Shift (SHS)

The SHS command does a set of parallel register-to-register move and shift operations for implementing SHA-1. The following source and destination assignments are made:

Register	Value prior to command	Value after command executes
CA4	CA4	CA3
CA3	CA3	CA2
CA2	CA2	CA1<<<30
CA1	CA1	CA0
CA0	CA0	CAA
CAA	CAA	CAA<<<5

38.4.1.21 Message Digest Shift (MDS)

The MDS command does a set of parallel register-to-register move operations for implementing MD5. The following source and destination assignments are made:

Register	Value prior to command	Value after command executes
CA3	CA3	CA2
CA2	CA2	CA1
CA1	CA1	CAA
CAA	CAA	CA3

38.4.1.22 Secure Hash Shift 2 (SHS2)

The SHS2 command does an addition and a set of register to register moves in parallel for implementing SHA-256. The following source and destination assignments are made:

Register	Value prior to command	Value after command executes
CA7	CA7	CA6
CA6	CA6	CA5
CA5	CA5	CA4
CA4	CA4	CA3+CA8
CA3	CA3	CA2
CA2	CA2	CA1
CA1	CA1	CA0
CA0	CA0	CAA

38.4.1.23 Illegal command (ILL)

The ILL command is a specific illegal command that sets CASR[IC]. All other illegal commands are reserved for use in future implementations.

38.5 Application/initialization information

This section discusses how to initialize and use the CAU.

38.5.1 Code example

A code fragment is shown below as an example of how the CAU is used. This example shows the round function of the AES algorithm.

38.5.2 Assembler equate values

The following equates ease programming of the CAU.

```
; CAU Registers (CAx)
    .set CASR,0x0

Chapter 39

True Random Number Generator

39.1 Standalone True Random Number Generator (SA-TRNG).

The Standalone True Random Number Generator (SA-TRNG) is a hardware accelerator module that generates a 512-bit entropy as needed by an entropy-consuming module or by other post-processing functions. A typical entropy consumer is a pseudo random-number generator (PRNG) that can be implemented to achieve both true randomness and cryptographic-strength random numbers using the TRNG output as its entropy seed. The PRNG is not part of this module.

The entropy generated by a TRNG is intended for direct use by functions that generate secret keys, per-message secrets, random challenges, and other similar quantities used in cryptographic algorithms. In each of these cases, it is important that a random number be difficult to guess or predict. It is important that a random number is at least as difficult to predict as it is difficult to break the cryptographic algorithm with which it is being used. This stringent requirement is particularly difficult to fulfill if the entropy source from a TRNG contains bias and/or correlation. To increase the trustworthiness/quality of the generated random data, PRNGs are often used to post process the output of a TRNG.

This document describes only the TRNG design functionality and usage.

Note that before entropy can be obtained from the TRNG, it must be initialized and instantiated in a particular mode by setting the appropriate TRNG registers.

The TRNG contains the following sub modules: IP Slave bus (SkyBlue bus) interface, the TRNG Core and the free running oscillator (OSC).

39.1.1 Standalone True Random Number Generator Block Diagram

The following figure is a top-level diagram of the True Random Number Generator.

Figure 39-1. SA TRNG Block Diagram

39.1.2 TRNG Functional Description.

The TRNG consists of several functional sub-modules. Its overall functionality can be easily described from the top level in terms of generating entropy for seed generation. The functionality of each sub-module is briefly described in the following subsections.

TRNG is based on collecting bits from a random noise source. This random noise source is a ring oscillator that is sensitive to random noise (temperature variations, voltage variations, cross-talk and other random noise) within the device in which the TRNG is used. This noise causes various small changes in the period of the oscillator. Therefore, if the count of the ring oscillator clock cycles is sampled after a known period of time, this count will vary each time the sample is taken. By using the variance in this count over a large number of samples, random bits can be derived.

The TRNG comprises two entropy sources, each of which provides a single bit of output. Concatenated together, these 2 output bits are expected to provide 1 bit of entropy every 100 clock cycles. In addition to generating entropy, the TRNG also performs several statistical tests on its output.

39.1.3 SA-TRNG hardware functional description.

SA-TRNG functionality consists of several major subcomponents. This table describes these subcomponents.

Table 39-1. SA-TRNG subcomponents.

Description	Cross-reference(s)
Interfaces	
Register interface Used for access to configuration, control, status and debugging registers	Register interface (IP Slave bus)
True Random Number Generator (TRNG)	Standalone True Random Number Generator (SA-TRNG).

39.1.3.1 Software Use Cases for the Stand Alone TRNG.

There are four things that a user (programmer/integrator) will want to do with a TRNG.

- Initialization.

Set up the parameters to proper values, and start generation of the first block of entropy. This is done once.

- Read entropy from the TRNG, and start generation of the next block of entropy.

This is done many times and is the normal flow of operation.

- Run a self-test on the TRNG, to assure proper continued operation.

This involves taking TRNG off-line, setting some self-test parameters, running TRNG, and then reading the statistical test registers, to see that they are within proper operation values. This may not be needed, as TRNG has built-in self-test.

- Off-line determination and checking of TRNG parameter values.

This is done in development in order to determine the proper initialization and self-test parameters. The TRNG is taken off-line. Test parameter values are written and entropy generation is started. If the statistical tests indicate poor operation (i.e., failing statistical tests), the entropy_delay value should be increased and entropy generation should be re-started. Every case is a variation of setting TRNG parameter values, starting or re-starting entropy generation and reading out the entropy. This process requires pausing or stopping and re-starting the TRNG.

The TRNG is designed to operate as a slave module on the standard IP Slave Bus. By understanding the TRNG register descriptions in "TRNG Register Descriptions" section below, the TRNG module can be controlled via the IP slave bus. In order to write to most TRNG registers, the MCTL register must be initialized in programming mode as described in the "TRNG Register Descriptions" section. At Power On Reset (POR), the TRNG resets to programming mode. And the it will not generate entropy until it is out of programming mode (in run mode) and access to Entropy Registers have been enabled.

Here is an example program flow of using the TRNG.

- After POR the TRNG will be reset into programming mode with the OK to stop bit set (MCTL[TSTOP_OK]=1). The TRNG must be put into Run Mode for Entropy Generation to begin (MCTL[PRGM]=0). Additionally, in order to have access to the Entropy registers and other critical TRNG registers, the TRNG access bit must be set (MCTL[TRNG_ACC]=1). Using the default self test limits that exist after bootup, the entropy valid bit can be polled until asserted (MCTL[ENT_VAL]=1). Alternatively, if using the interrupt, and the interrupts are enabled via the INT_MASK register and the ipi_rng_int_b is asserted when MCTL[ENT_VAL]=1.
- After the polling completes, the 512-bit entropy generated by the TRNG can be read. The values can be read in any order from entropy register 0 to register 15 (ENT0 to ENT 15). After reading ENT 15, the old entropy value is reset and a new entropy value is generated.

NOTE

Reading ENT 15 always resets the entropy, so should always be read last.

- You can poll again for the new entropy value or you can use the Interrupt Status Register to handle reading the entropy values when the entropy valid interrupt is triggered.
- The interrupt can be masked or cleared as needed. See the Interrupt Status Register description.
- To change the self-test limits, the seed counters, how fast the entropy is generated, and how entropy is sampled, see the register description section. In particular, see the the TRNG Frequency Count Minimum Limit Register (FRQMIN), the seed control register (SCML), the statistical run length registers, and other parameter registers.
- Once in Run Mode, the entropy is re-generated automatically after ENT 15 is read. To stop the TRNG or access to TRNG registers at any point while in running mode, you can always set MCTL[TRNG_ACC]=0. Setting the TRNG back to programming mode (MCTL[PRGM]=1) also achieves the purpose of stopping entropy generation.

39.1.3.2 Register interface (IP Slave bus)

The TRNG's register interface (32-bit IP bus) is used to read and write registers within TRNG for the following purposes:

Table 39-2. Summary of register interface uses

Purpose	For more information, see
During chip initialization time	
To configure TRNG including initialization of the - Registers - TRNG Register Interface	
During hardware and software debugging	
Read status registers	- RNG TRNG Status Register - For all registers, see the TRNG Register Descriptions" appendix.

NOTE

Accesses to registers must use full-word (32-bit) reads or writes.

39.1.3.3 TRNG0 Register Descriptions

All accesses of undefined addresses always return zero and assert IPS transfer error. Writes to undefined and read-only addresses are ignored. Undefined addresses are those undocumented, protected or reserved addresses within and outside the range of the addresses defined in the memory map below. Although many of the TRNG0 registers hold more than 32 bits, the register addresses shown in the Memory Map below represent how these registers are accessed over the register bus as 32-bit words.

The format and fields in each TRNG0 register are defined below. Some of the register format figures apply to several different registers. In such cases a different register name will be associated with each of the register offset addresses that appear at the top of the register format figure. Although these registers share the same format, they are independent registers. In addition, many registers can be accessed at multiple addresses. In these cases there will be a single register name and the list of addresses at which that register is accessible will be indicated as aliases. Unless noted in the individual register descriptions, registers are reset only at Power-On Reset (POR).

39.1.3.3.1 TRNG0 Memory Map

A0h	TRNG0 Security Configuration (TRNG0_SEC_CFG)	32	RW	00000000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
A4h	TRNG0 Interrupt Control (TRNG0_INT_CTRL)	32	RW	FFFFFFFFh
A8h	TRNG0 Mask (TRNG0_INT_MASK)	32	RW	00000000h
ACH	TRNG0 Interrupt Status (TRNG0_INT_STATUS)	32	RW	00000000h
F0h	TRNG0 Version ID (MS) (TRNG0_VID1)	32	RO	00300100h
F4h	TRNG0 Version ID (LS) (TRNG0_VID2)	32	RO	00000000h

- Reset occurs at POR, and when TRNG0_MCTL[RST_DEF] is written to 1.

39.1.3.3.2 TRNG0 Miscellaneous Control (TRNG0_MCTL)

39.1.3.3.2.1 Address

Register	Offset
TRNG0_MCTL	0h

39.1.3.3.2.2 Function

This register is intended to be used for programming, configuring and testing the RNG. It is the main register to read/write, in order to enable Entropy generation, to stop entropy generation and to block access to entropy registers. This is done via the special TRNG_ACC and PRGM bits below.

The TRNG0 Miscellaneous Control Register is a read/write register used to control the RNG's True Random Number Generator (TRNG) access, operation and test.

NOTE

Note that in many cases two RNG registers share the same address, and a particular register at the shared address is selected based upon the value in the PRGM field of the TRNG0_MCTL register.

39.1.3.3.2.3 Diagram

39.1.3.3.2.4 Fields

Field	Function
31-17 —	Reserved.
16 PRGM	Programming Mode Select. When this bit is 1, the TRNG is in Program Mode, otherwise it is in Run Mode. No Entropy value will be generated while the TRNG is in Program Mode. Note that different RNG registers are accessible at the same address depending on whether PRGM is set to 1 or 0. This is noted in the RNG register descriptions.
15-14 —	Reserved.
13 TSTOP_OK	TRNG_OK_TO_STOP. Software should check that this bit is a 1 before transitioning TRNG0 to low power mode (TRNG0 clock stopped). TRNG0 turns on the TRNG free-running ring oscillator whenever new entropy is being generated and turns off the ring oscillator when entropy generation is complete. If the TRNG0 clock is stopped while the TRNG ring oscillator is running, the oscillator will continue running even though the TRNG0 clock is stopped. TSTOP_OK is asserted when the TRNG ring oscillator is not running. and therefore it is ok to stop the TRNG0 clock.
12 ERR	Read: Error status. 1 = error detected. 0 = no error. Write: Write 1 to clear errors. Writing 0 has no effect.
11 TST_OUT	Read only: Test point inside ring oscillator.
10 ENT_VAL	Read only: Entropy Valid. Will assert only if TRNG ACC bit is set, and then after an entropy value is generated. Will be cleared at most one (1) bus clock cycle after reading the TRNG0_ENT15 register. (TRNG0_ENT0 through TRNG0_ENT14 should be read before reading TRNG0_ENT15).
9 FCT_VAL	Read only: Frequency Count Valid. Indicates that a valid frequency count may be read from TRNG0_FRQCNT.
8 FCT_FAIL	Read only: Frequency Count Fail. The frequency counter has detected a failure. This may be due to improper programming of the TRNG0_FRQMAX and/or TRNG0_FRQMIN registers, or a hardware failure in the ring oscillator. This error may be cleared by writing a 1 to the ERR bit.

Table continues on the next page...

Field	Function
7 FOR_SCLK	Force System Clock. If set, the system clock is used to operate the TRNG, instead of the ring oscillator. This is for test use only, and indeterminate results may occur. This bit is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this bit. This bit is cleared by writing the RST_DEF bit to 1.
6 RST_DEF	Reset Defaults. Writing a 1 to this bit clears various TRNG registers, and bits within registers, to their default state. This bit is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this bit. Reading this bit always produces a 0.
5 TRNG_ACC	TRNG Access Mode. If this bit is set to 1, the TRNG will generate an Entropy value that can be read via the TRNG0_ENT0-TRNG0_ENT15 registers. The Entropy value may be read once the ENT VAL bit is asserted. Also see TRNG0_ENTa register descriptions (For a = 0 to 15).
4 UNUSED	This bit is unused but write-able. Must be left as zero.
3-2 OSC_DIV	Oscillator Divide. Determines the amount of dividing done to the ring oscillator before it is used by the TRNG. This field is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this field. This field is cleared to the default POR value by writing the RST_DEF bit to 1. 00 - use ring oscillator with no divide 01 - use ring oscillator divided-by-2 10 - use ring oscillator divided-by-4 11 - use ring oscillator divided-by-8
1-0 SAMP_MODE	Sample Mode. Determines the method of sampling the ring oscillator while generating the Entropy value: This field is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously with writing this field. This field is cleared to the POR default value by writing the RST_DEF bit to 1. 00 - use Von Neumann data into both Entropy shifter and Statistical Checker 01 - use raw data into both Entropy shifter and Statistical Checker 10 - use Von Neumann data into Entropy shifter. Use raw data into Statistical Checker 11 - undefined/reserved.

39.1.3.3.3 TRNG0 Statistical Check Miscellaneous (TRNG0_SCMISC)

39.1.3.3.3.1 Address

Register	Offset
TRNG0_SCMISC	4h

39.1.3.3.3.2 Function

The TRNG0 Statistical Check Miscellaneous Register contains the Long Run Maximum Limit value and the Retry Count value. This register is accessible only when the TRNG0_MCTL[PRGM] bit is 1, otherwise this register will read zeroes, and cannot be written.

39.1.3.3.3 Diagram

- Reset occurs at POR, and when TRNG0_MCTL[RST_DEF] is written to 1.

39.1.3.3.4 Fields

Field	Function
31-20 —	Reserved.
19-16 RTY_CT	RETRY COUNT. If a statistical check fails during the TRNG Entropy Generation, the RTY_CT value indicates the number of times a retry should occur before generating an error. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.
15-8 —	Reserved.
7-0 LRUN_MAX	LONG RUN MAX LIMIT. This value is the largest allowable number of consecutive samples of all 1, or all 0, that is allowed during the Entropy generation. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the POR reset value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.4 TRNG0 Poker Range (TRNG0_PKRRNG)

39.1.3.3.4.1 Address

Register	Offset
TRNG0_PKRRNG	8h

39.1.3.3.4.2 Function

The TRNG0 Poker Range Register defines the difference between the TRNG Poker Maximum Limit and the minimum limit. These limits are used during the TRNG Statistical Check Poker Test.

39.1.3.3.4.3 Diagram

39.1.3.3.4.4 Fields

Field	Function
31-16 —	Reserved. Always 0.
15-0 PKR_RNG	Poker Range. During the TRNG Statistical Checks, a "Poker Test" is run which requires a maximum and minimum limit. The maximum is programmed in the PKRMAX[PKR_MAX] register, and the minimum is derived by subtracting the PKR_RNG value from the programmed maximum value. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. Note that the minimum allowable Poker result is PKR_MAX - PKR_RNG + 1.

39.1.3.3.5 TRNG0 Poker Maximum Limit (TRNG0_PKRMAX)

39.1.3.3.5.1 Address

Register	Offset	Description
TRNG0_PKRMAX	Ch	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.5.2 Function

The TRNG0 Poker Maximum Limit Register defines Maximum Limit allowable during the TRNG Statistical Check Poker Test. Note that this offset (0x0C) is used as TRNG0_PKRMAX only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as the TRNG0_PKRSQ readback register.

39.1.3.3.5.3 Diagram

39.1.3.3.5.4 Fields

Field	Function
31-24 —	
23-0 PKR_MAX	Poker Maximum Limit. During the TRNG Statistical Checks, a "Poker Test" is run which requires a maximum and minimum limit. The maximum allowable result is programmed in the TRNG0_PKRMAX[PKR_MAX] register. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. Note that the TRNG0_PKRMAX and TRNG0_PKRRNG registers combined are used to define the minimum allowable Poker result, which is $PKR\_MAX - PKR\_RNG + 1$. Note that if TRNG0_MCTL[PRGM] bit is 0, this register address is used to read the Poker Test Square Calculation result in register TRNG0_PKRSQ, as defined in the following section.

39.1.3.3.6 TRNG0 Poker Square Calculation Result (TRNG0_PKRSQ)

39.1.3.3.6.1 Address

Register	Offset	Description
TRNG0_PKRSQ	Ch	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.6.2 Function

The TRNG0 Poker Square Calculation Result Register is a read-only register used to read the result of the TRNG Statistical Check Poker Test's Square Calculation. This test starts with the TRNG0_PKRMAX value and decreases towards a final result, which is read here. For the Poker Test to pass, this final result must be less than the programmed TRNG0_PKRRNG value. Note that this offset (0x0C) is used as TRNG0_PKRMAX if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_PKRSQ readback register, as described here.

39.1.3.3.6.3 Diagram

39.1.3.3.6.4 Fields

Field	Function
31-24 —	
23-0 PKR_SQ	Poker Square Calculation Result. During the TRNG Statistical Checks, a "Poker Test" is run which starts with the value TRNG0_PKRMAX[PKR_MAX]. This value decreases according to a "sum of squares" algorithm, and must remain greater than zero, but less than the TRNG0_PKRRNG[PKR_RNG] limit. The resulting value may be read through this register, if TRNG0_MCTL[PRGM] bit is 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Poker Test Maximum Limit in register TRNG0_PKRMAX, as defined in the previous section.

39.1.3.3.7 TRNG0 Seed Control (TRNG0_SDCTL)

39.1.3.3.7.1 Address

Register	Offset
TRNG0_SDCTL	10h

39.1.3.3.7.2 Function

The TRNG0 Seed Control Register contains two fields. One field defines the length (in system clocks) of each Entropy sample (ENT_DLY), and the other field indicates the number of samples that will taken during each TRNG Entropy generation (SAMP_SIZE).

39.1.3.3.7.3 Diagram

39.1.3.3.7.4 Fields

Field	Function
31-16 ENT_DLY	Entropy Delay. Defines the length (in system clocks) of each Entropy sample taken. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to its reset value at POR.
15-0 SAMP_SIZE	Sample Size. Defines the total number of Entropy samples that will be taken during Entropy generation. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.8 TRNG0 Sparse Bit Limit (TRNG0_SBLIM)

39.1.3.3.8.1 Address

Register	Offset	Description
TRNG0_SBLIM	14h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.8.2 Function

The TRNG0 Sparse Bit Limit Register is used when Von Neumann sampling is selected during Entropy Generation. It defines the maximum number of consecutive Von Neumann samples which may be discarded before an error is generated. Note that this address (0x14) is used as TRNG0_SBLIM only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_TOTSAM readback register.

39.1.3.3.8.3 Diagram

39.1.3.3.8.4 Fields

Field	Function
31-10 —	Reserved. Always 0.
9-0 SB_LIM	Sparse Bit Limit. During Von Neumann sampling (if enabled by TRNG0_MCTL[SAMP_MODE], samples are discarded if two consecutive raw samples are both 0 or both 1. If this discarding occurs for a long period of time, it indicates that there is insufficient Entropy. The Sparse Bit Limit defines the maximum number of consecutive samples that may be discarded before an error is generated. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. Note that if TRNG0_MCTL[PRGM] bit is 0, this register address is used to read the Total Samples count in register TRNG0_TOTSAM, as defined in the following section.

39.1.3.3.9 TRNG0 Total Samples (TRNG0_TOTSAM)

39.1.3.3.9.1 Address

Register	Offset	Description
TRNG0_TOTSAM	14h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.9.2 Function

The TRNG0 Total Samples Register is a read-only register used to read the total number of samples taken during Entropy generation. It is used to give an indication of how often a sample is actually used during Von Neumann sampling. Note that this offset (0x14) is used as TRNG0_SBLIM if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_TOTSAM readback register, as described here.

39.1.3.3.9.3 Diagram

39.1.3.3.9.4 Fields

Field	Function
31-20 —	Reserved. Always 0.
19-0 TOT_SAM	Total Samples. During Entropy generation, the total number of raw samples is counted. This count is useful in determining how often a sample is used during Von Neumann sampling. The count may be read through this register, if TRNG0_MCTL[PRGM] bit is 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Sparse Bit Limit in register TRNG0_SBLIM, as defined in the previous section.

39.1.3.3.10 TRNG0 Frequency Count Minimum Limit (TRNG0_FRQMIN)

39.1.3.3.10.1 Address

Register	Offset
TRNG0_FRQMIN	18h

39.1.3.3.10.2 Function

The TRNG0 Frequency Count Minimum Limit Register defines the minimum allowable count taken by the Entropy sample counter during each Entropy sample. During any sample period, if the count is less than this programmed minimum, a Frequency Count Fail is flagged in TRNG0_MCTL[FCT_FAIL] and an error is generated.

39.1.3.3.10.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved										FRQ_MIN					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FRQ_MIN															
W																
Reset	0	0	0	0	0	1	1	0	0	1	0	0	0	0	0	0

39.1.3.3.10.4 Fields

Field	Function
31-22 —	Reserved. Always 0.
21-0 FRQ_MIN	Frequency Count Minimum Limit. Defines the minimum allowable count taken during each entropy sample. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to its reset value at POR.

39.1.3.3.11 TRNG0 Frequency Count (TRNG0_FRQCNT)

39.1.3.3.11.1 Address

Register	Offset	Description
TRNG0_FRQCNT	1Ch	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.11.2 Function

The TRNG0 Frequency Count Register is a read-only register used to read the frequency counter within the TRNG entropy generator. It will read all zeroes unless TRNG0_MCTL[TRNG_ACC] = 1. Note that this offset (0x1C) is used as TRNG0_FRQMAX if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_FRQCNT readback register, as described here.

39.1.3.3.11.3 Diagram**39.1.3.3.11.4 Fields**

Field	Function
31-22 —	Reserved. Always 0.
21-0 FRQ_CT	Frequency Count. If TRNG0_MCTL[TRNG_ACC] = 1, reads a sample frequency count taken during entropy generation. Requires TRNG0_MCTL[PRGM] = 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Poker Test Maximum Limit in register TRNG0_PKRMAX, as defined in the previous section.

39.1.3.3.12 TRNG0 Frequency Count Maximum Limit (TRNG0_FRQMAX)

39.1.3.3.12.1 Address

Register	Offset	Description
TRNG0_FRQMAX	1Ch	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.12.2 Function

The TRNG0 Frequency Count Maximum Limit Register defines the maximum allowable count taken by the Entropy sample counter during each Entropy sample. During any sample period, if the count is greater than this programmed maximum, a Frequency Count Fail is flagged in TRNG0_MCTL[FCT_FAIL] and an error is generated. Note that this address (001C) is used as TRNG0_FRQMAX only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_FRQCNT readback register.

39.1.3.3.12.3 Diagram

39.1.3.3.12.4 Fields

Field	Function
31-22 —	Reserved. Always 0.
21-0 FRQ_MAX	Frequency Counter Maximum Limit. Defines the maximum allowable count taken during each entropy sample. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field is cleared to its reset value at POR. Note that if TRNG0_MCTL[PRGM] bit is 0, this register address is used to read the Frequency Count result in register TRNG0_FRQCNT, as defined in the following section.

39.1.3.3.13 TRNG0 Statistical Check Monobit Count (TRNG0_SCMC)

39.1.3.3.13.1 Address

Register	Offset	Description
TRNG0_SCMC	20h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.13.2 Function

The TRNG0 Statistical Check Monobit Count Register is a read-only register used to read the final monobit count after entropy generation. This counter starts with the value in TRNG0_SCML[MONO_MAX], and is decremented each time a one is sampled. Note that this offset (0x20) is used as TRNG0_SCML if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCMC readback register, as described here.

39.1.3.3.13.3 Diagram

39.1.3.3.13.4 Fields

Field	Function
31-16 —	Reserved. Always 0.
15-0 MONO_CT	Monobit Count. Reads the final Monobit count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Statistical Check Monobit Limit in register TRNG0_SCML, as defined in the previous section.

39.1.3.3.14 TRNG0 Statistical Check Monobit Limit (TRNG0_SCML)

39.1.3.3.14.1 Address

Register	Offset	Description
TRNG0_SCML	20h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.14.2 Function

The TRNG0 Statistical Check Monobit Limit Register defines the allowable maximum and minimum number of ones/zero detected during entropy generation. To pass the test, the number of ones/zeros generated must be less than the programmed maximum value, and the number of ones/zeros generated must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this offset (0x20) is used as TRNG0_SCML only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCMC readback register.

39.1.3.3.14.3 Diagram

39.1.3.3.14.4 Fields

Field	Function
31-16 MONO_RNG	Monobit Range. The number of ones/zeros detected during entropy generation must be greater than MONO_MAX - MONO_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

Table continues on the next page...

Standalone True Random Number Generator (SA-TRNG).

Field	Function
15-0 MONO_MAX	Monobit Maximum Limit. Defines the maximum allowable count taken during entropy generation. The number of ones/zeros detected during entropy generation must be less than MONO_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.15 TRNG0 Statistical Check Run Length 1 Count (TRNG0_SCR1C)

39.1.3.3.15.1 Address

Register	Offset	Description
TRNG0_SCR1C	24h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.15.2 Function

The TRNG0 Statistical Check Run Length 1 Counters Register is a read-only register used to read the final Run Length 1 counts after entropy generation. These counters start with the value in TRNG0_SCRxC1L[RUN1_MAX]. The R1_1_CT decrements each time a single one is sampled (preceded by a zero and followed by a zero). The R1_0_CT decrements each time a single zero is sampled (preceded by a one and followed by a one). Note that this offset (0x24) is used as TRNG0_SCRxC1L if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCRxC1C readback register, as described here.

39.1.3.3.15.3 Diagram

39.1.3.3.15.4 Fields

Field	Function
31 —	Reserved. Always 0.
30-16 R1_1_CT	Runs of One, Length 1 Count. Reads the final Runs of Ones, length 1 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.
15 —	Reserved. Always 0.
14-0 R1_0_CT	Runs of Zero, Length 1 Count. Reads the final Runs of Zeroes, length 1 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.16 TRNG0 Statistical Check Run Length 1 Limit (TRNG0_SCR1L)

39.1.3.3.16.1 Address

Register	Offset	Description
TRNG0_SCR1L	24h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.16.2 Function

The TRNG0 Statistical Check Run Length 1 Limit Register defines the allowable maximum and minimum number of runs of length 1 detected during entropy generation. To pass the test, the number of runs of length 1 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 1 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x24) is used as TRNG0_SCRxC1L only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_SCRxC1C readback register.

39.1.3.3.16.3 Diagram**39.1.3.3.16.4 Fields**

Field	Function
31 —	Reserved. Always 0.
30-16 RUN1_RNG	Run Length 1 Range. The number of runs of length 1 (for both 0 and 1) detected during entropy generation must be greater than RUN1_MAX - RUN1_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.
15 —	Reserved. Always 0.
14-0 RUN1_MAX	Run Length 1 Maximum Limit. Defines the maximum allowable runs of length 1 (for both 0 and 1) detected during entropy generation. The number of runs of length 1 detected during entropy generation must be less than RUN1_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.17 TRNG0 Statistical Check Run Length 2 Count (TRNG0_SCR2C)**39.1.3.3.17.1 Address**

Register	Offset	Description
TRNG0_SCR2C	28h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.17.2 Function

The TRNG0 Statistical Check Run Length 2 Counters Register is a read-only register used to read the final Run Length 2 counts after entropy generation. These counters start with the value in TRNG0_SCRxC2L[RUN2_MAX]. The R2_1_CT decrements each time two consecutive ones are sampled (preceded by a zero and followed by a zero). The

R2_0_CT decrements each time two consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x28) is used as TRNG0_SCRxC2L if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCRxC2C readback register, as described here.

39.1.3.3.17.3 Diagram

39.1.3.3.17.4 Fields

Field	Function
31-30 —	Reserved. Always 0.
29-16 R2_1_CT	Runs of One, Length 2 Count. Reads the final Runs of Ones, length 2 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.
15-14 —	Reserved. Always 0.
13-0 R2_0_CT	Runs of Zero, Length 2 Count. Reads the final Runs of Zeroes, length 2 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.18 TRNG0 Statistical Check Run Length 2 Limit (TRNG0_SCR2L)

39.1.3.3.18.1 Address

Register	Offset	Description
TRNG0_SCR2L	28h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.18.2 Function

The TRNG0 Statistical Check Run Length 2 Limit Register defines the allowable maximum and minimum number of runs of length 2 detected during entropy generation. To pass the test, the number of runs of length 2 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 2 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x28) is used as TRNG0_SCRxC2L only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_SCRxC2C readback register.

39.1.3.3.18.3 Diagram

39.1.3.3.19.4 Fields

Field	Function
31-29 —	Reserved. Always 0.
28-16 R3_1_CT	Runs of Ones, Length 3 Count. Reads the final Runs of Ones, length 3 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.
15-13	Reserved. Always 0.

Table continues on the next page...

Field	Function
—	
12-0 R3_0_CT	Runs of Zeroes, Length 3 Count. Reads the final Runs of Zeroes, length 3 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.20 TRNG0 Statistical Check Run Length 3 Limit (TRNG0_SCR3L)

39.1.3.3.20.1 Address

Register	Offset	Description
TRNG0_SCR3L	2Ch	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.20.2 Function

The TRNG0 Statistical Check Run Length 3 Limit Register defines the allowable maximum and minimum number of runs of length 3 detected during entropy generation. To pass the test, the number of runs of length 3 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 3 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x2C) is used as TRNG0_SCRxC3L only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_SCRxC3C readback register.

39.1.3.3.20.3 Diagram

39.1.3.3.20.4 Fields

Field	Function
31-29 —	Reserved. Always 0.
28-16 RUN3_RNG	Run Length 3 Range. The number of runs of length 3 (for both 0 and 1) detected during entropy generation must be greater than RUN3_MAX - RUN3_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.
15-13 —	Reserved. Always 0.
12-0 RUN3_MAX	Run Length 3 Maximum Limit. Defines the maximum allowable runs of length 3 (for both 0 and 1) detected during entropy generation. The number of runs of length 3 detected during entropy generation must be less than RUN3_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.21 TRNG0 Statistical Check Run Length 4 Count (TRNG0_SCR4C)

39.1.3.3.21.1 Address

Register	Offset	Description
TRNG0_SCR4C	30h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.21.2 Function

The TRNG0 Statistical Check Run Length 4 Counters Register is a read-only register used to read the final Run Length 4 counts after entropy generation. These counters start with the value in TRNG0_SCRxC4L[RUN4_MAX]. The R4_1_CT decrements each time four consecutive ones are sampled (preceded by a zero and followed by a zero). The R4_0_CT decrements each time four consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x30) is used as TRNG0_SCRxC4L if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCRxC4C readback register, as described here.

39.1.3.3.21.3 Diagram

39.1.3.3.21.4 Fields

Field	Function
31-28 —	Reserved. Always 0.
27-16 R4_1_CT	Runs of One, Length 4 Count. Reads the final Runs of Ones, length 4 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.
15-12 —	Reserved. Always 0.
11-0 R4_0_CT	Runs of Zero, Length 4 Count. Reads the final Runs of Ones, length 4 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.22 TRNG0 Statistical Check Run Length 4 Limit (TRNG0_SCR4L)

39.1.3.3.22.1 Address

Register	Offset	Description
TRNG0_SCR4L	30h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.22.2 Function

The TRNG0 Statistical Check Run Length 4 Limit Register defines the allowable maximum and minimum number of runs of length 4 detected during entropy generation. To pass the test, the number of runs of length 4 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 4 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC

will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x30) is used as TRNG0_SCRxC4L only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_SCRxC4C readback register.

39.1.3.3.22.3 Diagram

39.1.3.3.22.4 Fields

Field	Function
31-28 —	Reserved. Always 0.
27-16 RUN4_RNG	Run Length 4 Range. The number of runs of length 4 (for both 0 and 1) detected during entropy generation must be greater than RUN4_MAX - RUN4_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.
15-12 —	Reserved. Always 0.
11-0 RUN4_MAX	Run Length 4 Maximum Limit. Defines the maximum allowable runs of length 4 (for both 0 and 1) detected during entropy generation. The number of runs of length 4 detected during entropy generation must be less than RUN4_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.23 TRNG0 Statistical Check Run Length 5 Count (TRNG0_SCR5C)

39.1.3.3.23.1 Address

Register	Offset	Description
TRNG0_SCR5C	34h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.23.2 Function

The TRNG0 Statistical Check Run Length 5 Counters Register is a read-only register used to read the final Run Length 5 counts after entropy generation. These counters start with the value in TRNG0_SCRxC5L[RUN5_MAX]. The R5_1_CT decrements each time five consecutive ones are sampled (preceded by a zero and followed by a zero). The R5_0_CT decrements each time five consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x34) is used as TRNG0_SCRxC5L if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCRxC5C readback register, as described here.

39.1.3.3.23.3 Diagram

39.1.3.3.23.4 Fields

Field	Function
31-27 —	Reserved. Always 0.
26-16 R5_1_CT	Runs of One, Length 5 Count. Reads the final Runs of Ones, length 5 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.
15-11 —	Reserved. Always 0.
10-0 R5_0_CT	Runs of Zero, Length 5 Count. Reads the final Runs of Ones, length 5 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.24 TRNG0 Statistical Check Run Length 5 Limit (TRNG0_SCR5L)

39.1.3.3.24.1 Address

Register	Offset	Description
TRNG0_SCR5L	34h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.24.2 Function

The TRNG0 Statistical Check Run Length 5 Limit Register defines the allowable maximum and minimum number of runs of length 5 detected during entropy generation. To pass the test, the number of runs of length 5 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 5 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x34) is used as TRNG0_SCRxC5L only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this address is used as TRNG0_SCRxC5C readback register.

39.1.3.3.24.4 Fields

Field	Function
31-27 —	Reserved. Always 0.
26-16 RUN5_RNG	Run Length 5 Range. The number of runs of length 5 (for both 0 and 1) detected during entropy generation must be greater than RUN5_MAX - RUN5_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.
15-11	Reserved. Always 0.

Table continues on the next page...

Standalone True Random Number Generator (SA-TRNG).

Field	Function
—	
10-0 RUN5_MAX	Run Length 5 Maximum Limit. Defines the maximum allowable runs of length 5 (for both 0 and 1) detected during entropy generation. The number of runs of length 5 detected during entropy generation must be less than RUN5_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.25 TRNG0 Statistical Check Run Length 6+ Count (TRNG0_SCR6PC)

39.1.3.3.25.1 Address

Register	Offset	Description
TRNG0_SCR6PC	38h	Accessible at this address when TRNG0_MCTL[PRGM] = 0]

39.1.3.3.25.2 Function

The TRNG0 Statistical Check Run Length 6+ Counters Register is a read-only register used to read the final Run Length 6+ counts after entropy generation. These counters start with the value in TRNG0_SCRxC6PL[RUN6P_MAX]. The R6P_1_CT decrements each time six or more consecutive ones are sampled (preceded by a zero and followed by a zero). The R6P_0_CT decrements each time six or more consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x38) is used as TRNG0_SCRxC6PL if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCRxC6PC readback register, as described here.

39.1.3.3.25.3 Diagram

39.1.3.3.25.4 Fields

Field	Function
31-27 —	Reserved. Always 0.
26-16 R6P_1_CT	Runs of One, Length 6+ Count. Reads the final Runs of Ones, length 6+ count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.
15-11 —	Reserved. Always 0.
10-0 R6P_0_CT	Runs of Zero, Length 6+ Count. Reads the final Runs of Ones, length 6+ count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.26 TRNG0 Statistical Check Run Length 6+ Limit (TRNG0_SCR6PL)

39.1.3.3.26.1 Address

Register	Offset	Description
TRNG0_SCR6PL	38h	Accessible at this address when TRNG0_MCTL[PRGM] = 1]

39.1.3.3.26.2 Function

The TRNG0 Statistical Check Run Length 6+ Limit Register defines the allowable maximum and minimum number of runs of length 6 or more detected during entropy generation. To pass the test, the number of runs of length 6 or more (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 6 or more must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this offset (0x38) is used as TRNG0_SCRxC6PL only if TRNG0_MCTL[PRGM] is 1. If TRNG0_MCTL[PRGM] is 0, this offset is used as TRNG0_SCRxC6PC readback register.

39.1.3.3.26.3 Diagram

39.1.3.3.26.4 Fields

Field	Function
31-27 —	Reserved. Always 0.
26-16 RUN6P_RNG	Run Length 6+ Range. The number of runs of length 6 or more (for both 0 and 1) detected during entropy generation must be greater than RUN6P_MAX - RUN6P_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.
15-11 —	Reserved. Always 0.
10-0 RUN6P_MAX	Run Length 6+ Maximum Limit. Defines the maximum allowable runs of length 6 or more (for both 0 and 1) detected during entropy generation. The number of runs of length 6 or more detected during entropy generation must be less than RUN6P_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.

39.1.3.3.27 TRNG0 Status (TRNG0_STATUS)

39.1.3.3.27.1 Address

Register	Offset
TRNG0_STATUS	3Ch

39.1.3.3.27.2 Function

Various statistical tests are run as a normal part of the TRNG's entropy generation process. The least-significant 16 bits of the TRNG0_STATUS register reflect the result of each of these tests. The status of these bits will be valid when the TRNG has finished its entropy generation process. Software can determine when this occurs by polling the ENT_VAL bit in the TRNG0 Miscellaneous Control Register.

Note that there is a very small probability that a statistical test will fail even though the TRNG is operating properly. If this happens the TRNG will automatically retry the entire entropy generation process, including running all the statistical tests. The value in RETRY_CT is decremented each time an entropy generation retry occurs. If a statistical check fails when the retry count is nonzero, a retry is initiated. But if a statistical check fails when the retry count is zero, an error is generated by the RNG. By default RETRY_CT is initialized to 1, but software can increase the retry count by writing to the RTY_CT field in the TRNG0_SCMISC register.

All 0s will be returned if this register address is read while the RNG is in Program Mode (see PRGM field in TRNG0_MCTL register. If this register is read while the RNG is in Run Mode the value returned will be formatted as follows.

39.1.3.3.27.3 Diagram

39.1.3.3.27.4 Fields

Field	Function
31-20 —	Reserved. Always 0.
19-16 RETRY_CT	RETRY COUNT. This represents the current number of entropy generation retries left before a statistical test failure will cause the RNG to generate an error condition.
15	Test Fail, Mono Bit. If TFMB=1, the Mono Bit Test has failed.

Table continues on the next page...

Standalone True Random Number Generator (SA-TRNG).

Field	Function
TFMB	
14 TFP	Test Fail, Poker. If TFP=1, the Poker Test has failed.
13 TFLR	Test Fail, Long Run. If TFLR=1, the Long Run Test has failed.
12 TFSB	Test Fail, Sparse Bit. If TFSB=1, the Sparse Bit Test has failed.
11 TF6PBR1	Test Fail, 6 Plus Bit Run, Sampling 1s. If TF6PBR1=1, the 6 Plus Bit Run, Sampling 1s Test has failed.
10 TF6PBR0	Test Fail, 6 Plus Bit Run, Sampling 0s. If TF6PBR0=1, the 6 Plus Bit Run, Sampling 0s Test has failed.
9 TF5BR1	Test Fail, 5-Bit Run, Sampling 1s. If TF5BR1=1, the 5-Bit Run, Sampling 1s Test has failed.
8 TF5BR0	Test Fail, 5-Bit Run, Sampling 0s. If TF5BR0=1, the 5-Bit Run, Sampling 0s Test has failed.
7 TF4BR1	Test Fail, 4-Bit Run, Sampling 1s. If TF4BR1=1, the 4-Bit Run, Sampling 1s Test has failed.
6 TF4BR0	Test Fail, 4-Bit Run, Sampling 0s. If TF4BR0=1, the 4-Bit Run, Sampling 0s Test has failed.
5 TF3BR1	Test Fail, 3-Bit Run, Sampling 1s. If TF3BR1=1, the 3-Bit Run, Sampling 1s Test has failed.
4 TF3BR0	Test Fail, 3-Bit Run, Sampling 0s. If TF3BR0=1, the 3-Bit Run, Sampling 0s Test has failed.
3 TF2BR1	Test Fail, 2-Bit Run, Sampling 1s. If TF2BR1=1, the 2-Bit Run, Sampling 1s Test has failed.
2 TF2BR0	Test Fail, 2-Bit Run, Sampling 0s. If TF2BR0=1, the 2-Bit Run, Sampling 0s Test has failed.
1 TF1BR1	Test Fail, 1-Bit Run, Sampling 1s. If TF1BR1=1, the 1-Bit Run, Sampling 1s Test has failed.
0 TF1BR0	Test Fail, 1-Bit Run, Sampling 0s. If TF1BR0=1, the 1-Bit Run, Sampling 0s Test has failed.

39.1.3.3.28 TRNG0 Entropy Read (TRNG0_ENTa)

39.1.3.3.28.1 Address

For a = 0 to 15:

Register	Offset	Description
TRNG0_ENTa	40h + (a × 4h)	Word a

39.1.3.3.28.2 Function

The RNG TRNG can be programmed to generate an entropy value that is readable via the SkyBlue bus. To do this, set the TRNG0_MCTL[TRNG_ACC] bit to 1. Once the entropy value has been generated, the TRNG0_MCTL[ENT_VAL] bit will be set to 1. At this point, TRNG0_ENT0 through TRNG0_ENT15 may be read to retrieve the 512-bit entropy value. Note that once TRNG0_ENT15 is read, the entropy value will be cleared and a new value will begin generation, so it is important that TRNG0_ENT15 be read last. These registers are readable only when TRNG0_MCTL[PRGM] = 0 (Run Mode), TRNG0_MCTL[TRNG_ACC] = 1 (TRNG access mode) and TRNG0_MCTL[ENT_VAL] = 1. After at most one (1) bus clock cycle of reading a valid TRNG0_ENT15 register value, reading any TRNG0_ENT0 through TRNG0_ENT15 register would return zeroes.

39.1.3.3.28.3 Diagram

39.1.3.3.28.4 Fields

Field	Function
31-0 ENT	Entropy Value. Will be non-zero only if TRNG0_MCTL[PRGM] = 0 (Run Mode) and TRNG0_MCTL[ENT_VAL] = 1 (Entropy Valid). The most significant bits of the entropy are read from the lowest offset, and the least significant bits are read from the highest offset. Note that reading the highest offset also clears the entire entropy value, and starts a new entropy generation.

39.1.3.3.29 TRNG0 Statistical Check Poker Count 1 and 0 (TRNG0_PKRCNT10)

39.1.3.3.29.1 Address

Register	Offset
TRNG0_PKRCNT10	80h

39.1.3.3.29.2 Function

The TRNG0 Statistical Check Poker Count 1 and 0 Register is a read-only register used to read the final Poker test counts of 1h and 0h patterns. The Poker 0h Count increments each time a nibble of sample data is found to be 0h. The Poker 1h Count increments each time a nibble of sample data is found to be 1h. Note that this register is readable only if TRNG0_MCTL[PRGM] is 0, otherwise zeroes will be read.

39.1.3.3.29.3 Diagram

39.1.3.3.29.4 Fields

Field	Function
31-16 PKR_1_CT	Poker 1h Count. Total number of nibbles of sample data which were found to be 1h. Requires TRNG0_MCTL[PRGM] = 0.
15-0 PKR_0_CT	Poker 0h Count. Total number of nibbles of sample data which were found to be 0h. Requires TRNG0_MCTL[PRGM] = 0.

39.1.3.3.30 TRNG0 Statistical Check Poker Count 3 and 2 (TRNG0_PKRCNT32)

39.1.3.3.30.1 Address

Register	Offset
TRNG0_PKRCNT32	84h

39.1.3.3.30.2 Function

The TRNG0 Statistical Check Poker Count 3 and 2 Register is a read-only register used to read the final Poker test counts of 3h and 2h patterns. The Poker 2h Count increments each time a nibble of sample data is found to be 2h. The Poker 3h Count increments each time a nibble of sample data is found to be 3h. Note that this register is readable only if TRNG0_MCTL[PRGM] is 0, otherwise zeroes will be read.

39.1.3.3.30.3 Diagram

39.1.3.3.37 TRNG0 Security Configuration (TRNG0_SEC_CFG)

39.1.3.3.37.1 Address

Register	Offset
TRNG0_SEC_CFG	A0h

39.1.3.3.37.2 Function

The TRNG0 Security Configuration Register is a read/write register used to control the test mode, programmability and state modes of the TRNG0. Many bits are place holders for this version. More configurability will be added here. Clears on asynchronous reset. For TRNG0 releases before 2014/July/01, offsets 0xA0 to 0xAC used to be 0xB0 to 0xBC respectively. So, update newer tests that use these registers, if hard coded.

39.1.3.3.37.3 Diagram**39.1.3.3.37.4 Fields**

Field	Function
31-3 —	Reserved.
2 SK_VAL	Reserved. DRNG-specific, not applicable to this version. 0 - See DRNG version. 1 - See DRNG version.
1 NO_PRGM	If set, the TRNG registers cannot be programmed. That is, regardless of the TRNG access mode in the TRNG0 Miscellaneous Control Register. 0 - Programmability of registers controlled only by the TRNG0 Miscellaneous Control Register's access mode bit. 1 - Overrides TRNG0 Miscellaneous Control Register access mode and prevents TRNG register programming.
0 SH0	Reserved. DRNG specific, not applicable to this version. 0 - See DRNG version. 1 - See DRNG version.

39.1.3.3.38 TRNG0 Interrupt Control (TRNG0_INT_CTRL)

39.1.3.3.38.1 Address

Register	Offset
TRNG0_INT_CTRL	A4h

39.1.3.3.38.2 Function

The TRNG0 Interrupt Control Register is a read/write register used to control the status for the (currently) three important interrupts that are generated by the TRNG. See TRNG0_INT_STATUS register description above. Each interrupt can be cleared by de-asserting the corresponding bit in the TRNG0_INT_CTRL register. Only a new interrupt will reassert the corresponding bit in the status register. Even if the interrupt is cleared or masked, interrupt status information can be read from the TRNG0_MCTL register.

39.1.3.3.38.3 Diagram

39.1.3.3.38.4 Fields

Field	Function
31-3 UNUSED	Reserved but writeable.
2 FRQ_CT_FAIL	Same behavior as bit 0 above. 0 - Same behavior as bit 0 above.

Standalone True Random Number Generator (SA-TRNG).

Field	Function
	1 - Same behavior as bit 0 above.
1 ENT_VAL	Same behavior as bit 0 above. 0 - Same behavior as bit 0 above. 1 - Same behavior as bit 0 above.
0 HW_ERR	Bit position that can be cleared if corresponding bit of TRNG0_INT_STATUS has been asserted. 0 - Corresponding bit of TRNG0_INT_STATUS cleared. 1 - Corresponding bit of TRNG0_INT_STATUS active.

39.1.3.3.39 TRNG0 Mask (TRNG0_INT_MASK)

39.1.3.3.39.1 Address

Register	Offset
TRNG0_INT_MASK	A8h

39.1.3.3.39.2 Function

The TRNG0 Interrupt Mask Register is a read/write register used to disable/mask the status reporting of the (currently) three important interrupts that are generated by the TRNG. See TRNG0_INT_STATUS register description above. Each interrupt can be masked/disabled by de-asserting the corresponding bit in the TRNG0_INT_MASK register. Only setting this bit high will re-enable the interrupt in the status register. Even if the interrupt is cleared or masked, interrupt status information can be read from the TRNG0_MCTL register.

39.1.3.3.39.3 Diagram

39.1.3.3.39.4 Fields

Field	Function
31-3 —	Reserved.
2 FRQ_CT_FAIL	Same behavior as bit 0 above. 0 - Same behavior as bit 0 above. 1 - Same behavior as bit 0 above.
1 ENT_VAL	Same behavior as bit 0 above. 0 - Same behavior as bit 0 above. 1 - Same behavior as bit 0 above.
0 HW_ERR	Bit position that can be cleared if corresponding bit of TRNG0_INT_STATUS has been asserted. 0 - Corresponding interrupt of TRNG0_INT_STATUS is masked. 1 - Corresponding bit of TRNG0_INT_STATUS is active.

39.1.3.3.40 TRNG0 Interrupt Status (TRNG0_INT_STATUS)

39.1.3.3.40.1 Address

Register	Offset
TRNG0_INT_STATUS	ACh

39.1.3.3.40.2 Function

The TRNG0 Interrupt Status Register is a read register used to control and provide status for the (currently) three important interrupts that are generated by the TRNG. The `ipi_rng_int_b` interrupt signals that TRNG0 has either generated a Frequency Count Fail, Entropy Valid or Error Interrupt. The cause of the interrupt can be decoded by checking the least significant bits of the TRNG0_INT_STATUS register. Each interrupt can be temporarily cleared by de-asserting the corresponding bit in the TRNG0_INT_CTRL register. To mask the interrupts, clear the corresponding bits in the TRNG0_INT_MASK register. The description of each of the 3 interrupts is defined in the Block Guide under the TRNG0_MCTL register description. Even if the interrupt is cleared or masked, interrupt status information can be read from the TRNG0_MCTL register.

39.1.3.3.40.3 Diagram

39.1.3.3.40.4 Fields

Field	Function
31-3 —	Reserved.
2 FRQ_CT_FAIL	Read only: Frequency Count Fail. The frequency counter has detected a failure. This may be due to improper programming of the TRNG0_FRQMAX and/or TRNG0_FRQMIN registers, or a hardware failure in the ring oscillator. 0 - No hardware nor self test frequency errors. 1 - The frequency counter has detected a failure.
1 ENT_VAL	Read only: Entropy Valid. Will assert only if TRNG ACC bit is set, and then after an entropy value is generated. Will be cleared when TRNG0_ENT15 is read. (TRNG0_ENT0 through TRNG0_ENT14 should be read before reading TRNG0_ENT15). 0 - Busy generation entropy. Any value read is invalid. 1 - TRNG can be stopped and entropy is valid if read.
0 HW_ERR	Read: Error status. 1 = error detected. 0 = no error. Any HW error in the TRNG will trigger this interrupt. 0 - no error 1 - error detected.

39.1.3.3.41 TRNG0 Version ID (MS) (TRNG0_VID1)

39.1.3.3.41.1 Address

Register	Offset
TRNG0_VID1	F0h

39.1.3.3.41.2 Function

The TRNG0 Version ID Register is a read only register used to identify the version of the TRNG in use. This register as well as TRNG0_VID2 should both be read to verify the expected version.

39.1.3.3.41.3 Diagram

23-16 TRNG0_INTG_OPT	Shows the integration options for the TRNG. 00000000 - INTG_OPT for TRNG.
15-8 TRNG0_ECO_REV	Shows the IP's ECO revision of the TRNG. 00000000 - TRNG_ECO_REV for TRNG.
7-0 TRNG0_CONFIG_OPT	Shows the IP's Configuration options for the TRNG. 00000000 - TRNG_CONFIG_OPT for TRNG.

39.1.4 Another TRNG usage example.

The TRNG can be used by a post processing pseudo-random number generator function. For example, TRNG can be used to seed a hardware or software based implementation of a DRBG defined by SP800-90.

Chapter 40

Analog-to-Digital Converter (ADC)

40.1 Chip-specific ADC information

40.1.1 DMA Support on ADC

Applications may require continuous sampling of the ADC (4K samples/sec) that may have considerable load on the CPU. Though using PDB to trigger ADC may reduce some CPU load, the ADC supports DMA request functionality for higher performance when the ADC is sampled at a very high rate or cases where PDB is bypassed. The ADC can trigger the DMA (via DMA req) on conversion completion.

40.1.2 ADC0 Connections/Channel Assignment

NOTE

As indicated by the following sections, each ADCx_DPx input and certain ADCx_DMx inputs may operate as single-ended ADC channels in single-ended mode.

NOTE

Some ADC inputs may not appear on all packages. See [Pinout](#) for more information.

ADC Channel (SC1n[ADCH])	Channel	Input signal (SC1n[DIFF]= 1)	Input signal (SC1n[DIFF]= 0)	Direct connection
00000	AD0	ADC0_DP0 and ADC0_DM0	ADC0_DP0	Yes
00001	AD1	ADC0_DP1 and ADC0_DM1	ADC0_DP1	Yes
00010	AD2	Reserved	Reserved	Yes

Table continues on the next page...

Chip-specific ADC information

ADC Channel (SC1n[ADCH])	Channel	Input signal (SC1n[DIFF]= 1)	Input signal (SC1n[DIFF]= 0)	Direct connection

1. This is the PMC bandgap 1V reference voltage. Prior to reading from this ADC channel, ensure that you enable the bandgap buffer by setting the PMC_REGSC[BGBE] bit. Refer to the device data sheet for the bandgap voltage (VBG) specification.

40.1.3 ADC Channels MUX Selection

The following figure shows the assignment of ADCx_SEn channels a and b through a MUX selection to ADC. To select between alternate set of channels, refer to ADCx_CFG2[MUXSEL] bit settings for more details.

Figure 40-1. ADCx_SEn channels a and b selection

40.1.4 ADC Reference Options

The ADC supports the following references:

- VREFH/VREFL - connected as the primary reference option
- 1.2 V VREF_OUT - connected as the V_{ALT} reference option

ADCx_SC2[REFSEL] bit selects the voltage reference sources for ADC. Refer to REFSEL description in ADC chapter for more details.

40.1.5 VBAT connection to ADC input channel

The VBAT supply input can be converted as a single ended input to an ADC channel input. See [ADC0 Connections/Channel Assignment](#) for more details. When VBAT is greater than the selected voltage reference, the conversion result will show a saturated result (~0xFFFF in 16-bit operation). When measuring the VBAT voltage level the ADC should be configured for a long sample time (ADCx_CFG1[ADLSMP]=1, ADCx_CFG2[ADLSTS]=00).

40.1.6 ADC triggers

The ADC supports both software and hardware triggers. The primary hardware mechanism for triggering the ADC is the PDB. The PDB itself can be triggered by other peripherals. For example: RTC (Alarm, Seconds) signal is connected to the PDB. The PDB input trigger can receive the RTC (alarm/seconds) trigger forcing ADC conversions in run mode (where PDB is enabled). On the other hand, the ADC can conduct conversions in low power modes, not triggered by PDB. This allows the ADC to do conversions in low power mode and store the output in the result register. The ADC generates interrupt when the data is ready in the result register that wakes the system from low power mode. The PDB can also be bypassed by using the ADCxTRGSEL bits in the SIM_SOPT7 register.

Table 40-1. ADC Alternate trigger options

SIM_SOPT7[ADCxTRGSEL]	Selected source
00000	PDB external trigger pin input (PDB0_EXTRG)
00001	High speed comparator 0 output
00010	High speed comparator 1 output
00011	High speed comparator 2 output
00100	PIT trigger 0
00101	PIT trigger 1
00110	PIT trigger 2
00111	PIT trigger 3
01000	FTM0 trigger
01001	FTM1 trigger
01010	FTM2 trigger
01011	FTM3 trigger
01100	RTC alarm
01101	RTC Seconds
01110	Low-power timer (LPTMR0) trigger
01111	TPM1 channel 0 (A pretrigger) and channel 1 (B pretrigger)

The TPM can also trigger the ADC. TPM1 can trigger ADC0.

For operation of triggers in different modes, refer to Power Management chapter.

40.1.7 ADC conversion clock options

The ADC has multiple input clock sources. Selection is determined by ADCx_CFG1[ADICLK] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

NOTE

The ALTCLK option is only usable when OSCERCLK is in the MHz range. A system with OSCERCLK in the kHz range has the optional clock source below minimum ADC clock operating frequency.

Table 40-2. ADC Conversion Clock Options

ADCx_CFG1[ADICLK]	ADC defined selection	Chip clock	Note
00	Bus Clock	Bus Clock	
01	ALTCLK2	IRC48MCLK	Note ¹
10	ALTCLK	OSCERCLK	Note ¹
11	Asynchronous clock (ADACK)	N/A - sourced from within ADC block	Note ¹

1. For ADC operation in Compute only, PSTOP1, Stop and VLPS, ADACK and the alternate clock sources are allowed clock sources. Note however that ALTCLK2 is force disabled and therefore not available in VLPS.

40.1.8 ADC low-power modes

This table shows the ADC low-power modes and the corresponding chip low-power modes.

Table 40-3. ADC low-power modes

Module mode	Chip mode
Wait	Wait, VLPW
Normal Stop	Stop, VLPS
Low Power Stop	LLS, VLLS3, VLLS2, VLLS1, VLLS0

40.2 Introduction

The 16-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

NOTE

For the chip specific modes of operation, see the power management information of the device.

40.2.1 Features

Following are the features of the ADC module.

- Linear successive approximation algorithm with up to 16-bit resolution
- Up to four pairs of differential and 24 single-ended external analog inputs
- Output modes:
 - differential 16-bit, 13-bit, 11-bit, and 9-bit modes
 - single-ended 16-bit, 12-bit, 10-bit, and 8-bit modes
- Output format in 2's complement 16-bit sign extended for differential modes
- Output in right-justified unsigned format for single-ended
- Single or continuous conversion, that is, automatic return to idle after single conversion
- Configurable sample time and conversion speed/power
- Conversion complete/hardware average complete flag and interrupt
- Input clock selectable from up to four sources
- Operation in low-power modes for lower noise
- Asynchronous clock source for lower noise operation with option to output the clock
- Selectable hardware conversion trigger with hardware channel select
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Temperature sensor
- Hardware average function
- Selectable voltage reference: external or alternate
- Self-Calibration mode

40.2.2 Block diagram

The following figure is the ADC module block diagram.

Figure 40-2. ADC block diagram

40.3 ADC signal descriptions

The ADC module supports up to 4 pairs of differential inputs and up to 24 single-ended inputs.

Each differential pair requires two inputs, DADPx and DADMx. The ADC also requires four supply/reference/ground connections.

NOTE

For the number of channels supported on this device as well as information regarding other chip-specific inputs into the ADC block, see the chip-specific ADC configuration information.

Table 40-4. ADC signal descriptions

Signal	Description	I/O
DADP3–DADP0	Differential Analog Channel Inputs	I
DADM3–DADM0	Differential Analog Channel Inputs	I
AD n	Single-Ended Analog Channel Inputs	I
V _{REFSH}	Voltage Reference Select High	I
V _{REFSL}	Voltage Reference Select Low	I
V _{DDA}	Analog Power Supply	I
V _{SSA}	Analog Ground	I

40.3.1 Analog Power (V_{DDA})

The ADC analog portion uses V_{DDA} as its power connection. In some packages, V_{DDA} is connected internally to V_{DD}. If externally available, connect the V_{DDA} pin to the same voltage potential as V_{DD}. External filtering may be necessary to ensure clean V_{DDA} for good results.

40.3.2 Analog Ground (V_{SSA})

The ADC analog portion uses V_{SSA} as its ground connection. In some packages, V_{SSA} is connected internally to V_{SS}. If externally available, connect the V_{SSA} pin to the same voltage potential as V_{SS}.

40.3.3 Voltage Reference Select

V_{REFSH} and V_{REFSL} are the high and low reference voltages for the ADC module.

The ADC can be configured to accept one of two voltage reference pairs for V_{REFSH} and V_{REFSL}. Each pair contains a positive reference that must be between the minimum Ref Voltage High and V_{DDA}, and a ground reference that must be at the same potential as V_{SSA}. The two pairs are external (V_{REFH} and V_{REFL}) and alternate (V_{ALTH} and V_{ALTL}). These voltage references are selected using SC2[REFSEL]. The alternate V_{ALTH} and

V_{ALTL} voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the Voltage References specific to this MCU.

In some packages, V_{REFH} is connected in the package to V_{DDA} and V_{REFL} to V_{SSA} . If externally available, the positive reference(s) may be connected to the same potential as V_{DDA} or may be driven by an external source to a level between the minimum Ref Voltage High and the V_{DDA} potential. V_{REFH} must never exceed V_{DDA} . Connect the ground references to the same voltage potential as V_{SSA} .

40.3.4 Analog Channel Inputs (ADx)

The ADC module supports up to 24 single-ended analog inputs. A single-ended input is selected for conversion through the $SC1[ADCH]$ channel select bits when $SC1n[DIFF]$ is low.

40.3.5 Differential Analog Channel Inputs (DADx)

The ADC module supports up to four differential analog channel inputs. Each differential analog input is a pair of external pins, $DADPx$ and $DADMx$, referenced to each other to provide the most accurate analog to digital readings. A differential input is selected for conversion through $SC1[ADCH]$ when $SC1n[DIFF]$ is high. All $DADPx$ inputs may be used as single-ended inputs if $SC1n[DIFF]$ is low. In certain MCU configurations, some $DADMx$ inputs may also be used as single-ended inputs if $SC1n[DIFF]$ is low. For ADC connections specific to this device, see the chip-specific ADC information.

40.4 Memory map and register definitions

This section describes the ADC registers.

40.4.1 ADC Status and Control Registers 1 (ADCx_SC1n)

SC1A is used for both software and hardware trigger modes of operation.

To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC can have more than one status and control register: one for each conversion. The SC1B–SC1n registers indicate potentially multiple SC1 registers for use only in hardware trigger mode. See the chip configuration information about the number of SC1n registers specific to this device. The SC1n registers have identical fields, and are used in a "ping-pong" approach to control ADC operation.

At any one point in time, only one of the SC1n registers is actively controlling ADC conversions. Updating SC1A while SC1n is actively controlling a conversion is allowed, and vice-versa for any of the SC1n registers specific to this MCU.

Writing SC1A while SC1A is actively controlling a conversion aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, writes to SC1A subsequently initiate a new conversion, if SC1[ADCH] contains a value other than all 1s (module disabled).

Writing any of the SC1n registers while that specific SC1n register is actively controlling a conversion aborts the current conversion. None of the SC1B–SC1n registers are used for software trigger operation and therefore writes to the SC1B–SC1n registers do not initiate a new conversion.

Address: 4003_B000h base + 0h offset + (4d × i), where i=0d to 1d

ADCx_SC1n field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 COCO	Conversion Complete Flag This is a read-only field that is set each time a conversion is completed when the compare function is disabled, or SC2[ACFE]=0 and the hardware average function is disabled, or SC3[AVGE]=0. When the compare function is enabled, or SC2[ACFE]=1, COCO is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled, or SC3[AVGE]=1, COCO is set upon completion of the selected number of conversions (determined by AVGS). COCO in SC1A is also set at the completion of a calibration sequence. COCO is cleared when the respective SC1n register is written or when the respective Rn register is read. 0 Conversion is not completed. 1 Conversion is completed.
6 AIEN	Interrupt Enable Enables conversion complete interrupts. When COCO becomes set while the respective AIEN is high, an interrupt is asserted. 0 Conversion complete interrupt is disabled. 1 Conversion complete interrupt is enabled.
5 DIFF	Differential Mode Enable Configures the ADC to operate in differential mode. When enabled, this mode automatically selects from the differential channels, and changes the conversion algorithm and the number of cycles to complete a conversion. 0 Single-ended conversions and input channels are selected. 1 Differential conversions and input channels are selected.
ADCH	Input channel select Selects one of the input channels. The input channel decode depends on the value of DIFF. DAD0-DAD3 are associated with the input pin pairs DADPx and DADMx. NOTE: Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the actual ADC channel assignments for your device, see the Chip Configuration details. The successive approximation converter subsystem is turned off when the channel select bits are all set, that is, ADCH = 11111. This feature allows explicit disabling of the ADC and isolation of the input channel from all sources. Terminating continuous conversions this way prevents an additional single conversion from being performed. It is not necessary to set ADCH to all 1s to place the ADC in a low-power state when continuous conversions are not enabled because the module automatically enters a low-power state when a conversion completes. 00000 When DIFF=0, DADP0 is selected as input; when DIFF=1, DAD0 is selected as input. 00001 When DIFF=0, DADP1 is selected as input; when DIFF=1, DAD1 is selected as input. 00010 When DIFF=0, DADP2 is selected as input; when DIFF=1, DAD2 is selected as input. 00011 When DIFF=0, DADP3 is selected as input; when DIFF=1, DAD3 is selected as input. 00100 When DIFF=0, AD4 is selected as input; when DIFF=1, it is reserved. 00101 When DIFF=0, AD5 is selected as input; when DIFF=1, it is reserved. 00110 When DIFF=0, AD6 is selected as input; when DIFF=1, it is reserved. 00111 When DIFF=0, AD7 is selected as input; when DIFF=1, it is reserved.

11000	Reserved.
11001	Reserved.
11010	When DIFF=0, Temp Sensor (single-ended) is selected as input; when DIFF=1, Temp Sensor (differential) is selected as input.
11011	When DIFF=0, Bandgap (single-ended) is selected as input; when DIFF=1, Bandgap (differential) is selected as input.
11100	Reserved.
11101	When DIFF=0, V_{REFSH} is selected as input; when DIFF=1, $-V_{REFSH}$ (differential) is selected as input. Voltage reference selected is determined by SC2[REFSEL].
11110	When DIFF=0, V_{REFSL} is selected as input; when DIFF=1, it is reserved. Voltage reference selected is determined by SC2[REFSEL].
11111	Module is disabled.

40.4.2 ADC Configuration Register 1 (ADCx_CFG1)

The configuration Register 1 (CFG1) selects the mode of operation, clock source, clock divide, and configuration for low power or long sample time.

Address: 4003_B000h base + 8h offset = 4003_B008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADCx_CFG1 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 ADLPC	Low-Power Configuration Controls the power configuration of the successive approximation converter. This optimizes power consumption when higher sample rates are not required. 0 Normal power configuration. 1 Low-power configuration. The power is reduced at the expense of maximum clock speed.
6–5 ADIV	Clock Divide Select Selects the divide ratio used by the ADC to generate the internal clock ADCK. 00 The divide ratio is 1 and the clock rate is input clock. 01 The divide ratio is 2 and the clock rate is (input clock)/2. 10 The divide ratio is 4 and the clock rate is (input clock)/4. 11 The divide ratio is 8 and the clock rate is (input clock)/8.
4 ADLSMP	Sample Time Configuration Selects between different sample times based on the conversion mode selected. This field adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption if continuous conversions are enabled and high conversion rates are not required. When ADLSMP=1, the long sample time select bits, (ADLSTS[1:0]), can select the extent of the long sample time.

Table continues on the next page...

ADCx_CFG1 field descriptions (continued)

Field	Description
	0 Short sample time. 1 Long sample time.
3–2 MODE	Conversion mode selection Selects the ADC resolution mode. 00 When DIFF=0:It is single-ended 8-bit conversion; when DIFF=1, it is differential 9-bit conversion with 2's complement output. 01 When DIFF=0:It is single-ended 12-bit conversion ; when DIFF=1, it is differential 13-bit conversion with 2's complement output. 10 When DIFF=0:It is single-ended 10-bit conversion. ; when DIFF=1, it is differential 11-bit conversion with 2's complement output 11 When DIFF=0:It is single-ended 16-bit conversion..; when DIFF=1, it is differential 16-bit conversion with 2's complement output
ADICLK	Input Clock Select Selects the input clock source to generate the internal clock, ADCK. Note that when the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start, when CFG2[ADACKEN]=0, the asynchronous clock is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated. 00 Bus clock 01 Alternate clock 2 (ALTCLK2) 10 Alternate clock (ALTCLK) 11 Asynchronous clock (ADACK)

40.4.3 ADC Configuration Register 2 (ADCx_CFG2)

Configuration Register 2 (CFG2) selects the special high-speed configuration for very high speed conversions and selects the long sample time duration during long sample mode.

Address: 4003_B000h base + Ch offset = 4003_B00Ch

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADCx_CFG2 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MUXSEL	ADC Mux Select Changes the ADC mux setting to select between alternate sets of ADC channels. 0 ADxxa channels are selected. 1 ADxxb channels are selected.
3 ADACKEN	Asynchronous Clock Output Enable Enables the asynchronous clock source and the clock source output regardless of the conversion and status of CFG1[ADICLK]. Based on MCU configuration, the asynchronous clock may be used by other modules. See chip configuration information. Setting this field allows the clock to be used even while the ADC is idle or operating from a different clock source. Also, latency of initiating a single or first-continuous conversion with the asynchronous clock selected is reduced because the ADACK clock is already operational. 0 Asynchronous clock output disabled; Asynchronous clock is enabled only if selected by ADICLK and a conversion is active. 1 Asynchronous clock and clock output is enabled regardless of the state of the ADC.
2 ADHSC	High-Speed Configuration Configures the ADC for very high-speed operation. The conversion sequence is altered with 2 ADCK cycles added to the conversion time to allow higher speed conversion clocks. 0 Normal conversion sequence selected. 1 High-speed conversion sequence selected with 2 additional ADCK cycles to total conversion time.
ADLSTS	Long Sample Time Select Selects between the extended sample times when long sample time is selected, that is, when CFG1[ADLSMP]=1. This allows higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required. 00 Default longest sample time; 20 extra ADCK cycles; 24 ADCK cycles total. 01 12 extra ADCK cycles; 16 ADCK cycles total sample time. 10 6 extra ADCK cycles; 10 ADCK cycles total sample time. 11 2 extra ADCK cycles; 6 ADCK cycles total sample time.

40.4.4 ADC Data Result Register (ADCx_Rn)

The data result registers (Rn) contain the result of an ADC conversion of the channel selected by the corresponding status and channel control register (SC1A:SC1n). For every status and channel control register, there is a corresponding data result register.

Unused bits in R_n are cleared in unsigned right-aligned modes and carry the sign bit (MSB) in sign-extended 2's complement modes. For example, when configured for 10-bit single-ended mode, D[15:10] are cleared. When configured for 11-bit differential mode, D[15:10] carry the sign bit, that is, bit 10 extended through bit 15.

The following table describes the behavior of the data result registers in the different modes of operation.

Table 40-5. Data result register description

Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
16-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Signed 2's complement
16-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned right justified
13-bit differential	S	S	S	S	D	D	D	D	D	D	D	D	D	D	D	D	Sign-extended 2's complement
12-bit single-ended	0	0	0	0	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned right-justified
11-bit differential	S	S	S	S	S	S	D	D	D	D	D	D	D	D	D	D	Sign-extended 2's complement
10-bit single-ended	0	0	0	0	0	0	D	D	D	D	D	D	D	D	D	D	Unsigned right-justified
9-bit differential	S	S	S	S	S	S	S	S	D	D	D	D	D	D	D	D	Sign-extended 2's complement
8-bit single-ended	0	0	0	0	0	0	0	0	D	D	D	D	D	D	D	D	Unsigned right-justified

NOTE

S: Sign bit or sign bit extension;

D: Data, which is 2's complement data if indicated

Address: 4003_B000h base + 10h offset + (4d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

D	Data result

40.4.5 Compare Value Registers (ADCx_CVn)

The Compare Value Registers (CV1 and CV2) contain a compare value used to compare the conversion result when the compare function is enabled, that is, SC2[ACFE]=1. This register is formatted in the same way as the Rn registers in different modes of operation for both bit position definition and value format using unsigned or sign-extended 2's complement. Therefore, the compare function uses only the CVn fields that are related to the ADC mode of operation.

The compare value 2 register (CV2) is used only when the compare range function is enabled, that is, SC2[ACREN]=1.

Address: 4003_B000h base + 18h offset + (4d × i), where i=0d to 1d

ADCx_CVn field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CV	Compare Value.

40.4.6 Status and Control Register 2 (ADCx_SC2)

The status and control register 2 (SC2) contains the conversion active, hardware/software trigger select, compare function, and voltage reference select of the ADC module.

Address: 4003_B000h base + 20h offset = 4003_B020h

ADCx_SC2 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 ADACT	Conversion Active Indicates that a conversion or hardware averaging is in progress. ADACT is set when a conversion is initiated and cleared when a conversion is completed or aborted. 0 Conversion not in progress. 1 Conversion in progress.
6 ADTRG	Conversion Trigger Select Selects the type of trigger used for initiating a conversion. Two types of trigger are selectable:

Table continues on the next page...

ADCx_SC2 field descriptions (continued)

Field	Description
	- Software trigger: When software trigger is selected, a conversion is initiated following a write to SC1A. - Hardware trigger: When hardware trigger is selected, a conversion is initiated following the assertion of the ADHWT input after a pulse of the ADHWTSn input. 0 Software trigger selected. 1 Hardware trigger selected.
5 ACFE	Compare Function Enable Enables the compare function. 0 Compare function disabled. 1 Compare function enabled.
4 ACFGT	Compare Function Greater Than Enable Configures the compare function to check the conversion result relative to the CV1 and CV2 based upon the value of ACREN. ACFE must be set for ACFGT to have any effect. 0 Configures less than threshold, outside range not inclusive and inside range not inclusive; functionality based on the values placed in CV1 and CV2. 1 Configures greater than or equal to threshold, outside and inside ranges inclusive; functionality based on the values placed in CV1 and CV2.
3 ACREN	Compare Function Range Enable Configures the compare function to check if the conversion result of the input being monitored is either between or outside the range formed by CV1 and CV2 determined by the value of ACFGT. ACFE must be set for ACFGT to have any effect. 0 Range function disabled. Only CV1 is compared. 1 Range function enabled. Both CV1 and CV2 are compared.
2 DMAEN	DMA Enable 0 DMA is disabled. 1 DMA is enabled and will assert the ADC DMA request during an ADC conversion complete event noted when any of the SC1n[COCO] flags is asserted.
REFSEL	Voltage Reference Selection Selects the voltage reference source used for conversions. 00 Default voltage reference pin pair, that is, external pins V_{REFH} and V_{REFL} 01 Alternate reference pair, that is, V_{ALTH} and V_{ALTTL}. This pair may be additional external pins or internal sources depending on the MCU configuration. See the chip configuration information for details specific to this MCU 10 Reserved 11 Reserved

40.4.7 Status and Control Register 3 (ADCx_SC3)

The Status and Control Register 3 (SC3) controls the calibration, continuous convert, and hardware averaging functions of the ADC module.

Address: 4003_B000h base + 24h offset = 4003_B024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADCx_SC3 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CAL	Calibration Begins the calibration sequence when set. This field stays set while the calibration is in progress and is cleared when the calibration sequence is completed. CALF must be checked to determine the result of the calibration sequence. Once started, the calibration routine cannot be interrupted by writes to the ADC registers or the results will be invalid and CALF will set. Setting CAL will abort any current conversion.
6 CALF	Calibration Failed Flag Displays the result of the calibration sequence. The calibration sequence will fail if SC2[ADTRG] = 1, any ADC register is written, or any stop mode is entered before the calibration sequence completes. Writing 1 to CALF clears it. 0 Calibration completed normally. 1 Calibration failed. ADC accuracy specifications are not guaranteed.

Table continues on the next page...

ADCx_SC3 field descriptions (continued)

Field	Description
5–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ADCO	Continuous Conversion Enable Enables continuous conversions. 0 One conversion or one set of conversions if the hardware average function is enabled, that is, AVGE=1, after initiating a conversion. 1 Continuous conversions or sets of conversions if the hardware average function is enabled, that is, AVGE=1, after initiating a conversion.
2 AVGE	Hardware Average Enable Enables the hardware average function of the ADC. 0 Hardware average function disabled. 1 Hardware average function enabled.
AVGS	Hardware Average Select Determines how many ADC conversions will be averaged to create the ADC average result. 00 4 samples averaged. 01 8 samples averaged. 10 16 samples averaged. 11 32 samples averaged.

40.4.8 ADC Offset Correction Register (ADCx_OFS)

The ADC Offset Correction Register (OFS) contains the user-selected or calibration-generated offset error correction value. This register is a 2's complement, left-justified, 16-bit value. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

Address: 4003_B000h base + 28h offset = 4003_B028h

40.4.18 ADC Minus-Side General Calibration Value Register (ADCx_CLMD)

The Minus-Side General Calibration Value (CLMx) registers contain calibration information that is generated by the calibration function. These registers contain seven calibration values of varying widths: CLM0[5:0], CLM1[6:0], CLM2[7:0], CLM3[8:0], CLM4[9:0], CLMS[5:0], and CLMD[5:0]. CLMx are automatically set when the self-calibration sequence is done, that is, CAL is cleared. If these registers are written by the user after calibration, the linearity error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

40.5 Functional description

The ADC module is disabled during reset, in Low-Power Stop mode, or when SC1n[ADCH] are all high; see the power management information for details. The module is idle when a conversion has completed and another conversion has not been initiated. When it is idle and the asynchronous clock output enable is disabled, or CFG2[ADACKEN]= 0, the module is in its lowest power state. The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications, the ADC module must be calibrated using the on-chip calibration function.

See [Calibration function](#) for details on how to perform calibration.

When the conversion is completed, the result is placed in the Rn data registers. The respective SC1n[COCO] is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, or, when SC1n[AIEN]=1.

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the CV1 and CV2 registers. The compare function is enabled by setting SC2[ACFE] and operates in any of the conversion modes and configurations.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting SC3[AVGE] and operates in any of the conversion modes and configurations.

NOTE

For the chip specific modes of operation, see the power management information of this MCU.

40.5.1 Clock select and divide control

One of four clock sources can be selected as the clock source for the ADC module.

This clock source is then divided by a configurable value to generate the input clock ADCK, to the module. The clock is selected from one of the following sources by means of CFG1[ADICLK].

- Bus clock. This is the default selection following reset.
- ALTCLK2: As defined for this MCU. See the chip configuration information. Conversions are possible using ALTCLK2 as the input clock source while the MCU is in Normal Stop mode.
- ALTCLK: As defined for this MCU. See the chip configuration information. Conversions are possible using ALTCLK as the input clock source while the MCU is in Normal Stop mode.
- Asynchronous clock (ADACK): This clock is generated from a clock source within the ADC module. When the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start CFG2[ADACKEN]=0, ADACK is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated. To avoid the conversion time variability and latency associated with the ADACK clock startup, set CFG2[ADACKEN]=1 and wait the worst-case startup time of 5 μ s prior to initiating any conversions using the ADACK clock source. Conversions are possible using ADACK as the input clock source while the MCU is in Normal Stop mode. See [Power Control](#) for more information.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by CFG1[ADIV] and can be divide-by 1, 2, 4, or 8.

40.5.2 Voltage reference selection

The ADC can be configured to accept one of the two voltage reference pairs as the reference voltage (V_{REFSH} and V_{REFSL}) used for conversions.

Each pair contains a positive reference that must be between the minimum Ref Voltage High and V_{DDA} , and a ground reference that must be at the same potential as V_{SSA} . The two pairs are external (V_{REFH} and V_{REFL}) and alternate (V_{ALTH} and V_{ALTL}). These voltage references are selected using $SC2[REFSEL]$. The alternate (V_{ALTH} and V_{ALTL}) voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

40.5.3 Hardware trigger and channel selects

The ADC module has a selectable asynchronous hardware conversion trigger, ADHWT, that is enabled when $SC2[ADTRG]$ is set and a hardware trigger select event, ADHWTSn, has occurred.

This source is not available on all MCUs. See the chip-specific ADC information for information on the ADHWT source and the ADHWTSn configurations specific to this MCU.

When an ADHWT source is available and hardware trigger is enabled, that is $SC2[ADTRG]=1$, a conversion is initiated on the rising-edge of ADHWT after a hardware trigger select event, that is, ADHWTSn, has occurred. If a conversion is in progress when a rising-edge of a trigger occurs, the rising-edge is ignored. In continuous convert configuration, only the initial rising-edge to launch continuous conversions is observed, and until conversion is aborted, the ADC continues to do conversions on the same SCn register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The hardware trigger select event, ADHWTSn, must be set prior to the receipt of the ADHWT signal. If these conditions are not met, the converter may ignore the trigger or use the incorrect configuration. If a hardware trigger select event is asserted during a conversion, it must stay asserted until the end of current conversion and remain set until the receipt of the ADHWT signal to trigger a new conversion. The channel and status fields selected for the conversion depend on the active trigger select signal:

- ADHWTSn active selects SC1A.
- ADHWTSn active selects SC1n.

Note

Asserting more than one hardware trigger select signal (ADHWTSn) at the same time results in unknown results. To avoid this, select only one hardware trigger select signal (ADHWTSn) prior to the next intended conversion.

When the conversion is completed, the result is placed in the Rn registers associated with the ADHWTSn received. For example:

- ADHWTSa active selects RA register
- ADHWTSn active selects Rn register

The conversion complete flag associated with the ADHWTSn received, that is, SC1n[COCO], is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, that is, SC1[AIEN]=1.

40.5.4 Conversion control

Conversions can be performed as determined by CFG1[MODE] and SC1n[DIFF] as shown in the description of CFG1[MODE].

Conversions can be initiated by a software or hardware trigger.

In addition, the ADC module can be configured for:

- Low-power operation
- Long sample time
- Continuous conversion
- Hardware average
- Automatic compare of the conversion result to a software determined compare value

40.5.4.1 Initiating conversions

A conversion is initiated:

- Following a write to SC1A, with SC1n[ADCH] not all 1's, if software triggered operation is selected, that is, when SC2[ADTRG]=0.
- Following a hardware trigger, or ADHWT event, if hardware triggered operation is selected, that is, SC2[ADTRG]=1, and a hardware trigger select event, ADHWTSn, has occurred. The channel and status fields selected depend on the active trigger select signal:
 - ADHWTSa active selects SC1A.

- ADHWTSn active selects SC1n.
- if neither is active, the off condition is selected

Note

Selecting more than one ADHWTSn prior to a conversion completion will result in unknown results. To avoid this, select only one ADHWTSn prior to a conversion completion.

- Following the transfer of the result to the data registers when continuous conversion is enabled, that is, when $SC3[ADCO] = 1$.

If continuous conversions are enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation, that is, when $SC2[ADTRG] = 0$, continuous conversions begin after SC1A is written and continue until aborted. In hardware triggered operation, that is, when $SC2[ADTRG] = 1$ and one ADHWTSn event has occurred, continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions are completed. In software triggered operation, conversions begin after SC1A is written. In hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions are also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

40.5.4.2 Completing conversions

A conversion is completed when the result of the conversion is transferred into the data result registers, Rn. If the compare functions are disabled, this is indicated by setting of $SC1n[COCO]$. If hardware averaging is enabled, the respective $SC1n[COCO]$ sets only if the last of the selected number of conversions is completed. If the compare function is enabled, the respective $SC1n[COCO]$ sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then the respective $SC1n[COCO]$ sets only if the last of the selected number of conversions is completed and the compare condition is true. An interrupt is generated if the respective $SC1n[AIEN]$ is high at the time that the respective $SC1n[COCO]$ is set.

40.5.4.3 Aborting conversions

Any conversion in progress is aborted when:

- Writing to SC1A while it is actively controlling a conversion, aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, a write to SC1A initiates a new conversion if SC1A[ADCH] is equal to a value other than all 1s. Writing to any of the SC1B–SC1n registers while that specific SC1B–SC1n register is actively controlling a conversion aborts the current conversion. The SC1(B-n) registers are not used for software trigger operation and therefore writes to the SC1(B-n) registers do not initiate a new conversion.
- A write to any ADC register besides the SC1A-SC1n registers occurs. This indicates that a change in mode of operation has occurred and the current conversion is therefore invalid.
- The MCU is reset or enters Low-Power Stop modes.
- The MCU enters Normal Stop mode with ADACK or Alternate Clock Sources not enabled.

When a conversion is aborted, the contents of the data registers, Rn, are not altered. The data registers continue to be the values transferred after the completion of the last successful conversion. If the conversion was aborted by a reset or Low-Power Stop modes, RA and Rn return to their reset states.

40.5.4.4 Power control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source, but the asynchronous clock output is disabled, that is CFG2[ADACKEN]=0, the ADACK clock generator also remains in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled, that is, CFG2[ADACKEN]=1, it remains active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting CFG1[ADLPC]. This results in a lower maximum value for f_{ADCK} .

40.5.4.5 Sample time and total conversion time

For short sample, that is, when CFG1[ADLSMP]=0, there is a 2-cycle adder for first conversion over the base sample time of four ADCK cycles. For high-speed conversions, that is, when CFG2[ADHSC]=1, there is an additional 2-cycle adder on any conversion. The table below summarizes sample times for the possible ADC configurations.

ADC configuration			Sample time (ADCK cycles)	
CFG1[ADLSMP]	CFG2[ADLSTS]	CFG2[ADHSC]	First or Single	Subsequent
0	X	0	6	4
1	00	0	24	
1	01	0	16	
1	10	0	10	
1	11	0	6	
0	X	1	8	6
1	00	1	26	
1	01	1	18	
1	10	1	12	
1	11	1	8	

The total conversion time depends upon:

- The sample time as determined by CFG1[ADLSMP] and CFG2[ADLSTS]
- The MCU bus frequency
- The conversion mode, as determined by CFG1[MODE] and SC1n[DIFF]
- The high-speed configuration, that is, CFG2[ADHSC]
- The frequency of the conversion clock, that is, f_{ADCK} .

CFG2[ADHSC] is used to configure a higher clock input frequency. This will allow faster overall conversion times. To meet internal ADC timing requirements, CFG2[ADHSC] adds additional ADCK cycles. Conversions with CFG2[ADHSC]=1 take two more ADCK cycles. CFG2[ADHSC] must be used when the ADCLK exceeds the limit for CFG2[ADHSC]=0.

After the module becomes active, sampling of the input begins.

1. CFG1[ADLSMP] and CFG2[ADLSTS] select between sample times based on the conversion mode that is selected.
2. When sampling is completed, the converter is isolated from the input channel and a successive approximation algorithm is applied to determine the digital value of the analog signal.
3. The result of the conversion is transferred to Rn upon completion of the conversion algorithm.

If the bus frequency is less than f_{ADCK} , precise sample time for continuous conversions cannot be guaranteed when short sample is enabled, that is, when $CFG1[ADLSMP]=0$.

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by $CFG1[ADICLK]$, and the divide ratio is specified by $CFG1[ADIV]$.

The maximum total conversion time for all configurations is summarized in the equation below. See the following tables for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder} + \text{HSCAdder})$$

Equation 1. Conversion time equation

Table 40-6. Single or first continuous time adder (SFCAdder)

CFG1[ADLSMP]	CFG2[ADACKEN]	CFG1[ADICLK]	Single or first continuous time adder (SFCAdder)
1	x	0x, 10	3 ADCK cycles + 5 bus clock cycles
1	1	11	3 ADCK cycles + 5 bus clock cycles ¹
1	0	11	5 μ s + 3 ADCK cycles + 5 bus clock cycles
0	x	0x, 10	5 ADCK cycles + 5 bus clock cycles
0	1	11	5 ADCK cycles + 5 bus clock cycles ¹
0	0	11	5 μ s + 5 ADCK cycles + 5 bus clock cycles

1. To achieve this time, $CFG2[ADACKEN]$ must be 1 for at least 5 μ s prior to the conversion is initiated.

Note

The ADCK frequency must be between f_{ADCK} minimum and f_{ADCK} maximum to meet ADC specifications.

40.5.4.6 Conversion time examples

The following examples use the [Equation 1 on page 1123](#), and the information provided in [Table 40-6](#) through [Table 40-10](#).

40.5.4.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is:

- 10-bit mode, with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 8 MHz
- Long sample time disabled
- High-speed conversion disabled

The conversion time for a single conversion is calculated by using the [Equation 1 on page 1123](#), and the information provided in [Table 40-6](#) through [Table 40-10](#). The table below lists the variables of [Equation 1 on page 1123](#).

Table 40-11. Typical conversion time

Variable	Time
SFCAdder	5 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	20 ADCK cycles
LSTAdder	0
HSCAdder	0

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for a bus clock and an ADCK frequency equal to 8 MHz, the resulting conversion time is 3.75 μ s.

40.5.4.6.2 Long conversion time configuration

A configuration for long ADC conversion is:

- 16-bit differential mode with the bus clock selected as the input clock source
- The input clock divide-by-8 ratio selected
- Bus frequency of 8 MHz
- Long sample time enabled
- Configured for longest adder
- High-speed conversion disabled
- Average enabled for 32 conversions

The conversion time for this conversion is calculated by using the [Equation 1 on page 1123](#), and the information provided in [Table 40-6](#) through [Table 40-10](#). The following table lists the variables of the [Equation 1 on page 1123](#).

Table 40-12. Typical conversion time

Variable	Time
SFCAdder	3 ADCK cycles + 5 bus clock cycles
AverageNum	32
BCT	34 ADCK cycles
LSTAdder	20 ADCK cycles
HSCAdder	0

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for bus clock equal to 8 MHz and ADCK equal to 1 MHz, the resulting conversion time is 57.625 μ s, that is, AverageNum. This results in a total conversion time of 1.844 ms.

40.5.4.6.3 Short conversion time configuration

A configuration for short ADC conversion is:

- 8-bit Single-Ended mode with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 20 MHz
- Long sample time disabled
- High-speed conversion enabled

The conversion time for this conversion is calculated by using the [Equation 1 on page 1123](#), and the information provided in [Table 40-6](#) through [Table 40-10](#). The table below lists the variables of [Equation 1 on page 1123](#).

Table 40-13. Typical conversion time

Variable	Time
SFCAdder	5 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	17 ADCK cycles
LSTAdder	0 ADCK cycles
HSCAdder	2

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for bus clock and ADCK frequency equal to 20 MHz, the resulting conversion time is 1.45 μ s.

40.5.4.7 Hardware average function

The hardware average function can be enabled by setting SC3[AVGE]=1 to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which can select 4, 8, 16, or 32 conversions to be averaged. While the hardware average function is in progress, SC2[ADACT] will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated once the selected number of conversions have been completed. When hardware averaging is selected, the completion of a single conversion will not set SC1n[COCO].

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, Rn, and SC1n[COCO] is set. An ADC interrupt is generated upon the setting of SC1n[COCO] if the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

Note

The hardware average function can perform conversions on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the hardware average is completed if SC1n[AIEN] is set.

40.5.5 Automatic compare function

The compare function can be configured to check whether the result is less than or greater-than-or-equal-to a single compare value, or, if the result falls within or outside a range determined by two compare values.

The compare mode is determined by SC2[ACFGT], SC2[ACREN], and the values in the compare value registers, CV1 and CV2. After the input is sampled and converted, the compare values in CV1 and CV2 are used as described in the following table. There are six Compare modes as shown in the following table.

Table 40-14. Compare modes

SC2[ACFGT]	SC2[ACREN]	ADCCV1 relative to ADCCV2	Function	Compare mode description
0	0	—	Less than threshold	Compare true if the result is less than the CV1 registers.
1	0	—	Greater than or equal to threshold	Compare true if the result is greater than or equal to CV1 registers.
0	1	Less than or equal	Outside range, not inclusive	Compare true if the result is less than CV1 Or the result is greater than CV2.
0	1	Greater than	Inside range, not inclusive	Compare true if the result is less than CV1 And the result is greater than CV2.
1	1	Less than or equal	Inside range, inclusive	Compare true if the result is greater than or equal to CV1 And the result is less than or equal to CV2.
1	1	Greater than	Outside range, inclusive	Compare true if the result is greater than or equal to CV1 Or the result is less than or equal to CV2.

With SC2[ACREN] =1, and if the value of CV1 is less than or equal to the value of CV2, then setting SC2[ACFGT] will select a trigger-if-inside-compare-range inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than CV2, setting SC2[ACFGT] will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, SC1n[COCO] is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, SC1n[COCO] is not set and the conversion result data will not be transferred to the result register, Rn. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated when SC1n[COCO] is set and the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

Note

The compare function can monitor the voltage on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the compare condition is met.

40.5.6 Calibration function

The ADC contains a self-calibration function that is required to achieve the specified accuracy.

Calibration must be run, or valid calibration values written, after any reset and before a conversion is initiated. The calibration function sets the offset calibration value, the minus-side calibration values, and the plus-side calibration values. The offset calibration value is automatically stored in the ADC offset correction register (OFS), and the plus-side and minus-side calibration values are automatically stored in the ADC plus-side and minus-side calibration registers, CLPx and CLMx. The user must configure the ADC correctly prior to calibration, and must generate the plus-side and minus-side gain calibration results and store them in the ADC plus-side gain register (PG) after the calibration function completes.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, and high speed configuration according to the application's clock source availability and needs. If the

application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. For best calibration results:

- Set hardware averaging to maximum, that is, SC3[AVGE]=1 and SC3[AVGS]=11 for an average of 32
- Set ADC clock frequency f_{ADCK} less than or equal to 4 MHz
- $V_{\text{REFH}}=V_{\text{DDA}}$
- Calibrate at nominal voltage and temperature

The input channel, conversion mode continuous function, compare function, resolution mode, and differential/single-ended mode are all ignored during the calibration function.

To initiate calibration, the user sets SC3[CAL] and the calibration will automatically begin if the SC2[ADTRG] is 0. If SC2[ADTRG] is 1, SC3[CAL] will not get set and SC3[CALF] will be set. While calibration is active, no ADC register can be written and no stop mode may be entered, or the calibration routine will be aborted causing SC3[CAL] to clear and SC3[CALF] to set. At the end of a calibration sequence, SC1n[COCO] will be set. SC1n[AIEN] can be used to allow an interrupt to occur at the end of a calibration sequence. At the end of the calibration routine, if SC3[CALF] is not set, the automatic calibration routine is completed successfully.

To complete calibration, the user must generate the gain calibration values using the following procedure:

1. Initialize or clear a 16-bit variable in RAM.
2. Add the plus-side calibration results CLP0, CLP1, CLP2, CLP3, CLP4, and CLPS to the variable.
3. Divide the variable by two.
4. Set the MSB of the variable.
5. The previous two steps can be achieved by setting the carry bit, rotating to the right through the carry bit on the high byte and again on the low byte.
6. Store the value in the plus-side gain calibration register PG.
7. Repeat the procedure for the minus-side gain calibration value.

When calibration is complete, the user may reconfigure and use the ADC as desired. A second calibration may also be performed, if desired, by clearing and again setting SC3[CAL].

Overall, the calibration routine may take as many as 14k ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen. For an 8 MHz clock source, this length amounts to about 1.7 ms. To reduce this latency, the calibration values, which are offset, plus-side and minus-side gain, and plus-side and minus-side calibration values, may be stored in flash memory after an initial calibration and recovered prior to the first ADC conversion. This method can reduce the calibration latency to 20 register store operations on all subsequent power, reset, or Low-Power Stop mode recoveries.

Further information on the calibration procedure can be found in the Calibration section of [AN3949: ADC16 Calibration Procedure and Programmable Delay Block Synchronization](#).

40.5.7 User-defined offset function

OFS contains the user-selected or calibration-generated offset error correction value.

This register is a 2's complement, left-justified. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

The formatting of the OFS is different from the data result register, Rn, to preserve the resolution of the calibration value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8-bit single-ended mode, OFS[14:7] are subtracted from D[7:0]; OFS[15] indicates the sign (negative numbers are effectively added to the result) and OFS[6:0] are ignored. The same bits are used in 9-bit differential mode because OFS[15] indicates the sign bit, which maps to D[8]. For 16-bit differential mode, OFS[15:0] are directly subtracted from the conversion result data D[15:0]. In 16-bit single-ended mode, there is no field in the OFS corresponding to the least significant result D[0], so odd values, such as -1 or +1, cannot be subtracted from the result.

OFS is automatically set according to calibration requirements once the self-calibration sequence is done, that is, SC3[CAL] is cleared. The user may write to OFS to override the calibration result if desired. If the OFS is written by the user to a value that is different from the calibration value, the ADC error specifications may not be met. Storing the value generated by the calibration function in memory before overwriting with a user-specified value is recommended.

Note

There is an effective limit to the values of offset that can be set by the user. If the magnitude of the offset is too high, the results of the conversions will cap off at the limits.

The offset calibration function may be employed by the user to remove application offsets or DC bias values. OFS may be written with a number in 2's complement format and this offset will be subtracted from the result, or hardware averaged value. To add an offset, store the negative offset in 2's complement format and the effect will be an addition. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value. The minimum value for single-ended conversions is 0x0000; for a differential conversion it is 0x8000.

To preserve accuracy, the calibrated offset value initially stored in OFS must be added to the user-defined offset. For applications that may change the offset repeatedly during operation, store the initial offset calibration value in flash so it can be recovered and added to any user offset adjustment value and the sum stored in OFS.

40.5.8 Temperature sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs.

The following equation provides an approximate transfer function of the temperature sensor.

$$\text{Temp} = 25 - \left((V_{\text{TEMP}} - V_{\text{TEMP25}}) \div m \right)$$

Equation 2. Approximate transfer function of the temperature sensor

where:

- V_{TEMP} is the voltage of the temperature sensor channel at the ambient temperature.
- V_{TEMP25} is the voltage of the temperature sensor channel at 25 °C.
- m is referred as temperature sensor slope in the device data sheet. It is the hot or cold voltage versus temperature slope in V/°C.

For temperature calculations, use the V_{TEMP25} and temperature sensor slope values from the ADC Electricals table.

In application code, the user reads the temperature sensor channel, calculates V_{TEMP} , and compares to V_{TEMP25} . If V_{TEMP} is greater than V_{TEMP25} the cold slope value is applied in the preceding equation. If V_{TEMP} is less than V_{TEMP25} , the hot slope value is applied in the preceding equation. ADC Electricals table may only specify one temperature sensor slope value. In that case, the user could use the same slope for the calculation across the operational temperature range.

For more information on using the temperature sensor, see the application note titled *Temperature Sensor for the HCS08 Microcontroller Family* (document AN3031).

40.5.9 MCU wait mode operation

Wait mode is a lower-power consumption Standby mode from which recovery is fast because the clock sources remain active.

If a conversion is in progress when the MCU enters Wait mode, it continues until completion. Conversions can be initiated while the MCU is in Wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, ADACK, and Alternate Clock sources are available as conversion clock sources while in Wait mode. The use of ALTCLK as the conversion clock source in Wait is dependent on the definition of ALTCLK for this MCU. See the Chip Configuration information on ALTCLK specific to this MCU.

If the compare and hardware averaging functions are disabled, a conversion complete event sets $SC1n[COCO]$ and generates an ADC interrupt to wake the MCU from Wait mode if the respective ADC interrupt is enabled, that is, when $SC1n[AIEN]=1$. If the hardware averaging function is enabled, $SC1n[COCO]$ will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled, $SC1n[COCO]$ will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from Wait mode unless a new conversion is initiated by the hardware trigger.

40.5.10 MCU Normal Stop mode operation

Stop mode is a low-power consumption Standby mode during which most or all clock sources on the MCU are disabled.

40.5.10.1 Normal Stop mode with Bus Clock selected

If the Bus Clock is selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its Idle state. The contents of the ADC registers, including Rn, are unaffected by Normal Stop mode. After exiting from Normal Stop mode, a software or hardware trigger is required to resume conversions.

40.5.10.2 Normal Stop mode with ADACK or Alternate clock sources enabled

If ADACK or an Alternate clock source is selected as the conversion clock, the ADC continues operation during Normal Stop mode. See the chip-specific ADC information for configuration information for this device.

If a conversion is in progress when the MCU enters Normal Stop mode, it continues until completion. Conversions can be initiated while the MCU is in Normal Stop mode by means of the hardware trigger or if continuous conversions are enabled.

If the compare and hardware averaging functions are disabled, a conversion complete event sets SC1n[COCO] and generates an ADC interrupt to wake the MCU from Normal Stop mode if the respective ADC interrupt is enabled, that is, when SC1n[AIEN]=1. The result register, Rn, will contain the data from the first completed conversion that occurred during Normal Stop mode. If the hardware averaging function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare is not true, the ADC will return to its idle state and cannot wake the MCU from Normal Stop mode unless a new conversion is initiated by another hardware trigger.

40.5.11 MCU Low-Power Stop mode operation

The ADC module is automatically disabled when the MCU enters Low-Power Stop mode.

All module registers contain their reset values following exit from Low-Power Stop mode. Therefore, the module must be re-enabled and re-configured following exit from Low-Power Stop mode.

NOTE

For the chip specific modes of operation, see the power management information for the device.

40.6 Initialization information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module.

The user can configure the module for 16-bit, 12-bit, 10-bit, or 8-bit single-ended resolution or 16-bit, 13-bit, 11-bit, or 9-bit differential resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. For information used in this example, refer to [Table 40-9](#), [Table 40-10](#), and [Table 40-11](#).

Note

Hexadecimal values are designated by a preceding 0x, binary values designated by a preceding %, and decimal values have no preceding character.

40.6.1 ADC module initialization example

40.6.1.1 Initialization sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is:

1. Calibrate the ADC by following the calibration instructions in [Calibration function](#).
2. Update CFG to select the input clock source and the divide ratio used to generate ADCK. This register is also used for selecting sample time and low-power configuration.
3. Update SC2 to select the conversion trigger, hardware or software, and compare function options, if enabled.
4. Update SC3 to select whether conversions will be continuous or completed only once (ADCO) and whether to perform hardware averaging.
5. Update SC1:SC1n registers to select whether conversions will be single-ended or differential and to enable or disable conversion complete interrupts. Also, select the input channel which can be used to perform conversions.

40.6.1.2 Pseudo-code example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low-power with a long sample time on input channel 1, where ADCK is derived from the bus clock divided by 1.

CFG1 = 0x98 (%10011000)

Bit 7	ADLPC	1	Configures for low power, lowers maximum clock speed.
Bit 6:5	ADIV	00	Sets the ADCK to the input clock ÷ 1.
Bit 4	ADLSMP	1	Configures for long sample time.
Bit 3:2	MODE	10	Selects the single-ended 10-bit conversion, differential 11-bit conversion.
Bit 1:0	ADICLK	00	Selects the bus clock.

SC2 = 0x00 (%00000000)

Bit 7	ADACT	0	Flag indicates if a conversion is in progress.
Bit 6	ADTRG	0	Software trigger selected.
Bit 5	ACFE	0	Compare function disabled.
Bit 4	ACFGT	0	Not used in this example.
Bit 3	ACREN	0	Compare range disabled.
Bit 2	DMAEN	0	DMA request disabled.
Bit 1:0	REFSEL	00	Selects default voltage reference pin pair (External pins V _{REFH} and V _{REFL}).

SC1A = 0x41 (%01000001)

Bit 7	COCO	0	Read-only flag which is set when a conversion completes.
Bit 6	AIEN	1	Conversion complete interrupt enabled.
Bit 5	DIFF	0	Single-ended conversion selected.
Bit 4:0	ADCH	00001	Input channel 1 selected as ADC input channel.

RA = 0xxx

Holds results of conversion.

CV = 0xxx

Holds compare value when compare function enabled.

Figure 40-3. Initialization flowchart example

40.7 Application information

The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an ADC.

For guidance on selecting optimum external component values and converter parameters see [AN4373: Cookbook for SAR ADC Measurements](#).

40.7.1 External pins and routing

40.7.1.1 Analog supply pins

Depending on the device, the analog power and ground supplies, V_{DDA} and V_{SSA} , of the ADC module are available as:

- V_{DDA} and V_{SSA} available as separate pins—When available on a separate pin, both V_{DDA} and V_{SSA} must be connected to the same voltage potential as their corresponding MCU digital supply, V_{DD} and V_{SS} , and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.
- V_{SSA} is shared on the same pin as the MCU digital V_{SS} .
- V_{SSA} and V_{DDA} are shared with the MCU digital supply pins—In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the V_{SSA} pin. This must be the only ground connection between these supplies, if possible. V_{SSA} makes a good single point ground location.

40.7.1.2 Analog voltage reference pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs used by the converter:

- V_{REFSH} is the high reference voltage for the converter.
- V_{REFSL} is the low reference voltage for the converter.

The ADC can be configured to accept one of two voltage reference pairs for V_{REFSH} and V_{REFSL} . Each pair contains a positive reference and a ground reference. The two pairs are external, V_{REFH} and V_{REFL} and alternate, V_{ALTH} and V_{ALTL} . These voltage references are selected using $SC2[REFSEL]$. The alternate voltage reference pair, V_{ALTH} and V_{ALTL} , may select additional external pins or internal sources based on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

In some packages, the external or alternate pairs are connected in the package to V_{DDA} and V_{SSA} , respectively. One of these positive references may be shared on the same pin as V_{DDA} on some devices. One of these ground references may be shared on the same pin as V_{SSA} on some devices.

If externally available, the positive reference may be connected to the same potential as V_{DDA} or may be driven by an external source to a level between the minimum Ref Voltage High and the V_{DDA} potential. The positive reference must never exceed V_{DDA} . If externally available, the ground reference must be connected to the same voltage potential as V_{SSA} . The voltage reference pairs must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the V_{REFH} and V_{REFL} loop. The best external component to meet this current demand is a 0.1 μF capacitor with good

high-frequency characteristics. This capacitor is connected between V_{REFH} and V_{REFL} and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum, that is, parasitic only.

40.7.1.3 Analog input pins

The external analog inputs are typically shared with digital I/O pins on MCU devices.

Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01 μ F capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used, they must be placed as near as possible to the package pins and be referenced to V_{SSA} .

For proper conversion, the input voltage must fall between V_{REFH} and V_{REFL} . If the input is equal to or exceeds V_{REFH} , the converter circuit converts the signal to 0xFFF, which is full scale 12-bit representation, 0x3FF, which is full scale 10-bit representation, or 0xFF, which is full scale 8-bit representation. If the input is equal to or less than V_{REFL} , the converter circuit converts it to 0x000. Input voltages between V_{REFH} and V_{REFL} are straight-line linear conversions. There is a brief current associated with V_{REFL} when the sampling capacitor is charging.

For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins must not be transitioning during conversions.

40.7.2 Sources of error

40.7.2.1 Sampling error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy.

$$RAS + RADIN = SC / (FMAX * NUMTAU * CADIN)$$

Figure 40-4. Sampling equation

Where:

RAS = External analog source resistance

SC = Number of ADCK cycles used during sample window

CADIN = Internal ADC input capacitance

NUMTAU = $-\ln(\text{LSBERR} / 2^N)$

LSBERR = value of acceptable sampling error in LSBs

N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode or 16 in 16-bit mode

Higher source resistances or higher-accuracy sampling is possible by setting CFG1[ADLSMP] and changing CFG2[ADLSTS] to increase the sample window, or decreasing ADCK frequency to increase sample time.

40.7.2.2 Pin leakage error

Leakage on the I/O pins can cause conversion error if the external analog source resistance, R_{AS} , is high. If this error cannot be tolerated by the application, keep R_{AS} lower than $V_{REFH} / (4 \times I_{LEAK} \times 2^N)$ for less than 1/4 LSB leakage error, where N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode, or 16 in 16-bit mode.

40.7.2.3 Noise-induced errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1 μF low-ESR capacitor from V_{REFH} to V_{REFL} .
- There is a 0.1 μF low-ESR capacitor from V_{DDA} to V_{SSA} .
- If inductive isolation is used from the primary supply, an additional 1 μF capacitor is placed from V_{DDA} to V_{SSA} .
- V_{SSA} , and V_{REFL} , if connected, is connected to V_{SS} at a quiet point in the ground plane.
- Operate the MCU in Wait or Normal Stop mode before initiating (hardware-triggered conversions) or immediately after initiating (hardware- or software-triggered conversions) the ADC conversion.

- For software triggered conversions, immediately follow the write to SC1 with a Wait instruction or Stop instruction.
- For Normal Stop mode operation, select ADACK or an Alternate clock as the clock source. Operation in Normal Stop reduces V_{DD} noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive V_{DD} noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in Wait or Normal Stop mode, or I/O activity cannot be halted, the following actions may reduce the effect of noise on the accuracy:

- Place a 0.01 μF capacitor (C_{AS}) on the selected input channel to V_{REFL} or V_{SSA} . This improves noise issues, but affects the sample rate based on the external analog source resistance.
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1 LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock, that is, ADACK, and averaging. Noise that is synchronous to ADCK cannot be averaged out.

40.7.2.4 Code width and quantization error

The ADC quantizes the ideal straight-line transfer function into 65536 steps in the 16-bit mode.. Each step ideally has the same height, that is, 1 code, and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N-bit converter, where N can be 16, 12, 10, or 8, defined as 1 LSB, is:

$$1\text{LSB} = (V_{REFH}) / 2^N$$

Equation 3. Ideal code width for an N-bit converter

There is an inherent quantization error due to the digitization of the result. For 8-bit, 10-bit, or 12-bit conversions, the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be $\pm 1/2$ LSB in 8-bit, 10-bit, or 12-bit modes. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 LSB and the code width of the last (0xFF or 0x3FF) is 1.5 LSB.

For 16-bit conversions, the code transitions only after the full code width is present, so the quantization error is -1 LSB to 0 LSB and the code width of each step is 1 LSB.

40.7.2.5 Linearity errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors, but the system designers must be aware of these errors because they affect overall accuracy:

- Zero-scale error (E_{ZS}), sometimes called offset: This error is defined as the difference between the actual code width of the first conversion and the ideal code width. This is 1/2 LSB in 8-bit, 10-bit, or 12-bit modes and 1 LSB in 16-bit mode. If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 LSB) is used.
- Full-scale error (E_{FS}): This error is defined as the difference between the actual code width of the last conversion and the ideal code width. This is 1.5 LSB in 8-bit, 10-bit, or 12-bit modes and 1 LSB in 16-bit mode. If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1 LSB) is used.
- Differential non-linearity (DNL): This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL): This error is defined as the highest-value or absolute value that the running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE): This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

40.7.2.6 Code jitter, non-monotonicity, and missing codes

Analog-to-digital converters are susceptible to three special forms of error:

- Code jitter: Code jitter occurs when a given input voltage converts to one of the two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code, and vice-versa. However, even small amounts of system noise can cause the converter to be indeterminate, between two codes, for a range of input voltages around the transition voltage.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally, the techniques discussed in [Noise-induced errors](#) reduces this error.

- Non-monotonicity: Non-monotonicity occurs when, except for code jitter, the converter converts to a lower code for a higher input voltage.
- Missing codes: Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

Chapter 41

Comparator (CMP)

41.1 Chip-specific Comparator information

41.1.1 CMP instantiation information

NOTE

CMP0_out and CMP1_out inter-connected to the RX pin of LPUART0 and LPUART1 on chip. See [SIM](#) for details.

NOTE

CMP0_out inter-connects to the RX pin of UART0 on chip. See [SIM](#) for details.

41.1.2 CMP input connections

The following table shows the fixed internal connections to the CMP.

Table 41-1. CMP input connections

CMP Inputs	CMP0	CMP1
IN0	CMP0_IN0	CMP1_IN0
IN1	CMP0_IN1	CMP1_IN1
IN2	CMP0_IN2	CMP1_IN2
IN3	CMP0_IN3	12-bit DAC0_OUT/CMP1_IN3
IN4	—	—
IN5	VREF Output/CMP0_IN5	VREF Output/CMP1_IN5
IN6	Bandgap	Bandgap
IN7	6b DAC0 Reference	6b DAC1 Reference

41.1.3 CMP external references

The 6-bit DAC sub-block supports selection of two references. For this device, the references are connected as follows:

- VREF_OUT - V_{in1} input
- VDD - V_{in2} input

41.1.4 External window/sample input

Individual PDB pulse-out signals control each CMP Sample/Window timing.

41.1.5 CMP trigger mode

The CMP and 6-bit DAC sub-block supports trigger mode operation when the $CMPx\_CR1[TRIGM]$ is set. When trigger mode is enabled, the trigger event will initiate a compare sequence that must first enable the CMP and DAC prior to performing a CMP operation and capturing the output. In this device, control for this two staged sequencing is provided from the LPTMR0. The LPTMR0 provides a single trigger output to all implemented comparators. Through configuration of the $CMPx\_CR1[TRIGM]$ bits the trigger can be used to trigger a single comparator or multiple comparators concurrently. The LPTMR0 triggering output is always enabled when the LPTMR0 is enabled. The first signal is supplied to enable the CMP and DAC and is asserted at the same time as the TCF flag is set. The delay to the second signal that triggers the CMP to capture the result of the compare operation is dependent on the LPTMR0 configuration. In Time Counter mode with prescaler enabled, the delay is 1/2 Prescaler output period. In Time Counter mode with prescaler bypassed, the delay is 1/2 Prescaler clock period.

The delay between the first signal from LPTMR0 and the second signal from LPTMR0 must be greater than the Analog comparator initialization delay as defined in the device datasheet.

41.2 Introduction

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference V_{in} into 64 voltage levels. A 6-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/64$. V_{in} can be selected from two voltage sources, V_{in1} and V_{in2} . The 6-bit DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

41.2.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
 - Sampled
 - Windowed, which is ideal for certain PWM zero-crossing-detection applications
 - Digitally filtered:
 - Filter can be bypassed
 - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:
 - Shorter propagation delay at the expense of higher power
 - Low power, with longer propagation delay
- DMA transfer support
 - A comparison event can be selected to trigger a DMA transfer

- Functional in all modes of operation except VLLS0
- The window and filter functions are not available in the following modes:
 - Stop
 - VLPS
 - LLS
 - VLLSx

41.2.2 6-bit DAC key features

The 6-bit DAC has the following features:

- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

41.2.3 ANMUX key features

The ANMUX has the following features:

- Two 8-to-1 channel mux
- Operational over the entire supply range

41.2.4 CMP, DAC and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

Figure 41-1. CMP, DAC and ANMUX block diagram

41.2.5 CMP block diagram

The following figure shows the block diagram for the CMP module.

Figure 41-2. Comparator module block diagram

In the CMP block diagram:

- The Window Control block is bypassed when $CR1[WE] = 0$
- If $CR1[WE] = 1$, the comparator output will be sampled on every bus clock when $WINDOW=1$ to generate $COUTA$. Sampling does NOT occur when $WINDOW = 0$.
- The Filter block is bypassed when not in use.
- The Filter block acts as a simple sampler if the filter is bypassed and $CR0[FILTER\_CNT]$ is set to $0x01$.
- The Filter block filters based on multiple samples when the filter is bypassed and $CR0[FILTER\_CNT]$ is set greater than $0x01$.
 - If $CR1[SE] = 1$, the external $SAMPLE$ input is used as sampling clock
 - If $CR1[SE] = 0$, the divided bus clock is used as sampling clock

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which is crossing clock domain boundaries, must be resynchronized to the bus clock.
- CR1[WE] and CR1[SE] are mutually exclusive.

41.3 Memory map/register definitions

CMP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4007_3000	CMP Control Register 0 (CMP0_CR0)	8	R/W	00h	41.3.1/1149

Reset	0	0	0	0	0	0	0	0

CMPx_CR1 field descriptions

Field	Description
7 SE	Sample Enable At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing 1s to both field locations because this "11" case is reserved and may change in future implementations. 0 Sampling mode is not selected. 1 Sampling mode is selected.
6 WE	Windowing Enable

Table continues on the next page...

CMPx_CR1 field descriptions (continued)

Field	Description
	At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing 1s to both field locations because this "11" case is reserved and may change in future implementations. 0 Windowing mode is not selected. 1 Windowing mode is selected.
5 TRIGM	Trigger Mode Enable CMP and DAC are configured to CMP Trigger mode when CMP_CR1[TRIGM] is set to 1. In addition, the CMP should be enabled. If the DAC is to be used as a reference to the CMP, it should also be enabled. CMP Trigger mode depends on an external timer resource to periodically enable the CMP and 6-bit DAC in order to generate a triggered compare. Upon setting TRIGM, the CMP and DAC are placed in a standby state until an external timer resource trigger is received. See the chip configuration for details about the external timer resource. 0 Trigger mode is disabled. 1 Trigger mode is enabled.
4 PMODE	Power Mode Select See the electrical specifications table in the device Data Sheet for details. 0 Low-Speed (LS) Comparison mode selected. In this mode, CMP has slower output propagation delay and lower current consumption. 1 High-Speed (HS) Comparison mode selected. In this mode, CMP has faster output propagation delay and higher current consumption.
3 INV	Comparator INVERT Allows selection of the polarity of the analog comparator function. It is also driven to the COUT output, on both the device pin and as SCR[COUT], when OPE=0. 0 Does not invert the comparator output. 1 Inverts the comparator output.
2 COS	Comparator Output Select 0 Set the filtered comparator output (CMPO) to equal COUT. 1 Set the unfiltered comparator output (CMPO) to equal COUTA.
1 OPE	Comparator Output Pin Enable 0 CMPO is not available on the associated CMPO output pin. If the comparator does not own the pin, this field has no effect. 1 CMPO is available on the associated CMPO output pin. The comparator output (CMPO) is driven out on the associated CMPO output pin if the comparator owns the pin. If the comparator does not own the field, this bit has no effect.
0 EN	Comparator Module Enable Enables the Analog Comparator module. When the module is not enabled, it remains in the off state, and consumes no power. When the user selects the same input from analog mux to the positive and negative port, the comparator is disabled automatically.

Table continues on the next page...

CMPx_CR1 field descriptions (continued)

Field	Description
0	Analog Comparator is disabled.
1	Analog Comparator is enabled.

41.3.3 CMP Filter Period Register (CMPx_FPR)

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	FILT_PER							
Write								
Reset	0	0	0	0	0	0	0	0

CMPx_FPR field descriptions

Field	Description
FILT_PER	Filter Sample Period Specifies the sampling period, in bus clock cycles, of the comparator output filter, when CR1[SE]=0. Setting FILT_PER to 0x0 disables the filter. Filter programming and latency details appear in the Functional description. This field has no effect when CR1[SE]=1. In that case, the external SAMPLE signal is used to determine the sampling period.

41.3.4 CMP Status and Control Register (CMPx_SCR)

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0

41.4 Functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM.

CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CR1[INV] = 1.

SCR[IER] and SCR[IEF] are used to select the condition which will cause the CMP module to assert an interrupt to the processor. SCR[CFF] is set on a falling-edge and SCR[CFR] is set on rising-edge of the comparator output. The optionally filtered CMPO can be read directly through SCR[COUT].

41.4.1 CMP functional modes

There are the following main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CR0[FILTER_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CR1[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

Functional description

The "windowing mode" is enabled by setting CR1[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

Table 41-2. Comparator sample/filter controls

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation
1	0	X	X	X	X	Disabled See the Disabled mode (# 1) .
2A	1	0	0	0x00	X	Continuous Mode See the Continuous mode (#s 2A & 2B) .
2B	1	0	0	X	0x00	
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode See the Sampled, Non-Filtered mode (#s 3A & 3B) .
3B	1	0	0	0x01	> 0x00	
4A	1	0	1	> 0x01	X	Sampled, Filtered mode See the Sampled, Filtered mode (#s 4A & 4B) .
4B	1	0	0	> 0x01	> 0x00	
5A	1	1	0	0x00	X	Windowed mode Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA. See the Windowed mode (#s 5A & 5B) .
5B	1	1	0	X	0x00	
6	1	1	0	0x01	0x01–0xFF	Windowed/Resampled mode Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by FILT_PER to generate COUT. See the Windowed/Resampled mode (# 6) .
7	1	1	0	> 0x01	0x01–0xFF	Windowed/Filtered mode Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT. See the Windowed/Filtered mode (#7) .
All other combinations of CR1[EN], CR1[WE], CR1[SE], CR0[FILTER_CNT], and FPR[FILT_PER] are illegal.						

Note

Filtering and sampling settings must be changed only after setting CR1[SE]=0 and CR0[FILTER_CNT]=0x00. This resets the filter to a known state.

41.4.1.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

41.4.1.2 Continuous mode (#s 2A & 2B)

Figure 41-3. Comparator operation in Continuous mode

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. SCR[COUNT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unlocked mode. COUNT and COUNTA are identical.

For control configurations which result in disabling the filter block, see the [Filter Block Bypass Logic](#) diagram.

41.4.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)

Figure 41-4. Sampled, Non-Filtered (# 3A): sampling point externally driven

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising-edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

Figure 41-5. Sampled, Non-Filtered (# 3B): sampling interval internally derived

41.4.1.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, $CR0[FILTER\_CNT] > 1$, which activates filter operation.

Figure 41-6. Sampled, Filtered (# 4A): sampling point externally driven

Figure 41-8. Windowed mode operation

Figure 41-9. Windowed mode

For control configurations which result in disabling the filter block, see [Filter Block Bypass Logic](#) diagram.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

41.4.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in [Figure 41-8](#), and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

Figure 41-10. Windowed/resampled mode operation

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of CR0[FILTER_CNT] must be 1.

41.4.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function + $((CR0[FILTER\_CNT] * FPR[FILT\_PER]) + 1) * \text{bus clock}$ for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

Figure 41-11. Windowed/Filtered mode

41.4.2 Power modes

41.4.2.1 Wait mode operation

During Wait and VLPW modes, the CMP, if enabled, continues to operate normally and a CMP interrupt can wake the MCU.

41.4.2.2 Stop mode operation

Depending on clock restrictions related to the MCU core or core peripherals, the MCU is brought out of stop when a compare event occurs and the corresponding interrupt is enabled. Similarly, if CR1[OPE] is enabled, the comparator output operates as in the normal operating mode and comparator output is placed onto the external pin. In Stop modes, the comparator can be operational in both:

- High-Speed (HS) Comparison mode when CR1[PMODE] = 1
- Low-Speed (LS) Comparison mode when CR1[PMODE] = 0

It is recommended to use the LS mode to minimize power consumption.

If stop is exited with a reset, all comparator registers are put into their reset state.

41.4.2.3 Low-Leakage mode operation

When the chip is in Low-Leakage modes:

- The CMP module is partially functional and is limited to Low-Speed mode, regardless of CR1[PMODE] setting
- Windowed, Sampled, and Filtered modes are not supported
- The CMP output pin is latched and does not reflect the compare output state.

The positive- and negative-input voltage can be supplied from external pins or the DAC output. The MCU can be brought out of the Low-Leakage mode if a compare event occurs and the CMP interrupt is enabled. After wakeup from low-leakage modes, the CMP module is in the reset state except for SCR[CFF] and SCR[CFR].

41.4.3 Startup and operation

A typical startup sequence is listed here.

- The time required to stabilize COUT will be the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function and filter. See the Data Sheets for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the [Low-pass filter](#).
- During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and SCR[CFR]/SCR[CFF]

to reflect an input change or a configuration change to one of the components involved in the data path.

- When programmed for filtering modes, COUT will initially be equal to 0, until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

41.4.4 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT.

Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

41.4.4.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CR0[FILTER_CNT] > 0x01 and
- Setting FPR[FILT_PER] to a nonzero value or setting CR1[SE]=1

If using the divided bus clock to drive the filter, it will take samples of COUTA every FPR[FILT_PER] bus clock cycles.

The filter output will be at logic 0 when first initialized, and will subsequently change when all the consecutive CR0[FILTER_CNT] samples agree that the output value has changed. In other words, SCR[COUT] will be 0 for some initial period, even when COUTA is at logic 1.

Setting both CR1[SE] and FPR[FILT_PER] to 0 disables the filter and eliminates switching current associated with the filtering process.

Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CR0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CR1[SE]=1, the filter takes samples of COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CR0[FILTER_CNT] samples agree that the output value has changed.

41.4.4.2 Latency issues

The value of FPR[FILT_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CR0[FILTER_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CR0[FILTER_CNT].

The values of FPR[FILT_PER] or SAMPLE period and CR0[FILTER_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CR0[FILTER_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

Table 41-3. Comparator sample/filter maximum latencies

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation	Maximum latency ¹
1	0	X	X	X	X	Disabled	N/A
2A	1	0	0	0x00	X	Continuous Mode	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FPR[FILT\_PER] * T_{per}) + T_{per}$
4A	1	0	1	> 0x01	X	Sampled, Filtered mode	$T_{PD} + (CR0[FILTER\_CNT] * T_{SAMPLE}) + T_{per}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + T_{per}$

Table continues on the next page...

Table 41-3. Comparator sample/filter maximum latencies (continued)

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation	Maximum latency ¹
5A	1	1	0	0x00	X	Windowed mode	$T_{PD} + T_{per}$
5B	1	1	0	X	0x00		$T_{PD} + T_{per}$
6	1	1	0	0x01	0x01 - 0xFF	Windowed / Resampled mode	$T_{PD} + (FPR[FILT\_PER] * T_{per}) + 2T_{per}$
7	1	1	0	> 0x01	0x01 - 0xFF	Windowed / Filtered mode	$T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + 2T_{per}$

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

41.5 CMP interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both.

The following table gives the conditions in which the interrupt request is asserted and deasserted.

When	Then
SCR[IER] and SCR[CFR] are set	The interrupt request is asserted
SCR[IEF] and SCR[CFF] are set	The interrupt request is asserted
SCR[IER] and SCR[CFR] are cleared for a rising-edge interrupt	The interrupt request is deasserted
SCR[IEF] and SCR[CFF] are cleared for a falling-edge interrupt	The interrupt request is deasserted

41.6 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

41.7 CMP Asynchronous DMA support

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

41.8 Digital-to-analog converter

The figure found here shows the block diagram of the DAC module.

It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC Control Register (DACCR). Its supply reference source can be selected from two sources V_{in1} and V_{in2} . The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

Figure 41-12. 6-bit DAC block diagram

41.9 DAC functional description

This section provides DAC functional description information.

41.9.1 Voltage reference source select

- V_{in1} connects to the primary voltage source as supply reference of 64 tap resistor ladder
- V_{in2} connects to an alternate voltage source

41.10 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

41.11 DAC clocks

This module has a single clock input, the bus clock.

41.12 DAC interrupts

This module has no interrupts.

Chapter 42

Voltage Reference (VREFV1)

42.1 Chip-specific VREF information

42.1.1 VREF Overview

This device includes a voltage reference (VREF) to supply an accurate 1.2 V voltage output.

The voltage reference can provide a reference voltage to external peripherals or a reference to analog peripherals, such as the ADC , DAC, or CMP.

NOTE

PMC_REGSC[BGEN] bit must be set if the VREF regulator is required to remain operating in VLPx modes.

NOTE

For either an internal or external reference if the VREF_OUT functionality is being used, VREF_OUT signal must be connected to an output load capacitor. Refer the device data sheet for more details.

42.2 Introduction

The Voltage Reference (VREF) is intended to supply an accurate voltage output that can be trimmed in 0.5 mV steps. The VREF can be used in applications to provide a reference voltage to external devices or used internally as a reference to analog peripherals such as the ADC, DAC, or CMP. The voltage reference has three operating modes that provide different levels of supply rejection and power consumption.

The following figure is a block diagram of the Voltage Reference.

Figure 42-1. Voltage reference block diagram

42.2.1 Overview

The Voltage Reference provides a buffered reference voltage for use as an external reference. In addition, the buffered reference is available internally for use with on chip peripherals such as ADCs and DACs. Refer to the chip configuration details for a description of these options. The reference voltage signal is output on a dedicated output pin when the VREF is enabled. The Voltage Reference output can be trimmed with a resolution of 0.5mV by means of the TRM register TRIM[5:0] bitfield.

42.2.2 Features

The Voltage Reference has the following features:

- Programmable trim register with 0.5 mV steps, automatically loaded with factory trimmed value upon reset
- Programmable buffer mode selection:

- Off
- Bandgap enabled/standby (output buffer disabled)
- Low power buffer mode (output buffer enabled)
- High power buffer mode (output buffer enabled)
- 1.2 V output at room temperature
- Dedicated output pin, VREF_OUT

42.2.3 Modes of Operation

The Voltage Reference continues normal operation in Run, Wait, and Stop modes. The Voltage Reference can also run in Very Low Power Run (VLPR), Very Low Power Wait (VLPW) and Very Low Power Stop (VLPS). If it is desired to use the VREF regulator and/or the chop oscillator in the very low power modes, the system reference voltage (also referred to as the bandgap voltage reference) must be enabled in these modes. Refer to the chip configuration details for information on enabling this mode of operation. Having the VREF regulator enabled does increase current consumption. In very low power modes it may be desirable to disable the VREF regulator to minimize current consumption. Note however that the accuracy of the output voltage will be reduced (by as much as several mVs) when the VREF regulator is not used.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

42.2.4 VREF Signal Descriptions

The following table shows the Voltage Reference signals properties.

Table 42-1. VREF Signal Descriptions

Signal	Description	I/O
VREF_OUT	Internally-generated Voltage Reference output	O

NOTE

When the VREF output buffer is disabled, the status of the VREF_OUT signal is high-impedance.

42.3 Memory Map and Register Definition

VREF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4007_4000	VREF Trim Register (VREF_TRM)	8	R/W	See section	42.3.1/1176
4007_4001	VREF Status and Control Register (VREF_SC)	8	R/W	00h	42.3.2/1177

42.3.1 VREF Trim Register (VREF_TRM)

This register contains bits that contain the trim data for the Voltage Reference.

Address: 4007_4000h base + 0h offset = 4007_4000h

Bit	7	6	5	4	3	2	1	0
Read								
Write								
Reset	x*	0	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

VREF_TRM field descriptions

Field	Description
7 Reserved	This field is reserved. Upon reset this value is loaded with a factory trim value.
6 CHOPEN	Chop oscillator enable. When set, internal chopping operation is enabled and the internal analog offset will be minimized. This bit is set during factory trimming of the VREF voltage. This bit should be written to 1 to achieve the performance stated in the data sheet. If the internal voltage regulator is being used (REGEN bit is set to 1), the chop oscillator must also be enabled. If the chop oscillator is to be used in very low power modes, the system (bandgap) voltage reference must also be enabled. See the chip-specific VREF information (also known as "chip configuration" details) for a description of how this can be achieved. 0 Chop oscillator is disabled. 1 Chop oscillator is enabled.

Table continues on the next page...

VREF_TRM field descriptions (continued)

Field	Description
TRIM	Trim bits These bits change the resulting VREF by approximately ± 0.5 mV for each step. NOTE: Min = minimum and max = maximum voltage reference output. For minimum and maximum voltage reference output values, refer to the Data Sheet for this chip. 000000 Min 111111 Max

42.3.2 VREF Status and Control Register (VREF_SC)

This register contains the control bits used to enable the internal voltage reference and to select the buffer mode to be used.

Address: 4007_4000h base + 1h offset = 4007_4001h

Bit	7	6	5	4	3	2	1	0
Read	VREFEN	REGEN	ICOMPEN	0	0	VREFST	MODE_LV	
Write								
Reset	0	0	0	0	0	0	0	0

VREF_SC field descriptions

Field	Description
7 VREFEN	Internal Voltage Reference enable This bit is used to enable the bandgap reference within the Voltage Reference module. NOTE: After the VREF is enabled, turning off the clock to the VREF module via the corresponding clock gate register will not disable the VREF. VREF must be disabled via this VREFEN bit. 0 The module is disabled. 1 The module is enabled.
6 REGEN	Regulator enable This bit is used to enable the internal 1.75 V regulator to produce a constant internal voltage supply in order to reduce the sensitivity to external supply noise and variation. If it is desired to keep the regulator enabled in very low power modes, refer to the Chip Configuration details for a description on how this can be achieved. This bit should be written to 1 to achieve the performance stated in the data sheet. NOTE: See section Internal voltage regulator for details on the required sequence to enable the internal regulator.

Table continues on the next page...

VREF_SC field descriptions (continued)

Field	Description
	0 Internal 1.75 V regulator is disabled. 1 Internal 1.75 V regulator is enabled.
5 ICOMPEN	Second order curvature compensation enable This bit should be written to 1 to achieve the performance stated in the data sheet. 0 Disabled 1 Enabled
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 VREFST	Internal Voltage Reference stable This bit indicates that the bandgap reference within the Voltage Reference module has completed its startup and stabilization. NOTE: This bit is valid only when the chop oscillator is not being used. 0 The module is disabled or not stable. 1 The module is stable.
MODE_LV	Buffer Mode selection These bits select the buffer modes for the Voltage Reference module. 00 Bandgap on only, for stabilization and startup 01 High power buffer mode enabled 10 Low-power buffer mode enabled 11 Reserved

42.4 Functional Description

The Voltage Reference is a bandgap buffer system. Unity gain amplifiers are used.

The VREF_OUT signal can be used by both internal and external peripherals in low and high power buffer mode. A 100 nF capacitor must always be connected between VREF_OUT and VSSA if the VREF is being used.

The following table shows all possible function configurations of the Voltage Reference.

Table 42-2. Voltage Reference function configurations

SC[VREFEN]	SC[MODE_LV]	Configuration	Functionality
0	X	Voltage Reference disabled	Off
1	00	Voltage Reference enabled, bandgap on only	Startup and standby

Table continues on the next page...

Table 42-2. Voltage Reference function configurations (continued)

SC[VREFEN]	SC[MODE_LV]	Configuration	Functionality
1	01	Voltage Reference enabled, high-power buffer on	VREF_OUT available for internal and external use. 100 nF capacitor is required.
1	10	Voltage Reference enabled, low power buffer on	VREF_OUT available for internal and external use. 100 nF capacitor is required.
1	11	Reserved	Reserved

42.4.1 Voltage Reference Disabled, SC[VREFEN] = 0

When SC[VREFEN] = 0, the Voltage Reference is disabled, the VREF bandgap and the output buffers are disabled. The Voltage Reference is in off mode.

42.4.2 Voltage Reference Enabled, SC[VREFEN] = 1

When SC[VREFEN] = 1, the Voltage Reference is enabled, and different modes should be set by the SC[MODE_LV] bits.

42.4.2.1 SC[MODE_LV]=00

The internal VREF bandgap is enabled to generate an accurate 1.2 V output that can be trimmed with the TRM register's TRIM[5:0] bitfield. The bandgap requires some time for startup and stabilization. SC[VREFST] can be monitored to determine if the stabilization and startup is complete when the chop oscillator is not enabled.

If the chop oscillator is being used, the internal bandgap reference voltage settles within the chop oscillator start up time, T_{chop_osc_stup}.

The output buffer is disabled in this mode, and there is no buffered voltage output. The Voltage Reference is in standby mode. If this mode is first selected and the low power or high power buffer mode is subsequently enabled, there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (T_{stup}) and the value is specified in the appropriate device data sheet.

42.4.2.2 SC[MODE_LV] = 01

The internal VREF bandgap is on. The high power buffer is enabled to generate a buffered 1.2 V voltage to VREF_OUT. It can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from the standby mode (SC[MODE_LV] = 00, SC[VREFEN] = 1) there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled then you must wait the longer of Tstup or until SC[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, you must wait the time specified by Tchop_osc_stup (chop oscillator start up time) to ensure the VREF output has stabilized.

In this mode, a 100 nF capacitor is required to connect between the VREF_OUT pin and VSSA.

42.4.2.3 SC[MODE_LV] = 10

The internal VREF bandgap is on. The low power buffer is enabled to generate a buffered 1.2 V voltage to VREF_OUT. It can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from the standby mode (SC[MODE_LV] = 00, SC[VREFEN] = 1) there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled then you must wait the longer of Tstup or until SC[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, you must wait the time specified by Tchop_osc_stup (chop oscillator start up time) to ensure the VREF output has stabilized.

In this mode, a 100 nF capacitor is required to connect between the VREF_OUT pin and VSSA.

42.4.2.4 SC[MODE_LV] = 11

Reserved

42.4.3 Internal voltage regulator

The VREF module contains an internal voltage regulator that can be enabled to provide additional supply noise rejection. It is recommended that when possible, this regulator be enabled to provide the optimum VREF performance.

If the internal voltage regulator is being used, the chop oscillator must also be enabled. A specific sequence must be followed when enabling the internal regulator as follows:

1. Enable the chop oscillator ($VREF\_TRM[CHOPEN] = 1$)
2. Configure the $VREF\_SC$ register to the desired settings with the internal regulator disabled, $VREF\_SC[REGEN] = 0$
3. Wait $> 300ns$
4. Enable the internal regulator by setting $VREF\_SC[REGEN]$ to 1

42.5 Initialization/Application Information

The Voltage Reference requires some time for startup and stabilization. After $SC[VREFEN] = 1$, $SC[VREFST]$ can be monitored to determine if the stabilization and startup is completed when the chop oscillator is not enabled. When the chop oscillator is enabled, the settling time of the internal bandgap reference is defined by $T_{chop\_osc\_stup}$ (chop oscillator start up time). You must wait this time ($T_{chop\_osc\_stup}$) after the internal bandgap has been enabled to ensure the VREF internal reference voltage has stabilized.

When the Voltage Reference is already enabled and stabilized, changing $SC[MODE\_LV]$ will not clear $SC[VREFST]$ but there will be some startup time before the output voltage at the $VREF\_OUT$ pin has settled. This is the buffer start up delay (T_{stup}) and the value is specified in the appropriate device data sheet. Also, there will be some settling time when a step change of the load current is applied to the $VREF\_OUT$ pin. When the 1.75V VREF regulator is disabled, the $VREF\_OUT$ voltage will be more sensitive to supply voltage variation. It is recommended to use this regulator to achieve optimum $VREF\_OUT$ performance.

The $TRM[CHOPEN]$, $SC[REGEN]$ and $SC[ICOMPEN]$ bits must be written to 1 to achieve the performance stated in the device data sheet.

NOTE

See section "Internal voltage regulator" for details on the required sequence to enable the internal regulator.

Chapter 43

12-bit Digital-to-Analog Converter (DAC)

43.1 Chip-specific DAC information

43.1.1 12-bit DAC Overview

This device contains 1 instance of a 12-bit digital-to-analog converter (DAC) with programmable reference generator output. The DAC includes a FIFO for DMA support.

43.1.2 12-bit DAC Output

The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.

43.1.3 12-bit DAC Reference

For this device VREF_OUT and VDDA are selectable as the DAC reference. VREF_OUT is connected to the DACREF_1 input and VDDA is connected to the DACREF_2 input. Use DACx_C0[DACRFS] control bit to select between these two options.

Be aware that if the DAC and ADC use the VREF_OUT reference simultaneously, some degradation of ADC accuracy is to be expected due to DAC switching.

43.2 Introduction

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

43.3 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from $1/4096 V_{in}$ to V_{in} , and the step is $1/4096 V_{in}$, where V_{in} is the input voltage.
- V_{in} can be selected from two reference sources
- Static operation in Normal Stop mode
- 16-word data buffer supported with configurable watermark and multiple operation modes
- DMA support

43.4 Block diagram

The block diagram of the DAC module is as follows:

Figure 43-1. DAC block diagram

43.5 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

43.5.1 DAC Data Low Register (DACx_DATnL)

Address: 400C_C000h base + 0h offset + (2d × i), where i=0d to 15d

Bit	7	6	5	4	3	2	1	0
Read	DATA0							
Write								
Reset	0	0	0	0	0	0	0	0

DACx_DATnL field descriptions

Field	Description
DATA0	DATA0 When the DAC buffer is not enabled, DATA[11:0] controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DACDAT0[11:0])/4096$ When the DAC buffer is enabled, DATA is mapped to the 16-word buffer.

43.5.2 DAC Data High Register (DACx_DATnH)

Address: 400C_C000h base + 1h offset + (2d × i), where i=0d to 15d

Bit	7	6	5	4	3	2	1	0
Read	0				DATA1			
Write								
Reset	0	0	0	0	0	0	0	0

DACx_DATnH field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DATA1	DATA1 When the DAC Buffer is not enabled, DATA[11:0] controls the output voltage based on the following formula. $V_{out} = V_{in} * (1 + DACDAT0[11:0])/4096$ When the DAC buffer is enabled, DATA[11:0] is mapped to the 16-word buffer.

43.5.3 DAC Status Register (DACx_SR)

If DMA is enabled, the flags can be cleared automatically by DMA when the DMA request is done. Writing 0 to a field clears it whereas writing 1 has no effect. After reset, DACBFRPTF is set and can be cleared by software, if needed. The flags are set only when the data buffer status is changed.

Address: 400C_C000h base + 20h offset = 400C_C020h

Bit	7	6	5	4	3	2	1	0
Read	0					DACBFWM	DACBFRPT	DACBFRPB
Write						F	F	F
Reset	0	0	0	0	0	0	1	0

DACx_SR field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 DACBFWMF	DAC Buffer Watermark Flag This bit is set if the remaining FIFO data is less than the watermark setting. It is cleared automatically by writing data into FIFO by DMA or CPU. Write to this bit is ignored in FIFO mode. 0 The DAC buffer read pointer has not reached the watermark level. 1 The DAC buffer read pointer has reached the watermark level.
1 DACBFRPTF	DAC Buffer Read Pointer Top Position Flag In FIFO mode, it is FIFO nearly empty flag. It is set when only one data remains in FIFO. Any DAC trigger does not increase the Read Pointer if this bit is set to avoid any possible glitch or abrupt change at DAC output. It is cleared automatically if FIFO is not empty. 0 The DAC buffer read pointer is not zero. 1 The DAC buffer read pointer is zero.
0 DACBFRPBF	DAC Buffer Read Pointer Bottom Position Flag In FIFO mode, it is FIFO FULL status bit. It means FIFO read pointer equals Write Pointer because of Write Pointer increase. If this bit is set, any write to FIFO from either DMA or CPU is ignored by DAC. It is cleared if there is any DAC trigger making the DAC read pointer increase. Write to this bit is ignored in FIFO mode. 0 The DAC buffer read pointer is not equal to C2[DACBFUP]. 1 The DAC buffer read pointer is equal to C2[DACBFUP].

43.5.4 DAC Control Register (DACx_C0)

Address: 400C_C000h base + 21h offset = 400C_C021h

Bit	7	6	5	4	3	2	1	0
Read	DACEN	DACRFS	DACTRGSEL	0	LPEN	DACBWIEN	DACBTIEN	DACBBIEN
Write			L	DACSWTRG				
Reset	0	0	0	0	0	0	0	0

DACx_C0 field descriptions

Field	Description
7 DACEN	DAC Enable Starts the Programmable Reference Generator operation. 0 The DAC system is disabled. 1 The DAC system is enabled.
6 DACRFS	DAC Reference Select 0 The DAC selects DACREF_1 as the reference voltage. 1 The DAC selects DACREF_2 as the reference voltage.
5 DACTRGSEL	DAC Trigger Select 0 The DAC hardware trigger is selected. 1 The DAC software trigger is selected.
4 DACSCTR	DAC Software Trigger Active high. This is a write-only field, which always reads 0. If DAC software trigger is selected and buffer is enabled, writing 1 to this field will advance the buffer read pointer once. 0 The DAC soft trigger is not valid. 1 The DAC soft trigger is valid.
3 LPEN	DAC Low Power Control NOTE: See the 12-bit DAC electrical characteristics of the device data sheet for details on the impact of the modes below. 0 High-Power mode 1 Low-Power mode
2 DACBWIEN	DAC Buffer Watermark Interrupt Enable 0 The DAC buffer watermark interrupt is disabled. 1 The DAC buffer watermark interrupt is enabled.
1 DACBTIEN	DAC Buffer Read Pointer Top Flag Interrupt Enable 0 The DAC buffer read pointer top flag interrupt is disabled. 1 The DAC buffer read pointer top flag interrupt is enabled.
0 DACBBIEN	DAC Buffer Read Pointer Bottom Flag Interrupt Enable

Table continues on the next page...

DACx_C0 field descriptions (continued)

Field	Description
0	The DAC buffer read pointer bottom flag interrupt is disabled.
1	The DAC buffer read pointer bottom flag interrupt is enabled.

43.5.5 DAC Control Register 1 (DACx_C1)

Address: 400C_C000h base + 22h offset = 400C_C022h

Bit	7	6	5	4	3	2	1	0
Read	DMAEN	0			DACBFWM	DACBFMD		DACBFEN
Write								
Reset	0	0	0	0	0	0	0	0

DACx_C1 field descriptions

Field	Description
7 DMAEN	DMA Enable Select 0 DMA is disabled. 1 DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.
6–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–3 DACBFWM	DAC Buffer Watermark Select In normal mode it controls when SR[DACBFWMF] is set. When the DAC buffer read pointer reaches the word defined by this field, which is 1–4 words away from the upper limit (DACBUP), SR[DACBFWMF] will be set. This allows user configuration of the watermark interrupt. In FIFO mode, it is FIFO watermark select field. 00 In normal mode, 1 word . In FIFO mode, 2 or less than 2 data remaining in FIFO will set watermark status bit. 01 In normal mode, 2 words . In FIFO mode, Max/4 or less than Max/4 data remaining in FIFO will set watermark status bit. 10 In normal mode, 3 words . In FIFO mode, Max/2 or less than Max/2 data remaining in FIFO will set watermark status bit. 11 In normal mode, 4 words . In FIFO mode, Max-2 or less than Max-2 data remaining in FIFO will set watermark status bit.
2–1 DACBFMD	DAC Buffer Work Mode Select 00 Normal mode 01 Swing mode 10 One-Time Scan mode 11 FIFO mode
0 DACBFEN	DAC Buffer Enable 0 Buffer read pointer is disabled. The converted data is always the first word of the buffer. 1 Buffer read pointer is enabled. The converted data is the word that the read pointer points to. It means converted data can be from any word of the buffer.

43.5.6 DAC Control Register 2 (DACx_C2)

Address: 400C_C000h base + 23h offset = 400C_C023h

Bit	7	6	5	4	3	2	1	0
Read	DACBFRP				DACBFUP			
Write								
Reset	0	0	0	0	1	1	1	1

DACx_C2 field descriptions

Field	Description
7–4 DACBFRP	DAC Buffer Read Pointer In normal mode it keeps the current value of the buffer read pointer. FIFO mode, it is the FIFO read pointer. It is writable in FIFO mode. User can configure it to same address to reset FIFO as empty.
DACBFUP	DAC Buffer Upper Limit In normal mode it selects the upper limit of the DAC buffer. The buffer read pointer cannot exceed it. In FIFO mode it is the FIFO write pointer. User cannot set Buffer Up limit in FIFO mode. In Normal mode its reset value is MAX. When IP is configured to FIFO mode, this register becomes Write_Pointer, and its value is initially set to equal READ_POINTER automatically, and the FIFO status is empty. It is writable and user can configure it to the same address to reset FIFO as empty.

43.6 Functional description

The 12-bit DAC module can select one of the two reference inputs—DACREF_1 and DACREF_2 as the DAC reference voltage, V_{in} by C0 [DACRFS]. See the chip-specific DAC information to determine the source options for DACREF_1 and DACREF_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from V_{in} to $V_{in}/4096$, and the step is $V_{in}/4096$.

43.6.1 DAC data buffer operation

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in DAT0 to the analog output voltage.

When both the DAC and the buffer are enabled, the DAC converts the data in the data buffer to analog output voltage. The data buffer read pointer advances to the next word whenever a hardware or software trigger event occurs.

The data buffer can be configured to operate in Normal mode, Swing mode, One-Time Scan mode or FIFO mode. When the buffer operation is switched from one mode to another, the read pointer does not change. The read pointer can be set to any value between 0 and C2[DACBFUP] by writing C2[DACBFRP].

43.6.1.1 DAC data buffer interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer. SR[DACBFRPBF] is set when the DAC buffer read pointer reaches the DAC buffer upper limit, that is, C2[DACBFRP] = C2[DACBFUP]. SR[DACBFRPTF] is set when the DAC read pointer is equal to the start position, 0. Finally, SR[DACBFWMF] is set when the DAC buffer read pointer has reached the position defined by C1[DACBFWM]. C1[DACBFWM] can be used to generate an interrupt when the DAC buffer read pointer is between 1 to 4 words from C2[DACBFUP].

43.6.1.2 Modes of DAC data buffer operation

The following table describes the different modes of data buffer operation for the DAC module.

Table 43-1. Modes of DAC data buffer operation

Modes	Description
Buffer Normal mode	This is the default mode. The buffer works as a circular buffer. The read pointer increases by one, every time the trigger occurs. When the read pointer reaches the upper limit, it goes to 0 directly in the next trigger event.
Buffer Swing mode	This mode is similar to the normal mode. However, when the read pointer reaches the upper limit, it does not go to 0. It will descend by 1 in the next trigger events until 0 is reached.
Buffer One-time Scan mode	The read pointer increases by 1 every time the trigger occurs. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it will increase to the upper address and stop there again. NOTE: If the software set the read pointer to the upper limit, the read pointer will not advance in this mode.
FIFO Mode	In FIFO mode, the buffer is organized as a FIFO. For a valid write to any DACDATx, the data is put into the FIFO, and the write pointer is automatically incremented. The module is connected internally to a 32bit interface. For any 16bit or 8bit FIFO access, address bit[1] needs to be 0; otherwise, the write is ignored. For any 32bit FIFO access, the Write_Pointer needs to be an EVEN number; otherwise, the write is ignored.

Table 43-1. Modes of DAC data buffer operation

Modes	Description
	NOTE: A successful 32bit FIFO write will increase the write pointer by 2. Any write will cause the FIFO over-flow will be ignored, the cases includes: 1.FIFO is full, the write will be ignored. 2.FIFO is nearly full (FIFO_SIZE-1), 32bit write will be ignored. NOTE: For 8bit write, address bit[0] determine which byte lane will be written to the FIFO according to little endian alignment. Only both byte lanes are written will the write pointer increase. User need to make sure 8bit access happened in pair and both upper & lower bytes are written. There is no requirement on which byte write first. In FIFO mode, there is no change to read access of DACDATx (from normal mode), read to DACDATx will return the DATA addressed by the access address to the data buffer, and both write pointer and read pointer in FIFO mode will NOT be changed by read access. FIFO write can be happened when DAC is not enabled for 1st data conversion enable. But FIFO mode need to work at buffer Enabled at DACC1[DACBFEN]. In FIFO mode, the DATA BUF will be organized as FIFO.

43.6.2 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

43.6.3 Resets

During reset, the DAC is configured in the default mode and is disabled.

43.6.4 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

Table 43-2. Modes of operation

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	If enabled, the DAC module continues to operate in Normal Stop mode and the output voltage will hold the value before stop. In low-power stop modes, the DAC is fully shut down.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

Chapter 44

FlexTimer Module (FTM)

44.1 Chip-specific FTM information

44.1.1 Instantiation Information

This device contains FlexTimer modules:

- FTM0
- FTM1
- FTM2
- FTM3

The following table shows how these modules are configured.

Table 44-1. FTM Instantiations

FTM instance	Number of channels	Features/usage
FTM0	8	3-phase motor + 2 general purpose or stepper motor
FTM1	2	Quadrature decoder or general purpose
FTM2	2 ¹	Quadrature decoder or general purpose
FTM3	8	3-phase motor + 2 general purpose or stepper motor

1. Only channels 0 and 1 are available.

The configuration of FTM1 and FTM2 adds the Quadrature decoder feature and reduces the number of channels.

44.1.2 External Clock Options

By default each FTM is clocked by the internal bus clock (the FTM refers to it as system clock). Each module contains a register setting that allows the module to be clocked from an external clock instead. There are two external FTM_CLKINx pins that can be selected by any FTM module via the SIM_SOPT4 register.

44.1.3 Fixed frequency clock

The fixed frequency clock for each FTM is MCGFFCLK.

44.1.4 FTM Interrupts

The FlexTimer has multiple sources of interrupts. However, these sources are OR'd together to generate a single interrupt request per FTM module to the interrupt controller. When an FTM interrupt occurs, read the FTM status registers (FMS, SC, and STATUS) to determine the exact interrupt source.

44.1.5 FTM Fault Detection Inputs

The following fault detection input options for the FTM modules are selected via the SIM_SOPT4 register. The external pin option is selected by default.

- FTM0 FAULT0 = FTM0_FLT0 pin or CMP0 output
- FTM0 FAULT1 = FTM0_FLT1 pin or CMP1 output
- FTM0 FAULT2 = FTM0_FLT2 pin
- FTM0 FAULT3 = FTM0_FLT3 pin
- FTM1 FAULT0 = FTM1_FLT0 pin or CMP0 output
- FTM1 FAULT1 = CMP1 output
- FTM2 FAULT0 = FTM2_FLT0 pin or CMP0 output
- FTM2 FAULT1 = CMP1 output
- FTM3 FAULT0 = FTM3_FLT0 pin or CMP0 output

44.1.6 FTM Hardware Triggers

The FTM synchronization hardware triggers are connected in the chip as follows:

- FTM0 hardware trigger 0 = SIM_SOPT8[FTM0SYNCBIT] or CMP0 Output or FTM1 Match (when enabled in the FTM1 External Trigger (EXTTRIG) register)
- FTM0 hardware trigger 1 = PDB channel 1 Trigger Output or FTM2 Match (when enabled in the FTM2 External Trigger (EXTTRIG) register)
- FTM0 hardware trigger 2 = FTM0_FLT0 pin
- FTM1 hardware trigger 0 = SIM_SOPT8[FTM1SYNCBIT] or CMP0 Output
- FTM1 hardware trigger 1 = CMP1 Output
- FTM1 hardware trigger 2 = FTM1_FLT0 pin
- FTM2 hardware trigger 0 = SIM_SOPT8[FTM2SYNCBIT] or CMP0 Output
- FTM2 hardware trigger 1 = Reserved
- FTM2 hardware trigger 2 = FTM2_FLT0 pin
- FTM3 hardware trigger 0 = SIM_SOPT8[FTM3SYNCBIT] or FTM1 Match (when enabled in the FTM1 External Trigger (EXTTRIG) register)
- FTM3 hardware trigger 1 = FTM2 Match (when enabled in the FTM2 External Trigger (EXTTRIG) register)
- FTM3 hardware trigger 2 = FTM3_FLT0 pin

Having FTMxSYNCBIT fields in the same SOPTx register allows the user to synchronise all FTM timers via their respective TRIG0 input. For the triggers with more than one additional option, the SIM_SOPT4 register implements control fields for selecting the option.

44.1.7 Input capture options for FTM module instances

The following channel 0 input capture source options are selected via SIM_SOPT4. The external pin option is selected by default.

- FTM1 channel 0 input capture = FTM1_CH0 pin or CMP0 output or CMP1 output or USB start of frame pulse
- FTM2 channel 0 input capture = FTM2_CH0 pin or CMP0 output or CMP1 output
- FTM2 channel 1 input capture = FTM2_CH1 pin or exclusive OR of FTM2_CH0, FTM2_CH1, and FTM1_CH1. See [FTM Hall sensor support](#).

NOTE

When the USB start of frame pulse option is selected as an FTM channel input capture, disable the USB SOF token interrupt in the USB Interrupt Enable register (INTEN[SOFTOKEN]) to avoid USB enumeration conflicts.

44.1.8 FTM Hall sensor support

For 3 phase motor control sensor-ed applications the use of Hall sensors, generally 3 sensors placed 120 degrees apart around the rotor, are deployed to detect position and speed. Each of the 3 sensors provides a pulse that applied to an input capture pin, can then be analyzed and both speed and position can be deduced. This device has two 2-channel FTMs. (FTM1 and FTM2) and thus provides 4 input capture pins. To simplify the calculations required by the CPU on each hall sensor's input, if all 3 inputs are "exclusively OR'd " into one timer channel and the free running counter is refreshed on every edge then this can simplify the speed calculation.

Via the SIM module and SIM_SOPT4 register the FTM2CH1SRC bit provides the choice of normal FTM2_CH1 input or the XOR of FTM2_CH0, FTM2_CH1 and FTM1_CH1 pins that will be applied to FTM2_CH1.

Note: If the user utilizes FTM1_CH1 to be an input to FTM2_CH1, FTM1_CH0 can still be utilized for other functions.

Figure 44-1. FTM Hall Sensor Configuration

44.1.9 FTM modulation implementation

FTM0 and FTM3 support a modulation function where the output channels when configured as PWM or Output Compare mode modulate another timer output when the channel signal is asserted. Any of the 8 channels of FTM0 and any of the 8 channels of FTM3 can be configured to support this modulation function.

The SIM_SOPT8 register has eight control bits (FTM0CHySRC) that allow the user to select normal PWM/Output Compare mode on the corresponding FTM timer channel or modulate with FTM1_CH1. The diagram below shows the implementation for FTM0.

FTM3 has similar implementation controlled by SIM_SOPT8[FTM3CHySRC] on each of its 8 channels with modulation possible via FTM2_CH1. See SIM Block Guide for further information.

When FTM1_CH1 is used to modulate an FTM0 channel, then the user must configure FTM1_CH1 to provide a signal that has a higher frequency than the modulated FTM0 channel output. Also it limits the use of the FTM1_CH0 function, as the FTM1_CH1 will be programmed to provide a 50% duty PWM signal and limit the start and modulus values for the free running counter. FTM2 has a similar restriction when FTM2_CH1 is used for modulating an FTM3 channel.

Figure 44-2. FTM Output Modulation

44.1.10 FTM output triggers for other modules

FTM output triggers can be selected as input triggers for the PDB and ADC modules. See [PDB Instantiation](#) and [ADC triggers](#).

44.1.11 FTM Global Time Base

This chip provides the optional FTM global time base feature (see [Global time base \(GTB\)](#)).

FTM0 provides the only source for the FTM global time base. The other FTM modules can share the time base as shown in the following figure:

Figure 44-3. FTM Global Time Base Configuration

Figure 44-4. FTM Global Time Base Configuration

Figure 44-5. FTM Global Time Base Configuration

44.1.12 FTM BDM and debug halt mode

In the FTM chapter, references to the chip being in "BDM" are the same as the chip being in "debug halt mode".

44.2 Introduction

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

44.2.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the Timer PWM Module – TPM, used for many years on our HCS08 family of 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Fault control inputs
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, fault control, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

More than one FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

44.2.2 Features

The FTM features include:

- FTM source clock is selectable.
 - The source clock can be the system clock, the fixed frequency clock, or an external clock
 - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
 - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter
 - It can be a free-running counter or a counter with initial and final value
 - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:
 - The capture can occur on rising edges, falling edges or both edges
 - An input filter can be selected for some channels

- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Initialization trigger
- Software control of PWM outputs
- Up to 4 fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

44.2.3 Modes of operation

When the chip is in an active BDM mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a

real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

44.2.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CH_n (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

Figure 44-6. FTM block diagram

44.3 FTM signal descriptions

Table 44-2 shows the user-accessible signals for the FTM.

Table 44-2. FTM signal descriptions

Signal	Description	I/O	Function
EXTCLK	External clock. FTM external clock can be selected to drive the FTM counter.	I	The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.
CHn	FTM channel (n), where n can be 7-0	I/O	Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.
FAULTj	Fault input (j), where j can be 3-0	I	The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINEm register. Note that each FAULTj input may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Because there are several FAULTj inputs, maximum of 4 for the FTM module, each one of these inputs is activated by the FAULTJEN bit in the FLTCTRL register.
PHA	Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A.	I	The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder mode .
PHB	Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B.	I	The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder mode .

44.4 Memory map and register definition

44.4.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

Note

Do not write in the region from the CNTIN register through the PWMLOAD register when FTMEN = 0.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

44.4.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

44.4.3 Status And Control (FTMx_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

Address: Base address + 0h offset

FTMx_SC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TOF	Timer Overflow Flag Set by hardware when the FTM counter passes the value in the MOD register. The TOF bit is cleared by reading the SC register while TOF is set and then writing a 0 to TOF bit. Writing a 1 to TOF has no effect. If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case, a TOF interrupt request is not lost due to the clearing sequence for a previous TOF. 0 FTM counter has not overflowed. 1 FTM counter has overflowed.

Table continues on the next page...

FTMx_SC field descriptions (continued)

Field	Description
6 TOIE	Timer Overflow Interrupt Enable Enables FTM overflow interrupts. 0 Disable TOF interrupts. Use software polling. 1 Enable TOF interrupts. An interrupt is generated when TOF equals one.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the FTM to operate in Up-Down Counting mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 FTM counter operates in Up Counting mode. 1 FTM counter operates in Up-Down Counting mode.
4–3 CLKS	Clock Source Selection Selects FTM counter clock sources. This field is write protected. It can be written only when MODE[WPDIS] = 1. 00 No clock selected. This in effect disables the FTM counter. 01 System clock 10 Fixed frequency clock 11 External clock
PS	Prescale Factor Selection Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits. This field is write protected. It can be written only when MODE[WPDIS] = 1. 000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128

44.4.4 Counter (FTMx_CNT)

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter Value

44.4.5 Modulo (FTMx_MOD)

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see [Counter](#).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset

FTMx_CnSC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CHF	Channel Flag Set by hardware when an event occurs on the channel. CHF is cleared by reading the CSC register while CHnF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect. If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF. 0 No channel event has occurred. 1 A channel event has occurred.
6 CHIE	Channel Interrupt Enable Enables channel interrupts. 0 Disable channel interrupts. Use software polling. 1 Enable channel interrupts.
5 MSB	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See Table 44-3 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
4 MSA	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See Table 44-3 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
3 ELSB	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. See Table 44-3 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
2 ELSA	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. See Table 44-3 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
1 ICRST	FTM counter reset by the selected input capture event. FTM counter reset is driven by the selected event of the channel (n) in the Input Capture mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 FTM counter is not reset when the selected channel (n) input event is detected. 1 FTM counter is reset when the selected channel (n) input event is detected.
0 DMA	DMA Enable Enables DMA transfers for the channel. 0 Disable DMA transfers. 1 Enable DMA transfers.

44.4.7 Channel (n) Value (FTMx_CnV)

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FTMx_CnV field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
VAL	Channel Value Captured FTM counter value of the input modes or the match value for the output modes

44.4.8 Counter Initial Value (FTMx_CNTIN)

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

FTMx_CNTIN field descriptions

Field	Description
31–16 Reserved	This field is reserved.
INIT	Initial Value Of The FTM Counter

44.4.9 Capture And Compare Status (FTMx_STATUS)

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

44.4.10 Features Mode Selection (FTMx_MODE)

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Fault control mode and interrupt
- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

Address: Base address + 54h offset

FTMx_MODE field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 FAULTIE	Fault Interrupt Enable Enables the generation of an interrupt when a fault is detected by FTM and the FTM fault control is enabled. 0 Fault control interrupt is disabled. 1 Fault control interrupt is enabled.
6–5 FAULTM	Fault Control Mode Defines the FTM fault control mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 00 Fault control is disabled for all channels. 01 Fault control is enabled for even channels only (channels 0, 2, 4, and 6), and the selected mode is the manual fault clearing. 10 Fault control is enabled for all channels, and the selected mode is the manual fault clearing. 11 Fault control is enabled for all channels, and the selected mode is the automatic fault clearing.
4 CAPTEST	Capture Test Mode Enable Enables the capture test mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Capture test mode is disabled. 1 Capture test mode is enabled.
3 PWMSYNC	PWM Synchronization Mode Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See PWM synchronization . The PWMSYNC bit configures the synchronization when SYNCMODE is 0. 0 No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. 1 Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.
2 WPDIS	Write Protection Disable When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect. 0 Write protection is enabled. 1 Write protection is disabled.
1 INIT	Initialize The Channels Output When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect. The INIT bit is always read as 0.
0 FTMEN	FTM Enable This field is write protected. It can be written only when MODE[WPDIS] = 1.

Table continues on the next page...

FTMx_MODE field descriptions (continued)

Field	Description
0	TPM compatibility. Free running counter and synchronization compatible with TPM.
1	Free running counter and synchronization are different from TPM behavior.

44.4.11 Synchronization (FTMx_SYNC)

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

NOTE

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See [PWM synchronization](#).

Address: Base address + 58h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWSYNC	PWM Synchronization Software Trigger Selects the software trigger as the PWM synchronization trigger. The software trigger happens when a 1 is written to SWSYNC bit. 0 Software trigger is not selected. 1 Software trigger is selected.
6 TRIG2	PWM Synchronization Hardware Trigger 2 Enables hardware trigger 2 to the PWM synchronization. Hardware trigger 2 happens when a rising edge is detected at the trigger 2 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
5 TRIG1	PWM Synchronization Hardware Trigger 1 Enables hardware trigger 1 to the PWM synchronization. Hardware trigger 1 happens when a rising edge is detected at the trigger 1 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
4 TRIG0	PWM Synchronization Hardware Trigger 0 Enables hardware trigger 0 to the PWM synchronization. Hardware trigger 0 occurs when a rising edge is detected at the trigger 0 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
3 SYNCHOM	Output Mask Synchronization Selects when the OUTMASK register is updated with the value of its buffer. 0 OUTMASK register is updated with the value of its buffer in all rising edges of the system clock. 1 OUTMASK register is updated with the value of its buffer only by the PWM synchronization.
2 REINIT	FTM Counter Reinitialization By Synchronization (FTM counter synchronization) Determines if the FTM counter is reinitialized when the selected trigger for the synchronization is detected. The REINIT bit configures the synchronization when SYNCMODE is zero. 0 FTM counter continues to count normally. 1 FTM counter is updated with its initial value when the selected trigger is detected.

Table continues on the next page...

FTMx_SYNC field descriptions (continued)

Field	Description
1 CNTMAX	Maximum Loading Point Enable Selects the maximum loading point to PWM synchronization. See Boundary cycle and loading points. If CNTMAX is 1, the selected loading point is when the FTM counter reaches its maximum value (MOD register). 0 The maximum loading point is disabled. 1 The maximum loading point is enabled.
0 CNTMIN	Minimum Loading Point Enable Selects the minimum loading point to PWM synchronization. See Boundary cycle and loading points. If CNTMIN is one, the selected loading point is when the FTM counter reaches its minimum value (CNTIN register). 0 The minimum loading point is disabled. 1 The minimum loading point is enabled.

0 CH0OI	Channel 0 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.

44.4.13 Output Mask (FTMx_OUTMASK)

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Memory map and register definition

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

Address: Base address + 60h offset

31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FAULTEN3	Fault Control Enable For n = 6 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
29 SYNCEN3	Synchronization Enable For n = 6 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
28 DTEN3	Deadtime Enable For n = 6 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
27 DECAP3	Dual Edge Capture Mode Captures For n = 6 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
26 DECAPEN3	Dual Edge Capture Mode Enable For n = 6 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 44-3 . This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
25 COMP3	Complement Of Channel (n) for n = 6 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
24 COMBINE3	Combine Channels For $n = 6$ Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when $MODE[WPDIS] = 1$. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 FAULTEN2	Fault Control Enable For $n = 4$ Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when $MODE[WPDIS] = 1$. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
21 SYNCEN2	Synchronization Enable For $n = 4$ Enables PWM synchronization of registers $C(n)V$ and $C(n+1)V$. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
20 DTEN2	Deadtime Enable For $n = 4$ Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when $MODE[WPDIS] = 1$. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
19 DECAP2	Dual Edge Capture Mode Captures For $n = 4$ Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when $DECAPEN = 1$. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
18 DECAPEN2	Dual Edge Capture Mode Enable For $n = 4$ Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of $MSnA$, $ELSnB:ELSnA$ and $ELSn+1B:ELSn+1A$ bits in Dual Edge Capture mode according to Table 44-3. This field is write protected. It can be written only when $MODE[WPDIS] = 1$. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
17 COMP2	Complement Of Channel (n) For $n = 4$

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
16 COMBINE2	Combine Channels For n = 4 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 FAULTEN1	Fault Control Enable For n = 2 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
13 SYNCEN1	Synchronization Enable For n = 2 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
12 DTEN1	Deadtime Enable For n = 2 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
11 DECAP1	Dual Edge Capture Mode Captures For n = 2 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if Dual Edge Capture – One-Shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
10 DECAPEN1	Dual Edge Capture Mode Enable For n = 2 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 44-3.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
9 COMP1	Complement Of Channel (n) For n = 2 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
8 COMBINE1	Combine Channels For n = 2 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FAULTEN0	Fault Control Enable For n = 0 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
5 SYNCEN0	Synchronization Enable For n = 0 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
4 DTEN0	Deadtime Enable For n = 0 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
3 DECAP0	Dual Edge Capture Mode Captures For n = 0 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
2 DECAPEN0	Dual Edge Capture Mode Enable For n = 0 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 44-3. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
1 COMP0	Complement Of Channel (n) For n = 0 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
0 COMBINE0	Combine Channels For n = 0 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.

44.4.15 Deadtime Insertion Control (FTMx_DEADTIME)

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																DTPS								DTVAL							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

FTMx_DEADTIME field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 DTPS	Deadtime Prescaler Value Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0x Divide the system clock by 1.

Table continues on the next page...

FTMx_DEADTIME field descriptions (continued)

Field	Description
	10 Divide the system clock by 4. 11 Divide the system clock by 16.
DTVAL	Deadtime Value Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS. Deadtime insert value = (DTPS × DTVAL). DTVAL selects the number of deadtime counts inserted as follows: When DTVAL is 0, no counts are inserted. When DTVAL is 1, 1 count is inserted. When DTVAL is 2, 2 counts are inserted. This pattern continues up to a possible 63 counts. This field is write protected. It can be written only when MODE[WPDIS] = 1.

44.4.16 FTM External Trigger (FTMx_EXTTRIG)

This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period. See [Channel trigger output](#) and [Initialization trigger](#).

Channels 6 and 7 are not used to generate channel triggers.

Address: Base address + 6Ch offset

Memory map and register definition

FTMx_EXTTRIG field descriptions

Field	Description
31–8 Reserved	This field is reserved.
7 TRIGF	Channel Trigger Flag Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect. If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF. 0 No channel trigger was generated. 1 A channel trigger was generated.
6 INITTRIGEN	Initialization Trigger Enable Enables the generation of the trigger when the FTM counter is equal to the CNTIN register. 0 The generation of initialization trigger is disabled. 1 The generation of initialization trigger is enabled.
5 CH1TRIG	Channel 1 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
4 CH0TRIG	Channel 0 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
3 CH5TRIG	Channel 5 Trigger Enable

Table continues on the next page...

FTMx_EXTTRIG field descriptions (continued)

Field	Description
	Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
2 CH4TRIG	Channel 4 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
1 CH3TRIG	Channel 3 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
0 CH2TRIG	Channel 2 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.

44.4.17 Channels Polarity (FTMx_POL)

This register defines the output polarity of the FTM channels.

NOTE

The safe value that is driven in a channel output when the fault control is enabled and a fault condition is detected is the inactive state of the channel. That is, the safe value of a channel is the value of its POL bit.

Address: Base address + 70h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FTMx_POL field descriptions

Field	Description
31–8 Reserved	This field is reserved.
7 POL7	Channel 7 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
6 POL6	Channel 6 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
5 POL5	Channel 5 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
4 POL4	Channel 4 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
3 POL3	Channel 3 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
2 POL2	Channel 2 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
1 POL1	Channel 1 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1.

Table continues on the next page...

FTMx_POL field descriptions (continued)

Field	Description
	0 The channel polarity is active high. 1 The channel polarity is active low.
0 POL0	Channel 0 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.

44.4.18 Fault Mode Status (FTMx_FMS)

This register contains the fault detection flags, write protection enable bit, and the logic OR of the enabled fault inputs.

Address: Base address + 74h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

FTMx_FMS field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 FAULTF	Fault Detection Flag Represents the logic OR of the individual FAULTFj bits where j = 3, 2, 1, 0. Clear FAULTF by reading the FMS register while FAULTF is set and then writing a 0 to FAULTF while there is no existing fault condition at the enabled fault inputs. Writing a 1 to FAULTF has no effect. If another fault condition is detected in an enabled fault input before the clearing sequence is completed, the sequence is reset so FAULTF remains set after the clearing sequence is completed for the earlier fault condition. FAULTF is also cleared when FAULTFj bits are cleared individually. 0 No fault condition was detected. 1 A fault condition was detected.
6 WPEN	Write Protection Enable The WPEN bit is the negation of the WPDIS bit. WPEN is set when 1 is written to it. WPEN is cleared when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPEN has no effect. 0 Write protection is disabled. Write protected bits can be written. 1 Write protection is enabled. Write protected bits cannot be written.
5 FAULTIN	Fault Inputs Represents the logic OR of the enabled fault inputs after their filter (if their filter is enabled) when fault control is enabled. 0 The logic OR of the enabled fault inputs is 0. 1 The logic OR of the enabled fault inputs is 1.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FAULTF3	Fault Detection Flag 3 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF3 by reading the FMS register while FAULTF3 is set and then writing a 0 to FAULTF3 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF3 has no effect. FAULTF3 bit is also cleared when FAULTF bit is cleared. If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF3 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.
2 FAULTF2	Fault Detection Flag 2 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF2 by reading the FMS register while FAULTF2 is set and then writing a 0 to FAULTF2 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF2 has no effect. FAULTF2 bit is also cleared when FAULTF bit is cleared.

Table continues on the next page...

FTMx_FMS field descriptions (continued)

Field	Description
	If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF2 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.
1 FAULTF1	Fault Detection Flag 1 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF1 by reading the FMS register while FAULTF1 is set and then writing a 0 to FAULTF1 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF1 has no effect. FAULTF1 bit is also cleared when FAULTF bit is cleared. If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF1 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.
0 FAULTF0	Fault Detection Flag 0 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF0 by reading the FMS register while FAULTF0 is set and then writing a 0 to FAULTF0 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF0 has no effect. FAULTF0 bit is also cleared when FAULTF bit is cleared. If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF0 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.

44.4.19 Input Capture Filter Control (FTMx_FILTER)

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

NOTE

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

Memory map and register definition

Address: Base address + 78h offset

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PHAFLTREN	Phase A Input Filter Enable Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero. 0 Phase A input filter is disabled. 1 Phase A input filter is enabled.

Table continues on the next page...

FTMx_QDCTRL field descriptions (continued)

Field	Description
6 PHBFLTREN	Phase B Input Filter Enable Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero. 0 Phase B input filter is disabled. 1 Phase B input filter is enabled.
5 PHAPOL	Phase A Input Polarity Selects the polarity for the quadrature decoder phase A input. 0 Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.
4 PHBPOL	Phase B Input Polarity Selects the polarity for the quadrature decoder phase B input. 0 Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.
3 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in the Quadrature Decoder mode. 0 Phase A and phase B encoding mode. 1 Count and direction encoding mode.
2 QUADIR	FTM Counter Direction In Quadrature Decoder Mode Indicates the counting direction. 0 Counting direction is decreasing (FTM counter decrement). 1 Counting direction is increasing (FTM counter increment).
1 TOFDIR	Timer Overflow Direction In Quadrature Decoder Mode Indicates if the TOF bit was set on the top or the bottom of counting. 0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register). 1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).
0 QUADEN	Quadrature Decoder Mode Enable Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See Table 44-3. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Quadrature Decoder mode is disabled. 1 Quadrature Decoder mode is enabled.

44.4.22 Configuration (FTMx_CONF)

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset

10 GTBEOUT	Global Time Base Output Enables the global time base signal generation to other FTMs. 0 A global time base signal generation is disabled. 1 A global time base signal generation is enabled.
9 GTBEEN	Global Time Base Enable Configures the FTM to use an external global time base signal that is generated by another FTM. 0 Use of an external global time base is disabled. 1 Use of an external global time base is enabled.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 BDMMODE	BDM Mode Selects the FTM behavior in BDM mode. See BDM mode .
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
NUMTOF	TOF Frequency

Table continues on the next page...

FTMx_CONF field descriptions (continued)

Field	Description
	Selects the ratio between the number of counter overflows to the number of times the TOF bit is set. NUMTOF = 0: The TOF bit is set for each counter overflow. NUMTOF = 1: The TOF bit is set for the first counter overflow but not for the next overflow. NUMTOF = 2: The TOF bit is set for the first counter overflow but not for the next 2 overflows. NUMTOF = 3: The TOF bit is set for the first counter overflow but not for the next 3 overflows. This pattern continues up to a maximum of 31.

44.4.23 FTM Fault Input Polarity (FTMx_FLTPOL)

This register defines the fault inputs polarity.

Address: Base address + 88h offset

44.4.25 FTM Inverting Control (FTMx_INVCTRL)

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

Address: Base address + 90h offset

0 INV0EN	Pair Channels 0 Inverting Enable 0 Inverting is disabled. 1 Inverting is enabled.

44.4.26 FTM Software Output Control (FTMx_SWOCTRL)

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

44.4.27 FTM PWM Load (FTMx_PWMLOAD)

Enables the loading of the MOD, CNTIN, C(n)V, and C(n+1)V registers with the values of their write buffers when the FTM counter changes from the MOD register value to its next value or when a channel (j) match occurs. A match occurs for the channel (j) when FTM counter = C(j)V.

44.5 Functional description

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

FTM counting is up.
Channel (n) is in high-true EPWM mode.

PS[2:0] = 001
CNTIN = 0x0000
MOD = 0x0004
CnV = 0x0002

Figure 44-7. Notation used

44.5.1 Clock source

The FTM has only one clock domain: the system clock.

44.5.1.1 Counter clock source

The CLKS[1:0] bits in the SC register selects clock sources for the FTM counter or disables the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration; see the chip-specific FTM information for further details. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to assure that counter transitions are properly aligned to system clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

44.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

Figure 44-8. Example of the prescaler counter

44.5.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- [Up counting](#)
- [Up-down counting](#)
- [Quadrature Decoder mode](#)

44.5.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is $(MOD - CNTIN + 0x0001) \times \text{period of the FTM counter clock}$.

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

Figure 44-9. Example of FTM up and signed counting

Table 44-5. FTM counting based on CNTIN value

When	Then
CNTIN = 0x0000	The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.
CNTIN[15] = 1	The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed.
CNTIN[15] = 0 and CNTIN $\neq$ 0x0000	The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.

Functional description

FTM counting is up

CNTIN = 0x0000

MOD = 0x0004

Figure 44-10. Example of FTM up counting with CNTIN = 0x0000

Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

Figure 44-11. Example of up counting when the value of CNTIN is greater than the value of MOD

44.5.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is $2 \times (\text{MOD} - \text{CNTIN}) \times \text{period of the FTM counter clock}$.

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

Functional description

FTM counting is up-down
CNTIN = 0x0000
MOD = 0x0004

Figure 44-12. Example of up-down counting when CNTIN = 0x0000

Note

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if $\text{CnV} > \text{CNTIN}$, or
- if $\text{CnV} = 0$ or if $\text{CnV}[15] = 1$. In this case, 0% CPWM is generated.

44.5.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

Figure 44-13. Example when the FTM counter is free running

The FTM counter is also a free running counter when:

- FTMEN = 1
- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

44.5.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- [FTM counter synchronization](#).
- A channel in Input Capture mode with ICRST = 1 ([FTM Counter Reset in Input Capture Mode](#)).

44.5.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

Figure 44-14. Periodic TOF when NUMTOF = 0x02

Figure 44-15. Periodic TOF when NUMTOF = 0x00

44.5.4 Input Capture mode

The Input Capture mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0
- MSnB:MSnA = 0:0, and
- ELSnB:ELSnA ≠ 0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

Figure 44-16. Input Capture mode

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

44.5.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

Figure 44-17. Channel input filter

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

Functional description

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by $\text{CHnFVAL}[3:0]$ ($\times 4$ system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when $\text{CHnFVAL}[3:0]$ bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If ($\text{CHnFVAL}[3:0] \neq 0000$), then the input signal is delayed by the minimum pulse width ($\text{CHnFVAL}[3:0] \times 4$ system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer, one rising edge to the filter output, plus one more to the edge detector. In other words, CHnF is set $(4 + 4 \times \text{CHnFVAL}[3:0])$ system clock periods after a valid edge occurs on the channel input.

The clock for the counter in the channel input filter is the system clock divided by 4.

Figure 44-18. Channel input filter example

The figure below shows an example of input capture with filter enabled and the delay added by each part of the input capture logic. Note that the input signal is delayed only by the synchronizer and edge detector logic if the filter is disabled.

Figure 44-19. Input capture example

44.5.4.2 FTM Counter Reset in Input Capture Mode

If the channel (n) is in input capture mode and $\text{FTMx\_CnSC} [\text{ICRST} = 1]$, then when the selected input capture event occurs in the channel (n) input signal, the current value of the FTM counter is captured into the CnV register, the CHnF bit is set, the channel (n) interrupt is generated (if CHnIE = 1) and the FTM counter is reset to the CNTIN register value.

This allows the FTM to measure a period/pulse being applied to FTM_CHn (counts of the FTM clock input) without having to implement a subtraction calculation in software subsequent to the event occurring.

The figure below shows the FTM counter reset when the selected input capture event is detected in a channel in input capture mode with $\text{ICRST} = 1$.

Figure 44-20. Example of the Input Capture mode with ICRST = 1

NOTE

- It is expected that the ICRST bit be set only when the channel is in input capture mode.
- In this case, if the FTM counter is reset, then the prescaler counter ([Prescaler](#)) and the TOF counter ([When the TOF bit is set](#)) also are reset.

44.5.5 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB:MSnA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

MOD = 0x0005
CnV = 0x0003

Figure 44-21. Example of the Output Compare mode when the match toggles the channel output

MOD = 0x0005
CnV = 0x0003

Figure 44-22. Example of the Output Compare mode when the match clears the channel output

MOD = 0x0005
CnV = 0x0003

Figure 44-23. Example of the Output Compare mode when the match sets the channel output

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

44.5.6 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0

Functional description

- $DECAPEN = 0$
- $COMBINE = 0$
- $CPWMS = 0$, and
- $MSnB = 1$

The EPWM period is determined by $(MOD - CNTIN + 0x0001)$ and the pulse width (duty cycle) is determined by $(CnV - CNTIN)$.

The $CHnF$ bit is set and the channel (n) interrupt is generated if $CHnIE = 1$ at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

Figure 44-24. EPWM period and pulse width with $ELSnB:ELSnA = 1:0$

If ($ELSnB:ELSnA = 0:0$) when the counter reaches the value in the CnV register, the $CHnF$ bit is set and the channel (n) interrupt is generated if $CHnIE = 1$, however the channel (n) output is not controlled by FTM.

If ($ELSnB:ELSnA = 1:0$), then the channel (n) output is forced high at the counter overflow when the $CNTIN$ register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

Figure 44-25. EPWM signal with $ELSnB:ELSnA = 1:0$

If ($ELSnB:ELSnA = X:1$), then the channel (n) output is forced low at the counter overflow when the $CNTIN$ register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

Figure 44-26. EPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

Note

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if CNTIN < CnV ≤ MOD,
- 100% EPWM signal when CNTIN > CnV or CnV > MOD.

44.5.7 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by $2 \times (CnV - CNTIN)$ and the period is determined by $2 \times (MOD - CNTIN)$. See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

Functional description

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

Figure 44-27. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

Figure 44-28. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

Figure 44-29. CPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

44.5.8 Combine mode

The Combine mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1, and
- CPWMS = 0

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD – CNTIN + 0x0001) and the PWM pulse width (duty cycle) is determined by (IC(n+1)V – C(n)V).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)V). The CH(n+1)F bit is set and the channel (n+1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

Functional description

If $(ELSnB:ELSnA = 1:0)$, then the channel (n) output is forced low at the beginning of the period (FTM counter = $CNTIN$) and at the channel (n+1) match (FTM counter = $C(n+1)V$). It is forced high at the channel (n) match (FTM counter = $C(n)V$). See the following figure.

If $(ELSnB:ELSnA = X:1)$, then the channel (n) output is forced high at the beginning of the period (FTM counter = $CNTIN$) and at the channel (n+1) match (FTM counter = $C(n+1)V$). It is forced low at the channel (n) match (FTM counter = $C(n)V$). See the following figure.

In Combine mode, the $ELS(n+1)B$ and $ELS(n+1)A$ bits are not used in the generation of the channels (n) and (n+1) output. However, if $(ELSnB:ELSnA = 0:0)$ then the channel (n) output is not controlled by FTM, and if $(ELSnB:ELSnA = 0:0)$ then the channel (n+1) output is not controlled by FTM.

Figure 44-30. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

Figure 44-31. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(CNTIN < C(n+1)V < MOD)$ and $(C(n)V < C(n+1)V)$

Figure 44-32. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(C(n+1)V = MOD)$

Figure 44-33. Channel (n) output if $(C(n)V = CNTIN)$ and $(CNTIN < C(n+1)V < MOD)$

Figure 44-34. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(C(n)V$ is Almost Equal to $CNTIN$) and $(C(n+1)V = MOD)$

Figure 44-35. Channel (n) output if $C(n)V = \text{CNTIN}$ and $\text{CNTIN} < C(n+1)V < \text{MOD}$ and $C(n+1)V$ is Almost Equal to MOD)

Figure 44-36. Channel (n) output if $C(n)V$ and $C(n+1)V$ are not between CNTIN and MOD

Figure 44-42. Channel (n) output if $C(n+1)V < CNTIN$ and $CNTIN < C(n)V < MOD$

Figure 44-43. Channel (n) output if $C(n)V > MOD$ and $CNTIN < C(n+1)V < MOD$

Figure 44-44. Channel (n) output if $(C(n+1)V > MOD)$ and $(CNTIN < C(n)V < MOD)$

Figure 44-45. Channel (n) output if $(C(n+1)V > MOD)$ and $(CNTIN < C(n)V = MOD)$

44.5.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter = $C(n)V$, is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter = $C(n+1)V$. So, Combine mode allows the generation of asymmetrical PWM signals.

44.5.9 Complementary mode

The Complementary mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0

Figure 44-46. Channel (n+1) output in Complementary mode with $(ELSnB:ELSnA = 1:0)$

Figure 44-47. Channel (n+1) output in Complementary mode with $(ELSnB:ELSnA = X:1)$

NOTE

The complementary mode is not available in Output Compare mode.

44.5.10 Registers updated from write buffers

44.5.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

Table 44-6. CNTIN register update

When	Then CNTIN register is updated
CLKS[1:0] = 0:0	When CNTIN register is written, independent of FTMEN bit.
- FTMEN = 0, or - CNTINC = 0	At the next system clock after CNTIN was written.
- FTMEN = 1, - SYNCMODE = 1, and - CNTINC = 1	By the CNTIN register synchronization .

44.5.10.2 MOD register update

The following table describes when MOD register is updated:

Table 44-7. MOD register update

When	Then MOD register is updated
CLKS[1:0] = 0:0	When MOD register is written, independent of FTMEN bit.
- CLKS[1:0] ≠ 0:0, and - FTMEN = 0	According to the CPWMS bit, that is: - If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. - If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).
- CLKS[1:0] ≠ 0:0, and - FTMEN = 1	By the MOD register synchronization .

44.5.10.3 CnV register update

The following table describes when CnV register is updated:

Table 44-8. CnV register update

When	Then CnV register is updated
CLKS[1:0] = 0:0	When CnV register is written, independent of FTMEN bit.
- CLKS[1:0] ≠ 0:0, and - FTMEN = 0	According to the selected mode, that is:

Table continues on the next page...

Table 44-8. CnV register update (continued)

When	Then CnV register is updated
	- If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written. - If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. - If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).
- CLKS[1:0] ≠ 0:0, and - FTMEN = 1	According to the selected mode, that is: - If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization. - If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization.

44.5.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

Note

The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

44.5.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when TRIGn = 1, where n = 0, 1 or 2 corresponding to each one of the input signals, respectively. The hardware trigger input n is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the TRIGn bit is cleared when 0 is written to it or when the trigger n event is detected.

In this case, if two or more hardware triggers are enabled (for example, TRIG0 and TRIG1 = 1) and only trigger 1 event occurs, then only TRIG1 bit is cleared. If a trigger n event occurs together with a write setting TRIGn bit, then the synchronization is initiated, but TRIGn bit remains set due to the write operation.

Note
All hardware trigger inputs have the same behavior.

Figure 44-48. Hardware trigger event with HWTRIGMODE = 0

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

44.5.11.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see [Boundary cycle and loading points](#) and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

Figure 44-49. Software trigger event

44.5.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In **Up counting** mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in **Up-down counting** mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

Figure 44-50. Boundary cycles and loading points

44.5.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if $(FTMEN = 1)$.

The MOD register synchronization can be done by either the enhanced PWM synchronization ($SYNCMODE = 1$) or the legacy PWM synchronization ($SYNCMODE = 0$). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on $SWWRBUF$, $SWRSTCNT$, $HWWRBUF$, and $HWRSTCNT$ bits according to this flowchart:

Figure 44-51. MOD register synchronization flowchart

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 0), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected

loading point. If the trigger event was a hardware trigger, then the trigger enable bit (TRIGn) is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

Figure 44-52. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 0), and software trigger was used

Figure 44-53. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 1), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

Figure 44-54. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used

Figure 44-55. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

Figure 44-56. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)

44.5.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see [MOD register synchronization](#).

44.5.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the [MOD register synchronization](#). However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

44.5.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

Figure 44-57. OUTMASK register synchronization flowchart

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

Figure 44-58. OUTMASK synchronization with (SYNCMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used

Figure 44-59. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#). An example with a hardware trigger follows.

Figure 44-60. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used

44.5.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

Figure 44-61. INVCTRL register synchronization flowchart

44.5.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

Figure 44-62. SWOCTRL register synchronization flowchart

44.5.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n+1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

Figure 44-63. FTM counter synchronization

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

Figure 44-64. FTM counter synchronization flowchart

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGN bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

Figure 44-65. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used

Figure 44-66. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#).

Figure 44-67. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used

44.5.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INV_m = 1 (where m represents a channel pair)

The INV_m bit in INVCTRL register is updated with its buffer value according to [INVCTRL register synchronization](#)

In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

Figure 44-68. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode

Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

Figure 44-69. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode

Note

The inverting feature is not available in Output Compare mode.

44.5.13 Software output control

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CHnOC = 1

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to [SWOCTRL register synchronization](#).

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

NOTE

CH(n)OCV = 1 and CH(n+1)OCV = 0.

Figure 44-70. Example of software output control in Combine and Complementary mode

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

Table 44-9. Software output control behavior when (COMP = 0)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to one

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

Table 44-10. Software output control behavior when (COMP = 1)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to zero

Note

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

44.5.14 Deadtime insertion

The deadtime insertion is enabled when (DTEN = 1) and (DTVAL[5:0] is non-zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTPS[1:0] bits define the prescaler for the system clock and the DTVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If $POL(n) = 0$, $POL(n+1) = 0$, and the deadtime is enabled, then when the channel (n) match (FTM counter = $C(n)V$) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = $C(n+1)V$) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If $POL(n) = 1$, $POL(n+1) = 1$, and the deadtime is enabled, then when the channel (n) match (FTM counter = $C(n)V$) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

when the channel (n+1) match (FTM counter = $C(n+1)V$) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared.

Figure 44-71. Deadtime insertion with $ELSnB:ELSnA = 1:0$, $POL(n) = 0$, and $POL(n+1) = 0$

Figure 44-72. Deadtime insertion with $ELSnB:ELSnA = X:1$, $POL(n) = 0$, and $POL(n+1) = 0$

NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

44.5.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

Functional description

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ($((C(n)+1)V - C(n)V) \times \text{system clock}$), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ($((\text{MOD} - \text{CNTIN} + 1 - (C(n+1)V - C(n)V)) \times \text{system clock})$), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

Figure 44-73. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle

Figure 44-74. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle

44.5.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see [OUTMASK register synchronization](#).

If $CHnOM = 1$, then the channel (n) output is forced to its inactive state ($POLn$ bit value). If $CHnOM = 0$, then the channel (n) output is unaffected by the output mask. See the following figure.

Figure 44-75. Output mask with $POLn = 0$

The following table shows the output mask result before the polarity control.

Table 44-11. Output mask result for channel (n) before the polarity control

CHnOM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	inactive state

44.5.16 Fault control

The fault control is enabled if (FAULTM[1:0] $\neq$ 0:0).

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

First, each fault input signal is synchronized by the system clock; see the synchronizer block in the following figure. Following synchronization, the fault input n signal enters the filter block. When there is a state change in the fault input n signal, the 5-bit counter is reset and starts counting up. As long as the new state is stable on the fault input n, the counter continues to increment. If the 5-bit counter overflows, that is, the counter exceeds the value of the FFVAL[3:0] bits, the new fault input n value is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the fault input n signal before validation (counter overflow), the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by FFVAL[3:0] bits ($\times$ system clock) is regarded as a glitch and is not passed on to the edge detector.

The fault input n filter is disabled when the FFVAL[3:0] bits are zero or when FAULTnEN = 0. In this case, the fault input n signal is delayed 2 rising edges of the system clock and the FAULTFn bit is set on 3th rising edge of the system clock after a rising edge occurs on the fault input n.

If FFVAL[3:0] $\neq$ 0000 and FAULTnEN = 1, then the fault input n signal is delayed (3 + FFVAL[3:0]) rising edges of the system clock, that is, the FAULTFn bit is set (4 + FFVAL[3:0]) rising edges of the system clock after a rising edge occurs on the fault input n.

* where n = 3, 2, 1, 0

Figure 44-76. Fault input n control block diagram

If the fault control and fault input n are enabled and a rising edge at the fault input n signal is detected, a fault condition has occurred and the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

Figure 44-77. FAULTF and FAULTIN bits and fault interrupt

If the fault control is enabled ($\text{FAULTM}[1:0] \neq 0:0$), a fault condition has occurred and ($\text{FAULTEN} = 1$), then outputs are forced to their safe values:

- Channel (n) output takes the value of $\text{POL}(n)$
- Channel (n+1) takes the value of $\text{POL}(n+1)$

The fault interrupt is generated when ($\text{FAULTF} = 1$) and ($\text{FAULTIE} = 1$). This interrupt request remains set until:

- Software clears the FAULTF bit by reading FAULTF bit as 1 and writing 0 to it
- Software clears the FAULTIE bit
- A reset occurs

44.5.16.1 Automatic fault clearing

If the automatic fault clearing is selected ($\text{FAULTM}[1:0] = 1:1$), then the channels output disabled by fault control is again enabled when the fault input signal (FAULTIN) returns to zero and a new PWM cycle begins. See the following figure.

Figure 44-78. Fault control with automatic fault clearing

44.5.16.2 Manual fault clearing

If the manual fault clearing is selected (FAULTM[1:0] = 0:1 or 1:0), then the channels output disabled by fault control is again enabled when the FAULTF bit is cleared and a new PWM cycle begins. See the following figure.

NOTE
The channel (n) output is after the fault control with manual fault clearing and $POLn = 0$.

Figure 44-79. Fault control with manual fault clearing

44.5.16.3 Fault inputs polarity control

The $FLTjPOL$ bit selects the fault input j polarity, where $j = 0, 1, 2, 3$:

- If $FLTjPOL = 0$, the fault j input polarity is high, so the logical one at the fault input j indicates a fault.
- If $FLTjPOL = 1$, the fault j input polarity is low, so the logical zero at the fault input j indicates a fault.

44.5.17 Polarity control

The $POLn$ bit selects the channel (n) output polarity:

- If $POLn = 0$, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If $POLn = 1$, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

44.5.18 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

Table 44-12. Initialization behavior when (COMP = 0 and DTEN = 0)

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	0	is forced to zero	is forced to zero
0	1	is forced to zero	is forced to one
1	0	is forced to one	is forced to zero
1	1	is forced to one	is forced to one

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

Table 44-13. Initialization behavior when (COMP = 1 or DTEN = 1)

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	X	is forced to zero	is forced to one
1	X	is forced to one	is forced to zero

Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

44.5.19 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

pair channels (m) - channels (n) and (n+1)

**NOTE**

The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

Figure 44-80. Priority of the features used at the generation of channels (n) and (n+1) outputs signals

Note

The **Initialization** feature must not be used with **Inverting** and **Software output control** features.

44.5.20 Channel trigger output

If CH(j)TRIG bit of the FTM External Trigger (FTM_EXTTRIG) register is set, where $j = 0, 1, 2, 3, 4$, or 5 , then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal which has one FTM clock period width and is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

Figure 44-81. Channel match trigger

44.5.21 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.
- When there is a write to CNT register.
- When there is the [FTM counter synchronization](#).
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.
- If the channel (n) is in Input Capture mode, (ICRST = 1) and the selected input capture event occurs in the channel (n) input.

The following figures show these cases.

CNTIN = 0x0000
MOD = 0x000F
CPWMS = 0

Figure 44-82. Initialization trigger is generated when the FTM counting achieves the CNTIN register value

CNTIN = 0x0000
MOD = 0x000F
CPWMS = 0

Figure 44-83. Initialization trigger is generated when there is a write to CNT register

Functional description

CNTIN = 0x0000
MOD = 0x000F
CPWMS = 0

Figure 44-84. Initialization trigger is generated when there is the FTM counter synchronization

CNTIN = 0x0000
MOD = 0x000F
CPWMS = 0

Figure 44-85. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits

NOTE

Channel (n) input after its synchronizer and filter
MOD = 0xFFFF
CNTIN = 0x0000
PS[2:0] = 3'b000
ICRST = 1'b1

Figure 44-86. Initialization trigger is generated if the channel (n) is in Input Capture mode, ICRST = 1 and the selected input capture event occurs in the channel (n) input

The initialization trigger output provides a trigger signal that is used for on-chip modules.

44.5.22 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for [Input Capture mode](#) and FTM counter must be configured to the [Up counting](#).

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

NOTE

- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

Figure 44-87. Capture Test mode

44.5.23 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

Table 44-14. Channel DMA transfer request

DMA	CHnIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHnF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHnF = 1).	The channel interrupt is not generated.

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

Table 44-15. Clear CHnF bit when DMA = 1

CHnIE	How CHnF Bit Can Be Cleared
0	CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit.
1	CHnF bit is cleared when the channel DMA transfer is done.

44.5.24 Dual Edge Capture mode

The Dual Edge Capture mode is selected if DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.

Figure 44-88. Dual Edge Capture mode block diagram

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n+1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the C(n)V and C(n+1)V registers are read. The only requirement is that C(n)V must be read before C(n+1)V.

Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.

- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in [Free running counter](#).

44.5.24.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

44.5.24.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the CH(n)F and CH(n+1)F bits to start new measurements.

44.5.24.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1) and the channel (n+1) to capture falling edges (ELS(n+1)B:ELS(n+1)A = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0) and the channel (n+1) to capture rising edges (ELS(n+1)B:ELS(n+1)A = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 44-89. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

Figure 44-90. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement

44.5.24.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges ($ELS(n)B:ELS(n)A = 0:1$ and $ELS(n+1)B:ELS(n+1)A = 0:1$), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges ($ELS(n)B:ELS(n)A = 1:0$ and $ELS(n+1)B:ELS(n+1)A = 1:0$), then the period between two consecutive falling edges is measured.

The period measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 44-91. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set

when the second rising edge is detected, that is, the edge selected by $ELS(n+1)B:ELS(n+1)A$ bits. The $CH(n+1)F$ bit indicates when two edges of the period were captured and the $C(n)V$ and $C(n+1)V$ registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

Figure 44-92. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges

44.5.24.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in $C(n)V$ and $C(n+1)V$ registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal. C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

Figure 44-93. Dual Edge Capture mode read coherency mechanism

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

44.5.25 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

Figure 44-94. Quadrature Decoder block diagram

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; [Filter for Input Capture mode](#). The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n+1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

Note

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

Note

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADM0DE selects the encoding mode used in the Quadrature Decoder mode. If QUADM0DE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

Figure 44-95. Quadrature Decoder – Count and Direction Encoding mode

If QUADM0DE = 0, then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

Figure 44-96. Quadrature Decoder – Phase A and Phase B Encoding mode

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

Figure 44-97. FTM Counter overflow in up counting for Quadrature Decoder mode

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

Functional description

Figure 44-98. FTM counter overflow in down counting for Quadrature Decoder mode

44.5.25.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

Figure 44-99. Motor position jittering in a mid count value

The following figure shows motor jittering produced by the phase B and A pulses respectively:

Figure 44-100. Motor position jittering near maximum and minimum count value

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

44.5.26 BDM mode

When the chip is in BDM mode, the BDMMODE[1:0] bits select the behavior of the FTM counter, the CH(n)F bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

Table 44-16. FTM behavior when the chip is in BDM mode

BDMMODE	FTM Counter	CH(n)F Bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
00	Stopped	can be set	Functional mode	Writes to these registers bypass the registers buffers
01	Stopped	is not set	The channels outputs are forced to their safe value according to POLn bit	Writes to these registers bypass the registers buffers
10	Stopped	is not set	The channels outputs are frozen when the chip enters in BDM mode	Writes to these registers bypass the registers buffers

Table continues on the next page...

Table 44-16. FTM behavior when the chip is in BDM mode (continued)

BDMMODE	FTM Counter	CH(n)F Bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
11	Functional mode	can be set	Functional mode	Functional mode

Note that if BDMMODE[1:0] = 2'b00 then the channels outputs remain at the value when the chip enters in BDM mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this BDM mode.

- Write any value to CNT register; see [Counter reset](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see [FTM counter synchronization](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See [Initialization](#).

Note

The BDMMODE[1:0] = 2'b00 must not be used with the [Fault control](#). Even if the fault control is enabled and a fault condition exists, the channels outputs values are updated as above.

Note

If CLKS[1:0] = 2'b00 in BDM, a non-zero value is written to CLKS in BDM, and CnV = CNTIN when the BDM is disabled, then the CHnF bit is set (since if the channel is a 0% EPWM signal) when the BDM is disabled.

44.5.27 Intermediate load

The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

Table 44-17. When possible loading points are enabled

Loading point	Enabled
When the FTM counter wraps from MOD value to CNTIN value	Always
At the channel (j) match (FTM counter = C(j)V)	When CHjSEL = 1

The following figure shows some examples of enabled loading points.

**NOTE**

- (a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
 (b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
 (c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
 (d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
 (e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
 (f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

Figure 44-101. Loading points for intermediate load

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

Table 44-18. Conditions for loads occurring at the next enabled loading point

When a new value was written	Then
To the MOD register	The MOD register is updated with its write buffer value.

Table continues on the next page...

Table 44-18. Conditions for loads occurring at the next enabled loading point (continued)

When a new value was written	Then
To the CNTIN register and CNTINC = 1	The CNTIN register is updated with its write buffer value.
To the C(n)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n)V register is updated with its write buffer value.
To the C(n+1)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n+1)V register is updated with its write buffer value.

NOTE

- If ELSjB and ELSjA bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELSjB and ELSjA bits are zero, then the generated signal is not available on channel (j) output.
- If CHjIE = 1, then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.

44.5.28 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

**Figure 44-102. Global time base (GTB) block diagram**

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb_in*, and the output signal *gtb_out*. The GTBEEN bit enables *gtb_in* to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when *gtb_in* is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the *gtb_out* signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the *gtb_in* and *gtb_out* signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the *gtb_in* signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

44.5.28.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

44.6 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 00b);
- the timer overflow interrupt is zero, see [Timer Overflow Interrupt](#);
- the channels interrupts are zero, see [Channel \(n\) Interrupt](#);
- the fault interrupt is zero, see [Fault Interrupt](#);
- the channels are in input capture mode, see [Input Capture mode](#);
- the channels outputs are zero;
- the channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0:0) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).

Figure 44-103. FTM behavior after reset when the channel (n) is in Combine mode

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control ([Software output control](#)) or the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

Figure 44-104. FTM behavior after reset when the channel (n) is in Output Compare mode

44.7 FTM Interrupts

44.7.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

44.7.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

44.7.3 Fault Interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

44.8 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer operation. This procedure can also be used to do a new configuration of the FlexTimer operation.

- Define the POL bits.
- Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels output are in the safe value.
- (Re)Configuration FTM counter and channels to generation of periodic signals - Disable the clock. If the selected mode is Quadrature Decoder, then disable this mode. Examples of the (re)configuration:
 - Write to MOD.
 - Write to CNTIN.
 - Select OC, EPWM, CPWM, Combine, Complement modes for all channels that will be used
 - Select the high-true and low-true channels modes.
 - Write to CnV for all channels that will be used .
 - (Re)Configure deadtime and fault control.
 - Do not use the SWOC without SW synchronization (see item 6).
 - Do not use the Inverting without SW synchronization (see item 6).
 - Do not use the Initialization.
 - Do not change the polarity control.
 - Do not configure the HW synchronization

- Write any value to CNT. The FTM Counter is reset and the channels output are updated according to new configuration.
- Enable the clock. Write to CLKS[1:0] bits a value different from zero. If in the Quadrature Decoder mode, enable this mode.
- Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
 - Select synchronization for Output Mask Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
 - Write to SYNCONF.
 - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0).
 - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1].
 - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1].
 - SW Synchronization for SWOM (always): SWOM = 1. No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2'b00): SWWRBUF = 0 and CNTINC = 0.
 - SW Synchronization for counter reset (always): SWRSTCNT = 1.
 - Enhanced synchronization (always): SYNCMODE = 1
 - If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.
 - If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.
 - Write to OUTMASK to enable the masked channels.
- Generate the Software Trigger Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

Chapter 45

Timer/PWM Module (TPM)

45.1 Chip-specific TPM information

45.1.1 TPM Instantiation Information

This device contains 2 Low Power TPM module(s) (TPM). All TPM modules in the device are configured with basic TPM functionality with quadrature decoder function and all can be functional in Stop/VLPS mode. The clock source is either external or internal in Stop/VLPS mode.

The following table shows how these modules are configured.

Table 45-1. TPM configuration

TPM instance	Number of channels	Features/usage
TPM1	2	Basic TPM,functional in Stop/VLPS mode
TPM2	2	Basic TPM,functional in Stop/VLPS mode

45.1.2 Clock Options

The TPM blocks are clocked from a single TPM clock that can be selected from OSCERCLK, MCGIRCLK , MCGPLLCLK, or MCGFLLCLK. The selected source is controlled by SIM_SOPT2[TPMSRC] and SIM_SOPT2[PLLFLSEL]control registers.

Each TPM also supports an external clock mode (TPM_SC[CMOD]=1x) in which the counter increments after a synchronized (to the selected TPM clock source) rising edge detect of an external clock input. The available external clock (either TPM_CLKIN0 or

TPM_CLKIN1) is selected by SIM_SOPT9[TPMxCLKSEL] control register. To guarantee valid operation the selected external clock must be less than half the frequency of the selected TPM clock source.

45.1.3 Trigger Options

Each TPM has a selectable trigger input source controlled by the TPMx_CONF[TRGSEL] field to use for starting the counter and/or reloading the counter. The options available are shown in the following table.

Table 45-2. TPM trigger options

TPMx_CONF[TRGSEL]	Selected source
0000	External Trigger
0001	CMP 0
0010	CMP 1Reserved
0011	Reserved
0100	PIT Ch 0 Output
0101	PIT Ch 1 Output
0110	PIT Ch 2 Output
0111	PIT Ch 3 Output
1000	FTM0 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG)
1001	FTM1 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG)
1010	FTM2 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG)
1011	FTM3 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG)
1100	RTC Alarm
1101	RTC Seconds
1110	LPTMR Output
1111	Software Trigger

45.1.4 Global Timebase

Each TPM has a global timebase feature controlled by the TPMx_CONF[GTBEEN] bit. TPM1 is configured as the global time when this option is enabled.

45.1.5 TPM Interrupts

The TPM has multiple sources of interrupt. However, these sources are OR'd together to generate a single interrupt request to the interrupt controller. When an TPM interrupt occurs, read the TPM status registers to determine the exact interrupt source.

45.2 Introduction

The TPM (Timer/PWM Module) is a 2- to 8-channel timer which supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications.

The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low power modes. An example of using the TPM with the asynchronous DMA is described in [AN4631:Using the Asynchronous DMA features of the Kinetis L Series](#).

45.2.1 TPM Philosophy

The TPM is built upon a very simple timer (HCS08 Timer PWM Module – TPM) used for many years on NXP's 8-bit microcontrollers. The TPM extends the functionality to support operation in low power modes by clocking the counter, compare and capture registers from an asynchronous clock that can remain functional in low power modes.

45.2.2 Features

The TPM features include:

- TPM clock mode is selectable
 - Can increment on every edge of the asynchronous counter clock
 - Can increment on rising edge of an external clock input synchronized to the asynchronous counter clock
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- TPM includes a 16-bit counter
 - It can be a free-running counter or modulo counter
 - The counting can be up or up-down

- Includes 2 channels that can be configured for input capture, output compare, edge-aligned PWM mode, or center-aligned PWM mode
 - In input capture mode the capture can occur on rising edges, falling edges or both edges
 - In output compare mode the output signal can be set, cleared, pulsed, or toggled on match
 - All channels can be configured for edge-aligned PWM mode or center-aligned PWM mode
- Support the generation of an interrupt and/or DMA request per channel
- Support the generation of an interrupt and/or DMA request when the counter overflows
- Support selectable trigger input to optionally reset or cause the counter to start incrementing.
 - The counter can also optionally stop incrementing on counter overflow
- Support the generation of hardware triggers when the counter overflows and per channel

45.2.3 Modes of operation

During debug mode, the TPM can be configured to temporarily pause all counting until the core returns to normal user operating mode or to operate normally. When the counter is paused, trigger inputs and input capture events are ignored.

During doze mode, the TPM can be configured to operate normally or to pause all counting for the duration of doze mode. When the counter is paused, trigger inputs and input capture events are ignored.

During stop mode, the TPM counter clock can remain functional and the TPM can generate an asynchronous interrupt to exit the MCU from stop mode.

45.2.4 Block diagram

The TPM uses one input/output (I/O) pin per channel, CH_n (TPM channel (n)) where n is the channel number.

The following figure shows the TPM structure. The central component of the TPM is the 16-bit counter with programmable final value and its counting can be up or up-down.

Figure 45-1. TPM block diagram

45.3 TPM Signal Descriptions

Table 45-3 shows the user-accessible signals for the TPM.

Table 45-3. TPM signal descriptions

Signal	Description	I/O
TPM_EXTCLK	External clock. TPM external clock can be selected to increment the TPM counter on every rising edge synchronized to the counter clock.	I
TPM_CHn	TPM channel (n = 1 to 0). A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input.	I/O

45.3.1 TPM_EXTCLK — TPM External Clock

The rising edge of the external input signal is used to increment the TPM counter if selected by CMOD[1:0] bits in the SC register. This input signal must be less than half of the TPM counter clock frequency. The TPM counter prescaler selection and settings are also used when an external input is selected.

45.3.2 TPM_CHn — TPM Channel (n) I/O Pin

Each TPM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.

45.4 Memory Map and Register Definition

This section provides a detailed description of all TPM registers.

Attempting to access a reserved register location in the TPM memory map will generate a bus error.

TPM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400C_9000	Status and Control (TPM1_SC)	32	R/W	0000_0000h	45.4.1/1346
400C_9004	Counter (TPM1_CNT)	32	R/W	0000_0000h	45.4.2/1347
400C_9008	Modulo (TPM1_MOD)	32	R/W	0000_FFFFh	45.4.3/1348

45.4.1 Status and Control (TPMx_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, module configuration and prescaler factor. These controls relate to all channels within this module.

Address: Base address + 0h offset

TPMx_SC field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 DMA	DMA Enable Enables DMA transfers for the overflow flag. 0 Disables DMA transfers. 1 Enables DMA transfers.
7 TOF	Timer Overflow Flag Set by hardware when the TPM counter equals the value in the MOD register and increments. Writing a 1 to TOF clears it. Writing a 0 to TOF has no effect. If another TPM overflow occurs between the flag setting and the flag clearing, the write operation has no effect; therefore, TOF remains set indicating another overflow has occurred. In this case a TOF interrupt request is not lost due to a delay in clearing the previous TOF.

Table continues on the next page...

TPMx_SC field descriptions (continued)

Field	Description
	0 TPM counter has not overflowed. 1 TPM counter has overflowed.
6 TOIE	Timer Overflow Interrupt Enable Enables TPM overflow interrupts. 0 Disable TOF interrupts. Use software polling or DMA request. 1 Enable TOF interrupts. An interrupt is generated when TOF equals one.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the TPM to operate in up-down counting mode. This field is write protected. It can be written only when the counter is disabled. 0 TPM counter operates in up counting mode. 1 TPM counter operates in up-down counting mode.
4–3 CMOD	Clock Mode Selection Selects the TPM counter clock modes. When disabling the counter, this field remain set until acknowledged in the TPM clock domain. 00 TPM counter is disabled 01 TPM counter increments on every TPM counter clock 10 TPM counter increments on rising edge of TPM_EXTCLK synchronized to the TPM counter clock 11 Reserved.
PS	Prescale Factor Selection Selects one of 8 division factors for the clock mode selected by CMOD. This field is write protected. It can be written only when the counter is disabled. 000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128

45.4.2 Counter (TPMx_CNT)

The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT also clears the counter.

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

Memory Map and Register Definition

TPMx_CNT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter value

45.4.3 Modulo (TPMx_MOD)

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see [Counter](#)).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to [MOD Register Update](#) . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset

MOD	Modulo value This field must be written with single 16-bit or 32-bit access.

45.4.4 Channel (n) Status and Control (TPMx_CnSC)

CnSC contains the channel-interrupt-status flag and control bits used to configure the interrupt enable, channel configuration, and pin function. When switching from one channel mode to a different channel mode, the channel must first be disabled and this must be acknowledged in the TPM counter clock domain.

Table 45-4. Mode, Edge, and Level Selection

CPWMS	MSnB:MSnA	ELSnB:ELSnA	Mode	Configuration

TPMx_CnSC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CHF	Channel Flag Set by hardware when an event occurs on the channel. CHF is cleared by writing a 1 to the CHF bit. Writing a 0 to CHF has no effect. If another event occurs between the CHF sets and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the delay in clearing the previous CHF. 0 No channel event has occurred. 1 A channel event has occurred.
6 CHIE	Channel Interrupt Enable Enables channel interrupts. 0 Disable channel interrupts. 1 Enable channel interrupts.
5 MSB	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
4 MSA	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
3 ELSB	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
2 ELSA	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DMA	DMA Enable Enables DMA transfers for the channel. 0 Disable DMA transfers. 1 Enable DMA transfers.

45.4.5 Channel (n) Value (TPMx_CnV)

These registers contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to [CnV Register Update](#) . Additional writes to the CnV write buffer are ignored until the register has been updated.

Address: Base address + 10h offset + (8d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TPMx_CnV field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
VAL	Channel Value Captured TPM counter value of the input modes or the match value for the output modes. This field must be written with single 16-bit or 32-bit access.

45.4.6 Capture and Compare Status (TPMx_STATUS)

The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

TPMx_COMBINE field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 COMSWAP0	Combine Channel 0 and 1 Swap When set in combine mode, the even channel is used for the input capture and 1st compare, the odd channel is used for the 2nd compare. 0 Even channel is used for input capture and 1st compare. 1 Odd channel is used for input capture and 1st compare.
0 COMBINE0	Combine Channels 0 and 1 Enables the combine feature for channels 0 and 1. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare. 0 Channels 0 and 1 are independent. 1 Channels 0 and 1 are combined.

45.4.8 Channel Polarity (TPMx_POL)

This register defines the input and output polarity of each of the channels.

Address: Base address + 70h offset

TPMx_QDCTRL field descriptions

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in the quadrature decoder mode. 0 Phase encoding mode. 1 Count and direction encoding mode.
2 QUADIR	Counter Direction in Quadrature Decode Mode Indicates the counting direction. 0 Counter direction is decreasing (counter decrement). 1 Counter direction is increasing (counter increment).
1 TOFDIR	Indicates if the TOF bit was set on the top or the bottom of counting. 0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (zero) to its maximum value (MOD register). 1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (zero).
0 QUADEN	Enables the quadrature decoder mode. In this mode, the channel 0 and channel 1 inputs control the TPM counter direction and can only be used for software compare. The quadrature decoder mode has precedence over the other modes. 0 Quadrature decoder mode is disabled. 1 Quadrature decoder mode is enabled.

45.4.11 Configuration (TPMx_CONF)

This register selects the behavior in debug and wait modes and the use of an external global time base.

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TPMx_CONF field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 TRGSEL	Trigger Select Selects the input trigger to use for starting, reloading and/or pausing the counter. The source of the trigger (external or internal to the TPM) is configured by the TRGSRC field. This field should only be changed when the TPM counter is disabled. Refer to the chip configuration section for available external trigger options. The available internal trigger sources are listed below. 0001 Channel 0 pin input capture 0010 Channel 1 pin input capture 0011 Channel 0 or Channel 1 pin input capture
23 TRGSRC	Trigger Source Selects between internal (channel pin input capture) or external trigger sources. When selecting an internal trigger, the channel selected should be configured for input capture. Only a rising edge input capture can be used to initially start the counter using the CSOT configuration; either rising edge or falling edge input capture can be used to reload the counter using the CROT configuration; and the state of the channel input pin is used to pause the counter using the CPOT configuration. The channel polarity register can be used to invert the polarity of the channel input pins. This field should only be changed when the TPM counter is disabled.

Table continues on the next page...

TPMx_CONF field descriptions (continued)

Field	Description
	0 Trigger source selected by TRGSEL is external. 1 Trigger source selected by TRGSEL is internal (channel pin input capture).
22 TRGPOL	Trigger Polarity Selects the polarity of the external trigger source. This field should only be changed when the TPM counter is disabled. 0 Trigger is active high. 1 Trigger is active low.
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 CPOT	Counter Pause On Trigger When enabled, the counter will pause incrementing while the trigger remains asserted (level sensitive). This field should only be changed when the TPM counter is disabled.
18 CROT	Counter Reload On Trigger When set, the TPM counter will reload with 0 (and initialize PWM outputs to their default value) when a rising edge is detected on the selected trigger input. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. 0 Counter is not reloaded due to a rising edge on the selected input trigger 1 Counter is reloaded when a rising edge is detected on the selected input trigger
17 CSOO	Counter Stop On Overflow When set, the TPM counter will stop incrementing once the counter equals the MOD value and incremented (this also sets the TOF). Reloading the counter with 0 due to writing to the counter register or due to a trigger input does not cause the counter to stop incrementing. Once the counter has stopped incrementing, the counter will not start incrementing unless it is disabled and then enabled again, or a rising edge on the selected trigger input is detected when CSOT set. This field should only be changed when the TPM counter is disabled. 0 TPM counter continues incrementing or decrementing after overflow 1 TPM counter stops incrementing or decrementing after overflow.
16 CSOT	Counter Start on Trigger When set, the TPM counter will not start incrementing after it is enabled until a rising edge on the selected trigger input is detected. If the TPM counter is stopped due to an overflow, a rising edge on the selected trigger input will also cause the TPM counter to start incrementing again. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. 0 TPM counter starts to increment immediately, once it is enabled. 1 TPM counter only starts to increment when it a rising edge on the selected input trigger is detected, after it has been enabled or after it has stopped due to overflow.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 GTBEEN	Global time base enable

Table continues on the next page...

TPMx_CONF field descriptions (continued)

Field	Description
	Configures the TPM to use an externally generated global time base counter. When an externally generated timebase is used, the internal TPM counter is not used by the channels but can be used to generate a periodic interruptor DMA request using the Modulo register and timer overflow flag. 0 All channels use the internally generated TPM counter as their timebase 1 All channels use an externally generated global timebase as their timebase
8 GTBSYNC	Global Time Base Synchronization When enabled, the TPM counter is synchronized to the global time base. It uses the global timebase enable, trigger and overflow to ensure the TPM counter starts incrementing at the same time as the global timebase, stops incrementing at the same time as the global timebase and is reset at the same time as the global timebase. This field should only be changed when the TPM counter is disabled. 0 Global timebase synchronization disabled. 1 Global timebase synchronization enabled.
7–6 DBGMODE	Debug Mode Configures the TPM behavior in debug mode. All other configurations are reserved. 00 TPM counter is paused and does not increment during debug mode. Trigger inputs and input capture events are also ignored. 11 TPM counter continues in debug mode.
5 DOZEEN	Doze Enable Configures the TPM behavior in wait mode. 0 Internal TPM counter continues in Doze mode. 1 Internal TPM counter is paused and does not increment during Doze mode. Trigger inputs and input capture events are also ignored.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.5 Functional description

The following sections describe the TPM features.

45.5.1 Clock domains

The TPM module supports two clock domains.

The bus clock domain is used by the register interface and for synchronizing interrupts and DMA requests.

The TPM counter clock domain is used to clock the counter and prescaler along with the output compare and input capture logic. The TPM counter clock is considered asynchronous to the bus clock, can be a higher or lower frequency than the bus clock and can remain operational in Stop mode. Multiple TPM instances are all clocked by the same TPM counter clock in support of the external timebase feature.

45.5.1.1 Counter Clock Mode

The CMOD[1:0] bits in the SC register either disable the TPM counter or select one of two possible clock modes for the TPM counter. After any reset, CMOD[1:0] = 0:0 so the TPM counter is disabled.

The CMOD[1:0] bits may be read or written at any time. Disabling the TPM counter by writing zero to the CMOD[1:0] bits does not affect the TPM counter value or other registers, but must be acknowledged by the TPM counter clock domain before they read as zero.

The external clock input passes through a synchronizer clocked by the TPM counter clock to assure that counter transitions are properly aligned to counter clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must be less than half of the counter clock frequency.

45.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and TPM counter.

Figure 45-2. Example of the Prescaler Counter

45.5.3 Counter

The TPM has a 16-bit counter that is used by the channels either for input or output modes.

The counter updates from the selected clock divided by the prescaler.

The TPM counter has these modes of operation:

- up counting (see [Up counting](#))
- up-down counting (see [Up-down counting](#))

45.5.3.1 Up counting

Up counting is selected when $SC[CPWMS] = 0$.

The value of zero is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with zero.

The TPM period when using up counting is $(MOD + 0x0001) \times \text{period of the TPM counter clock}$.

The TOF bit is set when the TPM counter changes from MOD to zero.

Figure 45-3. Example of TPM Up Counting

Note

- MOD = 0000 is a redundant condition. In this case, the TPM counter is always equal to MOD and the TOF bit is set in each rising edge of the TPM counter clock.

45.5.3.2 Up-down counting

Up-down counting is selected when $SC[CPWMS] = 1$. When configured for up-down counting, configuring $CONF[MOD]$ to less than 2 is not supported.

The value of 0 is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to zero and the up-down counting restarts.

The TPM period when using up-down counting is $2 \times MOD \times \text{period of the TPM counter clock}$.

The TOF bit is set when the TPM counter changes from MOD to (MOD – 1).

Figure 45-4. Example of up-down counting

45.5.3.3 Counter Reset

Any write to CNT resets the TPM counter and the channel outputs to their initial values (except for channels in output compare mode).

45.5.3.4 Global time base (GTB)

The global time base (GTB) is a TPM function that allows multiple TPM modules to share the same timebase. When the global time base is enabled ($CONF[GTBEEN] = 1$), the local TPM channels use the counter value, counter enable and overflow indication from the TPM generating the global time base. If the local TPM counter is not generating the global time base, then it can be used as an independent counter or pulse accumulator.

The local TPM counter can also be configured to synchronize to the global time base, by configuring ($GTBSYNC = 1$). When synchronized to the global time base, the local counter will use the counter enable and counter overflow indication from the TPM

generating the global time base. This enables multiple TPM to be configured with the same phase, but with different periods (although the global time base must be configured with the longest period).

45.5.3.5 Counter trigger

The TPM counter can be configured to start, stop or reset in response to a hardware trigger input. The trigger input is synchronized to the asynchronous counter clock, so there is a 3 counter clock delay between the trigger assertion and the counter responding.

- When (CSOT = 1), the counter will not start incrementing until a rising edge is detected on the trigger input.
- When (CSOO = 1), the counter will stop incrementing whenever the TOF flag is set. The counter does not increment again unless it is disabled, or if CSOT = 1 and a rising edge is detected on the trigger input.
- When (CROT = 1), the counter will reset to zero as if an overflow occurred whenever a rising edge is detected on the trigger input.
- When (CPOT = 1), the counter will pause incrementing whenever the trigger input is asserted. The counter will continue incrementing when the trigger input negates.

The polarity of the external input trigger can be configured by the TRGPOL register bit.

When an internal trigger source is selected, the trigger input is selected from one or more channel input capture events. The input capture filters are used with the internal trigger sources and the POLn bits can be used to invert the polarity of the input channels. Note that following restrictions apply with input capture channel sources.

- When (CSOT = 1), the counter will only start incrementing on a rising edge on the channel input, provided ELSnA = 1.
- When (CROT = 1), the counter will reset to zero on either edge of the channel input, as configured by ELSnB:ELSnA.
- When (CPOT = 1), the counter will pause incrementing whenever the channel input is asserted.

45.5.4 Input Capture Mode

The input capture mode is selected when (CPWMS = 0), (MSnB:MSnA = 0:0), and (ELSnB:ELSnA ≠ 0:0).

When a selected edge occurs on the channel input, the current value of the TPM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1 (see the following figure).

When a channel is configured for input capture, the TPM_CHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is counter clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register are ignored in input capture mode.

Figure 45-5. Input capture mode

The CHnF bit is set on the third rising edge of the counter clock after a valid edge occurs on the channel input.

45.5.5 Output Compare Mode

The output compare mode is selected when (CPWMS = 0), and (MSnB:MSnA = X:1).

In output compare mode, the TPM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared or toggled if MSnB is clear. If MSnB is set then the channel (n) output is pulsed high or low for as long as the counter matches the value in the CnV register.

When a channel is initially configured to output compare mode, the channel output updates with its negated value (logic 0 for set/toggle/pulse high and logic one for clear/pulse low).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV).

MOD = 0x0005
CnV = 0x0003

Figure 45-6. Example of the output compare mode when the match toggles the channel output

MOD = 0x0005
CnV = 0x0003

Figure 45-7. Example of the output compare mode when the match clears the channel output

MOD = 0x0005
CnV = 0x0003

Figure 45-8. Example of the output compare mode when the match sets the channel output

It is possible to use the output compare mode with (ELSnB:ELSnA = 0:0). In this case, when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not modified and controlled by TPM.

45.5.6 Edge-Aligned PWM (EPWM) Mode

The edge-aligned mode is selected when (CPWMS = 0), and (MSnB:MSnA = 1:0).

The EPWM period is determined by $(MOD + 0x0001)$ and the pulse width (duty cycle) is determined by CnV .

The $CHnF$ bit is set and the channel (n) interrupt is generated (if $CHnIE = 1$) at the channel (n) match (TPM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an TPM.

Figure 45-9. EPWM period and pulse width with $ELSnB:ELSnA = 1:0$

If ($ELSnB:ELSnA = 0:0$) when the counter reaches the value in the CnV register, the $CHnF$ bit is set and the channel (n) interrupt is generated (if $CHnIE = 1$), however the channel (n) output is not controlled by TPM.

If ($ELSnB:ELSnA = 1:0$), then the channel (n) output is forced high at the counter overflow (when the zero is loaded into the TPM counter), and it is forced low at the channel (n) match (TPM counter = CnV) (see the following figure).

Figure 45-10. EPWM signal with $ELSnB:ELSnA = 1:0$

If ($ELSnB:ELSnA = X:1$), then the channel (n) output is forced low at the counter overflow (when zero is loaded into the TPM counter), and it is forced high at the channel (n) match (TPM counter = CnV) (see the following figure).

MOD = 0x0008
CnV = 0x0005

Figure 45-11. EPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal. If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set since there is never a channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

45.5.7 Center-Aligned PWM (CPWM) Mode

The center-aligned mode is selected when (CPWMS = 1) and (MSnB:MSnA = 1:0).

The CPWM pulse width (duty cycle) is determined by $2 \times \text{CnV}$ and the period is determined by $2 \times \text{MOD}$ (see the following figure). MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the TPM counter counts up until it reaches MOD and then counts down until it reaches zero.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV) when the TPM counting is down (at the begin of the pulse width) and when the TPM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are when the TPM counter is zero.

The other channel modes are not designed to be used with the up-down counter (CPWMS = 1). Therefore, all TPM channels should be used in CPWM mode when (CPWMS = 1).

Figure 45-12. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the TPM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by TPM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (TPM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up (see the following figure).

Figure 45-13. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (TPM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up (see the following figure).

Figure 45-14. CPWM signal with ELSnB:ELSnA = X:1

If ($CnV = 0x0000$) then the channel (n) output is a 0% duty cycle CPWM signal.

If ($CnV > MOD$), then the channel (n) output is a 100% duty cycle CPWM signal, although the $CHnF$ bit is set when the counter changes from incrementing to decrementing. Therefore, MOD must be less than $0xFFFF$ in order to get a 100% duty cycle CPWM signal.

45.5.8 Combine PWM mode

The Combine PWM mode is selected when:

- $MSnB:MSnA = 10$
- $COMBINEn = 1$
- $QUADEN = 0$, and
- $CPWMS = 0$

In Combine PWM mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by $(MOD + 0x0001)$ and the PWM pulse width (duty cycle) is determined by $(|C(n+1)V - C(n)V|)$.

The $CHnF$ bit is set and the channel (n) interrupt is generated (if $CHnIE = 1$) at the channel (n) match (TPM counter = $C(n)V$). The $CH(n+1)F$ bit is set and the channel (n+1) interrupt is generated, if $CH(n+1)IE = 1$, at the channel (n+1) match (TPM counter = $C(n+1)V$).

If channel (n) ($ELSnB:ELSnA = X:1$), then the channel (n) output is forced low at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = $C(n+1)V$). It is forced high at the channel (n) match (TPM counter = $C(n)V$).

If channel (n) ($ELSnB:ELSnA = 1:0$), then the channel (n) output is forced high at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = $C(n+1)V$). It is forced low at the channel (n) match (TPM counter = $C(n)V$).

When ($COMSWAPn = 1$), then the channel (n) output is forced low or high at the beginning of the period (TPM counter is zero) and at the channel (n) match (TPM counter = $C(n)V$). It is forced high or low at the channel (n+1) match (TPM counter = $C(n+1)V$).

The channel (n+1) output is generated the same as the channel (n) output, but the output polarity is controlled by the channel (n+1) $ELSnB:ELSnA$ configuration.

Functional description

Figure 45-15. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

Figure 45-16. Channel (n) output if $(C(n)V < MOD)$ and $(C(n+1)V < MOD)$ and $(C(n)V < C(n+1)V)$

Figure 45-17. Channel (n) output if $(C(n)V < MOD)$ and $(C(n+1)V = MOD)$

Figure 45-18. Channel (n) output if $(C(n)V = \text{zero})$ and $(C(n+1)V < \text{MOD})$

Figure 45-19. Channel (n) output if $(C(n)V < \text{MOD})$ and $(C(n+1)V < \text{MOD})$ and $(C(n)V = C(n+1)V)$

Figure 45-20. Channel (n) output if $(C(n)V = C(n+1)V = \text{zero})$

Figure 45-21. Channel (n) output if $(C(n)V = C(n+1)V = MOD)$

45.5.9 Combine Input Capture mode

The Combine Input Capture mode is selected if $COMBINEn = 1$ and $MSnB:MSnA = 00$ and $ELSnB:ELSnA \neq 00$. This mode allows to measure a pulse width of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode.

Figure 45-22. Combine Input Capture mode block diagram

The $ELSnB:ELSnA$ bits select the edge that is captured by channel (n), and $ELSn+1B:ELSn+1A$ bits select the edge that is captured by channel (n+1).

In the Combine Input Capture mode, only channel (n) input is used and channel (n+1) input is ignored, when $COMSWAPn=1$ then only channel (n+1) input is used and channel (n) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input, then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of TPM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of TPM counter when the selected edge by channel (n+1) is detected at channel (n) input.

Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Combine Input Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0.

45.5.10 Input Capture Filter

The input capture filter function is only in input capture mode, or in software compare mode when quadrature decoder mode is enabled.

First, the input signal is synchronized by the counter clock. Following synchronization, the input signal enters the filter block. See the following figure.

Figure 45-23. Channel input filter

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to $(CHnFVAL[3:0] \times 4)$, the state change of the input signal is validated.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by $(CHnFVAL[3:0] \times 4 \text{ counter clocks})$ is regarded as a glitch and is not passed through the filter. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when $CHnFVAL[3:0]$ bits are zero. In this case, the input signal is delayed by 2 rising edges of the counter clock. If $(CHnFVAL[3:0] \neq 0000)$, then the input signal is delayed by the minimum pulse width $(CHnFVAL[3:0] \times 4 \text{ system clocks})$ plus a further 3 rising edges of the system clock: two rising edges to the synchronizer, plus one more to the edge detector. In other words, $CHnF$ is set $(3 + 4 \times CHnFVAL[3:0])$ counter clock periods after a valid edge occurs on the channel input.

Figure 45-24. Channel input filter example

45.5.11 Deadtime insertion

The deadtime insertion is enabled in PWM combine modes when $CHnFVAL$ is non-zero. The deadtime delay that is used for each TPM channel is defined as $(CHnFVAL[3:0] \times 4)$.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If $POL(n) = 0$, $POL(n+1) = 1$, and the deadtime is enabled, then when the channel (n) match (TPM counter = $C(n)V$) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (TPM counter = $C(n+1)V$) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If $POL(n) = 1$, $POL(n+1) = 0$, and the deadtime is enabled, then when the channel (n) match (TPM counter = $C(n)V$) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

when the channel (n+1) match (TPM counter = $C(n+1)V$) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared.

Figure 45-25. Deadtime insertion with $ELSnB:ELSnA = X:1$, $POL(n) = 0$, and $POL(n+1) = 1$

Figure 45-26. Deadtime insertion with $ELSnB:ELSnA = 1:0$, $POL(n) = 0$, and $POL(n+1) = 1$

45.5.12 Quadrature Decoder mode

The Quadrature Decoder mode is selected if ($QUADEN = 1$). The Quadrature Decoder mode uses the channel 0 (phase A) and channel 1 (phase B) input signals to control the TPM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

Figure 45-27. Quadrature Decoder block diagram

The input capture filter and channel polarity registers are used to configure the input filter and polarity for the channel 0 and channel 1 inputs in quadrature decode mode.

Note

Notice that the TPM counter is clocked by the channel 0 and channel 1 input signals when quadrature decoder mode is selected. Therefore In quadrature decoder mode, channel 0 and channel 1 can only be used in software compare mode and other TPM channels can only be used in input capture or output compare modes.

The QUADM0DE selects the encoding mode used in the Quadrature Decoder mode. If QUADM0DE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the channel 1 input value indicates the counting direction, and the channel 0 input defines the counting rate. The TPM counter is updated when there is a rising edge at channel 0 input signal.

Figure 45-28. Quadrature Decoder – Count and Direction Encoding mode

If QUADM0DE = 0, then the Phase Encoding mode is enabled; see the following figure. In this mode, the relationship between channel 0 and channel 1 signals indicates the counting direction, and channel 0 and channel 1 signals define the counting rate. The TPM counter is updated when there is an edge either at the channel 0 or channel 1 signals.

If CH0POL= 0 and CH1POL = 0, then the TPM counter increment happens when:

- there is a rising edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic one;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a falling edge at channel 0 signal and channel 1 signal is at logic one;

and the TPM counter decrement happens when:

- there is a falling edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic one;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a rising edge at channel 0 signal and channel 1 signal is at logic one.

Functional description

Figure 45-29. Quadrature Decoder – Phase Encoding mode

The following figure shows the TPM counter overflow in up counting. In this case, when the TPM counter changes from MOD to zero, TOF and TOFDIR bits are set. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was up when the TPM counter overflow occurred.

Figure 45-30. TPM Counter overflow in up counting for Quadrature Decoder mode

The following figure shows the TPM counter overflow in down counting. In this case, when the TPM counter changes from zero to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was down when the TPM counter overflow occurred.

Figure 45-31. TPM counter overflow in down counting for Quadrature Decoder mode

45.5.13 Registers Updated from Write Buffers

45.5.13.1 MOD Register Update

If (CMOD[1:0] = 0:0) then MOD register is updated when MOD register is written.

If (CMOD[1:0] ≠ 0:0), then MOD register is updated according to the CPWMS bit, that is:

- If the selected mode is not CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to (MOD – 1).

45.5.13.2 CnV Register Update

If (CMOD[1:0] = 0:0) then CnV register is updated when CnV register is written.

If (CMOD[1:0] ≠ 0:0), then CnV register is updated according to the selected mode, that is:

- If the selected mode is output compare then CnV register is updated on the next TPM counter increment (end of the prescaler counting) after CnV register was written.

- If the selected mode is EPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to (MOD – 1).

45.5.14 DMA

The channel and overflow flags generate a DMA transfer request according to DMA and CHnIE/TOIE bits.

See the following table for more information.

Table 45-5. DMA Transfer Request

DMA	CHnIE/TOIE	Channel/Overflow DMA Transfer Request	Channel/Overflow Interrupt
0	0	The channel/overflow DMA transfer request is not generated.	The channel/overflow interrupt is not generated.
0	1	The channel/overflow DMA transfer request is not generated.	The channel/overflow interrupt is generated if (CHnF/TOF = 1).
1	0	The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1).	The channel/overflow interrupt is not generated.
1	1	The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1).	The channel/overflow interrupt is generated if (CHnF/TOF = 1).

If DMA = 1, the CHnF/TOF bit can be cleared either by DMA transfer done or writing a one to CHnF/TOF bit (see the following table).

Table 45-6. Clear CHnF/TOF Bit

DMA	How CHnF/TOF Bit Can Be Cleared
0	CHnF/TOF bit is cleared by writing a 1 to CHnF/TOF bit.
1	CHnF/TOF bit is cleared either when the DMA transfer is done or by writing a 1 to CHnF/TOF bit.

45.5.15 Output triggers

The TPM generates output triggers for the counter and each channel that can be used to trigger events in other peripherals.

The counter trigger asserts whenever the TOF is set and remains asserted until the next increment.

Each TPM channel generates both a pre-trigger output and a trigger output. The pre-trigger output asserts whenever the CHnF is set, the trigger output asserts on the first counter increment after the pre-trigger asserts, and then both the trigger and pre-trigger negate on the first counter increment after the trigger asserts.

When (COMBINEn = 1) in output compare modes, the pre-trigger output for both channel (n) and channel (n+1) will assert when CH(n)F is set and will negate when CH(n+1)F is set. The trigger continues to assert on the first counter increment after the pre-trigger asserts and negates at the same time as the pre-trigger negation.

45.5.16 Reset Overview

The TPM is reset whenever any chip reset occurs.

When the TPM exits from reset:

- the TPM counter and the prescaler counter are zero and are stopped (CMOD[1:0] = 0:0);
- the timer overflow interrupt is zero;
- the channels interrupts are zero;
- the channels are in input capture mode;
- the channels outputs are zero;
- the channels pins are not controlled by TPM (ELS(n)B:ELS(n)A = 0:0).

45.5.17 TPM Interrupts

This section describes TPM interrupts.

45.5.17.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

45.5.17.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

Chapter 46

Low-Power Timer (LPTMR)

46.1 Chip-specific LPTMR information

46.1.1 Low power timer instantiations

This device contains 2 LPTMR modules with one 32-bit channel for each module.

LPT/HSCMP0 pulse counting:

LPTMR0_ALT0 input is the selectable source to count pulses resulting from HSCMP0 Output (LPT_ALT0 = HSCMP0 Output).

LPTMR1_ALT0 input can be configured to count the trigger out pulse from LPTMR0, so that LPTMR1 and LPTMR0 can be cascaded as one 64-bit timer.

46.1.2 LPTMRx prescaler/glitch filter clocking options

The prescaler and glitch filter of the LPTMR module can be clocked from one of four sources determined by the LPTMRx_PSR[PCS] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

LPTMRx_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
00	0	MCGIRCLK — internal reference clock (not available in VLPS/LLS/VLLS modes)

Table continues on the next page...

LPTMRx_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
01	1	LPO — 1 kHz clock (not available in VLLS0 mode)
10	2	ERCLK32K — secondary external reference clock
11	3	OSCECLK — external reference clock (not available in VLLS0 mode)

See Clock Distribution chapter for more details on these clocks.

46.1.3 LPTMRx pulse counter input options

The LPTMRx_CSR[TPS] bitfield configures the input source used in pulse counter mode. The following table shows the chip-specific input assignments for this bitfield.

LPTMRx_CSR[TPS]	Pulse counter input number	Chip input
00	0	CMP0 output
01	1	LPTMRx_ALT1 pin
10	2	LPTMRx_ALT2 pin
11	3	LPTMRx_ALT3 pin

46.2 Introduction

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

46.2.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
 - Optional interrupt can generate asynchronous wakeup from any low-power mode
 - Hardware trigger output
 - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter

- Rising-edge or falling-edge

46.2.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

Table 46-1. Modes of operation

Modes	Description
Run	The LPTMR operates normally.
Wait	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Stop	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Low-Leakage	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Debug	The LPTMR operates normally in Pulse Counter mode, but counter does not increment in Time Counter mode.

LPTMRx_CSR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TCF	Timer Compare Flag TCF is set when the LPTMR is enabled and the CNR equals the CMR and increments. TCF is cleared when the LPTMR is disabled or a logic 1 is written to it. 0 The value of CNR is not equal to CMR and increments. 1 The value of CNR is equal to CMR and increments.
6 TIE	Timer Interrupt Enable When TIE is set, the LPTMR Interrupt is generated whenever TCF is also set. 0 Timer interrupt disabled. 1 Timer interrupt enabled.
5–4 TPS	Timer Pin Select Configures the input source to be used in Pulse Counter mode. TPS must be altered only when the LPTMR is disabled. The input connections vary by device. See the for information on the connections to these inputs. 00 Pulse counter input 0 is selected. 01 Pulse counter input 1 is selected. 10 Pulse counter input 2 is selected. 11 Pulse counter input 3 is selected.
3 TPP	Timer Pin Polarity Configures the polarity of the input source in Pulse Counter mode. TPP must be changed only when the LPTMR is disabled. 0 Pulse Counter input source is active-high, and the CNR will increment on the rising-edge. 1 Pulse Counter input source is active-low, and the CNR will increment on the falling-edge.
2 TFC	Timer Free-Running Counter When clear, TFC configures the CNR to reset whenever TCF is set. When set, TFC configures the CNR to reset on overflow. TFC must be altered only when the LPTMR is disabled. 0 CNR is reset whenever TCF is set. 1 CNR is reset on overflow.
1 TMS	Timer Mode Select Configures the mode of the LPTMR. TMS must be altered only when the LPTMR is disabled. 0 Time Counter mode. 1 Pulse Counter mode.
0 TEN	Timer Enable When TEN is clear, it resets the LPTMR internal logic, including the CNR and TCF. When TEN is set, the LPTMR is enabled. While writing 1 to this field, CSR[5:1] must not be altered. 0 LPTMR is disabled and internal logic is reset. 1 LPTMR is enabled.

46.4.2 Low Power Timer Prescale Register (LPTMRx_PSR)

LPTMRx_PSR field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–3 PRESCALE	Prescale Value Configures the size of the Prescaler in Time Counter mode or width of the glitch filter in Pulse Counter mode. PRESCALE must be altered only when the LPTMR is disabled. 0000 Prescaler divides the prescaler clock by 2; glitch filter does not support this configuration. 0001 Prescaler divides the prescaler clock by 4; glitch filter recognizes change on input pin after 2 rising clock edges. 0010 Prescaler divides the prescaler clock by 8; glitch filter recognizes change on input pin after 4 rising clock edges. 0011 Prescaler divides the prescaler clock by 16; glitch filter recognizes change on input pin after 8 rising clock edges. 0100 Prescaler divides the prescaler clock by 32; glitch filter recognizes change on input pin after 16 rising clock edges. 0101 Prescaler divides the prescaler clock by 64; glitch filter recognizes change on input pin after 32 rising clock edges. 0110 Prescaler divides the prescaler clock by 128; glitch filter recognizes change on input pin after 64 rising clock edges. 0111 Prescaler divides the prescaler clock by 256; glitch filter recognizes change on input pin after 128 rising clock edges. 1000 Prescaler divides the prescaler clock by 512; glitch filter recognizes change on input pin after 256 rising clock edges. 1001 Prescaler divides the prescaler clock by 1024; glitch filter recognizes change on input pin after 512 rising clock edges. 1010 Prescaler divides the prescaler clock by 2048; glitch filter recognizes change on input pin after 1024 rising clock edges. 1011 Prescaler divides the prescaler clock by 4096; glitch filter recognizes change on input pin after 2048 rising clock edges. 1100 Prescaler divides the prescaler clock by 8192; glitch filter recognizes change on input pin after 4096 rising clock edges. 1101 Prescaler divides the prescaler clock by 16,384; glitch filter recognizes change on input pin after 8192 rising clock edges.

Table continues on the next page...

LPTMRx_PSR field descriptions (continued)

Field	Description
	1110 Prescaler divides the prescaler clock by 32,768; glitch filter recognizes change on input pin after 16,384 rising clock edges. 1111 Prescaler divides the prescaler clock by 65,536; glitch filter recognizes change on input pin after 32,768 rising clock edges.
2 PBYP	Prescaler Bypass When PBYP is set, the selected prescaler clock in Time Counter mode or selected input source in Pulse Counter mode directly clocks the CNR. When PBYP is clear, the CNR is clocked by the output of the prescaler/glitch filter. PBYP must be altered only when the LPTMR is disabled. 0 Prescaler/glitch filter is enabled. 1 Prescaler/glitch filter is bypassed.
PCS	Prescaler Clock Select Selects the clock to be used by the LPTMR prescaler/glitch filter. PCS must be altered only when the LPTMR is disabled. The clock connections vary by device. NOTE: See the chip configuration details for information on the connections to these inputs. 00 Prescaler/glitch filter clock 0 selected. 01 Prescaler/glitch filter clock 1 selected. 10 Prescaler/glitch filter clock 2 selected. 11 Prescaler/glitch filter clock 3 selected.

46.4.3 Low Power Timer Compare Register (LPTMRx_CMCR)

Address: Base address + 8h offset

LPTMRx_CMCR field descriptions

Field	Description
COMPARE	Compare Value When the LPTMR is enabled and the CNR equals the value in the CMR and increments, TCF is set and the hardware trigger asserts until the next time the CNR increments. If the CMR is 0, the hardware trigger will remain asserted until the LPTMR is disabled. If the LPTMR is enabled, the CMR must be altered only when TCF is set.

46.4.4 Low Power Timer Counter Register (LPTMRx_CNR)

NOTE

See [LPTMR counter](#) for details on how to read counter value.

Address: Base address + Ch offset

LPTMRx_CNR field descriptions

Field	Description
COUNTER	Counter Value

46.5 Functional description

46.5.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

46.5.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

NOTE

The clock source selected need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency f_{LPTMR} defined in the device datasheet.

46.5.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

46.5.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every 2^2 to 2^{16} prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

46.5.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

46.5.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output will also deassert.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising-edges	The glitch filter output will also assert.

NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every 2^2 to 2^{16} prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

46.5.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

46.5.4 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

46.5.5 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

The CNR continues incrementing when the core is halted in Debug mode when configured for Pulse Counter mode, the CNR will stop incrementing when the core is halted in Debug mode when configured for Time Counter mode.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

46.5.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

When	Then
The CMR is set to 0 with CSR[TFC] clear	The LPTMR hardware trigger will assert on the first compare and does not deassert.
The CMR is set to a nonzero value, or, if CSR[TFC] is set	The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR.

46.5.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

Functional description

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

Chapter 47

Carrier Modulator Transmitter (CMT)

47.1 Chip-specific CMT information

47.1.1 Instantiation Information

This device contains one CMT module.

47.2 Introduction

The carrier modulator transmitter (CMT) module provides the means to generate the protocol timing and carrier signals for a wide variety of encoding schemes. The CMT incorporates hardware to off-load the critical and/or lengthy timing requirements associated with signal generation from the CPU, releasing much of its bandwidth to handle other tasks such as:

- Code data generation
- Data decompression, or,
- Keyboard scanning

The CMT does not include dedicated hardware configurations for specific protocols, but is intended to be sufficiently programmable in its function to handle the timing requirements of most protocols with minimal CPU intervention.

When the modulator is disabled, certain CMT registers can be used to change the state of the infrared output (IRO) signal directly. This feature allows for the generation of future protocol timing signals not readily producible by the current architecture.

47.3 Features

The features of this module include:

- Four modes of operation:
 - Time; with independent control of high and low times
 - Baseband
 - Frequency-shift key (FSK)
 - Direct software control of the IRO signal
- Extended space operation in Time, Baseband, and FSK modes
- Selectable input clock divider
- Interrupt on end-of-cycle
 - Ability to disable the IRO signal and use as timer interrupt

47.4 Block diagram

The following figure presents the block diagram of the CMT module.

Figure 47-1. CMT module block diagram

47.5 Modes of operation

The following table describes the operation of the CMT module operates in various modes.

Table 47-1. Modes of operation

Modes	Description
Time	In Time mode, the user independently defines the high and low times of the carrier signal to determine both period and duty cycle
Baseband	When MSC[BASE] is set, the carrier output (f_{cg}) to the modulator is held high continuously to allow for the generation of baseband protocols.

Table continues on the next page...

Table 47-1. Modes of operation (continued)

Modes	Description
Frequency-shift key	This mode allows the carrier generator to alternate between two sets of high and low times. When operating in FSK mode, the generator will toggle between the two sets when instructed by the modulator, allowing the user to dynamically switch between two carrier frequencies without CPU intervention.

The following table summarizes the modes of operation of the CMT module.

Table 47-2. CMT modes of operation

Mode	MSC[MCGEN] ¹	MSC[BASE]	MSC[FSK] ²	MSC[EXSPC]	Comment
Time	1	0	0	0	f_{cg} controlled by primary high and low registers. f_{cg} transmitted to the IRO signal when modulator gate is open.
Baseband	1	1	X	0	f_{cg} is always high. The IRO signal is high when the modulator gate is open.
FSK	1	0	1	0	f_{cg} control alternates between primary high/low registers and secondary high/low registers. f_{cg} transmitted to the IRO signal when modulator gate is open.
Extended Space	1	X	X	1	Setting MSC[EXSPC] causes subsequent modulator cycles to be spaces (modulator out not asserted) for the duration of the modulator period (mark and space times).
IRO Latch	0	X	X	X	OC[IROL] controls the state of the IRO signal.

1. To prevent spurious operation, initialize all data and control registers before beginning a transmission when MSC[MCGEN]=1.
2. This field is not double-buffered and must not be changed during a transmission while MSC[MCGEN]=1.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

47.5.1 Wait mode operation

During Wait mode, the CMT if enabled, will continue to operate normally. However, there is no change in operating modes of CMT during Wait mode, because the CPU is not operating.

47.5.2 Stop mode operation

This section describes the CMT Stop mode operations.

47.5.2.1 Normal Stop mode operation

During Normal Stop mode, clocks to the CMT module are halted. No registers are affected.

The CMT module will resume upon exit from Normal Stop mode because the clocks are halted. Software must ensure that the Normal Stop mode is not entered while the modulator is still in operation so as to prevent the IRO signal from being asserted while in Normal Stop mode. This may require a timeout period from the time that MSC[MCGEN] is cleared to allow the last modulator cycle to complete.

47.5.2.2 Low-Power Stop mode operation

During Low-Power Stop mode, the CMT module is completely powered off internally and the IRO signal state is latched and held at the time when the CMT enters this mode. To prevent the IRO signal from being asserted during Low-Power Stop mode, the software must assure that the signal is not active when entering Low-Power Stop mode. Upon wakeup from Low-Power Stop mode, the CMT module will be in the reset state.

47.6 CMT external signal descriptions

The following table shows the description of the external signal.

Table 47-3. CMT signal description

Signal	Description	I/O
CMT_IRO	Infrared Output	O

47.6.1 CMT_IRO — Infrared Output

This output signal is driven by the modulator output when MSC[MCGEN] and OC[IROPEN] are set. The IRO signal starts a valid transmission with a delay, after MSC[MCGEN] bit be asserted to high, that can be calculated based on two register bits. [Table 47-4](#) shows how to calculate this delay.

The following table describes conditions for the IRO signal to be active.

If	Then
MSC[MCGEN] is cleared and OC[IROPEN] is set	The signal is driven by OC[IROL] . This enables user software to directly control the state of the IRO signal by writing to OC[IROL] .
OC[IROPEN] is cleared	The signal is disabled and is not driven by the CMT module. Therefore, CMT can be configured as a modulo timer for generating periodic interrupts without causing signal activity.

Table 47-4. CMT_IRO signal delay calculation

Condition	Delay (bus clock cycles)
MSC[CMTDIV] = 0	PPS[PPSDIV] + 2
MSC[CMTDIV] > 0	(PPS[PPSDIV] *2) + 3

47.7 Memory map/register definition

The following registers control and monitor the CMT operation.

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level. The address offset is defined at the module level.

CMT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_2000	CMT Carrier Generator High Data Register 1 (CMT_CGH1)	8	R/W	Undefined	47.7.1/1401

47.7.1 CMT Carrier Generator High Data Register 1 (CMT_CGH1)

This data register contains the primary high value for generating the carrier output.

Address: 4006_2000h base + 0h offset = 4006_2000h

Bit	7	6	5	4	3	2	1	0
Read	PH							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

CMT_CGH1 field descriptions

Field	Description
PH	Primary Carrier High Time Data Value Contains the number of input clocks required to generate the carrier high time period. When operating in Time mode, this register is always selected. When operating in FSK mode, this register and the secondary register pair are alternately selected under the control of the modulator. The primary carrier high time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled to avoid spurious results.

47.7.2 CMT Carrier Generator Low Data Register 1 (CMT_CGL1)

This data register contains the primary low value for generating the carrier output.

Address: 4006_2000h base + 1h offset = 4006_2001h

Bit	7	6	5	4	3	2	1	0
Read	PL							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

CMT_CGL1 field descriptions

Field	Description
PL	Primary Carrier Low Time Data Value Contains the number of input clocks required to generate the carrier low time period. When operating in Time mode, this register is always selected. When operating in FSK mode, this register and the secondary register pair are alternately selected under the control of the modulator. The primary carrier low time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled to avoid spurious results.

47.7.3 CMT Carrier Generator High Data Register 2 (CMT_CGH2)

This data register contains the secondary high value for generating the carrier output.

CMT_CGH2 field descriptions

Field	Description
SH	Secondary Carrier High Time Data Value Contains the number of input clocks required to generate the carrier high time period. When operating in Time mode, this register is never selected. When operating in FSK mode, this register and the primary register pair are alternately selected under control of the modulator.

CMT_CGH2 field descriptions (continued)

Field	Description
	The secondary carrier high time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled when operating in FSK mode.

47.7.4 CMT Carrier Generator Low Data Register 2 (CMT_CGL2)

This data register contains the secondary low value for generating the carrier output.

Address: 4006_2000h base + 3h offset = 4006_2003h

Bit	7	6	5	4	3	2	1	0
Read	SL							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

CMT_CGL2 field descriptions

Field	Description
SL	Secondary Carrier Low Time Data Value Contains the number of input clocks required to generate the carrier low time period. When operating in Time mode, this register is never selected. When operating in FSK mode, this register and the primary register pair are alternately selected under the control of the modulator. The secondary carrier low time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled when operating in FSK mode.

47.7.5 CMT Output Control Register (CMT_OC)

This register is used to control the IRO signal of the CMT module.

Address: 4006_2000h base + 4h offset = 4006_2004h

Bit	7	6	5	4	3	2	1	0
Read	IROL	CMPOL	IROPEN	0				
Write								
Reset	0	0	0	0	0	0	0	0

CMT_OC field descriptions

Field	Description
7 IROL	IRO Latch Control Reads the state of the IRO latch. Writing to IROL changes the state of the IRO signal when MSC[MCGEN] is cleared and IROPEN is set.
6 CMTPOL	CMT Output Polarity Controls the polarity of the IRO signal. 0 The IRO signal is active-low. 1 The IRO signal is active-high.
5 IROPEN	IRO Pin Enable Enables and disables the IRO signal. When the IRO signal is enabled, it is an output that drives out either the CMT transmitter output or the state of IROL depending on whether MSC[MCGEN] is set or not. Also, the state of output is either inverted or non-inverted, depending on the state of CMTPOL. When the IRO signal is disabled, it is in a high-impedance state and is unable to draw any current. This signal is disabled during reset. 0 The IRO signal is disabled. 1 The IRO signal is enabled as output.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.6 CMT Modulator Status and Control Register (CMT_MSC)

This register contains the modulator and carrier generator enable (MCGEN), end of cycle interrupt enable (EOCIE), FSK mode select (FSK), baseband enable (BASE), extended space (EXSPC), prescaler (CMTDIV) bits, and the end of cycle (EOCF) status bit.

Address: 4006_2000h base + 5h offset = 4006_2005h

Bit	7	6	5	4	3	2	1	0
Read	EOCF	CMTDIV		EXSPC	BASE	FSK	EOCIE	MCGEN
Write								
Reset	0	0	0	0	0	0	0	0

CMT_MSC field descriptions

Field	Description
7 EOCF	End Of Cycle Status Flag Sets when:

Table continues on the next page...

CMT_MSC field descriptions (continued)

Field	Description
	- The modulator is not currently active and MCGEN is set to begin the initial CMT transmission. - At the end of each modulation cycle while MCGEN is set. This is recognized when a match occurs between the contents of the space period register and the down counter. At this time, the counter is initialized with, possibly new contents of the mark period buffer, CMD1 and CMD2, and the space period register is loaded with, possibly new contents of the space period buffer, CMD3 and CMD4. This flag is cleared by reading MSC followed by an access of CMD2 or CMD4, or by the DMA transfer. 0 End of modulation cycle has not occurred since the flag last cleared. 1 End of modulator cycle has occurred.
6–5 CMTDIV	CMT Clock Divide Prescaler Causes the CMT to be clocked at the IF signal frequency, or the IF frequency divided by 2, 4, or 8. This field must not be changed during a transmission because it is not double-buffered. 00 IF ÷ 1 01 IF ÷ 2 10 IF ÷ 4 11 IF ÷ 8
4 EXSPC	Extended Space Enable Enables the extended space operation. 0 Extended space is disabled. 1 Extended space is enabled.
3 BASE	Baseband Enable When set, BASE disables the carrier generator and forces the carrier output high for generation of baseband protocols. When BASE is cleared, the carrier generator is enabled and the carrier output toggles at the frequency determined by values stored in the carrier data registers. This field is cleared by reset. This field is not double-buffered and must not be written to during a transmission. 0 Baseband mode is disabled. 1 Baseband mode is enabled.
2 FSK	FSK Mode Select Enables FSK operation. 0 The CMT operates in Time or Baseband mode. 1 The CMT operates in FSK mode.
1 EOCIE	End of Cycle Interrupt Enable Requests to enable a CPU interrupt when EOCF is set if EOCIE is high.

Table continues on the next page...

CMT_MSC field descriptions (continued)

Field	Description
	0 CPU interrupt is disabled. 1 CPU interrupt is enabled.
0 MCGEN	Modulator and Carrier Generator Enable Setting MCGEN will initialize the carrier generator and modulator and will enable all clocks. When enabled, the carrier generator and modulator will function continuously. When MCGEN is cleared, the current modulator cycle will be allowed to expire before all carrier and modulator clocks are disabled to save power and the modulator output is forced low. NOTE: To prevent spurious operation, the user should initialize all data and control registers before enabling the system. 0 Modulator and carrier generator disabled 1 Modulator and carrier generator enabled

47.7.7 CMT Modulator Data Register Mark High (CMT_CMD1)

The contents of this register are transferred to the modulator down counter upon the completion of a modulation period.

Address: 4006_2000h base + 6h offset = 4006_2006h

Bit	7	6	5	4	3	2	1	0
Read	MB[15:8]							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

Field	Description
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DMA	DMA Enable Enables the DMA protocol. 0 DMA transfer request and done are disabled. 1 DMA transfer request and done are enabled.

47.8 Functional description

The CMT module primarily consists of clock divider, carrier generator, and modulator.

47.8.1 Clock divider

The CMT was originally designed to be based on an 8 MHz bus clock that could be divided by 1, 2, 4, or 8 according to the specification. To be compatible with higher bus frequency, the primary prescaler (PPS) was developed to receive a higher frequency and generate a clock enable signal called intermediate frequency (IF). This IF must be approximately equal to 8 MHz and will work as a clock enable to the secondary prescaler. The following figure shows the clock divider block diagram.

Figure 47-2. Clock divider block diagram

For compatibility with previous versions of CMT, when bus clock = 8 MHz, the PPS must be configured to zero. The PPS counter is selected according to the bus clock to generate an intermediate frequency approximately equal to 8 MHz.

47.8.2 Carrier generator

The carrier generator resolution is 125 ns when operating with an 8 MHz intermediate frequency signal and the secondary prescaler is set to divide by 1, or, when $MSC[CMTDIV] = 00$. The carrier generator can generate signals with periods between 250 ns (4 MHz) and 127.5 μ s (7.84 kHz) in steps of 125 ns. The following table shows the relationship between the clock divide bits and the carrier generator resolution, minimum carrier generator period, and minimum modulator period.

Table 47-5. Clock divider

Bus clock (MHz)	MSC[CMTDIV]	Carrier generator resolution (μ s)	Min. carrier generator period (μ s)	Min. modulator period (μ s)
8	00	0.125	0.25	1.0
8	01	0.25	0.5	2.0
8	10	0.5	1.0	4.0
8	11	1.0	2.0	8.0

The possible duty cycle options depend upon the number of counts required to complete the carrier period. For example, 1.6 MHz signal has a period of 625 ns and will therefore require 5 x 125 ns counts to generate. These counts may be split between high and low times, so the duty cycles available will be:

- 20% with one high and four low times
- 40% with two high and three low times
- 60% with three high and two low times, and
- 80% with four high and one low time

For low-frequency signals with large periods, high-resolution duty cycles as a percentage of the total period, are possible.

The carrier signal is generated by counting a register-selected number of input clocks (125 ns for an 8 MHz bus) for both the carrier high time and the carrier low time. The period is determined by the total number of clocks counted. The duty cycle is determined by the ratio of high-time clocks to total clocks counted. The high and low time values are user-programmable and are held in two registers.

An alternate set of high/low count values is held in another set of registers to allow the generation of dual-frequency FSK protocols without CPU intervention.

Note

Only nonzero data values are allowed. The carrier generator will not work if any of the count values are equal to zero.

MSC[MCGEN] must be set and MSC[BASE] must be cleared to enable carrier generator clocks. When MSC[BASE] is set, the carrier output to the modulator is held high continuously. The following figure represents the block diagram of the clock generator.

Figure 47-3. Carrier generator block diagram

The high/low time counter is an 8-bit up counter. After each increment, the contents of the counter are compared with the appropriate high or low count value register. When the compare value is reached, the counter is reset to a value of 0x01, and the compare is redirected to the other count value register.

Assuming that the high time count compare register is currently active, a valid compare will cause the carrier output to be driven low. The counter will continue to increment starting at the reset value of 0x01. When the value stored in the selected low count value register is reached, the counter will again be reset and the carrier output will be driven high.

The cycle repeats, automatically generating a periodic signal which is directed to the modulator. The lower frequency with maximum period, $f_{\max}$, and highest frequency with minimum period, $f_{\min}$, which can be generated, are defined as:

$$f_{\max} = f_{\text{CMTCLK}} \div (2 * 1) \text{ Hz}$$

$$f_{\min} = f_{\text{CMTCLK}} \div (2 * (2^8 - 1)) \text{ Hz}$$

In the general case, the carrier generator output frequency is:

$$f_{\text{cg}} = f_{\text{CMTCLK}} \div (\text{High count} + \text{Low count}) \text{ Hz}$$

Where: $0 < \text{High count} < 256$ and

$$0 < \text{Low count} < 256$$

The duty cycle of the carrier signal is controlled by varying the ratio of high time to low + high time. As the input clock period is fixed, the duty cycle resolution will be proportional to the number of counts required to generate the desired carrier period.

$$\text{DutyCycle} = \frac{\text{Highcount}}{\text{Highcount} + \text{Lowcount}}$$

47.8.3 Modulator

The modulator block controls the state of the infrared out signal (IRO). The modulator output is gated on to the IRO signal when the modulator/carrier generator is enabled. . When the modulator/carrier generator is disabled, the IRO signal is controlled by the state of the IRO latch. OC[CMTPOL] enables the IRO signal to be active-high or active-low.

The following table describes the functions of the modulators in different modes:

Table 47-6. Mode functions

Mode	Function
Time	The modulator can gate the carrier onto the modulator output.
Baseband	The modulator can control the logic level of the modulator output.
FSK	The modulator can count carrier periods and instruct the carrier generator to alternate between two carrier frequencies whenever a modulation period consisting of mark and space counts, expires.

The modulator provides a simple method to control protocol timing. The modulator has a minimum resolution of 1.0 μ s with an 8 MHz. It can count bus clocks to provide real-time control, or carrier clocks for self-clocked protocols.

The modulator includes a 17-bit down counter with underflow detection. The counter is loaded from the 16-bit modulation mark period buffer registers, CMD1 and CMD2. The most significant bit is loaded with a logic 0 and serves as a sign bit.

When	Then
The counter holds a positive value	The modulator gate is open and the carrier signal is driven to the transmitter block.
The counter underflows	The modulator gate is closed and a 16-bit comparator is enabled which compares the logical complement of the value of the down counter with the contents of the modulation space period register which has been loaded from the registers, CMD3 and CMD4.

When a match is obtained, the cycle repeats by opening the modulator gate, reloading the counter with the contents of CMD1 and CMD2, and reloading the modulation space period register with the contents of CMD3 and CMD4.

The modulation space period is activated when the carrier signal is low to prohibit cutting off the high pulse of a carrier signal. If the carrier signal is high, the modulator extends the mark period until the carrier signal becomes low. To deassert the space period and assert the mark period, the carrier signal must have gone low to ensure that a space period is not erroneously shortened.

If the contents of the modulation space period register are all zeroes, the match will be immediate and no space period will be generated, for instance, for FSK protocols that require successive bursts of different frequencies).

MSC[MCGEN] must be set to enable the modulator timer.

The following figure presents the block diagram of the modulator.

Figure 47-4. Modulator block diagram

47.8.3.1 Time mode

When the modulator operates in Time mode, or, when MSC[MCGEN] is set, and MSC[BASE] and MSC[FSK] are cleared:

- The modulation mark period consists of an integer number of $(\text{CMTCLK} \div 8)$ clock periods.
- The modulation space period consists of 0 or an integer number of $(\text{CMTCLK} \div 8)$ clock periods.

With an 8 MHz IF and $\text{MSC}[\text{CMTDIV}] = 00$, the modulator resolution is 1 μs and has a maximum mark and space period of about 65.535 ms each. See [Figure 47-5](#) for an example of the Time and Baseband mode outputs.

The mark and space time equations for Time and Baseband mode are:

$$t_{\text{mark}} = (\text{CMD1}:\text{CMD2} + 1) \div (f_{\text{CMTCLK}} \div 8)$$

$$t_{\text{space}} = \text{CMD3}:\text{CMD4} \div (f_{\text{CMTCLK}} \div 8)$$

where $\text{CMD1}:\text{CMD2}$ and $\text{CMD3}:\text{CMD4}$ are the decimal values of the concatenated registers.

Figure 47-5. Example: CMT output in Time and Baseband modes with $\text{OC}[\text{CMTPOL}] = 0$

47.8.3.2 Baseband mode

Baseband mode, that is, when $\text{MSC}[\text{MCGEN}]$ and $\text{MSC}[\text{BASE}]$ are set, is a derivative of Time mode, where the mark and space period is based on $(\text{CMTCLK} \div 8)$ counts. The mark and space calculations are the same as in Time mode.

In this mode, the modulator output will be at a logic 1 for the duration of the mark period and at a logic 0 for the duration of a space period. See [Figure 47-5](#) for an example of the output for both Baseband and Time modes. In the example, the carrier out frequency (f_{cg}) is generated with a high count of 0x01 and a low count of 0x02 that results in a divide of 3 of CMTCLK with a 33% duty cycle. The modulator down counter was loaded with the value 0x0003 and the space period register with 0x0002.

Note

The waveforms in [Figure 47-5](#) and [Figure 47-6](#) are for the purpose of conceptual illustration and are not meant to represent precise timing relationships between the signals shown.

47.8.3.3 FSK mode

When the modulator operates in FSK mode, that is, when MSC[MCGEN] and MSC[FSK] are set, and MSC[BASE] is cleared:

- The modulation mark and space periods consist of an integer number of carrier clocks (space period can be zero).
- When the mark period expires, the space period is transparently started as in Time mode.
- The carrier generator toggles between primary and secondary data register values whenever the modulator space period expires.

The space period provides an interpulse gap (no carrier). If CMD3:CMD4 = 0x0000, then the modulator and carrier generator will switch between carrier frequencies without a gap or any carrier glitches (zero space).

Using timing data for carrier burst and interpulse gap length calculated by the CPU, FSK mode can automatically generate a phase-coherent, dual-frequency FSK signal with programmable burst and interburst gaps.

The mark and space time equations for FSK mode are:

$$t_{\text{mark}} = (\text{CMD1:CMD2} + 1) \div f_{cg}$$

$$t_{\text{space}} = (\text{CMD3:CMD4}) \div f_{cg}$$

Where f_{cg} is the frequency output from the carrier generator. The example in [Figure 47-6](#) shows what the IRO signal looks like in FSK mode with the following values:

- CMD1:CMD2 = 0x0003
- CMD3:CMD4 = 0x0002
- Primary carrier high count = 0x01
- Primary carrier low count = 0x02

- Secondary carrier high count = 0x03
- Secondary carrier low count = 0x01

Figure 47-6. Example: CMT output in FSK mode

47.8.4 Extended space operation

In either Time, Baseband, or FSK mode, the space period can be made longer than the maximum possible value of the space period register. Setting MSC[EXSPC] will force the modulator to treat the next modulation period beginning with the next load of the counter and space period register, as a space period equal in length to the mark and space counts combined. Subsequent modulation periods will consist entirely of these extended space periods with no mark periods. Clearing MSC[EXSPC] will return the modulator to standard operation at the beginning of the next modulation period.

47.8.4.1 EXSPC operation in Time mode

To calculate the length of an extended space in Time or Baseband mode, add the mark and space times and multiply by the number of modulation periods when MSC[EXSPC] is set.

$$t_{\text{exspace}} = (t_{\text{mark}} + t_{\text{space}}) * (\text{number of modulation periods})$$

For an example of extended space operation, see [Figure 47-7](#).

Note

The extended space enable feature can be used to emulate a zero mark event.

Figure 47-7. Extended space operation

47.8.4.2 EXSPC operation in FSK mode

In FSK mode, the modulator continues to count carrier out clocks, alternating between the primary and secondary registers at the end of each modulation period.

To calculate the length of an extended space in FSK mode, it is required to know whether MSC[EXSPC] was set on a primary or secondary modulation period, and the total number of both primary and secondary modulation periods completed while MSC[EXSPC] is high. A status bit for the current modulation is not accessible to the CPU. If necessary, software must maintain tracking of the current primary or secondary modulation cycle. The extended space period ends at the completion of the space period time of the modulation period during which MSC[EXSPC] is cleared.

The following table depicts the equations which can be used to calculate the extended space period depending on when MSC[EXSPC] is set.

If	Then
MSC[EXSPC] was set during a primary modulation cycle	Use the equation: $t_{\text{exspace}} = (t_{\text{space}})_p + (t_{\text{mark}} + t_{\text{space}})_s + (t_{\text{mark}} + t_{\text{space}})_p + \dots$
MSC[EXSPC] bit was set during a secondary modulation cycle	Use the equation: $t_{\text{exspace}} = (t_{\text{space}})_s + (t_{\text{mark}} + t_{\text{space}})_p + (t_{\text{mark}} + t_{\text{space}})_s + \dots$

Where the subscripts p and s refer to mark and space times for the primary and secondary modulation cycles.

47.9 CMT interrupts and DMA

The CMT generates an interrupt request or a DMA transfer request according to MSC[EOCIE], MSC[EOCF], DMA[DMA] bits.

Table 47-7. DMA transfer request x CMT interrupt request

MSC[EOCF]	DMA[DMA]	MSC[EOCIE]	DMA transfer request	CMT interrupt request
0	X	X	0	0
1	X	0	0	0
1	0	1	0	1
1	1	1	1	0

MSC[EOCF] is set:

- When the modulator is not currently active and MSC[MCGEN] is set to begin the initial CMT transmission.
- At the end of each modulation cycle when the counter is reloaded from CMD1:CMD2, while MSC[MCGEN] is set.

When MSC[MCGEN] is cleared and then set before the end of the modulation cycle, MSC[EOCF] will not be set when MSC[MCGEN] is set, but will become set at the end of the current modulation cycle.

When MSC[MCGEN] becomes disabled, the CMT module does not set MSC[EOCF] at the end of the last modulation cycle.

If MSC[EOCIE] is high when MSC[EOCF] is set, the CMT module will generate an interrupt request or a DMA transfer request.

MSC[EOCF] must be cleared to prevent from being generated by another event like interrupt or DMA request, after exiting the service routine. See the following table.

Table 47-8. How to clear MSC[EOCF]

DMA[DMA]	MSC[EOCIE]	Description
0	X	MSC[EOCF] is cleared by reading MSC followed by an access of CMD2 or CMD4.
1	X	MSC[EOCF] is cleared by the CMT DMA transfer done.

The EOC interrupt is coincident with:

- Loading the down-counter with the contents of CMD1:CMD2
- Loading the space period register with the contents of CMD3:CMD4

The EOC interrupt provides a means for the user to reload new mark/space values into the modulator data registers. Modulator data register updates will take effect at the end of the current modulation cycle.

NOTE

The down-counter and space period register are updated at the end of every modulation cycle, irrespective of interrupt handling and the state of MSC[EOCF].

PDB trigger outputs	Connection
Channel 0 triggers	ADC0 trigger
Channel 1 triggers	synchronous input 1 of FTM0
DAC triggers	DAC0 trigger
Pulse-out	Pulse-out connected to each CMP module's sample/window input to control sample operation

48.1.3 Back-to-back acknowledgement connections

In this MCU, PDB back-to-back operation acknowledgment connections are implemented as follows:

- PDB channel 0 pre-trigger 0 acknowledgement input: ADC0SC1B_COCO
- PDB channel 0 pre-trigger 1 acknowledgement input: ADC0SC1A_COCO
- PDB channel 1 pre-trigger 0 acknowledgement input: Not Used
- PDB channel 1 pre-trigger 1 acknowledgement input: Not Used

So, the back-to-back chain is connected as a ring:

Figure 48-1. PDB back-to-back chain

The application code can set the `PDBx_CHnC1[BB]` bits to configure the PDB pre-triggers as a single chain or several chains.

48.1.4 PDB Interval Trigger Connections to DAC

In this MCU, PDB interval trigger connections to DAC are implemented as follows.

- PDB interval trigger 0 connects to DAC0 hardware trigger input.

48.1.5 DAC External Trigger Input Connections

In this MCU, the following DAC external trigger inputs are implemented.

- DAC external trigger input 0: `ADC0SC1A_COCO`

NOTE

Application code can set the `PDBx_DACINTCn[EXT]` bit to allow DAC external trigger input when the corresponding ADC Conversion complete flag, `ADCx_SC1n[COCO]`, is set.

48.1.6 Pulse-Out Connection

Individual PDB Pulse-Out signals are connected to each CMP block and used for sample window.

48.1.7 Pulse-Out Enable Register Implementation

The following table shows the comparison of pulse-out enable register at the module and chip level.

Table 48-3. PDB pulse-out enable register

Register	Module implementation	Chip implementation
POnEN	7:0 - POEN 31:8 - Reserved	0 - POEN[0] for CMP0 1 - POEN[1] for CMP1 31:2 - Reserved

48.2 Introduction

The Programmable Delay Block (PDB) provides controllable delays from either an internal or an external trigger, or a programmable interval tick, to the hardware trigger inputs of ADCs and/or generates the interval triggers to DACs, so that the precise timing between ADC conversions and/or DAC updates can be achieved. The PDB can optionally provide pulse outputs (Pulse-Out's) that are used as the sample window in the CMP block.

48.2.1 Features

- Up to 15 trigger input sources and one software trigger source
- Up to 8 configurable PDB channels for ADC hardware trigger
 - One PDB channel is associated with one ADC
 - One trigger output for ADC hardware trigger and up to 8 pre-trigger outputs for ADC trigger select per PDB channel
 - Trigger outputs can be enabled or disabled independently
 - One 16-bit delay register per pre-trigger output
 - Optional bypass of the delay registers of the pre-trigger outputs
 - Operation in One-Shot or Continuous modes
 - Optional back-to-back mode operation, which enables the ADC conversions complete to trigger the next PDB channel
 - One programmable delay interrupt

- One sequence error interrupt
- One channel flag and one sequence error flag per pre-trigger
- DMA support
- Up to 8 DAC interval triggers
 - One interval trigger output per DAC
 - One 16-bit delay interval register per DAC trigger output
 - Optional bypass of the delay interval trigger registers
 - Optional external triggers
- Up to 8 pulse outputs (pulse-out's)
 - Pulse-out's can be enabled or disabled independently
 - Programmable pulse width

NOTE

The number of PDB input and output triggers are chip-specific.
See the chip-specific PDB information for details.

48.2.2 Implementation

In this section, the following letters refer to the number of output triggers:

- *N*—Total available number of PDB channels.
- *n*—PDB channel number, valid from 0 to *N*-1.
- *M*—Total available pre-trigger per PDB channel.
- *m*—Pre-trigger number, valid from 0 to *M*-1.
- *X*—Total number of DAC interval triggers.
- *x*—DAC interval trigger output number, valid from 0 to *X*-1.
- *Y*—Total number of Pulse-Out's.
- *y*—Pulse-Out number, valid value is from 0 to *Y*-1.

NOTE

The number of module output triggers to core is chip-specific. For module to core output triggers implementation, see the chip configuration information.

48.2.3 Back-to-back acknowledgment connections

PDB back-to-back operation acknowledgment connections are chip-specific. For implementation, see the chip configuration information.

48.2.4 DAC External Trigger Input Connections

The implementation of DAC external trigger inputs is chip-specific. See the chip configuration information for details.

48.2.5 Block diagram

This diagram illustrates the major components of the PDB.

Figure 48-2. PDB block diagram

In this diagram, only one PDB channel n , one DAC interval trigger x , and one Pulse-Out y are shown. The PDB-enabled control logic and the sequence error interrupt logic are not shown.

48.2.6 Modes of operation

PDB ADC trigger operates in the following modes:

- Disabled—Counter is off, all pre-trigger and trigger outputs are low if PDB is not in back-to-back operation of Bypass mode.
- Debug—Counter is paused when processor is in Debug mode, and the counter for the DAC trigger is also paused in Debug mode.
- Enabled One-Shot—Counter is enabled and restarted at count zero upon receiving a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1. In each PDB channel, an enabled pre-trigger asserts once per trigger input event. The trigger output asserts whenever any of the pre-triggers is asserted.
- Enabled Continuous—Counter is enabled and restarted at count zero. The counter is rolled over to zero again when the count reaches the value specified in the modulus register, and the counting is restarted. This enables a continuous stream of pre-triggers/trigger outputs as a result of a single trigger input event.
- Enabled Bypassed—The pre-trigger and trigger outputs assert immediately after a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1, that is the delay registers are bypassed. It is possible to bypass any one or more of the delay registers; therefore, this mode can be used in conjunction with One-Shot or Continuous mode.

48.3 PDB signal descriptions

This table shows the detailed description of the external signal.

Table 48-4. PDB signal descriptions

Signal	Description	I/O
EXTRG	External Trigger Input Source If the PDB is enabled and external trigger input source is selected, a positive edge on the EXTRG signal resets and starts the counter.	I

48.4 Memory map and register definition

PDB memory map

PDBx_SC field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–18 LDMOD	Load Mode Select Selects the mode to load the MOD, IDLY, CH _n DLY _m , INT _x , and POyDLY registers, after 1 is written to LDOK. 00 The internal registers are loaded with the values from their buffers, immediately after 1 is written to LDOK. 01 The internal registers are loaded with the values from their buffers when the PDB counter (CNT) = MOD + 1 CNT delay elapsed, after 1 is written to LDOK. 10 The internal registers are loaded with the values from their buffers when a trigger input event is detected, after 1 is written to LDOK. 11 The internal registers are loaded with the values from their buffers when either the PDB counter (CNT) = MOD + 1 CNT delay elapsed, or a trigger input event is detected, after 1 is written to LDOK.
17 PDBEIE	PDB Sequence Error Interrupt Enable Enables the PDB sequence error interrupt. When PDBEIE is set, any of the PDB channel sequence error flags generates a PDB sequence error interrupt.

Table continues on the next page...

PDBx_SC field descriptions (continued)

Field	Description
	0 PDB sequence error interrupt disabled. 1 PDB sequence error interrupt enabled.
16 SWTRIG	Software Trigger When PDB is enabled and the software trigger is selected as the trigger input source, writing 1 to SWTRIG resets and restarts the counter. Writing 0 to SWTRIG has no effect. Reading SWTRIG yields 0.
15 DMAEN	DMA Enable When DMA is enabled, the PDBIF flag generates a DMA request instead of an interrupt. 0 DMA disabled. 1 DMA enabled.
14–12 PRESCALER	Prescaler Divider Select Counting uses the peripheral clock divided by the product of a factor (selected by MULT field) and an integer factor (set by PRESCALAR field), or in other words, (peripheral clock)/(MULT x PRESCALAR). 000 Counting uses the peripheral clock divided by MULT (the multiplication factor). 001 Counting uses the peripheral clock divided by 2 x MULT (the multiplication factor). 010 Counting uses the peripheral clock divided by 4 x MULT (the multiplication factor). 011 Counting uses the peripheral clock divided by 8 x MULT (the multiplication factor). 100 Counting uses the peripheral clock divided by 16 x MULT (the multiplication factor). 101 Counting uses the peripheral clock divided by 32 x MULT (the multiplication factor). 110 Counting uses the peripheral clock divided by 64 x MULT (the multiplication factor). 111 Counting uses the peripheral clock divided by 128 x MULT (the multiplication factor).
11–8 TRGSEL	Trigger Input Source Select Selects the trigger input source for the PDB. The trigger input source can be internal or external (EXTRG pin), or the software trigger. Refer to chip configuration details for the actual PDB input trigger connections. 0000 Trigger-In 0 is selected. 0001 Trigger-In 1 is selected. 0010 Trigger-In 2 is selected. 0011 Trigger-In 3 is selected. 0100 Trigger-In 4 is selected. 0101 Trigger-In 5 is selected. 0110 Trigger-In 6 is selected. 0111 Trigger-In 7 is selected. 1000 Trigger-In 8 is selected. 1001 Trigger-In 9 is selected. 1010 Trigger-In 10 is selected. 1011 Trigger-In 11 is selected. 1100 Trigger-In 12 is selected. 1101 Trigger-In 13 is selected. 1110 Trigger-In 14 is selected. 1111 Software trigger is selected.
7 PDBEN	PDB Enable

Table continues on the next page...

PDBx_SC field descriptions (continued)

Field	Description
	0 PDB disabled. Counter is off. 1 PDB enabled.
6 PDBIF	PDB Interrupt Flag PDBIF is set when the counter value is equal to the IDLY register + 1. Write zero to clear PDBIF.
5 PDBIE	PDB Interrupt Enable Enables the PDB interrupt. When PDBIE is set and DMAEN is cleared, PDBIF generates a PDB interrupt. 0 PDB interrupt disabled. 1 PDB interrupt enabled.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 MULT	Multiplication Factor Select for Prescaler Selects the multiplication factor of the prescaler divider for the counter clock. 00 Multiplication factor is 1. 01 Multiplication factor is 10. 10 Multiplication factor is 20. 11 Multiplication factor is 40.
1 CONT	Continuous Mode Enable Enables the PDB operation in Continuous mode. 0 PDB operation in One-Shot mode 1 PDB operation in Continuous mode
0 LDOK	Load OK Writing 1 to LDOK bit updates the MOD, IDLY, CHnDLYm, DACINTx, and POyDLY registers with the values previously written to their internal buffers (and stored there). The new values of MOD, IDLY, CHnDLYm, DACINTx, and POyDLY registers will take effect according to the setting of the LDMOD field (Load Mode Select). Before 1 is written to the LDOK field, the values in the internal buffers of these registers are not effective, and new values cannot be written to the internal buffers until the existing values in the internal buffers are loaded into their corresponding registers. - LDOK can be written only when PDBEN is set, or LDOK can be written at the same time when PDBEN is written to 1. - LDOK is automatically cleared when the values in the internal buffers are loaded into the registers or when PDBEN bit (PDB Enable) is cleared. - Writing 0 to LDOK has no effect.

48.4.2 Modulus register (PDBx_MOD)

Note: This register is internally buffered, and any values written to the register are written to its internal buffer instead; in other words, the internal device bus does not write directly to this register. The value in this register's internal buffer is loaded into this register only after "1" is written to the SC[LDOK] bit.

Address: 4003_6000h base + 4h offset = 4003_6004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PDBx_IDLY field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
IDLY	PDB Interrupt Delay Specifies the delay value to schedule the PDB interrupt. It can be used to schedule an independent interrupt at some point in the PDB cycle. If enabled, a PDB interrupt is generated, when the counter is equal to the IDLY. Reading this field returns the value of internal register that is effective for the current cycle of the PDB.

48.4.5 Channel n Control register 1 (PDBx_CHnC1)

Each PDB channel has one control register, CHnC1. The fields in this register control the functionality of each PDB channel operation.

Address: 4003_6000h base + 10h offset + (40d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PDBx_CHnC1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 BB	PDB Channel Pre-Trigger Back-to-Back Operation Enable Enables the PDB ADC pre-trigger operation as back-to-back mode. Only lower M pre-trigger bits are implemented in this MCU. Back-to-back operation enables the ADC conversions complete to trigger the next PDB channel pre-trigger and trigger output, so that the ADC conversions can be triggered on the next set of configuration and results registers. Application code must enable only the back-to-back operation of the PDB pre-triggers at the leading of the back-to-back connection chain. 0 PDB channel's corresponding pre-trigger back-to-back operation disabled. 1 PDB channel's corresponding pre-trigger back-to-back operation enabled.
15–8 TOS	PDB Channel Pre-Trigger Output Select These bits select the PDB ADC pre-trigger outputs. Only lower M pre-trigger bits are implemented in this MCU. 0 PDB channel's corresponding pre-trigger is in bypassed mode. The pre-trigger asserts one peripheral clock cycle after a rising edge is detected on selected trigger input source or software trigger is selected and SWTRIG is written with 1. 1 PDB channel's corresponding pre-trigger asserts when the counter reaches the channel delay register plus one peripheral clock cycle after a rising edge is detected on selected trigger input source or software trigger is selected and SWTRIG is written with 1.
EN	PDB Channel Pre-Trigger Enable Enables the PDB ADC pre-trigger outputs. Only lower M pre-trigger fields are implemented in this MCU. 0 PDB channel's corresponding pre-trigger disabled. 1 PDB channel's corresponding pre-trigger enabled.

48.4.6 Channel n Status register (PDBx_CHnS)

Address: 4003_6000h base + 14h offset + (40d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PDBx_POnDLY field descriptions

Field	Description
31–16 DLY1	PDB Pulse-Out Delay 1 Specifies the delay 1 value for the PDB Pulse-Out. Pulse-Out goes high when the PDB counter is equal to the DLY1. Reading this field returns the value of internal register that is effective for the current PDB cycle.
DLY2	PDB Pulse-Out Delay 2 Specifies the delay 2 value for the PDB Pulse-Out. Pulse-Out goes low when the PDB counter is equal to the DLY2. Reading this field returns the value of internal register that is effective for the current PDB cycle.

48.5 Functional description

48.5.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared to several different digital values. If the PDB is enabled, then a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on a selected trigger input source, or if a software trigger is selected and the Software Trigger bit (SC[SWTRIG]) is written with 1. For each channel, a delay m determines the time between assertion of the trigger input event to the time at which changes in the pre-trigger m output signal are started. The time is defined as:

- Trigger input event to pre-trigger $m = (\text{prescaler} \times \text{multiplication factor} \times \text{delay } m) + 2$ peripheral clock cycles
- Add 1 additional peripheral clock cycle to determine the time when the channel trigger output changes.

Each channel is associated with 1 ADC block. PDB channel n pre-trigger outputs 0 to M ; each pre-trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block before the actual trigger occurs. When the ADC receives the rising edge of the trigger, the ADC will start the conversion according to the precondition determined by the pre-triggers. The ADC contains M sets of configuration and result registers, allowing it to alternate conversions between M different analog sources (like a ping-pong game). The pre-trigger outputs are used to specify which signal will be sampled next. When a pre-trigger m is asserted, the ADC conversion is triggered with set m of the configuration and result registers.

The waveforms shown in the following diagram show the pre-trigger and trigger outputs of PDB channel n . The delays can be independently set using the channel delay registers (CH n DLY m), and the pre-triggers can be enabled or disabled using the PDB Channel Pre-Trigger Enables (CH n C1[EN[m]]).

Figure 48-3. Pre-trigger and trigger outputs

The delay in the channel delay register ($CHnDLYm$) can be optionally bypassed, if the PDB Channel Pre-Trigger Output Select ($CHnC1[TOS[m]]$) is cleared. In this case, when the trigger input event occurs, the pre-trigger m is asserted after 2 peripheral clock cycles.

The PDB can be configured for back-to-back operation. Back-to-back operation enables the ADC conversion completions to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on the next set of configuration and results registers. When back-to-back operation is enabled by setting the PDB Channel Pre-Trigger Back-to-Back Operation Enable ($CHnC1[BB[m]]$), then the delay m is ignored and the pre-trigger m is asserted 2 peripheral cycles after the acknowledgment m is received. The acknowledgment connections in this MCU are described in [Back-to-back acknowledgment connections](#).

When a pre-trigger from a PDB channel n is asserted, the associated lock of the pre-trigger becomes active. The associated lock is released by the rising edge of the corresponding $ADCnSC1[COCO]$; the $ADCnSC1[COCO]$ should be cleared after the conversion result is read, so that the next rising edge of $ADCnSC1[COCO]$ can be generated to clear the lock later. The lock becomes inactive when:

- the rising edge of corresponding $ADCnSC1[COCO]$ occurs,
- or the corresponding PDB pre-trigger is disabled,
- or the PDB is disabled

The channel n trigger output is suppressed when any of the locks of the pre-triggers in channel n is active.

- If a new pre-trigger m asserts when there is active lock in the PDB channel n , then a PDB Channel Sequence Error Flag ($CHnS[ERR[m]]$, associated with the pre-trigger m) is set. If the PDB Sequence Error Interrupt Enable ($SC[PDBEIE]$) is set, then the

sequence error interrupt is generated. A sequence error typically happens because the delay m is set too short and the pre-trigger m asserts before the previously triggered ADC conversion finishes.

- If the pre-trigger delay is 0 cycles, then both channels will flag a PDB channel sequence error and ADC will not perform a conversion. The PDB reports PDB channel sequence errors only for pretriggers in same PDB channel. For situations when PDB triggering is done through different PDB channels, software must ensure sufficient delays in between the pre-ptiggers.

When the PDB counter reaches the value (CNT + 1), the PDB Interrupt Flag (SC[PDBIF]) is set. A PDB interrupt can be generated if the PDB Sequence Error Interrupt Enable (SC[PDBEIE]) is set and the DMA Enable (SC[DMAEN]) is cleared. If the DMA Enable (SC[DMAEN]) is set, then the PDB requests a DMA transfer when the PDB Interrupt Flag (SC[PDBIF]) is set.

The modulus value in the Modulus register (MOD) is used to reset the counter back to zero at the end of the count. If the Continuous Mode Enable (SC[CONT]) is set, then the counter will then resume a new count; otherwise, the counter operation will stop until the next trigger input event occurs.

48.5.2 PDB trigger input source selection

The PDB has up to 15 trigger input sources, namely Trigger-In 0 to Trigger-In 14. They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through SC[SWTRIG].

For the trigger input sources implemented in this MCU, see chip configuration information.

48.5.3 DAC interval trigger outputs

PDB can generate the interval triggers for DACs to update their outputs periodically. DAC interval counter x is reset and started when a trigger input event occurs if DACINTCx[EXT] is cleared. When the interval counter x is equal to the value set in DACINTx register, the DAC interval trigger x output generates a pulse of one peripheral clock cycle width to update the DACx. If DACINTCx[EXT] is set, the DAC interval counter is bypassed and the interval trigger output x generates a pulse following the detection of a rising edge on the DAC external trigger input. The counter and interval trigger can be disabled by clearing the DACINTCx[TOE].

DAC interval counters are also reset when the PDB counter reaches the MOD register value; therefore, when the PDB counter rolls over to zero, the DAC interval counters starts anew.

The DAC interval trigger pulse and the ADC pre-trigger/trigger pulses together allow precise timing of DAC updates and ADC measurements. This is outlined in the typical use case described in the following diagram.

Figure 48-4. PDB ADC triggers and DAC interval triggers use case

NOTE

Because the DAC interval counters share the prescaler with PDB counter, PDB must be enabled if the DAC interval trigger outputs are used in the applications.

48.5.4 Pulse-Out's

PDB can generate pulse outputs of configurable width.

- When the PDB counter reaches the value set in POyDLY[DLY1], then the Pulse-Out goes high.
- When the PDB counter reaches POyDLY[DLY2], then it goes low.

POyDLY[DLY2] can be set either greater or less than POyDLY[DLY1].

ADC pre-trigger/trigger outputs and Pulse-Out generation have the same time base, because they both share the PDB counter. The pulse-out connections implemented in this MCU are described in the device's chip configuration details.

Pulse-Out generation with $DLY2 > DLY1$

Pulse-Out generation with $DLY1 > DLY2$

Figure 48-5. How Pulse Out is generated

48.5.5 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus register (MOD)
- PDB Interrupt Delay register (IDLY)
- PDB Channel n Delay m register (CH n DLY m)
- DAC Interval x register (DACINT x)
- PDB Pulse-Out y Delay register (PO y DLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized in the next table.

Table 48-5. When delay registers are updated

SC[LDMOD]	Update to the delay registers
00	The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].
01	The PDB counter reaches PDB_MOD[MOD] + 1 value, after 1 is written to SC[LDOK].
10	A trigger input event is detected after 1 is written to SC[LDOK].
11	Either the PDB counter reaches PDB_MOD[MOD] + 1 value or a trigger input event is detected, after 1 is written to SC[LDOK].

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

Figure 48-6. Registers update with SC[LDMOD] = 00

Figure 48-7. Registers update with SC[LDMOD] = x1

48.5.6 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

Table 48-6. PDB interrupt summary

Interrupt	Flags	Enable bit
PDB Interrupt	SC[PDBIF]	SC[PDBIE] = 1 and SC[DMAEN] = 0
PDB Sequence Error Interrupt	CHnS[ERRm]	SC[PDBEIE] = 1

48.5.7 DMA

If SC[DMAEN] is set, PDB can generate a DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt is not issued.

48.6 Application information

48.6.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use a prescaler set to 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

Chapter 49

Periodic Interrupt Timer (PIT)

49.1 Chip-specific PIT information

49.1.1 PIT Instantiations

This device contains one PIT module with four channels.

49.1.2 PIT/DMA Periodic Trigger Assignments

The PIT generates periodic trigger events to the DMA Mux as shown in the table below.

Table 49-1. PIT channel assignments for periodic DMA triggering

DMA Channel Number	PIT Channel
DMA Channel 0	PIT Channel 0
DMA Channel 1	PIT Channel 1
DMA Channel 2	PIT Channel 2
DMA Channel 3	PIT Channel 3

49.1.3 PIT/ADC Triggers

PIT triggers are selected as ADCx trigger sources using the SIM_SOPT7[ADCxTRGSEL] fields. For more details, refer to SIM chapter.

49.2 Introduction

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

49.2.1 Block diagram

The following figure shows the block diagram of the PIT module.

Figure 49-1. Block diagram of the PIT

NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

49.2.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses

- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

49.3 Signal description

The PIT module has no external pins.

49.4 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.

PIT memory map

49.4.1 PIT Module Control Register (PITx_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

Address: 4003_7000h base + 0h offset = 4003_7000h

PITx_MCR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved.
1 MDIS	Module Disable - (PIT section) Disables the standard timers. This field must be enabled before any other setup is done. 0 Clock for standard PIT timers is enabled. 1 Clock for standard PIT timers is disabled.

Table continues on the next page...

PITx_MCR field descriptions (continued)

Field	Description
0 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0 Timers continue to run in Debug mode. 1 Timers are stopped in Debug mode.

49.4.2 PIT Upper Lifetime Timer Register (PITx_LTMR64H)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 4003_7000h base + E0h offset = 4003_70E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PITx_LTMR64H field descriptions

Field	Description
LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

49.4.3 PIT Lower Lifetime Timer Register (PITx_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Memory map/register description

Address: 4003_7000h base + E4h offset = 4003_70E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PITx_LDVALn field descriptions

Field	Description
TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

49.4.5 Current Timer Value Register (PITx_CVALn)

These registers indicate the current timer position.

Access: User read only

Address: 4003_7000h base + 104h offset + (16d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PITx_TFLGn field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

49.5 Functional description

This section provides the functional description of the module.

49.5.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

49.5.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

Figure 49-2. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

Figure 49-3. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

Figure 49-4. Dynamically setting a new load value

49.5.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

49.5.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

49.5.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

49.6 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.

- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every $5.12 \text{ ms} / 20 \text{ ns} = 256,000$ cycles and Timer 3 every $30 \text{ ms} / 20 \text{ ns} = 1,500,000$ cycles. The value for the LDVAL register trigger is calculated as:

$\text{LDVAL trigger} = (\text{period} / \text{clock period}) - 1$

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

49.7 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

49.8 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
```

```
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period  
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;  
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 50

Real Time Clock (RTC)

50.1 Chip-specific RTC information

50.1.1 RTC_CLKOUT signal

When the RTC is enabled and the port control module selects the RTC_CLKOUT function, the RTC_CLKOUT signal outputs a 1 Hz or 32 kHz output derived from RTC oscillator as shown below.

Figure 50-1. RTC_CLKOUT generation

NOTE

It is possible on variants of this device with RTC_WAKEUP pin to output the RTC clock signal to the RTC_WAKEUP pin. See [RTC Control Register](#) for details.

50.2 Introduction

50.2.1 Features

The RTC module features include:

- Independent power supply, POR, and 32 kHz crystal oscillator
- 32-bit seconds counter with roll-over protection and 32-bit alarm
- 16-bit prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm
- Register write protection
 - Lock register requires VBAT POR or software reset to enable write access
 - Access control registers require system reset to enable read and/or write access
- 1 Hz square wave output with optional interrupt

50.2.2 Modes of operation

The RTC remains functional in all low power modes and can generate an interrupt to exit any low power mode. It operates in one of two modes of operation: chip power-up and chip power-down.

During chip power-down, RTC is powered from the backup power supply (VBAT) and is electrically isolated from the rest of the chip but continues to increment the time counter (if enabled) and retain the state of the RTC registers. The RTC registers are not accessible.

During chip power-up, RTC remains powered from the backup power supply (VBAT). All RTC registers are accessible by software and all functions are operational. If enabled, the 32.768 kHz clock can be supplied to the rest of the chip.

50.2.3 RTC signal descriptions

Table 50-1. RTC signal descriptions

Signal	Description	I/O
EXTAL32	32.768 kHz oscillator input	I
XTAL32	32.768 kHz oscillator output	O
RTC_CLKOUT	1 Hz square-wave output or OSCERCLK	O
RTC_WAKEUP	Wakeup for external device	O

50.2.3.1 RTC clock output

The clock to the seconds counter is available on the RTC_CLKOUT signal. It is a 1 Hz square wave output. See Chip specific RTC information for details.

50.2.3.2 RTC wakeup pin

The RTC wakeup pin is an open drain, active low, output that allows the RTC to wakeup the chip via an external component. The wakeup pin asserts when the wakeup pin enable is set and either the RTC interrupt is asserted or the wakeup pin is turned on via a register bit. The wakeup pin does not assert from the RTC seconds interrupt.

NOTE

The wakeup pin is optional and may not be implemented on all devices.

50.3 Register definition

All registers must be accessed using 32-bit writes and all register accesses incur three wait states.

Write accesses to any register by non-supervisor mode software, when the supervisor access bit in the control register is clear, will terminate with a bus error.

Read accesses by non-supervisor mode software complete as normal.

Writing to a register protected by the write access register or lock register does not generate a bus error, but the write will not complete.

Reading a register protected by the read access register does not generate a bus error, but the register will read zero.

RTC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_D000	RTC Time Seconds Register (RTC_TSR)	32	R/W	0000_0000h	50.3.1/1466

50.3.1 RTC Time Seconds Register (RTC_TSR)

Address: 4003_D000h base + 0h offset = 4003_D000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TSR																															
W	TSR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

RTC_TSR field descriptions

Field	Description
TSR	Time Seconds Register When the time counter is enabled, the TSR is read only and increments once a second provided SR[TOF] or SR[TIF] are not set. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TSR can be read or written. Writing to the TSR when the time counter is disabled will clear the SR[TOF] and/or the SR[TIF]. Writing to TSR with zero is supported, but not recommended because TSR will read as zero when SR[TIF] or SR[TOF] are set (indicating the time is invalid).

50.3.2 RTC Time Prescaler Register (RTC_TPR)

Address: 4003_D000h base + 4h offset = 4003_D004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RTC_TPR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

RTC_TPR field descriptions (continued)

Field	Description
TPR	Time Prescaler Register When the time counter is enabled, the TPR is read only and increments every 32.768 kHz clock cycle. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TPR can be read or written. The TSR[TSR] increments when bit 14 of the TPR transitions from a logic one to a logic zero.

50.3.3 RTC Time Alarm Register (RTC_TAR)

Address: 4003_D000h base + 8h offset = 4003_D008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TAR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RTC_TAR field descriptions

Field	Description
TAR	Time Alarm Register When the time counter is enabled, the SR[TAF] is set whenever the TAR[TAR] equals the TSR[TSR] and the TSR[TSR] increments. Writing to the TAR clears the SR[TAF].

50.3.4 RTC Time Compensation Register (RTC_TCR)

Address: 4003_D000h base + Ch offset = 4003_D00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RTC_TCR field descriptions

Field	Description
31–24 CIC	Compensation Interval Counter Current value of the compensation interval counter. If the compensation interval counter equals zero then it is loaded with the contents of the CIR. If the CIC does not equal zero then it is decremented once a second.
23–16 TCV	Time Compensation Value Current value used by the compensation logic for the present second interval. Updated once a second if the CIC equals 0 with the contents of the TCR field. If the CIC does not equal zero then it is loaded with zero (compensation is not enabled for that second increment).

Table continues on the next page...

RTC_TCR field descriptions (continued)

Field	Description
15–8 CIR	Compensation Interval Register Configures the compensation interval in seconds from 1 to 256 to control how frequently the TCR should adjust the number of 32.768 kHz cycles in each second. The value written should be one less than the number of seconds. For example, write zero to configure for a compensation interval of one second. This register is double buffered and writes do not take affect until the end of the current compensation interval.
TCR	Time Compensation Register Configures the number of 32.768 kHz clock cycles in each second. This register is double buffered and writes do not take affect until the end of the current compensation interval. 80h Time Prescaler Register overflows every 32896 clock cycles. FFh Time Prescaler Register overflows every 32769 clock cycles. 00h Time Prescaler Register overflows every 32768 clock cycles. 01h Time Prescaler Register overflows every 32767 clock cycles. 7Fh Time Prescaler Register overflows every 32641 clock cycles.

50.3.5 RTC Control Register (RTC_CR)

Address: 4003_D000h base + 10h offset = 4003_D010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 Reserved	This field is reserved. It must always be written to 0.
13 SC2P	Oscillator 2pF Load Configure 0 Disable the load. 1 Enable the additional load.
12 SC4P	Oscillator 4pF Load Configure 0 Disable the load. 1 Enable the additional load.

Table continues on the next page...

RTC_CR field descriptions (continued)

Field	Description
11 SC8P	Oscillator 8pF Load Configure 0 Disable the load. 1 Enable the additional load.
10 SC16P	Oscillator 16pF Load Configure 0 Disable the load. 1 Enable the additional load.
9 CLKO	Clock Output 0 The 32 kHz clock is output to other peripherals. 1 The 32 kHz clock is not output to other peripherals.
8 OSCE	Oscillator Enable 0 32.768 kHz oscillator is disabled. 1 32.768 kHz oscillator is enabled. After setting this bit, wait the oscillator startup time before enabling the time counter to allow the 32.768 kHz clock time to stabilize.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WPS	Wakeup Pin Select The wakeup pin is optional and not available on all devices. 0 Wakeup pin asserts (active low, open drain) if the RTC interrupt asserts or the wakeup pin is turned on. 1 Wakeup pin instead outputs the RTC 32kHz clock, provided the wakeup pin is turned on and the 32kHz clock is output to other peripherals.
3 UM	Update Mode Allows SR[TCE] to be written even when the Status Register is locked. When set, the SR[TCE] can always be written if the SR[TIF] or SR[TOF] are set or if the SR[TCE] is clear. 0 Registers cannot be written when locked. 1 Registers can be written when locked under limited conditions.
2 SUP	Supervisor Access 0 Non-supervisor mode write accesses are not supported and generate a bus error. 1 Non-supervisor mode write accesses are supported.
1 WPE	Wakeup Pin Enable The wakeup pin is optional and not available on all devices. 0 Wakeup pin is disabled. 1 Wakeup pin is enabled and wakeup pin asserts if the RTC interrupt asserts or the wakeup pin is turned on.
0 SWR	Software Reset 0 No effect. 1 Resets all RTC registers except for the SWR bit and the RTC_WAR and RTC_RAR registers. The SWR bit is cleared by VBAT POR and by software explicitly clearing it.

50.3.6 RTC Status Register (RTC_SR)

Address: 4003_D000h base + 14h offset = 4003_D014h

RTC_SR field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 TCE	Time Counter Enable When time counter is disabled the TSR register and TPR register are writeable, but do not increment. When time counter is enabled the TSR register and TPR register are not writeable, but increment. 0 Time counter is disabled. 1 Time counter is enabled.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 TAF	Time Alarm Flag Time alarm flag is set when the TAR[TAR] equals the TSR[TSR] and the TSR[TSR] increments. This bit is cleared by writing the TAR register. 0 Time alarm has not occurred. 1 Time alarm has occurred.
1 TOF	Time Overflow Flag Time overflow flag is set when the time counter is enabled and overflows. The TSR and TPR do not increment and read as zero when this bit is set. This bit is cleared by writing the TSR register when the time counter is disabled. 0 Time overflow has not occurred. 1 Time overflow has occurred and time counter is read as zero.
0 TIF	Time Invalid Flag The time invalid flag is set on VBAT POR or software reset. The TSR and TPR do not increment and read as zero when this bit is set. This bit is cleared by writing the TSR register when the time counter is disabled. 0 Time is valid. 1 Time is invalid and time counter is read as zero.

50.3.7 RTC Lock Register (RTC_LR)

Address: 4003_D000h base + 18h offset = 4003_D018h

50.4 Functional description

50.4.1 Power, clocking, and reset

The RTC is an always powered block that remains active in all low power modes and is powered by the battery power supply (VBAT). The battery power supply ensures that the RTC registers retain their state during chip power-down and that the RTC time counter remains operational.

The time counter within the RTC is clocked by a 32.768 kHz clock and can supply this clock to other peripherals. The 32.768 kHz clock can only be sourced from an external crystal using the oscillator that is part of the RTC module.

The RTC includes its own analog POR block, which generates a VBAT power-on-reset signal whenever the RTC module is powered up and initializes all RTC registers to their default state. A software reset bit can also initialize all RTC registers. The RTC also monitors the chip power supply and electrically isolates itself when the rest of the chip is powered down.

NOTE

An attempt to access an RTC register, except the access control registers, results in a bus error when:

- VBAT is powered down,
- the RTC is electrically isolated, or
- VBAT POR is asserted.

To determine if the VBAT domain is active, software can use the ADC to measure VBAT via an internal connection. See the chip-specific ADC information to find the ADC input channel assignments.

50.4.1.1 Oscillator control

The 32.768 kHz crystal oscillator is disabled at VBAT POR and must be enabled by software. After enabling the crystal oscillator, wait the oscillator startup time before setting SR[TCE] or using the oscillator clock external to the RTC.

The crystal oscillator includes tunable capacitors that can be configured by software. Do not change the capacitance unless the oscillator is disabled.

50.4.1.2 Software reset

Writing 1 to CR[SWR] forces the equivalent of a VBAT POR to the rest of the RTC module. CR[SWR] is not affected by the software reset and must be cleared by software. The access control registers are not affected by either VBAT POR or the software reset; they are reset by the chip reset.

50.4.1.3 Supervisor access

When the supervisor access control bit is clear, only supervisor mode software can write to the RTC registers, non-supervisor mode software will generate a bus error. Both supervisor and non-supervisor mode software can always read the RTC registers.

50.4.2 Time counter

The time counter consists of a 32-bit seconds counter that increments once every second and a 16-bit prescaler register that increments once every 32.768 kHz clock cycle.

Reading the time counter (either seconds or prescaler) while it is incrementing may return invalid data due to synchronization of the read data bus. If it is necessary for software to read the prescaler or seconds counter when they could be incrementing, it is recommended that two read accesses are performed and that software verifies that the same data was returned for both reads.

The time seconds register and time prescaler register can be written only when SR[TCE] is clear. Always write to the prescaler register before writing to the seconds register, because the seconds register increments on the falling edge of bit 14 of the prescaler register.

The time prescaler register increments provided SR[TCE] is set, SR[TIF] is clear, SR[TOF] is clear, and the 32.768 kHz clock source is present. After enabling the oscillator, wait the oscillator startup time before setting SR[TCE] to allow time for the oscillator clock output to stabilize.

If the time seconds register overflows then the SR[TOF] will set and the time prescaler register will stop incrementing. Clear SR[TOF] by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TOF] is set.

SR[TIF] is set on VBAT POR and software reset and is cleared by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TIF] is set.

50.4.3 Compensation

The compensation logic provides an accurate and wide compensation range and can correct errors as high as 3906 ppm and as low as 0.12 ppm. The compensation factor must be calculated externally to the RTC and supplied by software to the compensation register. The RTC itself does not calculate the amount of compensation that is required, although the 1 Hz clock is output to an external pin in support of external calibration logic.

Crystal compensation can be supported by using firmware and crystal characteristics to determine the compensation amount. Temperature compensation can be supported by firmware that periodically measures the external temperature via ADC and updates the compensation register based on a look-up table that specifies the change in crystal frequency over temperature.

The compensation logic alters the number of 32.768 kHz clock cycles it takes for the prescaler register to overflow and increment the time seconds counter. The time compensation value is used to adjust the number of clock cycles between -127 and +128. Cycles are added or subtracted from the prescaler register when the prescaler register equals 0x3FFF and then increments. The compensation interval is used to adjust the frequency at which the time compensation value is used, that is, from once a second to once every 256 seconds.

Updates to the time compensation register will not take effect until the next time the time seconds register increments and provided the previous compensation interval has expired. When the compensation interval is set to other than once a second then the compensation is applied in the first second interval and the remaining second intervals receive no compensation.

Compensation is disabled by configuring the time compensation register to zero.

50.4.4 Time alarm

The Time Alarm register (TAR), SR[TAF], and IER[TAIE] allow the RTC to generate an interrupt at a predefined time. The 32-bit TAR is compared with the 32-bit Time Seconds register (TSR) each time it increments. SR[TAF] will set when TAR equals TSR and TSR increments.

SR[TAF] is cleared by writing TAR. This will usually be the next alarm value, although writing a value that is less than TSR, such as 0, will prevent SR[TAF] from setting again. SR[TAF] cannot otherwise be disabled, although the interrupt it generates is enabled or disabled by IER[TAIE].

50.4.5 Update mode

The Update Mode field in the Control register (CR[UM]) configures software write access to the Time Counter Enable (SR[TCE]) field. When CR[UM] is clear, SR[TCE] can be written only when LR[SRL] is set. When CR[UM] is set, SR[TCE] can also be written when SR[TCE] is clear or when SR[TIF] or SR[TOF] are set. This allows the time seconds and prescaler registers to be initialized whenever time is invalidated, while preventing the time seconds and prescaler registers from being changed on the fly. When LR[SRL] is set, CR[UM] has no effect on SR[TCE].

50.4.6 Register lock

The Lock register (LR) can be used to block write accesses to certain registers until the next VBAT POR or software reset. Locking the Control register (CR) will disable the software reset. Locking LR will block future updates to LR.

Write accesses to a locked register are ignored and do not generate a bus error.

50.4.7 Access control

The read access and write access registers are implemented in the chip power domain and reset on the chip reset. They are not affected by the VBAT POR or the software reset. They are used to block read or write accesses to each register until the next chip system reset. When accesses are blocked, the bus access is not seen in the VBAT power supply and does not generate a bus error.

50.4.8 Interrupt

The RTC interrupt is asserted whenever a status flag and the corresponding interrupt enable bit are both set. It is always asserted on VBAT POR, and software reset, and when the VBAT power supply is powered down. The RTC interrupt is enabled at the chip level

by enabling the chip-specific RTC clock gate control bit. The RTC interrupt can be used to wakeup the chip from any low-power mode. If the RTC wakeup pin is enabled and the chip is powered down, the RTC interrupt will cause the wakeup pin to assert.

The optional RTC seconds interrupt is an edge-sensitive interrupt with a dedicated interrupt vector that is generated once a second and requires no software overhead (there is no corresponding status flag to clear). It is enabled in the RTC by the time seconds interrupt enable bit and enabled at the chip level by setting the chip-specific RTC clock gate control bit. The RTC seconds interrupt does not cause the RTC wakeup pin to assert. This interrupt is optional and may not be implemented on all devices.

Chapter 51

Universal Serial Bus Full Speed OTG Controller (USBFSOTG)

51.1 Chip-specific USBFSOTG information

51.1.1 Universal Serial Bus (USB) FS Subsystem

The USB FS subsystem includes these components:

- Dual-role USB OTG-capable (On-The-Go) controller that supports a full-speed (FS) device or FS/LS host. The module complies with the USB 2.0 specification.
- USB transceiver that includes internal 15 k Ω pulldowns on the D+ and D- lines for host mode functionality and a 1.5 k Ω pullup on the D+ line for device mode functionality.
- A 3.3V regulator
- In this device, the 3.3 V regulator is actually a 2.7-3.6V configurable output regulator and is shared between both USB modules.
- [USB device charger detection module](#)
- Status detection and wakeup functions for USB data pins, VBUS/VREGIN pins, and OTG ID pins.
- IRC48 with clock recovery block to eliminate the 48MHz crystal. This is available for USB device mode only.
- A configurable connection to allow LPUART2 transmit and receive pins to be connected to the Full Speed USB physical layer.

Figure 51-1. USB FS/LS Subsystem Overview

NOTE

Use the following code sequence to select USB clock source, USB clock divide ratio, and enable its clock gate to avoid potential clock glitches which may result in USB enumeration stage failure.

1. Select the USB clock source by configuring SIM_SOPT2.
2. Select the desired clock divide ratio by configuring SIM_CLKDIV2.
3. Enable USB clock gate by setting SIM_SCGC4.

51.1.2 FS/LS USB OTG Instantiation

51.1.2.1 LPUART Over USB Capability

This device supports a connection whereby LPUART2 may be connected to the FS USB physical layer (and the USB controller disconnected) to allow simple debugging capabilities for applications which do not have direct physical access to LPUART2.

By setting the UARTSEL bit in the USB_x_USBCTRL register, LPUART2 will be connected to the FS USB physical layer. This configures the FS USB DP/DM signals to be configured as normal LPUART2 signals, which do not operate in differential mode. When UARTCHLS bit in the USB_x_USBCTRL register is set to 1'b0, FS USB DP/DM signal pins will be used as LPUART2 TX/RX. When UARTCHLS bit in the USB_x_USBCTRL register is set to 1'b1, FS USB DP/DM signal pins will be used as LPUART2 RX/TX.

51.1.3 USB and VREGIN pin status detection and wakeup interrupt features

This device does not have a dedicated VBUS detect pin. For VBUS detection, use either VREGIN for bus-powered USB cases or a GPIO pin for both bus-powered and self-powered USB cases. Because the GPIO pins on this device do not directly support a 5V input, use an external resistive voltage divider to keep the input voltage within the valid range if a GPIO pin is used for VBUS detection.

This device does not have a dedicated OTG ID detect pin. For OTG ID pin detection, if needed, use a GPIO configured as an input pin with pullup enabled.

When the USB detects that there is no activity on the USB bus for more than 3 ms, the USB_x_ISTAT[SLEEP] bit is set. This bit can cause an interrupt and software decides the appropriate action.

Waking from a low power mode (except in LLS/VLLS mode where USB is not powered) occurs through an asynchronous interrupt triggered by activity on the USB bus. Setting the USB_x_USBTRC0[USBRESMEN] bit enables this function.

The following wakeup features are also supported:

- In Stop/VLPS, the USB controller can generate an interrupt on VREGIN detection using the USB_x_MISCCTRL[VFEDG_EN, VREDG_EN] and USB_x_USBTRC0[VFEDG_DET, VREDG_DET] fields.
- In LLS/VLLS except VLLS1/0, VREGIN is an input pin to the LLWU and a transition on it can generate a wakeup.
- In LLS/VLLS, USB0_DP and USB0_DM are input pins to the LLWU and a transition on those pins can generate a wakeup provided the USB is powered and in host mode.
- In LLS/VLLS, the GPIO pins chosen to detect VBUS and OTG ID are also input to the LLWU, so transitions on them can generate a wakeup.

51.1.4 USB Power Distribution

This device includes an internal 5 V to 3.3 V USB regulator that always powers the USB transceiver and the USB device charger detection module. The regulator output may optionally be used to supply power to the device itself (by connecting to VDD).

51.1.4.1 AA/AAA cells power supply

The chip can be powered by two AA/AAA cells. In this case, the MCU is powered through VDD which is within the 1.8 to 3.0 V range. After USB cable insertion is detected, the USB regulator is enabled to power the USB transceiver.

Figure 51-2. USB regulator AA cell usecase

51.1.4.2 Li-Ion battery power supply

The chip can also be powered by a single Li-ion battery. In this case, VOUT33 is connected to VDD. The USB regulator must be enabled by default to power the MCU. When connected to a USB host, the input source of this regulator is switched to the USB bus supply from the Li-ion battery. To charge the battery, the MCU can configure the battery charger according to the charger detection information.

Figure 51-3. USB regulator Li-ion usecase

51.1.4.3 USB bus power supply

The chip can also be powered by the USB bus directly. In this case, VOUT33 is connected to VDD. The USB regulator must be enabled by default to power the MCU, then to power USB transceiver or external sensor.

Figure 51-4. USB regulator bus supply

51.1.5 USB power management

The regulator should be put into STANDBY mode whenever the chip is in Stop mode and the USB bus is not in use. The regulator must remain in RUN mode for all USB communication including Suspend, Resume and Reset signaling.

51.2 Introduction

This chapter describes the USB full speed OTG controller. The OTG implementation in this module provides limited host functionality and device solutions for implementing a USB 2.0 full-speed/low-speed compliant peripheral. The OTG logic implements features required by the *On-The-Go and Embedded Host Supplement to the USB 2.0 Specification* (usb.org, 2008). The USB full speed controller interfaces to a USBFS/LS transceiver.

NOTE

This chapter describes the following registers that have similar names: USB_OTGCTL, USB_CTL, USBCTRL, and USB_CONTROL. These are all separate registers.

51.2.2 USB—Overview

The USB is a cable bus that supports data exchange between a host computer and a wide range of simultaneously accessible peripherals. The attached peripherals share USB bandwidth through a host-scheduled, token-based protocol. The bus allows peripherals to be attached, configured, used, and detached while the host and other peripherals are in operation.

USB software provides a uniform view of the system for all application software, hiding implementation details to make application software more portable. It manages the dynamic attach and detach of peripherals.

There is only one host in any USB system. The USB interface to the host computer system is referred to as the Host Controller.

There may be multiple USB devices in any system such as human interface devices, speakers, printers, etc. USB devices present a standard USB interface in terms of comprehension, response, and standard capability.

The host initiates transactions to specific peripherals, whereas the device responds to control transactions. The device sends and receives data to and from the host using a standard USB data format. USB 2.0 full-speed /low-speed peripherals operate at 12Mbit/s or 1.5 Mbit/s.

For additional information, see the USB 2.0 specification.

Figure 51-5. Example USB 2.0 system configuration

51.2.3 USB On-The-Go

USB is a popular standard for connecting peripherals and portable consumer electronic devices such as digital cameras and tablets to host PCs. The On-The-Go (OTG) Supplement to the USB Specification extends USB to peer-to-peer application. Using USB OTG technology, consumer electronics, peripherals, and portable devices can connect to each other to exchange data. For example, a digital camera can connect directly to a printer, or a keyboard can connect to a tablet to exchange data.

With the USB On-The-Go product, you can develop a fully USB-compliant peripheral device that can also assume the role of a USB host. Software determines the role of the device based on hardware signals, and then initializes the device in the appropriate mode of operation (host or peripheral) based on how it is connected. After connecting, the devices can negotiate using the OTG protocols to assume the role of host or peripheral based on the task to be accomplished.

For additional information, see the *On-The-Go and Embedded Host Supplement to the USB 2.0 Specification*.

Figure 51-6. Example USB 2.0 On-The-Go configurations

51.2.4 USBFS Features

- USB 1.1 and 2.0 compatible FS device and FS/LS host controller with On-The-Go protocol logic
- 16 bidirectional endpoints
- DMA or FIFO data stream interfaces
- Low-power consumption
- IRC48M with clock-recovery is supported to eliminate the 48 MHz crystal. It is used for USB device-only implementation.

51.3 Functional description

USBOTG communicates with the processor core through status registers, control registers, and data structures in memory.

51.3.1 Data Structures

To efficiently manage USB endpoint communications, USBFS implements a Buffer Descriptor Table (BDT) in system memory. See [Figure 51-10](#).

51.3.2 On-chip transceiver required external components

USB system operation requires external components to ensure that driver output impedance, eye diagram, and VBUS cable fault tolerance requirements are met. DM and DP I/O pads must connect through series resistors (approximately 33 Ω each) to the USB connector on the application printed circuit board (PCB). Additionally, signal quality optimizes when these 33 Ω resistors are mounted closer to the processor than to the USB board-level connector. The USB transceiver includes:

- An internal 1.5 k Ω pullup resistor on the USB_DP line for full-speed device (controlled by USB_CONTROL[DPPULLUPNONOTG] or USB_OTGCTL[DPHIGH])
- Internal 15 k Ω pulldown resistors on the USB_DP and USB_DM signals, which are primarily intended for Host mode operation but are also useful in Device mode as explained below.

NOTE

For device operation, the internal 15 k Ω pulldowns should be enabled to keep the DP and DM ports in a known quiescent state when the VBUS detection software determines that the USB connection is not activated, including the cases when no cable to a host is present or when the USB port is not used. The internal 15 k Ω pulldowns should be controlled by USB_CTRL[PDE] in this case.

For host operation, the internal 15 k Ω pulldowns are enabled automatically, as required by the USB 2.0 specification, when USB_CTL[HOSTMODEEN] is asserted high.

The following diagrams provide overviews of host-only, device-only, and dual-role connections, respectively. For more details, see the *Kinetis Peripheral Module Quick Reference*(KQRUG).

Figure 51-7. Host-only diagram

Figure 51-8. Typical Device-only diagram (bus-powered)

Figure 51-9. Dual-role diagram

51.4 Programmers interface

This section discusses the major components of the programming model for the USB module.

51.4.1 Buffer Descriptor Table

To efficiently manage USB endpoint communications USBFS implements a Buffer Descriptor Table (BDT) in system memory. The BDT resides on a 512-byte boundary in system memory and is pointed to by the BDT Page Registers. Every endpoint direction requires two 8-byte Buffer Descriptor (BD) entries. Therefore, a system with 16 fully bidirectional endpoints would require 512 bytes of system memory to implement the BDT. The two BD entries allows for an EVEN BD and ODD BD entry for each endpoint direction. This allows the microprocessor to process one BD while USBFS is processing the other BD. Double buffering BDs in this way allows USBFS to transfer data easily at the maximum throughput provided by USB.

Software should manage buffers for USBFS by updating the BDT when needed. This allows USBFS to efficiently manage data transmission and reception, while the microprocessor performs communication overhead processing and other function dependent applications. Because the buffers are shared between the microprocessor and

USBFS, a simple semaphore mechanism is used to distinguish who is allowed to update the BDT and buffers in system memory. A semaphore, the OWN bit, is cleared to 0 when the BD entry is owned by the microprocessor. The microprocessor is allowed read and write access to the BD entry and the buffer in system memory when the OWN bit is 0. When the OWN bit is set to 1, the BD entry and the buffer in system memory are owned by USBFS. USBFS now has full read and write access and the microprocessor must not modify the BD or its corresponding data buffer. The BD also contains indirect address pointers to where the actual buffer resides in system memory. This indirect address mechanism is shown in the following diagram.

Figure 51-10. Buffer descriptor table

51.4.2 RX vs. TX as a USB peripheral device or USB host

The USBFS core uses software control to switch between two modes of operation:

- USB peripheral device
- USB hosts

In either mode, USB host or USB peripheral device, the same data paths and buffer descriptors are used for the transmission and reception of data. For this reason, a USBFS core-centric nomenclature is used to describe the direction of the data transfer between the USBFS core and USB:

- "RX" (or "receive") describes transfers that move data from USB to memory.
- "TX" (or "transmit") describes transfers that move data from memory to USB.

The following table shows how the data direction corresponds to the USB token type in host and peripheral device applications.

Table 51-1. Data direction for USB host or USB peripheral device

	RX	TX
Device	OUT or SETUP	IN
Host	IN	OUT or SETUP

51.4.3 Addressing BDT entries

An understanding of the addressing mechanism of the Buffer Descriptor Table is useful when accessing endpoint data via USBFS or microprocessor. Some points of interest are:

- The BDT occupies up to 512 bytes of system memory.
- 16 bidirectional endpoints can be supported with a full BDT of 512 bytes.
- 16 bytes are needed for each USB endpoint direction.
- Applications with fewer than 16 endpoints require less RAM to implement the BDT.
- The BDT Page Registers (BDT_PAGE) point to the starting location of the BDT.
- The BDT must be located on a 512-byte boundary in system memory.
- All enabled TX and RX endpoint BD entries are indexed into the BDT to allow easy access via USBFS or MCU core.

When a USB token on an enabled endpoint is received, USBFS uses its integrated DMA controller to interrogate the BDT. USBFS reads the corresponding endpoint BD entry to determine whether it owns the BD and corresponding buffer in system memory.

To compute the entry point into the BDT, the BDT_PAGE registers are concatenated with the current endpoint and the TX and ODD fields to form a 32-bit address. This address mechanism is shown in the following tables:

Table 51-2. BDT Address Calculation

31:24	23:16	15:9	8:5	4	3	2:0
BDT_PAGE_03	BDT_PAGE_02	BDT_PAGE_01[7:1]	Endpoint	TX	ODD	000

Table 51-3. BDT address calculation fields

Field	Description
BDT_PAGE	BDT_PAGE registers in the Control Register Block
ENDPOINT	ENDPOINT field from the USB TOKEN
TX	1 for transmit transfers and 0 for receive transfers

Table continues on the next page...

Table 51-3. BDT address calculation fields (continued)

Field	Description
ODD	Maintained within the USBFS SIE. It corresponds to the buffer currently in use. The buffers are used in a ping-pong fashion.

51.4.4 Buffer Descriptors (BDs)

A buffer descriptor provides endpoint buffer control information for USBFS and the processor. The Buffer Descriptors have different meaning based on whether it is USBFS or the processor reading the BD in memory.

The USBFS Controller uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- Whether to release ownership upon packet completion
- No address increment (FIFO mode)
- Whether data toggle synchronization is enabled
- How much data is to be transmitted or received
- Where the buffer resides in system memory

While the processor uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- The received TOKEN PID
- How much data was transmitted or received
- Where the buffer resides in system memory

The format for the BD is shown in the following figure.

Table 51-4. Buffer descriptor format

31:26	25:16	15:8	7	6	5	4	3	2	1	0
RSVD	BC (10 bits)	RSVD	OWN	DATA0/1	KEEP/ TOK_PID[3]	NINC/ TOK_PID[2]	DTS/ TOK_PID[1]	BDT_STALL/ TOK_PID[0]	0	0

Table continues on the next page...

Table 51-4. Buffer descriptor format (continued)

Buffer Address (32-Bits)

Table 51-5. Buffer descriptor fields

Field	Description
31–26 RSVD	Reserved
25–16 BC	Byte Count Represents the 10-bit byte count. The USBFS SIE changes this field upon the completion of a RX transfer with the byte count of the data received.
15–8 RSVD	Reserved
7 OWN	Determines whether the processor or USBFS currently owns the buffer. Except when KEEP=1, the SIE hands ownership back to the processor after completing the token by clearing this bit. This must always be the last byte of the BD that the processor updates when it initializes a BD. 0 The processor has access to the BD. USBFS ignores all other fields in the BD. 1 USBFS has access to the BD. While USBFS owns the BD, the processor should not modify any other fields in the BD.
6 DATA0/1	Defines whether a DATA0 field (DATA0/1=0) or a DATA1 (DATA0/1=1) field was transmitted or received. It is unchanged by USBFS.
5 KEEP/ TOK_PID[3]	This bit has two functions: - KEEP bit—When written by the processor, it serves as the KEEP bit. Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed, the data is simply transferred to or from the FIFO. When KEEP is set, normally the NINC bit is also set to prevent address increment. 0 Allows USBFS to release the BD when a token has been processed. 1 This bit is unchanged by USBFS. Bit 3 of the current token PID is written back to the BD by USBFS. - TOK_PID[3]—If the OWN bit is also set, the BD remains owned by USBFS indefinitely; when written by USB, it serves as the TOK_PID[3] bit. 0 or 1 Bit 3 of the current token PID is written back to the BD by USBFS. Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed, the data is simply transferred to or from the FIFO. When KEEP is set, normally the NINC bit is also set to prevent address increment.
4 NINC/ TOK_PID[2]	No Increment (NINC) Disables the DMA engine address increment. This forces the DMA engine to read or write from the same address. This is useful for endpoints when data needs to be read from or written to a single location such as a FIFO. Typically this bit is set with the KEEP bit for ISO endpoints that are interfacing to a FIFO. 0 USBFS writes bit 2 of the current token PID to the BD. 1 This bit is unchanged by USBFS.
3 DTS/	Setting this bit enables USBFS to perform Data Toggle Synchronization.

Table continues on the next page...

Table 51-5. Buffer descriptor fields (continued)

Field	Description
TOK_PID[1]	- If KEEP=0, bit 1 of the current token PID is written back to the BD. - If KEEP=1, this bit is unchanged by USBFS. 0 Data Toggle Synchronization is disabled. 1 Enables USBFS to perform Data Toggle Synchronization.
2 BDT_STALL TOK_PID[0]	Setting this bit causes USBFS to issue a STALL handshake if a token is received by the SIE that would use the BDT in this location. The BDT is not consumed by the SIE (the owns bit remains set and the rest of the BDT is unchanged) when a BDT_STALL bit is set. - If KEEP=0, bit 0 of the current token PID is written back to the BD. - If KEEP=1, this bit is unchanged by USBFS. 0 No stall issued. 1 The BDT is not consumed by the SIE (the OWN bit remains set and the rest of the BDT is unchanged). Setting BDT_STALL also causes the corresponding USB_ENDPT_n[EPSTALL] bit to set. This causes USBOTG to issue a STALL handshake for both directions of the associated endpoint. To clear the stall condition: - Clear the associated USB_ENDPT_n[EPSTALL] bit. - Write the BDT to clear OWN and BDT_STALL.
TOK_PID[n]	Bits [5:2] can also represent the current token PID. The current token PID is written back in to the BD by USBFS when a transfer completes. The values written back are the token PID values from the USB specification: 0x1h for an OUT token. 0x9h for an IN token. 0xDh for a SETUP token. In host mode, this field is used to report the last returned PID or a transfer status indication. The possible values returned are: 0x3h DATA0 0xBh DATA1 0x2h ACK 0xEh STALL 0xAh NAK 0x0h Bus Timeout 0xFh Data Error
1–0 Reserved	Reserved, should read as zeroes.
ADDR[31:0]	Address Represents the 32-bit buffer address in system memory; this address must also be 32-bit aligned. These bits are unchanged by USBFS.

51.4.5 USB transaction

When USBFS transmits or receives data, it computes the BDT address using the address generation shown in "Addressing Buffer Descriptor Entries" table.

If OWN =1, the following process occurs:

1. USBFS reads the BDT.
2. The SIE transfers the data via the DMA to or from the buffer pointed to by the ADDR field of the BD.
3. When the TOKEN is complete, USBFS updates the BDT and, if KEEP=0, changes the OWN bit to 0.
4. The STAT register is updated and the TOK_DNE interrupt is set.
5. When the processor processes the TOK_DNE interrupt, it reads from the status register all the information needed to process the endpoint.
6. At this point, the processor allocates a new BD so that additional USB data can be transmitted or received for that endpoint, and then processes the last BD.

The following figure shows a timeline of how a typical USB token is processed after the BDT is read and OWN=1.

Figure 51-11. USB token transaction

The USB has two sources for the DMA overrun error:

Memory Latency

The memory latency may be too high and cause the receive FIFO to overflow. This is predominantly a hardware performance issue, usually caused by transient memory access issues.

Oversized Packets

The packet received may be larger than the negotiated *MaxPacket* size. Typically, this is caused by a software bug. For DMA overrun errors due to oversized data packets, the USB specification is ambiguous. It assumes correct software drivers on both sides.

NAK'ing the packet can result in retransmission of the already oversized packet data. Therefore, in response to oversized packets, the USB core continues ACK'ing the packet for non-isochronous transfers.

Table 51-6. USB responses to DMA overrun errors

Errors due to Memory Latency	Errors due to Oversized Packets
Non-Acknowledgment (NAK) or Bus Timeout (BTO) — See bit 4 in "Error Interrupt Status Register (ERRSTAT)" as appropriate for the class of transaction.	Continues acknowledging (ACK'ing) the packet for non-isochronous transfers.
—	The data written to memory is clipped to the MaxPacket size so as not to corrupt system memory.
The DMAERR bit is set in the ERRSTAT register for host and device modes of operation. Depending on the values of the INTENB and ERRENB register, the core may assert an interrupt to notify the processor of the DMA error.	Asserts ERRSTAT[DMAERR], which can trigger an interrupt and TOKDNE interrupt fires. Note: The TOK_PID field of the BDT is not 1111 because the DMAERR is not due to latency.
- For host mode, the TOKDNE interrupt is generated and the TOK_PID field of the BDT is 1111 to indicate the DMA latency error. Host mode software can decide to retry or move to next scheduled item. - In device mode, the BDT is not written back nor is the TOKDNE interrupt triggered because it is assumed that a second attempt is queued and will succeed in the future.	The packet length field written back to the BDT is the MaxPacket value that represents the length of the clipped data actually written to memory.
From here, the software can decide an appropriate course of action for future transactions such as stalling the endpoint, canceling the transfer, disabling the endpoint, etc.	

51.5 Memory map/Register definitions

This section provides the memory map and detailed descriptions of all USB interface registers.

USB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4007_2000	Peripheral ID register (USB0_PERID)	8	R	04h	51.5.1/1504
4007_2004	Peripheral ID Complement register (USB0_IDCOMP)	8	R	FBh	51.5.2/1504
4007_2008	Peripheral Revision register (USB0_REV)	8	R	33h	51.5.3/1505
4007_200C	Peripheral Additional Info register (USB0_ADDINFO)	8	R	01h	51.5.4/1505
4007_2010	OTG Interrupt Status register (USB0_OTGISTAT)	8	R/W	00h	51.5.5/1506
4007_2014	OTG Interrupt Control register (USB0_OTGICR)	8	R/W	00h	51.5.6/1507
4007_2018	OTG Status register (USB0_OTGSTAT)	8	R/W	00h	51.5.7/1508
4007_201C	OTG Control register (USB0_OTGCTL)	8	R/W	00h	51.5.8/1509
4007_2080	Interrupt Status register (USB0_ISTAT)	8	R/W	00h	51.5.9/1510

Table continues on the next page...

USB memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4007_2084	Interrupt Enable register (USB0_INTEN)	8	R/W	00h	51.5.10/1511
4007_2088	Error Interrupt Status register (USB0_ERRSTAT)	8	R/W	00h	51.5.11/1512
4007_208C	Error Interrupt Enable register (USB0_ERREN)	8	R/W	00h	51.5.12/1513
4007_2090	Status register (USB0_STAT)	8	R	00h	51.5.13/1514
4007_2094	Control register (USB0_CTL)	8	R/W	00h	51.5.14/1515
4007_2098	Address register (USB0_ADDR)	8	R/W	00h	51.5.15/1516
4007_209C	BDT Page register 1 (USB0_BDTPAGE1)	8	R/W	00h	51.5.16/1517
4007_20A0	Frame Number register Low (USB0_FRMNUML)	8	R/W	00h	51.5.17/1517
4007_20A4	Frame Number register High (USB0_FRMNUMH)	8	R/W	00h	51.5.18/1518
4007_20A8	Token register (USB0_TOKEN)	8	R/W	00h	51.5.19/1518
4007_20AC	SOF Threshold register (USB0_SOFTHLD)	8	R/W	00h	51.5.20/1519
4007_20B0	BDT Page Register 2 (USB0_BDTPAGE2)	8	R/W	00h	51.5.21/1520
4007_20B4	BDT Page Register 3 (USB0_BDTPAGE3)	8	R/W	00h	51.5.22/1520
4007_20C0	Endpoint Control register (USB0_ENDPT0)	8	R/W	00h	51.5.23/1521
4007_20C4	Endpoint Control register (USB0_ENDPT1)	8	R/W	00h	51.5.23/1521
4007_20C8	Endpoint Control register (USB0_ENDPT2)	8	R/W	00h	51.5.23/1521
4007_20CC	Endpoint Control register (USB0_ENDPT3)	8	R/W	00h	51.5.23/1521
4007_20D0	Endpoint Control register (USB0_ENDPT4)	8	R/W	00h	51.5.23/1521
4007_20D4	Endpoint Control register (USB0_ENDPT5)	8	R/W	00h	51.5.23/1521
4007_20D8	Endpoint Control register (USB0_ENDPT6)	8	R/W	00h	51.5.23/1521
4007_20DC	Endpoint Control register (USB0_ENDPT7)	8	R/W	00h	51.5.23/1521
4007_20E0	Endpoint Control register (USB0_ENDPT8)	8	R/W	00h	51.5.23/1521

Table continues on the next page...

USB memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4007_20E4	Endpoint Control register (USB0_ENDPT9)	8	R/W	00h	51.5.23/1521
4007_20E8	Endpoint Control register (USB0_ENDPT10)	8	R/W	00h	51.5.23/1521

4007_2108	USB OTG Control register (USB0_CONTROL)	8	R/W	00h	51.5.26/1524
4007_210C	USB Transceiver Control register 0 (USB0_USBTRC0)	8	R/W	00h	51.5.27/1524
4007_2114	Frame Adjust Register (USB0_USBFRTADJUST)	8	R/W	00h	51.5.28/1526
4007_212C	Miscellaneous Control register (USB0_MISCCTRL)	8	R/W	00h	51.5.29/1526
4007_2140	USB Clock recovery control (USB0_CLK_RECOVER_CTRL)	8	R/W	00h	51.5.30/1527
4007_2144	IRC48M oscillator enable register (USB0_CLK_RECOVER_IRC_EN)	8	R/W	01h	51.5.31/1528
4007_2154	Clock recovery combined interrupt enable (USB0_CLK_RECOVER_INT_EN)	8	R/W	10h	51.5.32/1529
4007_215C	Clock recovery separated interrupt status (USB0_CLK_RECOVER_INT_STATUS)	8	w1c	00h	51.5.33/1530

51.5.1 Peripheral ID register (USBx_PERID)

Reads back the value of 0x04. This value is defined for the USB peripheral.

Address: 4007_2000h base + 0h offset = 4007_2000h

USBx_PERID field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ID	Peripheral Identification This field always reads 0x4h.

51.5.2 Peripheral ID Complement register (USBx_IDCOMP)

Reads back the complement of the Peripheral ID register. For the USB peripheral, the value is 0xFB.

Address: 4007_2000h base + 4h offset = 4007_2004h

USBx_IDCOMP field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
NID	Ones' complement of PERID[ID] bits.

51.5.3 Peripheral Revision register (USBx_REV)

Contains the revision number of the USB module.

Address: 4007_2000h base + 8h offset = 4007_2008h

USBx_REV field descriptions

Field	Description
REV	Revision Indicates the revision number of the USB Core.

51.5.4 Peripheral Additional Info register (USBx_ADDINFO)

Reads back the value of the Host Enable bit.

Address: 4007_2000h base + Ch offset = 4007_200Ch

USBx_ADDINFO field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 IEHOST	This bit is set if host mode is enabled.

51.5.5 OTG Interrupt Status register (USBx_OTGISTAT)

Records changes to the state of the one-millisecond timer and line state stable logic. Software can read this register to determine the event that triggers an interrupt. Only bits that have changed since the last software read are set. Writing a one to a bit clears the associated interrupt.

Address: 4007_2000h base + 10h offset = 4007_2010h

Bit	7	6	5	4	3	2	1	0
Read	Reserved	ONEMSEC	LINE_STATE_CHG	0	Reserved	Reserved	0	Reserved
Write	w1c	w1c	w1c		w1c	w1c		w1c
Reset	0	0	0	0	0	0	0	0

USBx_OTGISTAT field descriptions

Field	Description
7 Reserved	This field is reserved. Software must not change the value of this bitfield.
6 ONEMSEC	This bit is set when the 1 millisecond timer expires. This bit stays asserted until cleared by software. The interrupt must be serviced every millisecond to avoid losing 1msec counts.
5 LINE_STATE_CHG	This interrupt is set when the USB line state (CTL[SE0] and CTL[JSTATE] bits) are stable without change for 1 millisecond, and the value of the line state is different from the last time when the line state was stable. It is set on transitions between SE0 and J-state, SE0 and K-state, and J-state and K-state. Changes in J-state while SE0 is true do not cause an interrupt. This interrupt can be used in detecting Reset, Resume, Connect, and Data Line Pulse signaling.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. Software must not change the value of this bitfield.
2 Reserved	This field is reserved. Software must not change the value of this bitfield.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 Reserved	This field is reserved. Software must not change the value of this bitfield.

51.5.6 OTG Interrupt Control register (USBx_OTGICR)

Enables the corresponding interrupt status bits defined in the OTG Interrupt Status Register.

Address: 4007_2000h base + 14h offset = 4007_2014h

Bit	7	6	5	4	3	2	1	0
Read	Reserved	ONEMSEC EN	LINESTATE EN	0	Reserved	Reserved	0	Reserved
Write								
Reset	0	0	0	0	0	0	0	0

USBx_OTGICR field descriptions

Field	Description
7 Reserved	Software must not change the value of this bitfield. This field is reserved.
6 ONEMSECEN	One Millisecond Interrupt Enable 0 Disables the 1ms timer interrupt. 1 Enables the 1ms timer interrupt.
5 LINESTATEEN	Line State Change Interrupt Enable 0 Disables the LINE_STAT_CHG interrupt. 1 Enables the LINE_STAT_CHG interrupt.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	Software must not change the value of this bitfield. This field is reserved.
2 Reserved	Software must not change the value of this bitfield. This field is reserved.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 Reserved	Software must not change the value of this bitfield. This field is reserved.

51.5.7 OTG Status register (USBx_OTGSTAT)

Displays the actual value from the one-millisecond timer and line state stable logic.

Address: 4007_2000h base + 18h offset = 4007_2018h

Bit	7	6	5	4
Read	0	ONEMSECEN	LINESTATESTABLE	0
Write				
Reset	0	0	0	0
Bit	3	2	1	0
Read	0	0	0	0
Write				
Reset	0	0	0	0

USBx_OTGSTAT field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ONEMSECEN	This bit is reserved for the 1ms count, but it is not useful to software.
5 LINESTATESTABLE	Indicates that the internal signals that control the LINE_STATE_CHG field of OTGISTAT are stable for at least 1 ms. This bit is used to provide a hardware debounce of the linestate in detection of Connect, Disconnect and Resume signaling. First read LINE_STATE_CHG field and then read this field. If this field reads as 1, then the value of LINE_STATE_CHG can be considered stable. 0 The LINE_STAT_CHG bit is not yet stable. 1 The LINE_STAT_CHG bit has been debounced and is stable.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.8 OTG Control register (USBx_OTGCTL)

Controls the operation of VBUS and Data Line termination resistors.

Address: 4007_2000h base + 1Ch offset = 4007_201Ch

Bit	7	6	5	4	3	2	1	0
Read	DPHIGH	0	DPLOW	DMLOW	0	OTGEN	0	
Write								
Reset	0	0	0	0	0	0	0	0

USBx_OTGCTL field descriptions

Field	Description
7 DPHIGH	D+ Data Line pullup resistor enable 0 D+ pullup resistor is not enabled 1 D+ pullup resistor is enabled
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 DPLOW	D+ Data Line pull-down resistor enable This bit should always be enabled together with bit 4 (DMLOW) 0 D+ pulldown resistor is not enabled. 1 D+ pulldown resistor is enabled.
4 DMLOW	D– Data Line pull-down resistor enable 0 D- pulldown resistor is not enabled. 1 D- pulldown resistor is enabled.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 OTGEN	On-The-Go pullup/pulldown resistor enable 0 If USB_EN is 1 and HOST_MODE is 0 in the Control Register (CTL), then the D+ Data Line pull-up resistors are enabled. If HOST_MODE is 1 the D+ and D– Data Line pull-down resistors are engaged. 1 The pull-up and pull-down controls in this register are used.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.9 Interrupt Status register (USBx_ISTAT)

Contains fields for each of the interrupt sources within the USB Module. Each of these fields are qualified with their respective interrupt enable bits. All fields of this register are logically OR'd together along with the OTG Interrupt Status Register (OTGSTAT) to form a single interrupt source for the processor's interrupt controller. After an interrupt bit has been set it may only be cleared by writing a one to the respective interrupt bit. This register contains the value of 0x00 after a reset.

Address: 4007_2000h base + 80h offset = 4007_2080h

Bit	7	6	5	4	3	2	1	0
Read	STALL	ATTACH	RESUME	SLEEP	TOKDNE	SOFTOK	ERROR	USBRS
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

USBx_ISTAT field descriptions

Field	Description
7 STALL	Stall Interrupt In Device mode this bit is asserted when a STALL handshake is sent by the SIE. In Host mode this bit is set when the USB Module detects a STALL acknowledge during the handshake phase of a USB transaction. This interrupt can be used to determine whether the last USB transaction was completed successfully or stalled.
6 ATTACH	Attach Interrupt This field is set when the USB Module detects an attach of a USB device. This field is only valid if CTL[HOSTMODEEN]=1. This interrupt signifies that a peripheral is now present and must be configured; it is asserted if there have been no transitions on the USB for 2.5 μs and the current bus state is not SE0." 0 No Attach is detected since the last time the ATTACH bit was cleared. 1 A peripheral is now present and must be configured (a stable non-SE0 state is detected for more than 2.5 μs).
5 RESUME	This bit is set when a K-state is observed on the DP/DM signals for 2.5 μs. When not in suspend mode this interrupt must be disabled.
4 SLEEP	This bit is set when the USB Module detects a constant idle on the USB bus for 3 ms. The sleep timer is reset by activity on the USB bus.
3 TOKDNE	This bit is set when the current token being processed has completed. The processor must immediately read the STATUS (STAT) register to determine the EndPoint and BD used for this token. Clearing this bit (by writing a one) causes STAT to be cleared or the STAT holding register to be loaded into the STAT register.
2 SOFTOK	This bit is set when the USB Module receives a Start Of Frame (SOF) token. In Host mode this field is set when the SOF threshold is reached (MISCCTRL[SOFBUSSET]=0), or when the SOF counter reaches 0 (MISCCTRL[SOFBUSSET]=1), so that software can prepare for the next SOF.

Table continues on the next page...

USBx_ISTAT field descriptions (continued)

Field	Description
1 ERROR	This bit is set when any of the error conditions within Error Interrupt Status (ERRSTAT) register occur. The processor must then read the ERRSTAT register to determine the source of the error.
0 USBRST	This bit is set when the USB Module has decoded a valid USB reset. This informs the processor that it should write 0x00 into the address register and enable endpoint 0. USBRST is set after a USB reset has been detected for 2.5 microseconds. It is not asserted again until the USB reset condition has been removed and then reasserted.

51.5.10 Interrupt Enable register (USBx_INTEN)

Contains enable fields for each of the interrupt sources within the USB Module. Setting any of these bits enables the respective interrupt source in the ISTAT register. This register contains the value of 0x00 after a reset.

Address: 4007_2000h base + 84h offset = 4007_2084h

Bit	7	6	5	4	3	2	1	0
Read	STALLEN	ATTACHEN	RESUMEEN	SLEEPEN	TOKDNEEN	SOFTOKEN	ERROREN	USBRSTEN
Write								
Reset	0	0	0	0	0	0	0	0

USBx_INTEN field descriptions

Field	Description
7 STALLEN	STALL Interrupt Enable 0 Disables the STALL interrupt. 1 Enables the STALL interrupt.
6 ATTACHEN	ATTACH Interrupt Enable 0 Disables the ATTACH interrupt. 1 Enables the ATTACH interrupt.
5 RESUMEEN	RESUME Interrupt Enable 0 Disables the RESUME interrupt. 1 Enables the RESUME interrupt.
4 SLEEPEN	SLEEP Interrupt Enable 0 Disables the SLEEP interrupt. 1 Enables the SLEEP interrupt.
3 TOKDNEEN	TOKDNE Interrupt Enable 0 Disables the TOKDNE interrupt. 1 Enables the TOKDNE interrupt.
2 SOFTOKEN	SOFTOK Interrupt Enable 0 Disables the SOFTOK interrupt. 1 Enables the SOFTOK interrupt.

Table continues on the next page...

USBx_INTEN field descriptions (continued)

Field	Description
1 ERROREN	ERROR Interrupt Enable 0 Disables the ERROR interrupt. 1 Enables the ERROR interrupt.
0 USBRSTEN	USBRST Interrupt Enable 0 Disables the USBRST interrupt. 1 Enables the USBRST interrupt.

51.5.11 Error Interrupt Status register (USBx_ERRSTAT)

Contains enable bits for each of the error sources within the USB Module. Each of these bits are qualified with their respective error enable bits. All bits of this register are logically OR'd together and the result placed in the ERROR bit of the ISTAT register. After an interrupt bit has been set it may only be cleared by writing a one to the respective interrupt bit. Each bit is set as soon as the error condition is detected. Therefore, the interrupt does not typically correspond with the end of a token being processed. This register contains the value of 0x00 after a reset.

Address: 4007_2000h base + 88h offset = 4007_2088h

Bit	7	6	5	4	3	2	1	0
Read	BTSERR	OWNERR	DMAERR	BTOERR	DFN8	CRC16	CRC5EOF	PIDERR
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

USBx_ERRSTAT field descriptions

Field	Description
7 BTSERR	This bit is set when a bit stuff error is detected. If set, the corresponding packet is rejected due to the error.
6 OWNERR	This field is valid when the USB Module is operating in peripheral mode (CTL[HOSTMODEEN]=0). It is set if the USB Module requires a new BD for SETUP, ISO IN, or ISO OUT transfer while a new BD is not available.
5 DMAERR	This bit is set if the USB Module has requested a DMA access to read a new BDT but has not been given the bus before it needs to receive or transmit data. If processing a TX transfer this would cause a transmit data underflow condition. If processing a RX transfer this would cause a receive data overflow condition. This interrupt is useful when developing device arbitration hardware for the microprocessor and the USB module to minimize bus request and bus grant latency. This bit is also set if a data packet to or from the host is larger than the buffer size allocated in the BDT. In this case the data packet is truncated as it is put in buffer memory.
4 BTOERR	This bit is set when a bus turnaround timeout error occurs. The USB module contains a bus turnaround timer that keeps track of the amount of time elapsed between the token and data phases of a SETUP or OUT TOKEN or the data and handshake phases of a IN TOKEN. If more than 16 bit times are counted from the previous EOP before a transition from IDLE, a bus turnaround timeout error occurs.

Table continues on the next page...

USBx_ERRSTAT field descriptions (continued)

Field	Description
3 DFN8	This bit is set if the data field received was not 8 bits in length. USB Specification 1.0 requires that data fields be an integral number of bytes. If the data field was not an integral number of bytes, this bit is set.
2 CRC16	This bit is set when a data packet is rejected due to a CRC16 error.
1 CRC5EOF	This error interrupt has two functions. When the USB Module is operating in peripheral mode (CTL[HOSTMODEEN]=0), this interrupt detects CRC5 errors in the token packets generated by the host. If set the token packet was rejected due to a CRC5 error. When the USB Module is operating in host mode (CTL[HOSTMODEEN]=1), this interrupt detects End Of Frame (EOF) error conditions. This occurs when the USB Module is transmitting or receiving data and the SOF counter reaches zero. This interrupt is useful when developing USB packet scheduling software to ensure that no USB transactions cross the start of the next frame.
0 PIDERR	This bit is set when the PID check field fails.

51.5.12 Error Interrupt Enable register (USBx_ERREN)

Contains enable bits for each of the error interrupt sources within the USB module. Setting any of these bits enables the respective interrupt source in ERRSTAT. Each bit is set as soon as the error condition is detected. Therefore, the interrupt does not typically correspond with the end of a token being processed. This register contains the value of 0x00 after a reset.

Address: 4007_2000h base + 8Ch offset = 4007_208Ch

Bit	7	6	5	4	3	2	1	0
Read	BTSE	OWNERR	DMAERR	BTOERR	DFN8EN	CRC16EN	CRC5EOFEN	PIDERR
Write	BTSE	OWNERR	DMAERR	BTOERR	DFN8EN	CRC16EN	CRC5EOFEN	PIDERR
Reset	0	0	0	0	0	0	0	0

USBx_ERREN field descriptions

Field	Description
7 BTSE	BTSE Interrupt Enable 0 Disables the BTSE interrupt. 1 Enables the BTSE interrupt.
6 OWNERR	OWNERR Interrupt Enable This field is valid when the USB module is operating in peripheral mode (CTL[HOSTMODEEN]=0). 0 Disables the OWNERR interrupt. 1 Enables the OWNERR interrupt.
5 DMAERR	DMAERR Interrupt Enable 0 Disables the DMAERR interrupt. 1 Enables the DMAERR interrupt.

Table continues on the next page...

USBx_ERREN field descriptions (continued)

Field	Description
4 BTOERREN	BTOERR Interrupt Enable 0 Disables the BTOERR interrupt. 1 Enables the BTOERR interrupt.
3 DFN8EN	DFN8 Interrupt Enable 0 Disables the DFN8 interrupt. 1 Enables the DFN8 interrupt.
2 CRC16EN	CRC16 Interrupt Enable 0 Disables the CRC16 interrupt. 1 Enables the CRC16 interrupt.
1 CRC5EOFEN	CRC5/EOF Interrupt Enable 0 Disables the CRC5/EOF interrupt. 1 Enables the CRC5/EOF interrupt.
0 PIDERREN	PIDERR Interrupt Enable 0 Disables the PIDERR interrupt. 1 Enters the PIDERR interrupt.

51.5.13 Status register (USBx_STAT)

Reports the transaction status within the USB module. When the processor's interrupt controller has received a TOKDNE, interrupt the Status Register must be read to determine the status of the previous endpoint communication. The data in the status register is valid when TOKDNE interrupt is asserted. The Status register is actually a read window into a status FIFO maintained by the USB module. When the USB module uses a BD, it updates the Status register. If another USB transaction is performed before the TOKDNE interrupt is serviced, the USB module stores the status of the next transaction in the STAT FIFO. Thus STAT is actually a four byte FIFO that allows the processor core to process one transaction while the SIE is processing the next transaction. Clearing the TOKDNE bit in the ISTAT register causes the SIE to update STAT with the contents of the next STAT value. If the data in the STAT holding register is valid, the SIE immediately reasserts to TOKDNE interrupt.

Address: 4007_2000h base + 90h offset = 4007_2090h

Bit	7	6	5	4	3	2	1	0
Read	ENDP				TX	ODD	0	
Write								
Reset	0	0	0	0	0	0	0	0

USBx_STAT field descriptions

Field	Description
7–4 ENDP	This four-bit field encodes the endpoint address that received or transmitted the previous token. This allows the processor core to determine the BDT entry that was updated by the last USB transaction.
3 TX	Transmit Indicator 0 The most recent transaction was a receive operation. 1 The most recent transaction was a transmit operation.
2 ODD	This bit is set if the last buffer descriptor updated was in the odd bank of the BDT.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.14 Control register (USBx_CTL)

Provides various control and configuration information for the USB module.

Address: 4007_2000h base + 94h offset = 4007_2094h

Bit	7	6	5	4
Read				
Write	JSTATE	SE0	TXSUSPENDTOKENBUSY	RESET
Reset	0	0	0	0

Bit	3	2	1	0
Read				
Write	HOSTMODEEN	RESUME	ODDRST	USBENSOFFEN
Reset	0	0	0	0

USBx_CTL field descriptions

Field	Description
7 JSTATE	Live USB differential receiver JSTATE signal The polarity of this signal is affected by the current state of LSEN .
6 SE0	Live USB Single Ended Zero signal
5 TXSUSPENDTOKENBUSY	In Host mode, TOKEN_BUSY is set when the USB module is busy executing a USB token. Software must not write more token commands to the Token Register when TOKEN_BUSY is set. Software should check this field before writing any tokens to the Token Register to ensure that token commands are not lost. In Device mode, TXD_SUSPEND is set when the SIE has disabled packet transmission and reception. Clearing this bit allows the SIE to continue token processing. This bit is set by the SIE when a SETUP Token is received allowing software to dequeue any pending packet transactions in the BDT before resuming token processing.
4 RESET	Setting this bit enables the USB Module to generate USB reset signaling. This allows the USB Module to reset USB peripherals. This control signal is only valid in Host mode (CTL[HOSTMODEEN]=1). Software must set RESET to 1 for the required amount of time and then clear it to 0 to end reset signaling.

Table continues on the next page...

USBx_CTL field descriptions (continued)

Field	Description
3 HOSTMODEEN	When set to 1, this bit enables the USB Module to operate in Host mode. In host mode, the USB module performs USB transactions under the programmed control of the host processor.
2 RESUME	When set to 1 this bit enables the USB Module to execute resume signaling. This allows the USB Module to perform remote wake-up. Software must set RESUME to 1 for the required amount of time and then clear it to 0. If HOSTMODEEN is set, the USB module appends a Low Speed End of Packet to the Resume signaling when the RESUME bit is cleared.
1 ODDRST	Setting this bit to 1 resets all the BDT ODD ping/pong fields to 0, which then specifies the EVEN BDT bank.
0 USBENSOFEN	USB Enable Setting this bit enables the USB-FS to operate; clearing it disables the USB-FS. Setting the bit causes the SIE to reset all of its ODD bits to the BDTs. Therefore, setting this bit resets much of the logic in the SIE. When host mode is enabled, clearing this bit causes the SIE to stop sending SOF tokens. 0 Disables the USB Module. 1 Enables the USB Module.

51.5.15 Address register (USBx_ADDR)

Holds the unique USB address that the USB module decodes when in Peripheral mode (CTL[HOSTMODEEN]=0). When operating in Host mode (CTL[HOSTMODEEN]=1) the USB module transmits this address with a TOKEN packet. This enables the USB module to uniquely address any USB peripheral. In either mode, CTL[USBENSOFEN] must be 1. The Address register is reset to 0x00 after the reset input becomes active or the USB module decodes a USB reset signal. This action initializes the Address register to decode address 0x00 as required by the USB specification.

Address: 4007_2000h base + 98h offset = 4007_2098h

Bit	7	6	5	4	3	2	1	0
Read	LSEN							
Write								
Reset	0	0	0	0	0	0	0	0

USBx_ADDR field descriptions

Field	Description
7 LSEN	Low Speed Enable bit Informs the USB module that the next token command written to the token register must be performed at low speed. This enables the USB module to perform the necessary preamble required for low-speed data transmissions.
ADDR	USB Address

Table continues on the next page...

USBx_ADDR field descriptions (continued)

Field	Description
	Defines the USB address that the USB module decodes in peripheral mode, or transmits when in host mode.

51.5.16 BDT Page register 1 (USBx_BDTPAGE1)

Provides address bits 15 through 9 of the base address where the current Buffer Descriptor Table (BDT) resides in system memory. See [Buffer Descriptor Table](#). The 32-bit BDT Base Address is always aligned on 512-byte boundaries, so bits 8 through 0 of the base address are always zero.

Address: 4007_2000h base + 9Ch offset = 4007_209Ch

Bit	7	6	5	4	3	2	1	0
Read	BDTBA							0
Write								0
Reset	0	0	0	0	0	0	0	0

USBx_BDTPAGE1 field descriptions

Field	Description
7–1 BDTBA	Provides address bits 15 through 9 of the BDT base address.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.17 Frame Number register Low (USBx_FRMNUML)

The Frame Number registers (low and high) contain the 11-bit frame number. These registers are updated with the current frame number whenever a SOF TOKEN is received.

Address: 4007_2000h base + A0h offset = 4007_20A0h

Bit	7	6	5	4	3	2	1	0
Read	FRM[7:0]							
Write								
Reset	0	0	0	0	0	0	0	0

USBx_FRMNUML field descriptions

Field	Description
FRM[7:0]	This 8-bit field and the 3-bit field in the Frame Number Register High are used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory.

51.5.18 Frame Number register High (USBx_FRMNUMH)

The Frame Number registers (low and high) contain the 11-bit frame number. These registers are updated with the current frame number whenever a SOF TOKEN is received.

Address: 4007_2000h base + A4h offset = 4007_20A4h

USBx_FRMNUMH field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FRM[10:8]	This 3-bit field and the 8-bit field in the Frame Number Register Low are used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory.

51.5.19 Token register (USBx_TOKEN)

Used to initiate USB transactions when in host mode (CTL[HOSTMODEEN]=1). When the software needs to execute a USB transaction to a peripheral, it writes the TOKEN type and endpoint to this register. After this register has been written, the USB module begins the specified USB transaction to the address contained in the address register. The processor core must always check that the TOKEN_BUSY bit in the control register is not 1 before writing to the Token Register. This ensures that the token commands are not overwritten before they can be executed. The address register and endpoint control register 0 are also used when performing a token command and therefore must also be written before the Token Register. The address register is used to select the USB peripheral address transmitted by the token command. The endpoint control register determines the handshake and retry policies used during the transfer.

Address: 4007_2000h base + A8h offset = 4007_20A8h

USBx_TOKEN field descriptions

Field	Description
7-4 TOKENPID	Contains the token type executed by the USB module. 0001 OUT Token. USB Module performs an OUT (TX) transaction. 1001 IN Token. USB Module performs an In (RX) transaction. 1101 SETUP Token. USB Module performs a SETUP (TX) transaction
TOKENENDPT	Holds the Endpoint address for the token command. The four bit value written must be a valid endpoint.

51.5.20 SOF Threshold register (USBx_SOFTHLD)

The SOF Threshold Register is used only in Host mode (CTL[HOSTMODEEN]=1). When in Host mode, the 14-bit SOF counter counts the interval between SOF frames. The SOF must be transmitted every 1ms so therefore the SOF counter is loaded with a value of 12000. When the SOF counter reaches zero, a Start Of Frame (SOF) token is transmitted.

The SOF threshold register is used to program the number of USB byte times when SOFDYNTHLD=0, or 8 byte times when SOFDYNTHLD=1, before the SOF stops initiating token packet transactions. This register must be set to a value that ensures that other packets are not actively being transmitted when the SOF time counts to zero. When the SOF counter reaches the threshold value, no more tokens are transmitted until after the SOF has been transmitted.

The value programmed into the threshold register must reserve enough time to ensure the worst case transaction completes. In general the worst case transaction is an IN token followed by a data packet from the peripheral device followed by the response from the host. The actual time required is a function of the maximum packet size on the bus.

Typical values for the SOF threshold are:

- 64-byte packets=74;
- 32-byte packets=42;
- 16-byte packets=26;
- 8-byte packets=18.

Address: 4007_2000h base + ACh offset = 4007_20ACh

Bit	7	6	5	4	3	2	1	0
Read	CNT							
Write								
Reset	0	0	0	0	0	0	0	0

USBx_SOFTHLD field descriptions

Field	Description
CNT	Represents the SOF count threshold in byte times when SOFDYNTHLD=0 or 8 byte times when SOFDYNTHLD=1.

51.5.21 BDT Page Register 2 (USBx_BDTPAGE2)

Contains an 8-bit value used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory. See [Buffer Descriptor Table](#).

Address: 4007_2000h base + B0h offset = 4007_20B0h

Bit	7	6	5	4	3	2	1	0
Read	BDTBA							
Write								
Reset	0	0	0	0	0	0	0	0

USBx_BDTPAGE2 field descriptions

Field	Description
BDTBA	Provides address bits 23 through 16 of the BDT base address that defines the location of Buffer Descriptor Table resides in system memory.

51.5.22 BDT Page Register 3 (USBx_BDTPAGE3)

Contains an 8-bit value used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory. See [Buffer Descriptor Table](#).

Address: 4007_2000h base + B4h offset = 4007_20B4h

Bit	7	6	5	4	3	2	1	0
Read	BDTBA							
Write								
Reset	0	0	0	0	0	0	0	0

USBx_BDTPAGE3 field descriptions

Field	Description
BDTBA	Provides address bits 31 through 24 of the BDT base address that defines the location of Buffer Descriptor Table resides in system memory.

51.5.23 Endpoint Control register (USBx_ENDPTn)

Contains the endpoint control bits for each of the 16 endpoints available within the USB module for a decoded address. The format for these registers is shown in the following figure. Endpoint 0 (ENDPT0) is associated with control pipe 0, which is required for all USB functions. Therefore, after a USBRST interrupt occurs the processor core should set ENDPT0 to contain 0x0D.

In Host mode ENDPT0 is used to determine the handshake, retry and low speed characteristics of the host transfer. For Control, Bulk and Interrupt transfers, the EPHSHK bit should be 1. For Isochronous transfers it should be 0. Common values to use for ENDPT0 in host mode are 0x4D for Control, Bulk, and Interrupt transfers, and 0x4C for Isochronous transfers.

The three bits EPCTLDIS, EPRXEN, and EPTXEN define if an endpoint is enabled and define the direction of the endpoint. The endpoint enable/direction control is defined in the following table.

Table 51-7. Endpoint enable and direction control

EPCTLDIS	EPRXEN	EPTXEN	Endpoint enable/direction control
X	0	0	Disable endpoint
X	0	1	Enable endpoint for Tx transfers only
X	1	0	Enable endpoint for Rx transfers only
1	1	1	Enable endpoint for Rx and Tx transfers
0	1	1	Enable Endpoint for RX and TX as well as control (SETUP) transfers.

Address: 4007_2000h base + C0h offset + (4d × i), where i=0d to 15d

Bit	7	6	5	4	3	2	1	0
Read	HOSTWOH	RETRYDIS	0	EPCTLDIS	EPRXEN	EPTXEN	EPSTALL	EPHSHK
Write	UB							
Reset	0	0	0	0	0	0	0	0

USBx_ENDPTn field descriptions

Field	Description
7 HOSTWOHUB	Host without a hub This is a Host mode only field and is present in the control register for endpoint 0 (ENDPT0) only.

Table continues on the next page...

USBx_ENDPTn field descriptions (continued)

Field	Description
	0 Low-speed device connected to Host through a hub. PRE_PID will be generated as required. 1 Low-speed device directly connected. No hub, or no low-speed device attached.
6 RETRYDIS	This is a Host mode only bit and is present in the control register for endpoint 0 (ENDPT0) only. When set this bit causes the host to not retry NAK'ed (Negative Acknowledgement) transactions. When a transaction is NAKed, the BDT PID field is updated with the NAK PID, and the TOKEN_DNE interrupt is set. When this bit is cleared, NAKed transactions are retried in hardware. This bit must be set when the host is attempting to poll an interrupt endpoint.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 EPCTLDIS	This bit, when set, disables control (SETUP) transfers. When cleared, control transfers are enabled. This applies if and only if the EPRXEN and EPTXEN bits are also set. See Table 51-7
3 EPRXEN	This bit, when set, enables the endpoint for RX transfers. See Table 51-7
2 EPTXEN	This bit, when set, enables the endpoint for TX transfers. See Table 51-7
1 EPSTALL	When set, this bit indicates that the endpoint is stalled. This bit has priority over all other control bits in this register, but it is only valid if EPTXEN=1 or EPRXEN=1. Any access to this endpoint causes the USB Module to return a STALL handshake. After an endpoint is stalled it requires intervention from the Host Controller.
0 EPHSK	When set this bit enables an endpoint to perform handshaking during a transaction to this endpoint. This bit is generally 1 unless the endpoint is Isochronous.

51.5.24 USB Control register (USBx_USBCTRL)

Address: 4007_2000h base + 100h offset = 4007_2100h

Bit	7	6	5	4	3	2	1	0
Read	SUSP	PDE	UARTCHLS	UARTSEL	0			
Write								
Reset	1	1	0	0	0	0	0	0

USBx_USBCTRL field descriptions

Field	Description
7 SUSP	Places the USB transceiver into the suspend state. 0 USB transceiver is not in suspend state. 1 USB transceiver is in suspend state.
6 PDE	Enables the weak pulldowns on the USB transceiver. 0 Weak pulldowns are disabled on D+ and D-. 1 Weak pulldowns are enabled on D+ and D-.
5 UARTCHLS	UART Signal Channel Select This field is valid only when USB signals are selected to be used as UART signals.

Table continues on the next page...

USBx_USBCTRL field descriptions (continued)

Field	Description
	0 USB DP/DM signals used as UART TX/RX. 1 USB DP/DM signals used as UART RX/TX.
4 UARTSEL	Selects USB signals to be used as UART signals. 0 USB signals not used as UART signals. 1 USB signals used as UART signals.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.25 USB OTG Observe register (USBx_OBSERVE)

Provides visibility on the state of the pull-ups and pull-downs at the transceiver. Useful when interfacing to an external OTG control module via a serial interface.

Address: 4007_2000h base + 104h offset = 4007_2104h

Bit	7	6	5	4	3	2	1	0
Read	DPPU	DPPD	0	DMPD	0			
Write								
Reset	0	1	0	1	0	0	0	0

USBx_OBSERVE field descriptions

Field	Description
7 DPPU	Provides observability of the D+ Pullup enable at the USB transceiver. 0 D+ pullup disabled. 1 D+ pullup enabled.
6 DPPD	Provides observability of the D+ Pulldown enable at the USB transceiver. 0 D+ pulldown disabled. 1 D+ pulldown enabled.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 DMPD	Provides observability of the D- Pulldown enable at the USB transceiver. 0 D- pulldown disabled. 1 D- pulldown enabled.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.26 USB OTG Control register (USBx_CONTROL)

Address: 4007_2000h base + 108h offset = 4007_2108h

Bit	7	6	5	4
Read	0			DPPULLUPNONOTG
Write				
Reset	0	0	0	0
Bit	3	2	1	0
Read	0			
Write				
Reset	0	0	0	0

USBx_CONTROL field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 DPPULLUPNONOTG	Provides control of the DP Pullup in USBOTG, if USB is configured in non-OTG device mode. 0 DP Pullup in non-OTG device mode is not enabled. 1 DP Pullup in non-OTG device mode is enabled.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.5.27 USB Transceiver Control register 0 (USBx_USBTRC0)

Includes signals for basic operation of the on-chip USB Full Speed transceiver and configuration of the USB data connection that are not otherwise included in the USB Full Speed controller registers. VREGIN interrupt detection using the VFEDG_DET and VREDG_DET bitfields may be used for VBUS detection in bus-powered device use cases when the USB receptacle VBUS pin is connected to VREGIN.

Address: 4007_2000h base + 10Ch offset = 4007_210Ch

Bit	7	6	5	4
Read		0	USBRESMEN	VFEDG_DET
Write	USBRESET			
Reset	0	0	0	0
Bit	3	2	1	0
Read	VREDG_DET	USB_CLK_RECOVERY_INT	SYNC_DET	USB_RESUME_INT
Write				
Reset	0	0	0	0

USBx_USBTRC0 field descriptions

Field	Description
7 USBRESET	USB Reset Generates a hard reset to USBOTG. After this bit is set and the reset occurs, this bit is automatically cleared. NOTE: This bit is always read as zero. Wait two USB clock cycles after setting this bit before accessing other USB register bit fields. 0 Normal USB module operation. 1 Returns the USB module to its reset state.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 USBRESMEN	Asynchronous Resume Interrupt Enable This bit, when set, allows the USB module to send an asynchronous wakeup event to the MCU upon detection of resume signaling on the USB bus. The MCU then re-enables clocks to the USB module. It is used for low-power suspend mode when USB module clocks are stopped or the USB transceiver is in Suspend mode. Async wakeup only works in device mode. 0 USB asynchronous wakeup from suspend mode disabled. 1 USB asynchronous wakeup from suspend mode enabled. The asynchronous resume interrupt differs from the synchronous resume interrupt in that it asynchronously detects K-state using the unfiltered state of the D+ and D- pins. This interrupt should only be enabled when the Transceiver is suspended.
4 VFEDG_DET	VREGIN Falling Edge Interrupt Detect Use USBx_MISCCTRL[VFEDG_EN] to enable this bitfield. 0 VREGIN falling edge interrupt has not been detected. 1 VREGIN falling edge interrupt has been detected.
3 VREDG_DET	VREGIN Rising Edge Interrupt Detect Use USBx_MISCCTRL[VREDG_EN] to enable this bitfield. 0 VREGIN rising edge interrupt has not been detected. 1 VREGIN rising edge interrupt has been detected.
2 USB_CLK_ RECOVERY_INT	Combined USB Clock Recovery interrupt status This read-only field will be set to value high at 1'b1 when any of USB clock recovery interrupt conditions are detected and those interrupts are unmasked. For customer use the only unmasked USB clock recovery interrupt condition results from an overflow of the frequency trim setting values indicating that the frequency trim calculated is out of the adjustment range of the IRC48M output clock. To clear this bit after it has been set, Write 0xFF to register USB_CLK_RECOVER_INT_STATUS.
1 SYNC_DET	Synchronous USB Interrupt Detect 0 Synchronous interrupt has not been detected. 1 Synchronous interrupt has been detected.
0 USB_RESUME_ INT	USB Asynchronous Interrupt 0 No interrupt was generated. 1 Interrupt was generated because of the USB asynchronous interrupt.

51.5.28 Frame Adjust Register (USBx_USBFRMADJUST)

Address: 4007_2000h base + 114h offset = 4007_2114h

Bit	7	6	5	4	3	2	1	0
Read	ADJ							
Write								
Reset	0	0	0	0	0	0	0	0

USBx_USBFRMADJUST field descriptions

Field	Description
ADJ	Frame Adjustment In Host mode, the frame adjustment is a twos complement number that adjusts the period of each USB frame in 12-MHz clock periods. A SOF is normally generated every 12,000 12-MHz clock cycles. The Frame Adjust Register can adjust this by -128 to +127 to compensate for inaccuracies in the USB 48-MHz clock. Changes to the ADJ bit take effect at the start of the next frame.

51.5.29 Miscellaneous Control register (USBx_MISCCTRL)

Address: 4007_2000h base + 12Ch offset = 4007_212Ch

Bit	7	6	5	4
Read	0			VFEDG_EN
Write				
Reset	0	0	0	0

Bit	3	2	1	0
Read	VREDG_EN	OWNERRISODIS	SOFBUSSET	SOFDYNTHLD
Write				
Reset	0	0	0	0

USBx_MISCCTRL field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 VFEDG_EN	VREGIN Falling Edge Interrupt Enable 0 VREGIN falling edge interrupt disabled. 1 VREGIN falling edge interrupt enabled.
3 VREDG_EN	VREGIN Rising Edge Interrupt Enable 0 VREGIN rising edge interrupt disabled. 1 VREGIN rising edge interrupt enabled.
2 OWNERRISODIS	OWN Error Detect for ISO IN / ISO OUT Disable This field is only valid for Peripheral mode, that is, CTL[HOSTMODEEN]=0.

Table continues on the next page...

USBx_MISCCTRL field descriptions (continued)

Field	Description
	0 OWN error detect for ISO IN / ISO OUT is not disabled. 1 OWN error detect for ISO IN / ISO OUT is disabled.
1 SOFBUSSET	SOF_TOK Interrupt Generation Mode Select This field is only valid for Host mode, that is, CTL[HOSTMODEEN]=1. 0 SOF_TOK interrupt is set according to SOF threshold value. 1 SOF_TOK interrupt is set when SOF counter reaches 0.
0 SOFDYNTHLD	Dynamic SOF Threshold Compare mode This field is only valid for Host mode, that is, CTL[HOSTMODEEN]=1. 0 SOF_TOK interrupt is set when byte times SOF threshold is reached. 1 SOF_TOK interrupt is set when 8 byte times SOF threshold is reached or overstepped.

51.5.30 USB Clock recovery control (USBx_CLK_RECOVER_CTRL)

Signals in this register control the crystal-less USB clock mode in which the internal IRC48M oscillator is tuned to match the clock extracted from the incoming USB data stream.

NOTE

The IRC48M internal oscillator module must be enabled in the CLK_RECOVER_IRC_EN register for this mode.

Address: 4007_2000h base + 140h offset = 4007_2140h

Bit	7	6	5	4	3	2	1	0
Read	CLOCK_RECOVER_EN	RESET_RESUME_ROUGH_EN	RESTART_IFRTRIM_EN	Reserved		Reserved	Reserved	Reserved
Write								
Reset	0	0	0	0	0	0	0	0

USBx_CLK_RECOVER_CTRL field descriptions

Field	Description
7 CLOCK_RECOVER_EN	Crystal-less USB enable This bit must be enabled if user wants to use the crystal-less USB mode for the Full Speed USB controller and transceiver. NOTE: This bit should not be set for USB host mode or OTG. 0 Disable clock recovery block (default) 1 Enable clock recovery block

Table continues on the next page...

USBx_CLK_RECOVER_CTRL field descriptions (continued)

Field	Description
6 RESET_ RESUME_ ROUGH_EN	Reset/resume to rough phase enable The clock recovery block tracks the IRC48M to get an accurate 48Mhz clock. It has two phases after user enables clock_recover_en bit, rough phase and tracking phase. The step to fine tune the IRC48M by adjusting the trim fine value is different during these 2 phases. The step in rough phase is larger than that in tracking phase. Switch back to rough stage whenever USB bus reset or bus resume occurs. 0 Always works in tracking phase after the first time rough to track transition (default) 1 Go back to rough stage whenever bus reset or bus resume occurs
5 RESTART_ IFRTRIM_EN	Restart from IFR trim value IRC48M has a default trim fine value whose default value is factory trimmed (the IFR trim value). Clock recover block tracks the accuracy of the clock 48Mhz and keeps updating the trim fine value accordingly 0 Trim fine adjustment always works based on the previous updated trim fine value (default) 1 Trim fine restarts from the IFR trim value whenever bus_reset/bus_resume is detected or module enable is desasserted
4–3 Reserved	This field is reserved.
2 Reserved	This field is reserved. This bit is for NXP use only. Customers should not change this bit from its default state.
1 Reserved	This field is reserved. This bit is for NXP use only. Customers should not change this bit from its default state.
0 Reserved	This field is reserved. Default should not be changed

51.5.31 IRC48M oscillator enable register (USBx_CLK_RECOVER_IRC_EN)

Controls basic operation of the on-chip IRC48M module used to produce nominal 48MHz clocks for USB crystal-less operation and other functions.

See additional information about the IRC48M operation in the Clock Distribution chapter.

Address: 4007_2000h base + 144h offset = 4007_2144h

Bit	7	6	5	4	3	2	1	0
Read								
Write								
Reset	0	0	0	0	0	0	0	1

USBx_CLK_RECOVER_IRC_EN field descriptions

Field	Description
7–2 Reserved	This field is reserved.

Table continues on the next page...

USBx_CLK_RECOVER_IRC_EN field descriptions (continued)

Field	Description
1 IRC_EN	IRC48M enable This bit is used to enable the on-chip IRC48M module to generate clocks for crystal-less USB. It can be used for FS USB device mode operation. This bit must be set before using the crystal-less USB clock configuration. 0 Disable the IRC48M module (default) 1 Enable the IRC48M module
0 REG_EN	IRC48M regulator enable This bit is used to enable the local analog regulator for IRC48M module. This bit must be set if user wants to use the crystal-less USB clock configuration. 0 IRC48M local regulator is disabled 1 IRC48M local regulator is enabled (default)

51.5.32 Clock recovery combined interrupt enable (USBx_CLK_RECOVER_INT_EN)

Enables or masks the individual interrupt flags which are logically OR'ed together to produce the combined interrupt indication on the USB_CLK_RECOVERY_INT bit in the USB_USBTRC0 register if the indicated conditions have been detected in the USB clock recovery algorithm operation.

Address: 4007_2000h base + 154h offset = 4007_2154h

Bit	7	6	5	4	3	2	1	0
Read	Reserved			OVF_ERROR_EN	Reserved			
Write								
Reset	0	0	0	1	0	0	0	0

USBx_CLK_RECOVER_INT_EN field descriptions

Field	Description
7–5 Reserved	This field is reserved. Should always be written as 0.
4 OVF_ERROR_EN	Determines whether OVF_ERROR condition signal is used in generation of USB_CLK_RECOVERY_INT. 0 The interrupt will be masked 1 The interrupt will be enabled (default)
Reserved	This field is reserved. Should always be written as 0.

51.5.33 Clock recovery separated interrupt status (USBx_CLK_RECOVER_INT_STATUS)

A Write operation with value high at 1'b1 on any combination of individual bits will clear those bits.

Address: 4007_2000h base + 15Ch offset = 4007_215Ch

Bit	7	6	5	4	3	2	1	0
Read	Reserved			OVF_ERROR	Reserved			
Write	w1c			w1c	w1c			
Reset	0	0	0	0	0	0	0	0

USBx_CLK_RECOVER_INT_STATUS field descriptions

Field	Description
7–5 Reserved	This field is reserved. Should always be written as 0.
4 OVF_ERROR	Indicates that the USB clock recovery algorithm has detected that the frequency trim adjustment needed for the IRC48M output clock is outside the available TRIM_FINE adjustment range for the IRC48M module. 0 No interrupt is reported 1 Unmasked interrupt has been generated
Reserved	This field is reserved. Should always be written as 0.

51.6 OTG and Host mode operation

The Host mode logic allows portable, mobile, and other devices using this SOC to function as a USB Embedded Host (EH) Controller. The OTG logic adds an interface to allow the OTG Host Negotiation and Session Request Protocols (HNP and SRP) to be implemented in software.

Host mode is intended for use in handheld-portable devices to allow easy connection to simple HID class devices such as printers and keyboards. It is not intended to perform the functions of a full OHCI or UHCI compatible host controller found on PC motherboards. Host mode allows bulk, isochronous, interrupt and control transfers. Bulk data transfers are performed at nearly the full USB interface bandwidth. Support is provided for ISO

transfers, but the number of ISO streams that can be practically supported is affected by the interrupt latency of the processor servicing the Token Done interrupts from the SIE. Custom drivers must be written to support Host mode operation.

Setting the HOST_MODE_EN bit in the CTL register enables Host mode. The USB-FS core can only operate as a peripheral device or in Host mode. It cannot operate in both modes simultaneously. When HOST_MODE is enabled, only endpoint zero is used. All other endpoints should be disabled by software.

51.7 Host Mode Operation Examples

The following sections illustrate the steps required to perform USB host functions using the USB-FS core. For more information about these procedures, see the *Universal Serial Bus Specification, Revision 2.0*, "Chapter 9 USB Device Framework."

To enable host mode and discover a connected device:

1. Enable Host Mode (CTL[HOST_MODE_EN]=1). The pull-down resistors are enabled, and pull-up disabled. Start of Frame (SOF) generation begins. SOF counter loaded with 12,000. Disable SOF packet generation to eliminate noise on the USB by writing the USB enable bit to 0 (CTL[USB_EN]=0).
2. Enable the ATTACH interrupt (INTEN[ATTACHEN]=1).
3. Wait for ATTACH interrupt (ISTAT[ATTACH]). Signaled by USB peripheral device pull-up resistor changing the state of DPLUS or DMINUS from 0 to 1 (SE0 to J or K state).
4. Check the state of the JSTATE and SE0 bits in the control register. If the connecting device is low speed (JSTATE bit is 0), set the low-speed bit in the address registers (ADDR[LS_EN]=1) and the Host Without Hub bit in endpoint 0 register control (ENDPT0[HOSTWOHUB]=1).
5. Enable RESET (CTL[RESET]=1) for 10 ms.
6. Enable SOF packet to keep the connected device from going to suspend (CTL[USB_EN]=1).
7. Enumerate the attached device by sending the appropriate commands to the default control pipe of the connected device.

To complete a control transaction to a connected device:

1. Complete all the steps to discover a connected device

2. Set up the endpoint control register for bidirectional control transfers `ENDPT0[4:0] = 0x0d`.
3. Place a copy of the device framework setup command in a memory buffer.
4. Initialize current even or odd TX EP0 BDT to transfer the 8 bytes of command data for a device framework command (for example, a GET DEVICE DESCRIPTOR).
 - Set the BDT command word to `0x00080080` –Byte count to 8, OWN bit to 1.
 - Set the BDT buffer address field to the start address of the 8 byte command buffer.
5. Set the USB device address of the peripheral device in the address register (`ADDR[6:0]`). After the USB bus reset, the device USB address is zero. It is set to some other value usually 1 by the Set Address device framework command.
6. Write the TOKEN register with a SETUP to Endpoint 0, the peripheral device default control pipe (`TOKEN=0xD0`). This initiates a setup token on the bus followed by a data packet. The device handshake is returned in the BDT PID field after the packets complete. When the BDT is written, a Token Done (`ISTAT[TOKDNE]`) interrupt is asserted. This completes the setup phase of the setup transaction.
7. To initiate the data phase of the setup transaction (that is, get the data for the GET DEVICE DESCRIPTOR command), set up a buffer in memory for the data to be transferred.
8. Initialize the current even or odd TX EP0 BDT to transfer the data.
 - Set the BDT command word to `0x004000C0` – BC to 64 (the byte count of the data buffer in this case), OWN bit to 1, Data toggle to Data1.
 - Set the BDT buffer address field to the start address of the data buffer
9. Write the TOKEN register with an IN or OUT token to Endpoint 0, the peripheral device default control pipe, an IN token for a GET DEVICE DESCRIPTOR command (`TOKEN=0x90`). This initiates an IN token on the bus followed by a data packet from the device to the host. When the data packet completes, the BDT is written and a Token Done (`ISTAT[DNE]`) interrupt is asserted. For control transfers with a single packet data phase this completes the data phase of the setup transaction.
10. To initiate the status phase of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
11. Initialize the current even or odd TX EP0 BDT to transfer the status data.

- Set the BDT command word to 0x00000080 – BC to 0 (the byte count of the data buffer in this case), OWN bit to 1, Data toggle to Data1.
 - Set the BDT buffer address field to the start address of the data buffer
12. Write the TOKEN register with a IN or OUT token to Endpoint 0, the peripheral device default control pipe, an OUT token for a GET DEVICE DESCRIPTOR command (TOKEN=0x10). This initiates an OUT token on the bus followed by a zero length data packet from the host to the device. When the data packet completes, the BDT is written with the handshake from the device and a Token Done (ISTAT[TOKDNE]) interrupt is asserted. This completes the data phase of the setup transaction.

To send a full speed bulk data transfer to a peripheral device:

1. Complete all steps to discover a connected device and to configure a connected device. Write the ADDR register with the address of the peripheral device. Typically, there is only one other device on the USB bus in host mode so it is expected that the address is 0x01 and should remain constant.
2. Write 0x1D to ENDPT0 register to enable transmit and receive transfers with handshaking enabled.
3. Setup the even TX EP0 BDT to transfer up to 64 bytes.
4. Set the USB device address of the peripheral device in the address register (ADDR[6:0]).
5. Write the TOKEN register with an OUT token to the desired endpoint. The write to this register triggers the USB-FS transmit state machines to begin transmitting the token and the data.
6. Setup the odd TX EP0 BDT to transfer up to 64 bytes.
7. Write the TOKEN register with an OUT token as in step 4. Two tokens can be queued at a time to allow the packets to be double buffered to achieve maximum throughput.
8. Wait for the TOKDNE interrupt. This indicates that one of the BDTs has been released back to the processor and the transfer has completed. If the peripheral device asserts NAKs, the USB-FS continues to retry the transfer indefinitely without processor intervention unless the ENDPT0[RETRYDIS] is 1. If the retry disable field is set, the handshake (ACK, NAK, STALL, or ERROR (0xf)) is returned in the BDT

PID field. If a stall interrupt occurs, the pending packet must be dequeued and the error condition in the peripheral device cleared. If a Reset interrupt occurs (SE0 for more than 2.5 μ s), the peripheral device has detached.

9. After the TOK_DNE interrupt occurs, the BDTs can be examined and the next data packet queued by returning to step 2.

51.8 On-The-Go operation

The USB-OTG core provides sensors and controls to enable On-The-Go (OTG) operation. These sensors are used by the OTG driver software to implement the Host Negotiation Protocol (HNP) and Session Request Protocol (SRP) and give access to the OTG protocol control signals. The following state machines show the OTG operations involved with HNP and SRP protocols from either end of the USB cable.

51.8.1 OTG dual role A device operation

A device is considered the A device because of the type of cable attached. If the USB Type Standard-A or Micro-A plug is plugged into the device, it is considered the A device.

A dual role A device operates as the following flow diagram and state description table illustrates.

Figure 51-12. Dual role A device flow diagram

Table 51-8. State descriptions for the dual role A device flow

State	Action	Response
A_IDLE	If ID Interrupt. The cable has been unplugged or a Type B cable has been attached. The device now acts as a Type B device.	Go to B_IDLE
	If the A application wants to use the bus or if the B device is doing an SRP as indicated by an A_SESS_VLD Interrupt or Attach or Port Status Change Interrupt check data line for 5 –10 msec pulsing.	Go to A_WAIT_VRISE Turn on DRV_VBUS
A_WAIT_VRISE	If ID Interrupt or if A_VBUS_VLD is false after 100 msec The cable has been changed or the A device cannot support the current required from the B device.	Go to A_WAIT_VFALL Turn off DRV_VBUS
	If A_VBUS_VLD interrupt	Go to A_WAIT_BCON
A_WAIT_BCON	After 200 ms without Attach or ID Interrupt. (This could wait forever if desired.)	Go to A_WAIT_FALL Turn off DRV_VBUS
	A_VBUS_VLD Interrupt and B device attaches	Go to A_HOST Turn on Host mode
A_HOST	Enumerate Device determine OTG Support.	
	If A_VBUS_VLD/ Interrupt or A device is done and does not think it wants to do something soon or the B device disconnects	Go to A_WAIT_VFALL Turn off Host mode Turn off DRV_VBUS
	If the A device is finished with session or if the A device wants to allow the B device to take bus.	Go to A_SUSPEND
	ID Interrupt or the B device disconnects	Go to A_WAIT_BCON
A_SUSPEND	If ID Interrupt, or if 150 ms B disconnect timeout (This timeout value could be longer) or if A_VBUS_VLD\ Interrupt	Go to A_WAIT_VFALL Turn off DRV_VBUS
	If HNP enabled, and B disconnects in 150 ms then B device is becoming the host.	Go to A_PERIPHERAL Turn off Host mode
	If A wants to start another session	Go to A_HOST
A_PERIPHERAL	If ID Interrupt or if A_VBUS_VLD interrupt	Go to A_WAIT_VFALL Turn off DRV_VBUS.
	If 3 –200 ms of Bus Idle	Go to A_WAIT_BCON Turn on Host mode
A_WAIT_VFALL	If ID Interrupt or (A_SESS_VLD/ & b_conn/)	Go to A_IDLE

51.8.2 OTG dual role B device operation

A device is considered a B device if it is connected to the bus with a USB Type Standard-B, Mini-B, or Micro-B plug inserted into the local USB receptacle. The Type Mini-B plug and receptacle are now only allowed for dedicated peripheral devices, not dual role/OTG devices.

A dual role B device operates as the following flow diagram and state description table illustrates.

Figure 51-13. Dual role B device flow diagram

Table 51-9. State descriptions for the dual role B device flow

State	Action	Response
B_IDLE	If ID\ Interrupt. A Type A cable has been plugged in and the device should now respond as a Type A device.	Go to A_IDLE
	If B_SESS_VLD Interrupt. The A device has turned on VBUS and begins a session.	Go to B_PERIPHERAL Turn on DP_HIGH
	If B application wants the bus and Bus is Idle for 2 ms and the B_SESS_END bit is set, the B device can perform an SRP.	Go to B_SRP_INIT Pulse CHRG_VBUS Pulse DP_HIGH 5-10 ms
B_SRP_INIT	If ID\ Interrupt or SRP Done (SRP must be done in less than 100 ms.)	Go to B_IDLE
B_PERIPHERAL	If HNP enabled and the bus is suspended and B wants the bus, the B device can become the host.	Go to B_WAIT_ACON Turn off DP_HIGH
B_WAIT_ACON	If A connects, an attach interrupt is received	Go to B_HOST Turn on Host Mode
	If ID\ Interrupt or B_SESS_VLD/ Interrupt If the cable changes or if VBUS goes away, the host doesn't support us. Go to B_IDLE	Go to B_IDLE
	If 3.125 ms expires or if a Resume occurs	Go to B_PERIPHERAL
B_HOST	If ID\ Interrupt or B_SESS_VLD\ Interrupt If the cable changes or if VBUS goes away, the host doesn't support us.	Go to B_IDLE
	If B application is done or A disconnects	Go to B_PERIPHERAL

51.9 Device mode IRC48M operation

The following are the IRC48M initialization code steps:

1. Enable the IRC48M clock: `USB_CLK_RECOVER_IRC_EN[IRC_EN] = 1b`
2. Enable the USB clock recovery tuning:
`USB_CLK_RECOVER_CTRL[CLOCK_RECOVER_EN] = 1b`
3. Choose the clock source of USB by configuring the muxes and dividers. The IRC48M is muxed by setting `SIM_SOPT2[MCGPLLFL]`=11b for USB usage.
4. The selected mux output clock can be divided by the USB clock divider, so set these fields so no clock division is enabled. This is the equation for the divider:

$\text{Divider output clock} = \text{Divider input clock} \times [(\text{USBFRAC}+1) / (\text{USBDIV}+1)]$.

So set `SIM_CLKDIV2[USBDIV] = 000b` and `SIM_CLKDIV2[USBFRAC] = 0b`

5. The USB clock source must choose the output of the divided clock.

For chip-specific details, see the USB FS OTG controller clocking information in the "Clock Distribution" chapter.

Chapter 52

USB Device Charger Detection Module (USBDCD)

52.1 Chip-specific USBDCD information

52.1.1 USB DCD Overview

This device includes 2 USBDCD blocks.

- USBDCD is used for control of device charger detect for USB FS/LS DCD function on USB0 port
- USBHSDCD is used for control of device charger detect for USB HS/FS/LS DCD function on USB1 port

52.2 Preface

52.2.1 References

The following publications are referenced in this document. For updates to these specifications, see <http://www.usb.org>.

- *USB Battery Charging Specification Revision 1.1, USB Implementers Forum*
- *USB Battery Charging Specification (Including errata and ECNs through March 15, 2012) Revision 1.2, USB Implementers Forum*

52.2.2 Acronyms and abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 52-1. Acronyms and abbreviated terms

Term	Meaning
CDP	Charging Downstream Port, as defined in <i>USB Battery Charging Specification, Rev. 1.2</i>
Charging Port	A Charging Port supported by this module is either a CDP or a DCP
DCP	Dedicated Charging Port, as defined in <i>USB Battery Charging Specification, Rev. 1.2</i>
FS	Full speed (12 Mbit/s)
HS	High speed (480 Mbit/s)
I_{CFG_MAX}	Current limit for a USB device attached to an SDP, after configuration
I_{DEV_CHG}	Current limit for a USB device attached to a Charging Port
I_{DM_SINK}	Current sink for the D– line
I_{DP_SINK}	Current sink for the D+ line
I_{DP_SRC}	Current source for the D+ line
I_{SUSP}	Current drawn when the USB device is suspended
LDO	Low dropout
LS	Low Speed (1.5 Mbit/s)
N/A	Not applicable
OTG	On-The-Go
R_{DM_DWN}	D– pulldown resistance for data pin contact detect
SDP	Standard Downstream Port, as defined in <i>USB Battery Charging Specification, Rev 1.2</i>
V_{DAT_REF}	Data detect reference voltage for the voltage comparator
V_{DP_SRC}	Voltage source for the D+ line
V_{DM_SRC}	Voltage source for the D– line
V_{LGC}	Threshold voltage for logic high

52.2.3 Glossary

The following table shows a glossary of terms used in this document.

Table 52-2. Glossary of terms

Term	Definition
Transceiver	Module that implements the physical layer of the USB standard (FS or LS only).
PHY	Module that implements the physical layer of the USB standard (HS capable).
Attached	Device is physically plugged into USB port, but has <i>not enabled</i> either D+ or D– pullup resistor.
Connected	Device is physically plugged into USB port, and has <i>enabled</i> either D+ or D– pullup resistor.
Suspended	After 3 ms of no bus activity, the USB device enters suspend mode.
Component	The hardware and software that make up a subsystem.

52.3 Block diagram

The following figure is a high level block diagram of the module.

Figure 52-1. Block diagram

The USBDCD module consists of two main blocks:

- A digital block provides the programming interface (memory-mapped registers) and includes the timer unit and the analog control unit.
- An analog block provides the circuitry for the physical detection of the charger, including the voltage source, current source, current sink, and voltage comparator circuitry.

52.4 Features

The USBDCD module offers the following features:

- Compliant with the latest industry standard specification: *USB Battery Charging Specification, Revision 1.1 and 1.2*
- Programmable timing parameters default to values required by the industry standards:
 - Having standard default values allows for easy configuration- simply set the clock frequency before enabling the module.
 - Programmability allows the flexibility to meet future updates of the standards.

52.5 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

Table 52-3. Module modes and their conditions

Module mode	Description	Conditions when used
Enabled	The module performs the charger detection sequence.	System software should enable the module only when <i>all</i> of the following conditions are true: - The system uses a rechargeable battery. - The device is being used in an FS USB device application. - The device has detected that it is attached to the USB cable.
Disabled	The module is not active and is held in a low power state.	System software should disable the module when <i>either</i> of the following conditions is true: - The charger detect sequence is complete. - The conditions for being enabled are not met.
Powered Off	The digital supply voltage dvdd is removed.	Low system performance requirements allow putting the device into a very low-power stop mode.

Operating mode transitions are shown in the following table.

Table 52-4. Entering and exiting module modes

Module mode	Entering	Exiting	Mode after exiting
Enabled	Set CONTROL[START].	Set CONTROL[SR]. ¹	Disabled
Disabled	Take <i>either</i> of the following actions: - Set CONTROL[SR].¹ - Reset the module. By default, the module is disabled.	Set CONTROL[START].	Enabled
Powered Off	Perform the following actions: - Put the device into very low-power stop mode. - Adjust the supply voltages.	Perform the following actions: - Restore the supply voltages. - Take the device out of very low-power stop mode.	Disabled

1. The effect of setting the SR bit is immediate; that is, the module is disabled even if the sequence has not completed.

52.6 Module signal descriptions

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

Table 52-5. Signal descriptions

Signal	Description	I/O
USB_DM	USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus.	I/O
USB_DP	USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus.	I/O
avdd33 ¹	3.3 V regulated analog supply	I
vss_bulk	Digital/Analog ground	I
dvdd	1.2 V digital supply	I

1. Voltage must be 3.3 V +/- 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] bit should not be set.

NOTE

The transceiver module also interfaces to the USB_DM and USB_DP signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 specification and in [Application information](#).

52.7 Memory map/Register definition

This section describes the memory map and registers for the USBDCD module.

USBDCD memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_5000	Control register (USBDCD_CONTROL)	32	R/W	0001_0000h	52.7.1/1544
4003_5004	Clock register (USBDCD_CLOCK)	32	R/W	0000_00C1h	52.7.2/1546
4003_5008	Status register (USBDCD_STATUS)	32	R	0000_0000h	52.7.3/1547
4003_500C	Signal Override Register (USBDCD_SIGNAL_OVERRIDE)	32	R/W	0000_0000h	52.7.4/1549

Table continues on the next page...

USBDCD memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4003_5010	TIMER0 register (USBDCD_TIMER0)	32	R/W	0010_0000h	52.7.5/1550
4003_5014	TIMER1 register (USBDCD_TIMER1)	32	R/W	000A_0028h	52.7.6/1551
4003_5018	TIMER2_BC11 register (USBDCD_TIMER2_BC11)	32	R/W	0028_0001h	52.7.7/1551
4003_5018	TIMER2_BC12 register (USBDCD_TIMER2_BC12)	32	R/W	0001_0028h	52.7.8/1552

52.7.1 Control register (USBDCD_CONTROL)

Contains the control and interrupt bit fields.

Address: 4003_5000h base + 0h offset = 4003_5000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0						0	0	0						BC12	IE
W							SR	START								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved							IF	0						IACK	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBDCD_CONTROL field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 SR	Software Reset This is a self-clearing field and always reads 0. Determines whether a software reset is performed. 0 Do not perform a software reset. 1 Perform a software reset.
24 START	Start Change Detection Sequence

Table continues on the next page...

USBDCD_CONTROL field descriptions (continued)

Field	Description
	This is a self-clearing field and always reads 0. Determines whether the charger detection sequence is initiated. 0 Do not start the sequence. Writes of this value have no effect. 1 Initiate the charger detection sequence. If the sequence is already running, writes of this value have no effect.
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 BC12	BC1.2 compatibility. This bit cannot be changed after start detection. 0 Compatible with BC1.1 (default) 1 Compatible with BC1.2
16 IE	Interrupt Enable Enables/disables interrupts to the system. 0 Disable interrupts to the system. 1 Enable interrupts to the system.
15–9 Reserved	This field is reserved.
8 IF	Interrupt Flag Determines whether an interrupt is pending. 0 No interrupt is pending. 1 An interrupt is pending.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 IACK	Interrupt Acknowledge This is a self-clearing field and always reads 0. Determines whether the interrupt is cleared. 0 Do not clear the interrupt. 1 Clear the IF bit (interrupt flag).

52.7.2 Clock register (USBD CD_CLOCK)

Address: 4003_5000h base + 4h offset = 4003_5004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				CLOCK_SPEED										0	CLOCK_UNIT
W																
Reset	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	1

USBD CD_CLOCK field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–2 CLOCK_SPEED	Numerical Value of Clock Speed in Binary The unit of measure is programmed in CLOCK_UNIT. The valid range is from 1 to 1023 when clock unit is MHz and 4 to 1023 when clock unit is kHz. Examples with CLOCK_UNIT = 1: - For 48 MHz: 0b00_0011_0000 (48) (Default) - For 24 MHz: 0b00_0001_1000 (24) Examples with CLOCK_UNIT = 0: - For 100 kHz: 0b00_0110_0100 (100) - For 500 kHz: 0b01_1111_0100 (500)
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CLOCK_UNIT	Unit of Measurement Encoding for Clock Speed Specifies the unit of measure for the clock speed. 0 kHz Speed (between 1 kHz and 1023 kHz) 1 MHz Speed (between 1 MHz and 1023 MHz)

52.7.3 Status register (USBDCD_STATUS)

Provides the current state of the module for system software monitoring.

Address: 4003_5000h base + 8h offset = 4003_5008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0									ACTIVE	TO	ERR	SEQ_STAT	SEQ_RES		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBDCD_STATUS field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 ACTIVE	Active Status Indicator Indicates whether the sequence is running. 0 The sequence is not running. 1 The sequence is running.
21 TO	Timeout Flag Indicates whether the detection sequence has passed the timeout threshold.

Table continues on the next page...

USBD CD_STATUS field descriptions (continued)

Field	Description
	0 The detection sequence has not been running for over 1 s. 1 It has been over 1 s since the data pin contact was detected and debounced.
20 ERR	Error Flag Indicates whether there is an error in the detection sequence. 0 No sequence errors. 1 Error in the detection sequence. See the SEQ_STAT field to determine the phase in which the error occurred.
19–18 SEQ_STAT	Charger Detection Sequence Status Indicates the status of the charger detection sequence. 00 The module is either not enabled, or the module is enabled but the data pins have not yet been detected. 01 Data pin contact detection is complete. 10 Charging port detection is complete. 11 Charger type detection is complete.
17–16 SEQ_RES	Charger Detection Sequence Results Reports how the charger detection is attached. 00 No results to report. 01 Attached to an SDP. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected. 10 Attached to a charging port. The exact meaning depends on bit 18: • 0: Attached to either a CDP or a DCP. The charger type detection has not completed. • 1: Attached to a CDP. The charger type detection has completed. 11 Attached to a DCP.
Reserved	This field is reserved. NOTE: Bits do not always read as 0.

52.7.4 Signal Override Register (USBDCD_SIGNAL_OVERRIDE)

The Signal Override register provides a way for the customer to enable signaling required by the USB BC v1.2 specification after the battery charger detection sequences have completed.

Address: 4003_5000h base + Ch offset = 4003_500Ch

USBDCD_SIGNAL_OVERRIDE field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	This field is reserved. Reserved, not for customer use. The value of this bit field may change during module operation.
8 Reserved	This field is reserved. Reserved, not for customer use. The value of this bit field may change during module operation.
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

USBDCD_SIGNAL_OVERRIDE field descriptions (continued)

Field	Description
PS	Phase Selection Used to enable specified voltage and current source circuits on the USB_DP and USB_DM pins. Customers may set this bit field to 2'b10 for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. 00 No overrides. Bit field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 01 Reserved, not for customer use. 10 Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 11 Reserved, not for customer use.

52.7.5 TIMER0 register (USBDCD_TIMER0)

TIMER0 has an TSEQ_INIT field that represents the system latency in ms. Latency is measured from the time when VBUS goes active until the time system software initiates charger detection sequence in USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT.

Valid values are 0–1023, however the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.

Address: 4003_5000h base + 10h offset = 4003_5010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						TSEQ_INIT										0		TUNITCON													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBDCD_TIMER0 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0–1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TUNITCON	Unit Connection Timer Elapse (in ms)

Table continues on the next page...

USBDCD_TIMER0 field descriptions (continued)

Field	Description
	Displays the amount of elapsed time since the event of setting the START bit plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count. This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of 0xFF (4095 ms). The timer does not rollover to zero. A software reset clears the timer.

52.7.6 TIMER1 register (USBDCD_TIMER1)

TIMER1 contains timing parameters. Note that register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Address: 4003_5000h base + 14h offset = 4003_5014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBDCD_TIMER1 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TDCD_DBNC	Time Period to Debounce D+ Signal Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See "Debouncing the data pin contact" Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 10 ms.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TVDPsrc_ON	Time Period Comparator Enabled This timing parameter is used after detection of the data pin. See "Charging Port Detection". Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.

52.7.7 TIMER2_BC11 register (USBDCD_TIMER2_BC11)

TIMER2_BC11 contains timing parameters for USB Battery Charging Specification, v1.1.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Address: 4003_5000h base + 18h offset = 4003_5018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBDcd_TIMER2_BC11 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TVDPsrc_CON	Time Period Before Enabling D+ Pullup Sets the time period (ms) that the module waits after charging port detection before system software must enable the D+ pullup to connect to the USB host. Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CHECK_DM	Time Before Check of D– Line Sets the amount of time (in ms) that the module waits after the device connects to the USB bus until checking the state of the D– line to determine the type of charging port. See "Charger Type Detection." Valid values are 1–15ms.

52.7.8 TIMER2_BC12 register (USBDcd_TIMER2_BC12)

TIMER2_BC12 contains timing parameters for USB Battery Charging Specification, v1.2.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Address: 4003_5000h base + 18h offset = 4003_5018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBDCD_TIMER2_BC12 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TWAIT_AFTER_PRD	Sets the amount of time (in ms) that the module waits after primary detection before start to secondary detection. Valid values are 1–1023ms. Default is 1ms.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TVDMSRC_ON	Sets the amount of time (in ms) that the module enables the V_{DM_SRC} . Valid values are 0–40ms.

52.8 Memory map/Register definition

This section describes the memory map and registers for the USBHSDCD module.

USBHSDCD memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
400A_3000	Control register (USBHSDCD_CONTROL)	32	R/W	0001_0000h	52.8.1/1554
400A_3004	Clock register (USBHSDCD_CLOCK)	32	R/W	0000_00C1h	52.8.2/1555
400A_3008	Status register (USBHSDCD_STATUS)	32	R	0000_0000h	52.8.3/1557
400A_300C	Signal Override Register (USBHSDCD_SIGNAL_OVERRIDE)	32	R/W	0000_0000h	52.8.4/1559
400A_3010	TIMER0 register (USBHSDCD_TIMER0)	32	R/W	0010_0000h	52.8.5/1560
400A_3014	TIMER1 register (USBHSDCD_TIMER1)	32	R/W	000A_0028h	52.8.6/1561
400A_3018	TIMER2_BC11 register (USBHSDCD_TIMER2_BC11)	32	R/W	0028_0001h	52.8.7/1561
400A_3018	TIMER2_BC12 register (USBHSDCD_TIMER2_BC12)	32	R/W	0001_0028h	52.8.8/1562

52.8.1 Control register (USBHSDCD_CONTROL)

Contains the control and interrupt bit fields.

Address: 400A_3000h base + 0h offset = 400A_3000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0						0	0	0						BC12	IE
W							SR	START								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved							IF	0							0
W																IACK
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

USBHSDCD_CONTROL field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 SR	Software Reset Determines whether a software reset is performed. 0 Do not perform a software reset. 1 Perform a software reset.
24 START	Start Change Detection Sequence Determines whether the charger detection sequence is initiated. 0 Do not start the sequence. Writes of this value have no effect. 1 Initiate the charger detection sequence. If the sequence is already running, writes of this value have no effect.
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 BC12	BC1.2 compatibility. This bit cannot be changed after start detection. 0 Compatible with BC1.1 (default) 1 Compatible with BC1.2

Table continues on the next page...

USBHSDCD_CONTROL field descriptions (continued)

Field	Description
16 IE	Interrupt Enable Enables/disables interrupts to the system. 0 Disable interrupts to the system. 1 Enable interrupts to the system.
15–9 Reserved	This field is reserved.
8 IF	Interrupt Flag Determines whether an interrupt is pending. 0 No interrupt is pending. 1 An interrupt is pending.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 IACK	Interrupt Acknowledge Determines whether the interrupt is cleared. 0 Do not clear the interrupt. 1 Clear the IF bit (interrupt flag).

52.8.2 Clock register (USBHSDCD_CLOCK)

Address: 400A_3000h base + 4h offset = 400A_3004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	0				CLOCK_SPEED											0	CLOCK_UNIT
W																	
Reset	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	1	

USBHSDCD_CLOCK field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–2 CLOCK_SPEED	Numerical Value of Clock Speed in Binary The unit of measure is programmed in CLOCK_UNIT. The valid range is from 1 to 1023 when clock unit is MHz and 4 to 1023 when clock unit is kHz. Examples with CLOCK_UNIT = 1: - For 48 MHz: 0b00_0011_0000 (48) (Default) - For 24 MHz: 0b00_0001_1000 (24) Examples with CLOCK_UNIT = 0: - For 100 kHz: 0b00_0110_0100 (100) - For 500 kHz: 0b01_1111_0100 (500)
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CLOCK_UNIT	Unit of Measurement Encoding for Clock Speed Specifies the unit of measure for the clock speed. 0 kHz Speed (between 1 kHz and 1023 kHz) 1 MHz Speed (between 1 MHz and 1023 MHz)

52.8.3 Status register (USBHSDCD_STATUS)

Provides the current state of the module for system software monitoring.

Address: 400A_3000h base + 8h offset = 400A_3008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0									ACTIVE	TO	ERR	SEQ_STAT		SEQ_RES	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBHSDCD_STATUS field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 ACTIVE	Active Status Indicator Indicates whether the sequence is running. 0 The sequence is not running. 1 The sequence is running.
21 TO	Timeout Flag Indicates whether the detection sequence has passed the timeout threshold.

Table continues on the next page...

USBHSDCD_STATUS field descriptions (continued)

Field	Description
	0 The detection sequence has not been running for over 1 s. 1 It has been over 1 s since the data pin contact was detected and debounced.
20 ERR	Error Flag Indicates whether there is an error in the detection sequence. 0 No sequence errors. 1 Error in the detection sequence. See the SEQ_STAT field to determine the phase in which the error occurred.
19–18 SEQ_STAT	Charger Detection Sequence Status Indicates the status of the charger detection sequence. 00 The module is either not enabled, or the module is enabled but the data pins have not yet been detected. 01 Data pin contact detection is complete. 10 Charging port detection is complete. 11 Charger type detection is complete.
17–16 SEQ_RES	Charger Detection Sequence Results Reports how the charger detection is attached. 00 No results to report. 01 Attached to an SDP. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected. 10 Attached to a charging port. The exact meaning depends on bit 18: • 0: Attached to either a CDP or a DCP. The charger type detection has not completed. • 1: Attached to a CDP. The charger type detection has completed. 11 Attached to a DCP.
Reserved	This field is reserved. NOTE: Bits do not always read as 0.

52.8.4 Signal Override Register (USBHSDCD_SIGNAL_OVERRIDE)

The Signal Override register provides a way for the customer to enable signaling required by the USB BC v1.2 specification after the battery charger detection sequences have completed.

Address: 400A_3000h base + Ch offset = 400A_300Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

USBHSDCD_SIGNAL_OVERRIDE field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	This field is reserved. Reserved, not for customer use. The value of this bit field may change during module operation.
8 Reserved	This field is reserved. Reserved, not for customer use. The value of this bit field may change during module operation.
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

USBHSDCD_SIGNAL_OVERRIDE field descriptions (continued)

Field	Description
PS	Phase Selection Used to enable specified voltage and current source circuits on the USB_DP and USB_DM pins. Customers may set this bit field to 2'b10 for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. 00 No overrides. Bit field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 01 Reserved, not for customer use. 10 Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 11 Reserved, not for customer use.

52.8.5 TIMER0 register (USBHSDCD_TIMER0)

TIMER0 has an TSEQ_INIT field that represents the system latency in ms. Latency is measured from the time when VBUS goes active until the time system software initiates charger detection sequence in USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT.

Valid values are 0–1023, however the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.

Address: 400A_3000h base + 10h offset = 400A_3010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHSDCD_TIMER0 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TUNITCON	Unit Connection Timer Elapse (in ms)

Table continues on the next page...

USBHSDCD_TIMER0 field descriptions (continued)

Field	Description
	Displays the amount of elapsed time since the event of setting the START bit plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count. This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of 0xFFFF (4095 ms). The timer does not rollover to zero. A software reset clears the timer.

52.8.6 TIMER1 register (USBHSDCD_TIMER1)

TIMER1 contains timing parameters. Note that register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Address: 400A_3000h base + 14h offset = 400A_3014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHSDCD_TIMER1 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TDCD_DBNC	Time Period to Debounce D+ Signal Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See "Debouncing the data pin contact" Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 10 ms.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TVDPsrc_ON	Time Period Comparator Enabled This timing parameter is used after detection of the data pin. See "Charging Port Detection". Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.

52.8.7 TIMER2_BC11 register (USBHSDCD_TIMER2_BC11)

TIMER2_BC11 contains timing parameters for USB Battery Charging Specification, v1.1.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Address: 400A_3000h base + 18h offset = 400A_3018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHSDCD_TIMER2_BC11 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TVDPsrc_CON	Time Period Before Enabling D+ Pullup Sets the time period (ms) that the module waits after charging port detection before system software must enable the D+ pullup to connect to the USB host. Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CHECK_DM	Time Before Check of D– Line Sets the amount of time (in ms) that the module waits after the device connects to the USB bus until checking the state of the D– line to determine the type of charging port. See "Charger Type Detection." Valid values are 1–15ms.

52.8.8 TIMER2_BC12 register (USBHSDCD_TIMER2_BC12)

TIMER2_BC12 contains timing parameters for USB Battery Charging Specification, v1.2.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Address: 400A_3000h base + 18h offset = 400A_3018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHSDCD_TIMER2_BC12 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 TWAIT_AFTER_PRD	Sets the amount of time (in ms) that the module waits after primary detection before start to secondary detection. Valid values are 1–1023ms. Default is 1ms.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TVDMSRC_ON	Sets the amount of time (in ms) that the module enables the V_{DM_SRC} . Valid values are 0–40ms.

52.9 Functional description

The sequence of detecting the presence of charging port and type of charging port involves several hardware components, coordinated by system software. This collection of interacting hardware and software is called the USB Battery Charging Subsystem. The following figure shows the USBDCD module as a component of the subsystem. The following table describes the components.

Figure 52-2. USB battery charging subsystem

Table continues on the next page...

Table 52-6. USB battery charger subsystem components (continued)

Component	Description
Comm Module	A communications module on the device can be used to control the charge rate of the battery charger IC.
System software	Coordinates the detection activities of the subsystem.
USB Controller	The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it. NOTE: The USB controller must be used only for USB device applications when using the USBDCD module. For USB host applications, the USBDCD module must be disabled.
USB Transceiver	The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence in BC1.1, but it is not used during charger detection in BC1.2. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus. The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence in BC1.1: The D+ pullup enable is output from the USB controller and is under software control. The USBDCD module controls the D– pulldown enable.
USBDCD Module	Detects whether the device has been plugged into either an SDP, a CDP, or a DCP.
VBUS_detect	This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low power mode on being plugged into the USB port, this interrupt should also be a low power wake up source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.

52.9.1 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the USB Battery Charging Specification Rev. 1.2.

Figure 52-3. Full speed charger detection timing for BC1.2

Timing parameter values used in this module for BC1.2 are listed in the following table.

Table 52-7. Timing parameters for the charger detection sequence for BC1.2

Parameter	USB Battery Charging Spec	Module default	Module programmable range
$T_{DCD\_DBNC}^1$	10 ms min (no max)	10 ms	0– 1023 ms
$T_{VDPSRC\_ON}^1$	40 ms min (no max)	40 ms	0 –1023 ms
$T_{WAIT\_AFTER\_PRD}$	N/A	1 ms	0– 1023 ms
T_{VDMSRC_ON}	40 ms	40 ms	0 –1023 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
$T_{UNIT\_CON}^1$	1 s	N/A	N/A
$T_{VDMSRC\_EN}^1$	1– 20 ms	From the USB host	N/A
$T_{VDMSRC\_DIS}^1$	0 – 20 ms	From the USB host	N/A
$T_{CON\_IDPSINK\_DIS}^1$	0 – 10 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.2*.

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the USB Battery Charging Specification Rev. 1.1.

Figure 52-4. Full speed charger detection timing for BC1.1

Timing parameter values used in this module for BC1.1 are listed in the following table.

Table 52-8. Timing parameters for the charger detection sequence for BC1.1

Parameter	USB Battery Charging Spec	Module default	Module programmable range
$T_{DCD\_DBNC}^1$	10 ms min (no max)	10 ms	0–1023 ms
$T_{VDPSRC\_ON}^1$	40 ms min (no max)	40 ms	0–1023 ms
$T_{VDPSRC\_CON}^1$	40 ms min (no max)	40 ms	0–1023 ms
CHECK_DM	N/A	1 ms	0–15 ms
T_{SEQ_INIT}	N/A	16 ms	0–1023 ms
$T_{UNIT\_CON}^1$	1 s	N/A	N/A
$T_{VDMSRC\_EN}^1$	1–20 ms	From the USB host	N/A
$T_{VDMSRC\_DIS}^1$	0–20 ms	From the USB host	N/A
$T_{CON\_IDPSINK\_DIS}^1$	0–20 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.1*.

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

Table 52-9. Overview of the charger detection sequence

Phase		Overview description	Full description
1	Initial Conditions	Initial system conditions that need to be met before the detection sequence is initiated.	Initial System Conditions
2	VBUS Detection	System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.	VBUS contact detection
3	Data Pin Contact Detection	The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.	Data pin contact detection
4	Charging Port Detection	The USBDCD module detects if the port is an SDP or either type of charging port, that is CDP or DCP.	Charging port detection
5	Charger Type Detection	The USBDCD module detects the type of charging port, if applicable.	Charger type detection
6	Sequence Timeout	The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software.	Charger detection sequence timeout

52.9.1.1 Initial System Conditions

The USBDCD module is intended for use with USB device applications using a rechargeable battery. The module does not have support for interfacing with ACA or ACA-Dock equipment as defined in the *USB Battery Charging Specification, Revision 1.2*, and it cannot be used with USB applications that are embedded host or OTG. In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode. The USBDCD instantiation of this module for a Full-Speed port does not directly depend on the VBUS voltage and can operate as long as the avdd33 supply is in a valid range.
- Due to the analog circuits used, the USBHSDCD instantiation of this module for a High-Speed capable port has the additional requirement that the voltage on the USB1_VBUS pin be > 4.5V for proper operation of its current and voltage sources.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus, except as allowed by the *USB 2.0 Connect Timing Update ECN*.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low power mode subsequently enters run mode upon being plugged into the USB bus.

52.9.1.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear the bit if software polling method is used.
5. Program CONTROL[BC12] based on which revision of the USB Battery Charging Specification is needed.
6. Set CONTROL[START] to start the charger detection sequence.

52.9.1.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ and D- signals. USB plugs and receptables are designed such that when the plug is inserted into the receptable, the power pins make contact before the data pins make contact. See the following figure.

Figure 52-5. Relative pin positions in USB plugs and receptacles

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptable. Delays of several hundred milliseconds are possible.

52.9.1.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in [Initial System Conditions](#), the USBDCD module turns on the I_{DP_SRC} current source and enables the R_{DM_DWN} pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the T_{DCD_DBNC} debounce time interval. By default, T_{DCD_DBNC} is 10 ms, but it can be programmed in the `TIMER0[TDCD_DBNC]` field. See the description of the `TIMER0` Register for register information.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see [Success in detecting data pin contact \(phase completion\)](#)).
- A timeout occurs (see [Charger detection sequence timeout](#)).

52.9.1.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the STATUS register to reflect phase completion (See [Table 52-13](#) for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See [Charging port detection](#).)

52.9.1.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source V_{DP_SRC} connects to the D+ line
- The current sink I_{DM_SINK} connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage V_{DAT_REF} .

After a time of T_{VDPSRC_ON} , the module samples the D– line. The T_{VDPSRC_ON} parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

Table 52-10. Sampling D– in the charging port detection phase

If the voltage on D- is...	Then...	See...
Below V_{DAT_REF}	The port is an SDP that does not support using charging currents above I_{CFG_MAX} .	Standard downstream port
Above V_{DAT_REF} but below V_{LGC}	The port is a charging port.	Charging port
Above V_{LGC}	This is an error condition.	Error in charging port detection

52.9.1.4.1 Standard downstream port

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the interval ($T_{\text{WAIT\_AFTER\_PRD}}$ or $T_{\text{VDPSRC\_CON}}$) to elapse:

- Updates the STATUS register to reflect that a standard downstream port (SDP) has been detected with $\text{SEQ\_RES} = 01$. See [Table 52-13](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software should perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see [Table 52-6](#).

52.9.1.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the interval ($T_{\text{WAIT\_AFTER\_PRD}}$ or $T_{\text{VDPSRC\_CON}}$) has elapsed before it does the following:

- Enables $V_{\text{DM\_SRC}}$ (for USB Battery Charging Specifications v1.2 only).
- Updates the STATUS register to reflect that a charging port has been detected with $\text{SEQ\_RES} = 10$. See [Table 52-13](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has passed to system software via the interrupt. Software should:

1. Read the STATUS register.

2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Issue a command to the USB controller to pullup the USB D+ line.
4. Wait for the module to complete the final phase of the sequence. See [Charger type detection](#).

52.9.1.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with SEQ_RES = 00. See [Table 52-13](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the interval ($T_{\text{WAIT\_AFTER\_PRD}}$ or $T_{\text{VDPSRC\_CON}}$) to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

52.9.1.5 Charger type detection

For *USB Battery Charging Specification, Rev. 1.2*:

After the USBDCD module enables the $V_{\text{DM\_SRC}}$, the module starts the $T_{\text{VDMSRC\_ON}}$ timer counting down the time interval programmed into the TIMER2[$T_{\text{VDMSRC\_ON}}$] field.

Once the $T_{\text{VDMSRC\_ON}}$ timer has elapsed, the module samples the USB D+ line to determine the type of charger. See the following table.

Table 52-11. Sampling D+ in the charger type detection phase (BC1.2)

If the voltage on D+ is...	Then...	See...
High ($D+ > V_{DAT\_REF}$)	The port is a DCP. ¹	Dedicated charging port
Low ($D+ < V_{DAT\_REF}$)	The port is a CDP. ²	Charging downstream port

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.

2. In a CDP, the D+ and D– lines are not shorted.

For *USB Battery Charging Specification, Rev. 1.1*:

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK_DM timer counting down the time interval programmed in the TIMER2[CHECK_DM] field.

After the CHECK_DM time has elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

Table 52-12. Sampling D– in the charger type detection phase (BC1.1)

If the voltage on D– is...	Then...	See...
High	The port is a DCP. ¹	Dedicated charging port
Low	The port is a CDP. ²	Charging downstream port

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.

2. In a CDPP, the D+ and D– lines are not shorted.

52.9.1.5.1 Dedicated charging port

For a dedicated charging port (DCP), the module does the following:

- Updates the STATUS register to reflect that a dedicated charging port has been detected with SEQ_RES = 11. See [Table 52-13](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] bit.

The *USB Battery Charging Specification Rev. 1.2* indicates that additionally if the detection sequence determines an attachment to a DCP, then the USB device should signal on the D+ pin by either enabling the D+ pullup resistor or enabling V_{DP_SRC} .

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.
6. Enable signaling on the D+ pin. This can be done by enabling the Transceiver D+ pullup resistor through configuration of register bit fields in the USB controller instance for this USB port. On this product this signaling can alternatively be done by enabling V_{DP_SRC} through setting the SIGNAL_OVERRIDE[PS] bit field to a value of 2'b10.
7. Communicate the appropriate charge rate to the external battery charger IC; see [Table 52-6](#).

52.9.1.5.2 Charging downstream port

For a charging downstream port (CDP), the module does the following:

- Updates the STATUS register to reflect that a CDP has been detected with SEQ_RES = 10. See [Table 52-13](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see [Table 52-6](#).

52.9.1.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] bit, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occurred. See [Table 52-13](#) for field values.
- Sets the CONTROL[IF] bit.
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting the CONTROL[SR] bit.
- The Unit Connection Timer continues counting. See the description of the TIMER0 Register.

At this point, control has been passed to system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software should:

1. Read the STATUS register.
2. Set the CONTROL[IACK] bit to acknowledge the interrupt.
3. Set the CONTROL[SR] bit to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the V_{BUS_DETECT} input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[T_{UNITCON}] periodically to track elapsed time after 1s;
or
2. For debug purposes.

Note that the T_{UNITCON} register field will stop incrementing when it reaches its maximum value so it will not rollover to zero and start counting up again.

52.9.1.7 Dead Battery Provision signaling

If the system needs to operate under the Dead Battery Provision of the *USB Battery Charging Specification Revision 1.2*, the USBDCD module must be configured to signal V_{DP_SRC} on the USB1_DP pin.

For information on Dead Battery Provision conditions and signaling, see the [Dead or weak battery](#) section later in this chapter.

52.9.2 Interrupts and events

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

Table 52-13. Events triggering an interrupt by sequence phase

Sequence phase	Event	Event description	STATUS fields ¹	Phase description
Data Pin Detection	Phase Complete	The module has detected data pin contact. <i>No interrupt occurs: CONTROL[IF] = 0.</i>	ERR = 0 SEQ_STAT = 01 SEQ_RES = 00 TO = 0	VBUS contact detection
Charging Port Detection	Phase Complete	The module has completed the process of identifying if the USB port is a charging port or not. NOTE: This only applies to USB Battery Charging Specification, v1.1.	ERR = 0 SEQ_STAT = 10 SEQ_RES = 01 or 10 TO = 0	Charging port detection
	Error	The module cannot identify the type of port because the D ⁻ line is above the USB's VLGC threshold.	ERR = 1 SEQ_STAT = 10 SEQ_RES = 00 TO = 0	Error in charging port detection
Charger Type Detection	Phase Complete	The module has completed the process of identifying the charger type detection. Note: The ERR flag always reads zero because no known error conditions are checked during this phase.	ERR = 0 SEQ_STAT = 11 SEQ_RES = 11 or 10 TO = 0	Charger type detection
Sequence Timeout	Error	The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.	ERR = 1 SEQ_STAT = last value ² SEQ_RES = last value ² TO = 1	Charger detection sequence timeout.

1. See the description of the Status register for register information.
2. The SEQ_STAT and SEQ_RES fields retain the values held at the time of the timeout error.

52.9.2.1 Interrupt Handling

Software can read which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] bit is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

52.9.3 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

52.9.3.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

52.9.3.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

Table 52-14. Software reset and register fields affected

Register	Fields affected	Fields not affected
CONTROL ¹	IF	IE, START
STATUS	All	None
CLOCK	None	All
TIMER _n	TUNITCON	All other

1. CONTROL[SR] and CONTROL[IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1), a software reset stops the sequence.

Note

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

52.10 Initialization information

This module has been designed for minimal configuration while retaining significant programmability. The CLOCK register needs to be initialized to the actual system clock frequency, unless the default value already matches the system requirements.

The proper operation of the USBHSDCD instantiation of this module requires that the USBPHY_ANACTRL[DEV_PULLDOWN] bit field be reset to value 1'b0 during the period when this module is in use.

The other registers generally do not need to be modified, because they default to values that comply with the USB Battery Charging Specification. However, several timing parameters can be changed for a great deal of flexibility if a particular system requires it.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

52.11 Application information

This section provides application information.

52.11.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

52.11.2 Dead or weak battery

According to the *USB Battery Charging Specification Revision 1.2*, a USB device with a dead or weak battery that is attached to a downstream port can draw charging current from VBUS without connecting for several minutes, until the battery is charged to the point that the USB device can connect. The conditions for this operation are referred to as the Dead Battery Provision.

The *USB Battery Charging Specification Revision 1.2* limits this charging condition to 100mA for a duration of 45 minutes. The later *USB 2.0 Connect Timing Update ECN* modifies this charging condition to 500mA for a duration of 2 minutes. Customers designing systems to take advantage of the Dead Battery Provision should study both specifications closely.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the USB_DP pin high after the USBDCD module has determined that the device is attached to an SDP or CDP. (By definition, a DCP does not support connection but still requires a signaling event, see [Dedicated charging port](#) section.)

The module is also compatible with systems that have other circuitry to check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging using the Dead Battery Provision. Once the battery is charged to the good battery threshold, software must then connect to the USB host by pulling the USB_DP pin high.

While using the Dead Battery Provision, the USB_DP pin must signal by enabling V_{DP_SRC} . On this product that signaling can be done most simply by setting the USBDCD_SIGNAL_OVERRIDE[PS] bit field to value 2'b10.

52.11.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in [Software reset](#).

Chapter 53

USB Voltage Regulator

53.1 Chip-specific USB Voltage Regulator information

53.1.1 USB Voltage Regulator Configuration

This section summarizes how the module has been configured in the chip.

Figure 53-1. USB Voltage Regulator configuration

NOTE

When USB is not used in the application, it is recommended to connect VREGOUT and VREG_INx together and tie to ground through a 10kΩ resistor. Do not tie directly to ground, as this causes a latch-up risk. For systems where only one of the VREG_INx pins is ever used, it is also recommended to connect the two VREG_INx pins together. For systems using the power muxing capabilities of this regulator, a 100 Kohm

and 4.7 uF capacitor should be added to each VREG_INx pin to help keep the voltage on the used but undriven VREF_INx pin from rising.

53.2 Introduction

The module is a LDO linear voltage regulator designed to provide a user programmable output voltage in the 3.0 V to 3.6 V range from a muxable power supply varying from 2.7 V to 5.5 V. The design implements a power mux internally which allows the output to be sourced from either supply input, when both present. When the selected input power supply is below the programmed output voltage, the regulator control loop will fully turn on the regulation FET at which point the output of the regulator will be equal to the input voltage minus an IR drop in the FET, the part and the board. This is termed as PASS-THROUGH mode. The figure below shows the ideal relation between the unloaded regulator output and the selected input power supply for the case when the regulator output is programmed for 3.3 V.

Figure 53-2. Ideal Relation Between the Regulator Output and Selected Input Power Supply with a Programmed 3.3V Output Target Voltage

53.2.1 Overview

A simplified block diagram for the Voltage Regulator module is shown below.

Figure 53-3. Voltage Regulator Block Diagram

This module uses 2 regulators in parallel. In run mode, the RUN regulator with the bandgap voltage reference is enabled and is capable of sourcing enough current for the on-chip USB modules plus external loads up to the regulator capacity or device power dissipation limit. In run mode, the STANDBY regulator and the low power reference are also enabled, but a switch disconnects its output from the external pin. In STANDBY mode, the RUN regulator is disabled and the STANDBY regulator output is connected to the external pin. STANDBY mode is intended for applications with Li-ion battery and with the regulator powering the MCU where a low current consumption is needed when the MCU is in stop mode.

Internal power mode signals control whether the module is in RUN or STANDBY mode. See the descriptions of register bits USBREGEN, URWE, USBSSTBY, USSWE, USBVSTBY, and UVSWE in the SIM chapter for information on controlling the regulator in RUN and STANDBY modes.

This module includes some additional features described in more detail below.

A supply comparator circuit is included in the design to automatically select the highest of the input supplies during power-up. This comparator circuit is set up by default to preferentially select power from VREG_IN0 in the event that both supplies are present and at the same voltage level.

An input-power mux override is included in the regulator to allow the user to select the source of power for the regulator when both supplies are present. This power-mux is controlled by register bit USBVREGSEL described in the SIM chapter.

This regulator module has a start-up current limit which is controlled by register bit USBDISILIM described in the SIM chapter. For systems needing this feature, it is recommended to clear this bit every time that the regulator is powered-down. After a

successful boot-up, the current limit needs to be disabled prior to applying loads to the regulator greater than the current limit. The current limit function should always be disabled before beginning USB data communication on either of the USB0 or USB1 ports.

The regulator output is programmable via the USB3VOUTTRG bits described in the SIM chapter. The range is programmable in several discrete values from 3 V to 3.6 V.

The regulator output also has an internal switchable pulldown resistor which may be useful in cases when the regulator is disabled by the customer. The pulldown resistor has a value of approximately 50K ohms to ground when enabled, but is disabled by default. The pulldown resistor is controlled by register bit USBVREGPD described in the SIM chapter.

In either case, controlling software should select the desired power source as soon as it can determine which VREG input sources are valid and desired.

53.2.2 Features

- Output brown-out detector to monitor and signal to the system when regulator output voltage is below 2.8V.
- Integrated power-mux to allow output sourcing from either power-source when both present.
- 3-bits of output voltage programmability (3.0 V to 3.6 V)
- Low drop-out voltage: 300 mV at 180mA load
- Automatic start-up in current limiting mode (less than 100mA) to reduce the maximum inrush current when the regulator first has power supplied. The current limit function should always be disabled before beginning USB data communication on either of the USB0 or USB1 ports.
- Three different power modes: RUN, STANDBY, and SHUTDOWN.
- Low quiescent current in RUN mode.
- Very low quiescent current in STANDBY mode.
- Automatic current limiting if the load current is greater than 315 mA.
- Automatic power-up once some minimum voltage is applied to the regulator input.
- Pass-through mode when the regulator input voltage is lower than the programmed output voltage.

- Internal switchable pulldown resistor available on VREG_OUT.
- Small external decoupling capacitor required: 2.2 μ F
- Stable with aluminum, tantalum or ceramic capacitors.

53.2.3 Modes of Operation

The regulator has these power modes:

- **RUN**—The regulating loop of the RUN regulator and the STANDBY regulator are active, but the switch connecting the STANDBY regulator output to the external pin is open.
- **STANDBY**—The regulating loop of the RUN regulator is disabled and the standby regulator is active. The switch connecting the STANDBY regulator output to the external pin is closed.
- **SHUTDOWN**—The module is disabled.

The regulator is enabled by default. This means that once the power supply is provided, the module power-up sequence to RUN mode starts.

53.3 USB Voltage Regulator Module Signal Descriptions

The following table shows the external signals for the regulator.

Table 53-1. Voltage Regulator Module Signal Descriptions

Signal	Description	I/O
VREG_IN0	Unregulated power supply	I
VREG_IN1	Unregulated power supply	I
VREG_OUT	Regulator output voltage	O

Chapter 54

USB High Speed OTG Controller (USBHS)

54.1 Chip-specific USBHSOTG information

54.1.1 HS/FS/LS USB OTG Instantiation

The USB HS transceiver includes 15k pulldowns on the D+ and D- lines for host mode functionality.

54.1.1.1 Wake-up functionality on USBHS

Following wake-up functionality is supported by the USB HS Controller and PHY:

- In Stop/VLPS, the USB controller can generate an interrupt on VBUS detection or on Resume/Wakeup signaling on the USB1_DP and USB1_DM pins.
- In LLS/VLLS, the USB1_VBUS, USB1_DP and USB1_DM are input pins to the LLWU and a transition on those pins can generate a wakeup provided the USB is powered. In VLLS0 and VLLS1, a wakeup is only generated if the USB PHY was powered on entry into the low power mode.

54.2 Introduction

This chapter describes the USB high speed OTG controller (USBHS), which implements many industry standards. However, it is beyond the scope of this document to document the intricacies of these standards. Instead, you should refer to the governing specifications. Readers of this chapter are assumed to be fluent in the operation and requirements of a USB network.

Visit the USB Implementers Forum web page at <http://www.usb.org/developers/docs> for:

- *Universal Serial Bus Specification, Revision 2.0*
- *On-The-Go Supplement to the USB 2.0 Specification, Revision 1.0a*

Visit the Intel USB specifications web page at <http://www.intel.com/technology/usb/ehcispec> for:

- *Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 1.0*

54.2.1 Overview

The USB high speed OTG controller (USBHS) is a USB 2.0-compliant serial interface engine for implementing a USB interface. The registers and data structures are based on the *Enhanced Host Controller Interface Specification for Universal Serial Bus* (EHCI) from Intel Corporation. The USBHS module can act as a host, a device, or an On-The-Go negotiable host/device on the USB bus.

The USBHS controller interfaces to the processor's core. The controller is programmable to support host or device operations under firmware control. The on-chip UTMI PHY supports high-speed(HS) applications, as well as full-speed and low-speed.

54.2.2 Features

The USB On-The-Go module includes these features:

- Complies with USB specification rev 2.0
- USB host mode
 - Supports enhanced-host-controller interface (EHCI).
 - Supported by Linux and other commercially available operating systems.
- USB device mode
 - Supports full-speed/high-speed operation via on-chip UTMI transceiver.
 - Supports one upstream facing port.
 - Supports eight programmable, bidirectional USB endpoints, including endpoint 0. See endpoint configurations:

Table 54-1. Endpoint Configurations

Endpoint	Type	FIFO Size	Data Transfer	Comments
0	Bidirectional	Variable	Control	Mandatory
1-7	IN or OUT	Variable	Ctrl, Int, Bulk, or Iso	Optional

- Suspend mode/low power
 - As host, firmware can suspend individual devices or the entire USB and disable chip clocks for low-power operation
 - Device supports low-power suspend
 - Remote wake-up supported for host and device
 - Integrated with the processor's low power modes
- On-chip HS/FS/LS transceiver
 - On-chip UTMI transceiver supports high speed (480 Mbps), full speed, and low speed operation in host mode, and high-speed and full-speed operation in device mode

54.2.3 Modes of Operation

The USBHS module has two basic operating modes: host and device. Selection of operating mode is accomplished via the USBMODE[CM] bit field.

Speed selection is auto-detected at connect time using enumeration procedures in the USB network. The USBHS module provides these operation modes:

- USB disabled. In this mode, the USBHS's datapath does not accept transactions received on the USB interface.
- USB enabled. In this mode, the USB host's datapath is enabled to accept transactions received on the USB interface.
- USB enabled, low-power modes.

54.3 Memory Map/Register Definition

This section provides the memory map and detailed descriptions of the USBHS registers.

Table 54-2. USBHS Register Overview

Address	Register	EHCI ¹	H/D ²
Module Identification Registers: Declare the slave interface presence and include a table of the hardware configuration parameters.			
0x000	Identification Register (ID)	N	H/D
0x004	General Hardware Parameters (HWGENERAL)	N	H/D
0x008	Host Hardware Parameters (HWHOST)	N	H/D
0x00C	Device Hardware Parameters (HWDEVICE)	N	D
0x010	TX Buffer Hardware Parameters (HWTXBUF)	N	H/D
0x014	RX Buffer Hardware Parameters (HWRXBUF)	N	H/D
Device/Host Timer Registers: Used by host/device controller drivers to measure time-related activities.			
0x080	General Purpose Timer 0 Load (GPTIMER0LD)	N	H/D
0x084	General Purpose Timer 0 Control (GPTIMER0CTL)	N	H/D
0x088	General Purpose Timer 1 Load (GPTIMER1LD)	N	H/D
0x08C	General Purpose Timer 1 Control (GPTIMER1CTL)	N	H/D
Capability Registers: Specifies software limits, restrictions, and capabilities of the host/device controller implementation.			
0x100	Host Interface Version Number (HCVERSION)	Y	H
0x103	Capability Register Length (CAPLENGTH)	Y	H/D
0x104	Host Structural Parameters (HCSPARAMS)	Y	H
0x108	Host Capability Parameters (HCCPARAMS)	Y	H
0x122	Device Interface Version Number (DCVERSION)	N	D
0x124	Device Capability Parameters (DCCPARAMS)	N	D
Operational Registers: Comprised of dynamic control or status registers.			
0x140	USB Command (USBCMD)	Y	H/D
0x144	USB Status (USBSTS)	Y	H/D
0x148	USB Interrupt Enable (USBINTR)	Y	H/D
0x14C	USB Frame Index (FRINDEX)	Y	H/D
0x154	Periodic Frame List Base Address (PERIODICLISTBASE)	Y	H
0x154	Device Address (DEVICEADDR)	N	D
0x158	Current Asynchronous List Address (ASYNCLISTADDR)	Y	H
0x158	Address at Endpoint List (EPLISTADDR)	N	D
0x15C	Host TT Asynchronous Buffer Control (TTCTRL)	N	H
0x160	Master Interface Data Burst Size (BURSTSIZE)	N	H/D
0x164	Host Transmit FIFO Tuning Control (TXFILLTUNING)	N	H
0x180	Configure Flag Register (CONFIGFLAG)	Y	H/D
0x184	Port Status/Control (PORTSC1)	Y	H/D
0x1A4	On-The-Go Status and Control (OTGSC)	N	H/D
0x1A8	USB Mode Register (MODE)	N	H/D
0x1AC	Endpoint Setup Status Register (EPSETUPSR)	N	D
0x1B0	Endpoint Initialization (EPPRIME)	N	D
0x1B4	Endpoint De-initialize (EPFLUSH)	N	D
0x1B8	Endpoint Status Register (EPSR)	N	D

Table continues on the next page...

**Table 54-2. USBHS Register Overview
(continued)**

Address	Register	EHCI ¹	H/D ²
0x1BC	Endpoint Complete (EPCOMPLETE)	N	D
0x1C0	Endpoint Control Register 0 (EPCR0)	N	D
0x1C4	Endpoint Control Register 1 (EPCR1)	N	D
0x1C8	Endpoint Control Register 2 (EPCR2)	N	D
0x1CC	Endpoint Control Register 3 (EPCR3)	N	D
0x1D0	Endpoint Control Register 4 (EPCR4)	N	D
0x1D4	Endpoint Control Register 5 (EPCR5)	N	D
0x1D8	Endpoint Control Register 6 (EPCR6)	N	D
0x1DC	Endpoint Control Register 7 (EPCR7)	N	D

1. Indicates if the register is present in the EHCI specification.
2. Indicates if the register is available in host and/or device modes.

54.3.1 Identification Register (USBHS_ID)

The ID register provides a simple way to determine if the module is provided in the system. The ID register identifies the module and its revision.

Address: 400A_1000h base + 0h offset = 400A_1000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	VERSIONID			VERSION				REVISION				TAG

R	1		NID						0		ID					
W																
Reset	1	1	1	1	1	0	1	0	0	0	0	0	0	1	0	1

USBHS_ID field descriptions

Field	Description
31–29 VERSIONID	Version ID Internal version counter.
28–25 VERSION	Version Version of the module.
24–21 REVISION	Revision Revision number of the module.
20–16 TAG	Tag Tag of the module.
15–14 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 1.
13–8 NID	Ones complement version of ID.
7–6 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
ID	Configuration number This number is set to 0x05.

54.3.2 General Hardware Parameters Register (USBHS_HWGENERAL)

The HWGENERAL register contains parameters defining the particular implementation of the module. These values depend on the configuration of the controller chosen by the manufacturer for each product.

Address: 400A_1000h base + 4h offset = 400A_1004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

USBHS_HWGENERAL field descriptions

Field	Description
31–11 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
10–9 SM	Serial mode Indicates presence of serial interface in controller configuration. Value is specific to controller configuration selected by manufacturer for this product. 00 No Serial Engine, always use parallel signaling.
8–6 PHYM	PHY Mode Indicates interface to USB Phy used. Value is specific to controller configuration selected by manufacturer for this product. 000 Controller configured for UTMI/UTMI+ interface.
5–4 PHYW	PHY Width Indicates width of data interface to USB Phy. This field is relevant for UTMI mode only and has value 00 for products with other Phy interfaces. 01 16 bit wide data bus
Reserved	Reserved This field is reserved. These read-only bits reflect other configuration parameters for this controller configuration.

54.3.3 Host Hardware Parameters Register (USBHS_HWHOST)

The HWHOST register provides host hardware parameters for this implementation of the module.

Address: 400A_1000h base + 8h offset = 400A_1008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TTPER								TTASY							
W

R	0												NPORT		HC	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

USBHS_HWHOST field descriptions

Field	Description
31–24 TTPER	Transaction translator periodic contexts. The number of supported transaction translator periodic contexts. Always reads as 0x10 (16 contexts supported).
23–16 TTASY	Transaction translator contexts. The number of transaction translator contexts. Always reads as 0x02.
15–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
3–1 NPORT	Number of Ports Always 0, indicating the number of ports available (NPORT + 1) for this host implementation.
0 HC	Host Capable Always reads as 0b1, indicating the module is host capable.

54.3.4 Device Hardware Parameters Register (USBHS_HWDEVICE)

Provides device hardware parameters for this implementation of the USBHS module.

Address: 400A_1000h base + Ch offset = 400A_100Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								DEVEP						DC	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

USBHS_HWDEVICE field descriptions

Field	Description
31–6 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
5–1 DEVEP	Device endpoints. The number of supported endpoints. Always reads as 0b01000.
0 DC	Device Capable Always reads as 0b1, indicating the USBHS module is device capable.

54.3.5 Transmit Buffer Hardware Parameters Register (USBHS_HWTXBUF)

The HWTXBUF register provides the transmit buffer parameters for this implementation of the module.

Address: 400A_1000h base + 10h offset = 400A_1010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TXLC	0							TXCHANADD							
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Reset	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

USBHS_HWTXBUF field descriptions

Field	Description
31 TXLC	Transmit local Context Registers Indicates how the device transmit context registers implement. Always set. 0 Store device transmit contexts in the TX FIFO 1 Store device transmit contexts in a register file
30–24 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
23–16 TXCHANADD	Transmit Channel Address The number of address bits required to address one channel's worth of TX data. Always 0x7.
15–8 TXADD	Transmit Address. The number of address bits for the entire TX buffer. Always 0x9.
TXBURST	Transmit Burst. Indicates the number of data beats in a burst for transmit DMA data transfers. Always 0x8.

54.3.6 Receive Buffer Hardware Parameters Register (USBHS_HWRXBUF)

The HWRXBUF register provide the receive buffer parameters for this implementation of the module.

Address: 400A_1000h base + 14h offset = 400A_1014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_HWRXBUF field descriptions

Field	Description
31–16 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
15–8 RXADD	Receive Address. The number of address bits for the entire RX buffer. Always reads as 0x08.
RXBURST	Receive Burst. Indicates the number of data beats in a burst for receive DMA data transfers. Always reads as 0x08.

54.3.7 General Purpose Timer n Load Register (USBHS_GPTIMERnLD)

The GPTIMERnLD register contains the timer duration or load value.

Address: 400A_1000h base + 80h offset + (8d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

USBHS_GPTIMERnLD field descriptions

Field	Description
31–24 Reserved	Reserved This field is reserved.

Table continues on the next page...

USBHS_GPTIMER_nLD field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
GPTLD	Specifies the value to be loaded into the countdown timer on a reset. The value in this register represents the time in microseconds minus 1 for the timer duration. For example, for a one millisecond timer, load $1000 - 1 = 999$ (0x00_03E7). NOTE: Maximum value is 0xFF_FFFF or 16.777215 seconds.

54.3.8 General Purpose Timer n Control Register (USBHS_GPTIMER_nCTL)

The GPTIMER_nCTL register controls the various functions of the general purpose timers.

Address: 400A_1000h base + 84h offset + (8d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBHS_GPTIMER_nCTL field descriptions

Field	Description
31 RUN	Timer Run Enables the general purpose timer. Setting or clearing this bit does not have an effect on the GPTCNT field.

Table continues on the next page...

USBHS_GPTIMERnCTL field descriptions (continued)

Field	Description
	0 Timer stop 1 Timer run
30 RST	Timer Reset Setting this bit reloads GPTCNT with the value in GPTIMERnLD[GPTLD]. 0 No action 1 Load counter value
29–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
24 MODE	Timer Mode Selects between a single timer countdown and a looped countdown. In one-shot mode, the timer counts down to zero, generates an interrupt, and stops until the counter is reset by software. In repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter and begins another countdown. 0 One shot 1 Repeat
GPTCNT	Timer Count Indicates the current value of the running timer.

54.3.9 System Bus Interface Configuration Register (USBHS_USB_SBUSCFG)

The System Bus Interface Configuration (USB_SBUSCFG) register contains the control for the system bus interface.

Address: 400A_1000h base + 90h offset = 400A_1090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0													BURSTMODE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

USBHS_USB_SBUSCFG field descriptions

Field	Description
31–3 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
BURSTMODE	Burst mode Selects the options for the burst signal of the Master Interface. In all cases where the unspecified length burst is allowed, single accesses may also occur; this is mostly true when the transaction is not 32-bit aligned. Two consecutive single accesses should not happen. When an INCRx burst size is selected and the transfer is not multiple of the INCRx burst, the burst is decomposed in the different ways. With BURSTMODE[2] = 1, the smaller bursts is unspecified length. with BURSTMODE[2] = 0, the smaller bursts are smaller INCRx or singles. For example, if it were required at a given time to transfer 22 words of information, for the following values of BURSTMODE the master sequences are: 101 INCR4 + INCR4 + INCR4 + INCR4 + INCR4 + INCR unspec. length. 110 INCR8 + INCR8 + INCR4 + INCR unspec. length. 111 INCR16 + INCR4 + INCR unspec. length. 001 INCR4 + INCR4 + INCR4 + INCR4 + INCR4 + SINGLE + SINGLE. 010 INCR8 + INCR8 + INCR4 + SINGLE + SINGLE. 011 INCR16 + INCR4 + SINGLE + SINGLE. When this field is different from zero, the values in the TXBURST/RXBURST bitfields in the USB_BURSTSIZE register are ignored by the controller. Internally the BURSTMODE is set to the value of the INCRx burst. Since this has a direct relation with the burst sizes you must be careful with AHB burst selected. Although the TXBURST/RXBURST are bypassed, this register can be written/read with no effect while the BURSTMODE field is non-zero. NOTE: Setting the BURSTMODE value to 000 might cause bus allocation during BULK or ISO transfers. NOTE: Changing this BURSTMODE field while a transaction is in progress yields undefined results. One possible way to prevent undefined results is to clear the Run/Stop (RS) bit in the USB_USBCMD register, after the HCHALTED is detected in USB_USBSTS. 000 INCR burst of unspecified length 001 INCR4, non-multiple transfers of INCR4 is decomposed into singles. 010 INCR8, non-multiple transfers of INCR8, is decomposed into INCR4 or singles. 011 INCR16, non-multiple transfers of INCR16, is decomposed into INCR8, INCR4 or singles. 100 Reserved, do not use. 101 INCR4, non-multiple transfers of INCR4 is decomposed into smaller unspecified length bursts. 110 INCR8, non-multiple transfers of INCR8 is decomposed into smaller unspecified length bursts. 111 INCR16, non-multiple transfers of INCR16 is decomposed into smaller unspecified length bursts.

54.3.10 Host Controller Interface Version and Capability Registers
Length Register (USBHS_HCIVERSION)

Contains the CAPLENGTH field used as an offset to add to the register base address to find the beginning of the operational register space, the location of the USBCMD register. Also contains a BCD encoding of the EHCI revision number supported by this OTG controller. The most-significant byte of the HCIVERSION field represents a major revision; the least-significant byte is the minor revision.

Address: 400A_1000h base + 100h offset = 400A_1100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_HCSPARAMS field descriptions

Field	Description
31–28 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27–24 N_TT	Number of Transaction Translators. Non-EHCI field. Indicates number of embedded transaction translators associated with host controller. This field always reads as 0x0. See section “Embedded Transaction Translator Function,” for more information on embedded transaction translators.
23–20 N_PTT	Ports per Transaction Translator Non-EHCI field. Indicates number of ports assigned to each transaction translator within host controller.
19–17 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
16 PI	Port Indicators Indicates whether the ports support port indicator control. Always set. 0 No port indicator fields 1 The port status and control registers include a R/W field for controlling the state of the port indicator
15–12 N_CC	Number of Companion Controllers Indicates number of companion controllers associated with USBHS controller. Always cleared.

Table continues on the next page...

USBHS_HCSPARAMS field descriptions (continued)

Field	Description
11–8 N_PCC	Number Ports per CC Indicates number of ports supported per internal companion controller. This field reads as 0x0 because no companion controllers are present.
7–5 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
4 PPC	Power Port Control Indicates whether host controller supports port power control. Always reads as 0b1. 1 Ports have power port switches
N_PORTS	Number of Ports Indicates number of physical downstream ports implemented for host applications. Field value determines how many addressable port registers in the operational register. Always reads as 0x1.

54.3.12 Host Controller Capability Parameters Register (USBHS_HCCPARAMS)

Identifies multiple mode control (time-base bit functionality) addressing capability.

Address: 400A_1000h base + 108h offset = 400A_1108h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBHS_HCCPARAMS field descriptions

Field	Description
31–16 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
15–8 EECP	EHCI Extended Capabilities Pointer This optional field indicates the existence of a capabilities list. This field always reads as 0x000.

Table continues on the next page...

USBHS_HCCPARAMS field descriptions (continued)

Field	Description
	0x00 No extended capabilities are implemented
7–4 IST	Isochronous Scheduling Threshold Indicates where software can reliably update the isochronous schedule, relative to the current position of the executing host controller. This field always reads as 0x0. 0 The value of the least significant 3 bits indicates the number of microframes a host controller can hold a set of isochronous data structures (one or more) before flushing the state
3 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
2 ASP	Asynchronous Schedule Park capability Indicates if the host controller supports the park feature for high-speed queue heads in the asynchronous schedule. The feature can be disabled or enabled and set to a specific level by using the asynchronous schedule park mode enable and asynchronous schedule park mode count fields in the USBCMD register. This bit always reads as 0b1. 0 Park not supported. 1 Park supported.
1 PFL	Programmable Frame List flag Indicates that system software can specify and use a frame list length less than 1024 elements. This bit always reads as 0b1. 1 Frame list size is configured via the USBCMD register frame list size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.
0 ADC	64-bit addressing capability. This bit always reads as 0b0, indicating 64-bit addressing is not supported. 0 Data structures use 32-bit address memory pointers

54.3.13 Device Controller Interface Version (USBHS_DCIVERSION)

Not defined in the EHCI specification. DCIVERSION is a two-byte register containing a BCD encoding of the device controller interface. The most-significant byte of the register represents a major revision and the least-significant byte is the minor revision.

Address: 400A_1000h base + 120h offset = 400A_1120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_USBCMD field descriptions

Field	Description
31–24 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
23–16 ITC	Interrupt Threshold Control System software uses this field to set the maximum rate at which the module issues interrupts. ITC contains maximum interrupt interval measured in microframes. 0x00 Immediate (no threshold) 0x01 1 microframe 0x02 2 microframes 0x04 4 microframes 0x08 8 microframes 0x10 16 microframes 0x20 32 microframes 0x40 64 microframes Else Reserved
15 FS2	Frame list Size 2 See the FS bit description below. This is a non-EHCI bit.
14 ATDTW	Add dTD TripWire This is a non-EHCI bit. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software. This bit is also cleared by hardware when the state

Table continues on the next page...

USBHS_USBCMD field descriptions (continued)

Field	Description
	machine is in a hazard region where adding a dTD to a primed endpoint may go unrecognized. More information appears in section “Executing a Transfer Descriptor.”
13 SUTW	Setup TripWire This is a non-EHCI bit. Used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by driver software without being corrupted. If the setup lockout mode is off (USBMODE[SLOM] = 1) then a hazard exists when new setup data arrives, and the software copies setup from the QH for a previous setup packet. This bit is set and cleared by software and is cleared by hardware when a hazard exists. More information appears in section “Control Endpoint Operation.”
12 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
11 ASPE	Asynchronous Schedule Park mode Enable Software uses this bit to enable or disable park mode. 0 Park mode disabled 1 Park mode enabled
10 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
9–8 ASP	Asynchronous Schedule Park mode count Contains a count of the successive transactions the host controller can execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0b1 to 0b11. Software must not write a zero to this field when ASPE is set as this results in undefined behavior.
7 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
6 IAA	Interrupt on Async Advance doorbell Used as a doorbell by software to tell controller to issue an interrupt the next time it advances the asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When controller has evicted all appropriate cached schedule states, it sets USBSTS[AAI] register. If the USBINTR[AAE] bit is set, the host controller asserts an interrupt at the next interrupt threshold. The controller clears this bit after it has set the USBSTS[AAI] bit. Software must not write a 1 to this bit when the asynchronous schedule is inactive. Doing so yields undefined results. This bit used only in host mode. Writing a 1 to this bit when the USBHS module is in device mode has undefined results.
5 ASE	Asynchronous Schedule Enable Controls whether the controller skips processing the asynchronous schedule. Only used in host mode. 0 Do not process asynchronous schedule. 1 Use the ASYNCLISTADDR register to access asynchronous schedule.
4 PSE	Periodic Schedule Enable Controls whether the controller skips processing periodic schedule. Used only in host mode.

Table continues on the next page...

USBHS_USBCMD field descriptions (continued)

Field	Description
	0 Do not process periodic schedule. 1 Use the PERIODICLISTBASE register to access the periodic schedule.
3–2 FS	Frame list Size With bit 15, these bits make the FS[2:0] field, which specifies the frame list size controlling which bits in the frame index register must be used for the frame list current index. Used only in host mode. NOTE: Values below 256 elements are not defined in the EHCI specification. 00 When FS2 = 0, the size is 1024 elements (4096 bytes). When FS2 = 1, the size is 64 elements (256 bytes). 01 When FS2 = 0, the size is 512 elements (2048 bytes). When FS2 = 1, the size is 32 elements (128 bytes). 10 When FS2 = 0, the size is 256 elements (1024 bytes). When FS2 = 1, the size is 16 elements (64 bytes). 11 When FS2 = 0, the size is 128 elements (512 bytes). When FS2 = 1, the size is 8 elements (32 bytes).
1 RST	Controller Reset Software uses this bit to reset controller. Controller clears this bit when reset process completes. Clearing this register does not allow software to terminate the reset process early. Host mode: When software sets this bit, the controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction in progress on the USB immediately terminates. A USB reset is not driven on downstream ports. Software must not set this bit when the USBSTS[HCH] bit is cleared. Attempting to reset an actively running host controller results in undefined behavior. Device mode: When software sets this bit, the controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Setting this bit with the device in the attached state is not recommended because it has an undefined effect on an attached host. To ensure the device is not in an attached state before initiating a device controller reset, all primed endpoints must be flushed and the USBCMD[RS] bit must be cleared.
0 RS	Run/Stop Host mode: When set, the controller proceeds with the execution of the schedule. The controller continues execution as long as this bit is set. When this bit is cleared, the controller completes the current transaction on the USB and then halts. The USBSTS[HCH] bit indicates when the host controller finishes the transaction and enters the stopped state. Software must not set this bit unless controller is in halted state (USBSTS[HCH] = 1). Device mode: Setting this bit causes the controller to enable a pull-up on DP and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up becomes disabled upon transitioning into high-speed mode. Software must use this bit to prevent an attach event before the USBHS controller has properly initialized. Clearing this bit causes a detach event.

54.3.16 USB Status Register (USBHS_USBSTS)

This register indicates various states of each module and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus. Software clears certain bits in this register by writing a 1 to them.

Address: 400A_1000h base + 144h offset = 400A_1144h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBHS_USBSTS field descriptions

Field	Description
31–26 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
25 TI1	General purpose Timer 1 Interrupt Set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit clears it. 0 No interrupt 1 Interrupt occurred
24 TI0	General purpose Timer 0 Interrupt Set when the counter in the GPTIMER0CTRL register transitions to zero. Writing a one to this bit clears it. 0 No interrupt 1 Interrupt occurred
23–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19 UPI	USB host Periodic Interrupt Set by the host controller when the cause of an interrupt is a completion of a USB transaction where the transfer descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule.

Table continues on the next page...

USBHS_USBSTS field descriptions (continued)

Field	Description
	This bit is also set by the host controller when a short packet is detected and the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. NOTE: This bit is not used by the device controller and is always zero.
18 UAI	USB host Asynchronous Interrupt Set by the host controller when the cause of an interrupt is a completion of a USB transaction where the transfer descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the asynchronous schedule. This bit is also set by the host controller when a short packet is detected and the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. NOTE: This bit is not used by the device controller and is always zero.
17 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
16 NAKI	NAK Interrupt Set by hardware for a particular endpoint when the TX/RX endpoint's NAK bit and the corresponding TX/RX endpoint's NAK enable bit are set. The hardware automatically clears this bit when all the enabled TX/RX endpoint NAK bits are cleared.
15 AS	Asynchronous schedule Status Reports the current real status of asynchronous schedule. Controller is not immediately required to disable or enable the asynchronous schedule when software transitions the USBCMD[ASE] bit. When this bit and the USBCMD[ASE] bit have the same value, the asynchronous schedule is enabled (1) or disabled (0). Used only in host mode. 0 Disabled 1 Enabled
14 PS	Periodic schedule Status Reports current real status of periodic schedule. Controller is not immediately required to disable or enable the periodic schedule when software transitions the USBCMD[PSE] bit. When this bit and the USBCMD[PSE] bit have the same value, the periodic schedule is enabled or disabled. Used only in host mode. 0 Disabled 1 Enabled
13 RCL	Reclamation Detects an empty asynchronous schedule. Used only by the host mode. 0 Non-empty asynchronous schedule 1 Empty asynchronous schedule
12 HCH	Host Controller Halted This bit is cleared when the USBCMD[RS] bit is set. The controller sets this bit after it stops executing because of the USBCMD[RS] bit being cleared, by software or the host controller hardware (for example, internal error). Used only in host mode.

Table continues on the next page...

USBHS_USBSTS field descriptions (continued)

Field	Description
	0 Running 1 Halted
11 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
8 SLI	Device-controller suspend Non-EHCI bit. When a device controller enters a suspend state from an active state, this bit is set. The device controller clears the bit upon exiting from a suspend state. Used only by the device controller. 0 Active 1 Suspended
7 SRI	SOF Received This is a non-EHCI status bit. Software writes a 1 to this bit to clear it. Host mode: In host mode, this bit is set every 125 ms, provided PHY clock is present and running (for example, the port is NOT suspended) and can be used by the host-controller driver as a time base. Device mode: When controller detects a start of (micro) frame, bit is set. When a SOF is extremely late, controller automatically sets this bit to indicate an SOF was expected. Therefore, this bit is set roughly every 1 ms in device FS mode and every 125 us in HS mode, and it is synchronized to the actual SOF received. Because the controller is initialized to FS before connect, this bit is set at an interval of 1 ms during the prelude to the connect and chirp.
6 URI	USB Reset received A non-EHCI bit. When the controller detects a USB reset and enters the default state, this bit is set. Software can write a 1 to this bit to clear it. Used only by in device mode. 0 No reset received 1 Reset received
5 AAI	Interrupt on Async Advance By setting the USBCMD[IAA] bit, system software can force the controller to issue an interrupt the next time the controller advances the asynchronous schedule. This status bit indicates the assertion of that interrupt source. Used only by the host mode. 0 No async advance interrupt 1 Async advance interrupt
4 SEI	System Error Set when an error is detected on the system bus. If the system error enable bit (USBINTR[SEE]) is set, interrupt generates. The interrupt and status bits remain set until cleared by writing a 1 to this bit.

Table continues on the next page...

USBHS_USBSTS field descriptions (continued)

Field	Description
	Additionally, when in host mode, the USBCMD[RS] bit is cleared, effectively disabling controller. An interrupt generates for the USBHS controller in device mode, but no other action is taken. 0 Normal operation 1 Error
3 FRI	Frame-list Rollover Controller sets this bit when the frame list index (FRINDEX) rolls over from its maximum value to 0. The exact value the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in the USBCMD[FS] field) is 1024, the frame index register rolls over every time FRINDEX[13] toggles. Similarly, if the size is 512, the controller sets this bit each time FRINDEX[12] toggles. Used only in the host mode.
2 PCI	Port Change detect This bit is not EHCI compatible. Host mode: Controller sets this bit when a connect status occurs on any port, a port enable/disable change occurs, an over-current change occurs, or the force port resume (PORTSCn[FPR]) bit is set as the result of a J-K transition on the suspended port. Device mode: The controller sets this bit when it enters the full- or high-speed operational state. When it exits the full- or high-speed operation states due to reset or suspend events, the notification mechanisms are URI and SLI bits respectively. The device controller detects resume signaling only.
1 UEI	USB Error Interrupt When completion of USB transaction results in error condition, the controller sets this bit. If the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set, this bit is set along with the USBINT bit. See Section 4.15.1 in the EHCI specification for a complete list of host error interrupt conditions. See Table 24-62 for more information on device error matrix. 0 No error 1 Error detected
0 UI	USB Interrupt (USBINT) This bit is set by the controller when the cause of an interrupt is a completion of a USB transaction where the TD has an interrupt on complete (IOC) bit set. This bit is also set by the controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

54.3.17 USB Interrupt Enable Register (USBHS_USBINTR)

The interrupts to software are enabled with this register. An interrupt generates when a bit is set and the corresponding interrupt is active. The USB status register (USBSTS) continues to show interrupt sources (even if the USBINTR register disables them), allowing polling of interrupt events by the software.

3 FRE	Frame list Rollover Enable When this bit and the USBSTS[FRI] bit are set, controller issues an interrupt. Software clearing the USBSTS[FRI] bit acknowledges the interrupt. Used only in host mode. 0 Disabled 1 Enabled
2 PCE	Port Change detect Enable When this bit and the USBSTS[PCI] bit are set, controller issues an interrupt. Software clearing the USBSTS[PCI] bit acknowledges the interrupt. 0 Disabled 1 Enabled
1 UEE	USB Error interrupt Enable When this bit and the USBSTS[UEI] bit are set, controller issues an interrupt at the next interrupt threshold. Software clearing the USBSTS[UEI] bit acknowledges the interrupt. 0 Disabled 1 Enabled
0 UE	USB interrupt Enable When this bit is 1 and the USBSTS[UI] bit is set, the USBHS controller issues an interrupt at the next interrupt threshold. Software clearing the USBSTS[UI] bit acknowledges the interrupt. 0 Disabled 1 Enabled

54.3.18 Frame Index Register (USBHS_FRINDEX)

In host mode, the controller uses this register to index the periodic frame list. The register updates every 125 microseconds (once each microframe). Bits [N–3] select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the USBCMD[FS] field.

Only perform 32-bit accesses to this register. Byte writes produce undefined results. This register cannot be written unless the USBHS controller is in halted state as the USBSTS[HCH] bit indicates. A write to this register while the USBSTS[RS] bit is set produces undefined results. Writes to this register also affect the SOF value.

In device mode, this register is read-only, and the USBHS controller updates the FRINDEX[13–3] bits from the frame number the SOF marker indicates. When the USB bus receives a SOF, FRINDEX[13–3] checks against the SOF marker. If FRINDEX[13–3] is different from the SOF marker, FRINDEX[13–3] is set to the SOF value and FRINDEX[2–0] is cleared (SOF for 1 ms frame). If FRINDEX[13–3] equals the SOF value, FRINDEX[2–0] is incremented (SOF for 125 microsec microframe.)

USBHS_FRINDEX field descriptions

Field	Description									
31–14 Reserved	Reserved This read-only field is reserved and always has the value 0.									
FRINDEX	Frame Index The value in this register increments at the end of each time frame (microframe). Bits [N– 3] are for the frame list current index. This means each location of the frame list is accessed 8 times per frame (once each microframe) before moving to the next index. In device mode, the value is the current frame number of the last frame transmitted and not used as an index. In either mode, bits 2–0 indicate current microframe. The table illustrates values of N based on the value of the USBCMD[FS] field when used in host mode. <table><tr><th colspan="3">Table 54-3. 54.3.19 Periodic Frame List Base Address Register (USBHS_PERIODICLISTBASE)

This register contains the beginning address of the periodic frame list in the system memory. The host controller driver loads this register prior to starting the schedule execution by the controller. The memory structure referenced by this physical memory pointer assumes to be 4-Kbyte aligned. The contents combine with the FRINDEX register to enable the controller to step through the periodic frame list in sequence.

The host and device mode functions share this register. In host mode, it is the PERIODICLISTBASE register; in device mode, it is the DEVICEADDR register. See section “Device Address Register (DEVICEADDR),” for more information.

Address: 400A_1000h base + 154h offset = 400A_1154h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_PERIODICLISTBASE field descriptions

Field	Description
31–12 PERBASE	Base address These bits correspond to memory address signal [31:12]. Used only in the host mode.
Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

54.3.20 Device Address Register (USBHS_DEVICEADDR)

This register is not defined in the EHCI specification. For device mode, the upper seven bits of this register represent the device address. After any controller or USB reset, the device address is set to the default address (0). The default address matches all incoming addresses. Software reprograms the address after receiving a SET_ADDRESS descriptor.

The host and device mode functions share this register. In device mode, it is the DEVICEADDR register; in host mode, it is the PERIODICLISTBASE register. See section “Periodic Frame List Base Address Register (PERIODICLISTBASE),” for more information.

Address: 400A_1000h base + 154h offset = 400A_1154h

USBHS_DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address This field corresponds to the USB device address.
24 USBADRA	Device Address Advance This field provides a mechanism for staging the device address in advance. After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism ensures this specification is met when the DCD cannot write to the device address within 2 ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA equaling 1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR is programmed instantly at the correct time and meets the 2 ms USB requirement. Hardware automatically clears this bit on the following conditions: • IN is ACKed to endpoint 0. (USBADR is updated from staging register.) • OUT/SETUP occur to endpoint 0. (USBADR is not updated.) • Device Reset occurs. (USBADR is reset to 0.)

Table continues on the next page...

USBHS_DEVICEADDR field descriptions (continued)

Field	Description
0	Writes to USBADR are instantaneous.
1	When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR is loaded from the holding register.
Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

54.3.21 Current Asynchronous List Address Register (USBHS_ASYNCLISTADDR)

The ASYNCLISTADDR register contains the address of the next asynchronous queue head to executed by the host.

The host and device mode functions share this register. In host mode, it is the ASYNCLISTADDR register; in device mode, it is the EPLISTADDR register. See section “Endpoint List Address Register (EPLISTADDR),” for more information.

Address: 400A_1000h base + 158h offset = 400A_1158h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_ASYNCLISTADDR field descriptions

Field	Description
31–5 ASYBASE	Link pointer low (LPL) These bits correspond to memory address signal [31:5]. This field may only reference a queue head (QH). Used only in host mode.
Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

54.3.22 Endpoint List Address Register (USBHS_EPLISTADDR)

This register is not defined in the EHCI specification. For device mode, this register contains the address of the endpoint list top in system memory. The memory structure referenced by this physical memory pointer assumes to be 64-bytes. The queue head is actually a 48-byte structure, but must be aligned on 64-byte boundary. However, the EPBASE field has a granularity of 2 Kbytes; in practice, the queue head should be 2-Kbyte aligned.

The host and device mode functions share this register. In device mode, it is the EPLISTADDR register; in host mode, it is the ASYNCLISTADDR register. See section “Current Asynchronous List Address Register (ASYNCLISTADDR),” for more information.

Address: 400A_1000h base + 158h offset = 400A_1158h

USBHS_TTCTRL field descriptions

Field	Description
31 Reserved	Reserved This read-only field is reserved and always has the value 0.
30–24 TTHA	TT Hub Address This field is used to match against the Hub Address field in a QH or siTD to determine if the packet is routed to the internal TT for directly attached FS/LS devices. If the hub address in the QH or siTD does not match this address then the packet is broadcast on the high speed ports destined for a downstream HS hub with the address in the QH or siTD.
Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

54.3.24 Master Interface Data Burst Size Register (USBHS_BURSTSIZE)

This register is not defined in the EHCI specification. BURSTSIZE dynamically controls the burst size during data movement on the initiator (master) interface.

Address: 400A_1000h base + 160h offset = 400A_1160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_BURSTSIZE field descriptions

Field	Description
31–16 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
15–8 TXPBURST	Programable TX Burst length Represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus. Must not be set to greater than 16. If the BURSTSIZE field of register SBUSCFG is non-zero, the TXPBURST field returns the value of the INCRx length.
RXPBURST	Programable RX Burst length This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory. Must not be set to greater than 16. If the BURSTSIZE field of register SBUSCFG is non-zero, the RXPBURST field returns the value of the INCRx length.

54.3.25 Transmit FIFO Tuning Control Register (USBHS_TXFILLTUNING)

This register is not defined in the EHCI specification. The TXFILLTUNING register controls performance tuning associated with how the module posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include how much data to post into the FIFO and an estimate for how long that operation takes in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_s = Total packet flight time (send-only) packet ($T_s = T_0 + T_1$)

T_{ff} Time to fetch packet into TX FIFO up to specified level

T_p Total packet time (fetch and send) packet ($T_p = T_{ff} + T_s$)

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, the host controller checks to ensure T_p remains before the end of the (micro)frame. If so, it pre-fills the TX FIFO. If at anytime during the pre-fill operation the time remaining the (micro)frame is less than T_s , packet attempt ceases and tries at a later time. Although this is not an error condition and the module eventually recovers, a mark is made in the scheduler health counter to mark the occurrence of a back-off event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic beginning after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and should be minimized (not necessarily eliminated). The TSCHEALTH (T_{ff}) parameter described below can minimize back-offs.

Address: 400A_1000h base + 164h offset = 400A_1164h

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBHS_TXFILLTUNING field descriptions

Field	Description
31–22 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
21–16 TXFIFOTHRES	FIFO burst Threshold FIFO burst threshold. Controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. Systems with unpredictable latency and/or insufficient bandwidth can use a higher value where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can replenish from system memory. This value is ignored if the USBMODE[SDIS] bit is set. When the USBMODE[SDIS] bit is set, the host controller behaves as if TXFIFOTHRES is set to its maximum value.
15–13 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
12–8 TXSCHHEALTH	Scheduler Health counter These bits increment when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next SOF. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register clears the counter and this counter stops counting after reaching the maximum of 31.
7 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
TXSCHOH	Scheduler Overhead These bits add an additional fixed offset to the schedule time estimator described as T_{ff} . As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH field to less than 10 per second in a highly utilized bus. Choosing a value too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 ms when a device connects in high-speed mode. The time unit represented in this register is 6.333 ms when a device connects in low-/full-speed mode. For most applications, TXSCHOH can be set to 4 or less. A good value to begin with is: $(TXFIFOTHRES \times BURSTSIZE \times 4) / (40 \times \text{TimeUnit})$ Always rounded to the next higher integer. TimeUnit is 1.267 or 6.333 as noted earlier in this description. For example, if TXFIFOTHRES is 5 and BURSTSIZE is 8, set TXSCHOH to $5 \times (8 \times 4) / (40 \times 1.267)$ equals 4 for a high-speed link. If this value of TXSCHOH results in a TXSCHHEALTH count of 0 per second, low the value by 1 if optimizing performance is desired. If TXSCHHEALTH exceeds 10 per second, raise the value by 1. If streaming mode is disabled via the USBMODE register, treat TXFIFOTHRES as the maximum value for purposes of the TXSCHOH calculation.

54.3.26 Endpoint NAK Register (USBHS_ENDPTNAK)

Address: 400A_1000h base + 178h offset = 400A_1178h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_ENDPTNAKEN field descriptions

Field	Description
31–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19–16 EPTNE	TX Endpoint NAK Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. • EPTNE[3]—Endpoint #3 • EPTNE[2]—Endpoint #2 • EPTNE[1]—Endpoint #1 • EPTNE[0]—Endpoint #0
15–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
EPRNE	RX Endpoint NAK Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. • EPRNE[3]—Endpoint #3 • EPRNE[2]—Endpoint #2 • EPRNE[1]—Endpoint #1 • EPRNE[0]—Endpoint #0

54.3.28 Configure Flag Register (USBHS_CONFIGFLAG)

This EHCI register is not used in this implementation. A read from this register returns a constant of a 0x0000_0001 to indicate that all port routings default to this host controller.

Address: 400A_1000h base + 180h offset = 400A_1180h

USBHS_CONFIGFLAG field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
0 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 1.

54.3.29 Port Status and Control Registers (USBHS_PORTSC1)

The USB module contains a single PORTSC register. This register only resets when power is initially applied or in response to a controller reset. Initial conditions of a port are:

- No device connected
- Port disabled

If the port has port power control, this state remains until software applies power to the port by setting port power to one.

For the USBHS module in device mode, the USBHS controller does not support power control. Port control in device mode is used only for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling, and allows software to place the PHY into low-power suspend mode and disable the PHY clock.

Address: 400A_1000h base + 184h offset = 400A_1184h

Memory Map/Register Definition

USBHS_PORTSC1 field descriptions

Field	Description
31–30 PTS[1:0]	Port Transceiver Select [1:0] Bit field comprised of {bit 25, bit31, bit30} Controls which parallel transceiver interface is selected for controller configured by the manufacturer to support multiple Phy interfaces. Otherwise this is a read-only field reflecting the configuration when the controller is configured by the manufacturer to support a single Phy interface type. This field is not defined in the EHCI specification. 000 Use UTMI transceiver interface.
29 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27–26 PSPD	Port Speed This read-only register field indicates the speed the port operates. This bit is not defined in the EHCI specification. 00 Full speed 01 Low speed 10 High speed 11 Undefined
25 PTS2	Port Transceiver Select [2] See description at bits 31-30.
24 PFSC	Port force Full-Speed Connect Disables the chirp sequence that allows the port to identify itself as a HS port. useful for testing FS configurations with a HS host, hub, or device. Not defined in the EHCI specification.

Table continues on the next page...

USBHS_PORTSC1 field descriptions (continued)

Field	Description
	This bit is for debugging purposes. 0 Allow the port to identify itself as high speed 1 Force the port to only connect at full speed
23 PHCD	PHY low power suspend This bit is not defined in the EHCI specification. Host mode: The PHY can be placed into low-power suspend when downstream device is put into suspend mode or when no downstream device connects. Software completely controls low-power suspend. Device mode: For the USBHS module in device mode, the PHY can be put into low power suspend when the device is not running (USBCMD[RS] = 0) or suspend signaling is detected on the USB. The PHCD bit is cleared automatically when the resume signaling is detected or when forcing port resumes. Reading this bit indicates the status of the PHY.
22 WKOC	Wake on Over-Current enable Enables the port to be sensitive to over-current conditions as wake-up events. This field is 0 if the PP bit is cleared. In host mode, this bit can work with an external power control circuit.
21 WKDS	Wake on Disconnect enable Enables the port to be sensitive to device disconnects as wake-up events. This field is 0 if the PP bit is cleared or the module is in device mode. In host mode, this bit can work with an external power control circuit.
20 WKN	Wake on Connect enable Enables the port to be sensitive to device connects as wake-up events. This field is 0 if the PP bit is cleared or the module is in device mode. In host mode, this can work with an external power control circuit.
19–16 PTC	Port Test Control Any value other than 0 indicates the port operates in test mode. Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. NOTE: The FORCE_ENABLE_FS and FORCE_ENABLE_LS settings are extensions to the test mode support in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE values forces the port into the connected and enabled state at the selected speed. Then clearing the PTC field allows the port state machines to progress normally from that point. 0000 Not enabled 0001 J_STATE 0010 K_STATE 0011 SE0_NAK 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS Else Reserved
15–14 PIC	Port Indicator Control

Table continues on the next page...

USBHS_PORTSC1 field descriptions (continued)

Field	Description												
	Not supported on this module.												
13 PO	Port Owner Port owner handoff is not implemented in this device.												
12 PP	Port Power Represents the current setting of the port power control switch (0 equals off, 1 equals on). When power is not available on a port (PP = 0), it is non-functional and does not report attaches, detaches, etc. When an over-current condition is detected on a powered port, the host controller driver from a 1 to a 0 (removing power from the port) transitions the PP bit in each affected port.												
11–10 LS	Line Status Reflects current logical levels of the USB DP (bit 11) and DM (bit 10) signal lines. In host mode, the line status by the host controller driver is not necessary (unlike EHCI) because hardware manages the connection of FS and LS. In device mode, LS by the device controller is not necessary. 00 SE0 01 J-state 10 K-state 11 Undefined												
9 HSP	High Speed Port. Indicates if the host/device connected is in high speed mode. NOTE: This bit is redundant with the PSPD bit field. 0 FS or LS 1 HS												
8 PR	Port Reset This field is cleared if the PP bit is cleared. Host mode: When software sets this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 starts. This bit automatically clears after the reset sequence completes. This behavior is different from EHCI where the host controller driver is required to clear this bit after the reset duration is timed in the driver. Device mode: This bit is a read-only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 Port is not in reset 1 Port is in reset												
7 SUSP	Suspend Host mode: The PE and SUSP bits define the port state as follows: <table><tr><th>PE</th><th>SUSP</th><th>Port State</th></tr><tr><td>0</td><td>x</td><td>Disable</td></tr><tr><td>1</td><td>0</td><td>Enable</td></tr><tr><td>1</td><td>1</td><td>Suspend</td></tr></table>	PE	SUSP	Port State	0	x	Disable	1	0	Enable	1	1	Suspend
PE	SUSP	Port State											
0	x	Disable											
1	0	Enable											
1	1	Suspend											

Table continues on the next page...

USBHS_PORTSC1 field descriptions (continued)

Field	Description
	When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was set. In the suspend state, the port is sensitive to resume detection. The bit status does not change until the port is suspended and there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The module unconditionally clears this bit when software clears the FPR bit. The host controller ignores clearing this bit. If host software sets this bit when the port is not enabled (PE = 0), the results are undefined. This bit is cleared if the PP bit is cleared in host mode. Device mode: In device mode, this bit is a read-only status bit. 0 Port not in suspend state 1 Port in suspend state
6 FPR	Force Port Resume This bit is not-EHCI compatible. Host mode: Software sets this bit to drive resume signaling. The controller sets this bit if a J-to-K transition is detected while the port is in suspend state (PE = SUSP = 1), which in turn sets the USBSTS[PCI] bit. This bit automatically clears after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to clear this bit after the resume duration is timed in the driver. When the controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (full-speed K) is driven on the port as long as this bit remains set. This bit remains set until the port switches to the high-speed idle. Clearing this bit has no affect because the port controller times the resume operation to clear the bit the port control state switches to HS or FS idle. This bit is cleared if the PP bit is cleared in host mode. Device mode: If remote wakeup is enabled, after the device is in suspend for 5 ms or more, software can set this bit to drive resume signaling before clearing. The device controller sets this bit if a J-to-K transition is detected while port is in suspend state, which in turn sets the USBSTS[PCI] bit. The bit is cleared when the device returns to normal operation. 0 No resume (K-state) detected/driven on port 1 Resume detected/driven on port
5 OCC	Over-Current Change Indicates a change to the OCA bit. Software clears this bit by writing a 1. For host mode, the user can provide over-current detection to the USBn_PWRFAULT signal for this condition. For device-only implementations, this bit must always be cleared. 0 No over-current 1 Over-current detect
4 OCA	Over-current active

Table continues on the next page...

USBHS_PORTSC1 field descriptions (continued)

Field	Description
	This bit automatically transitions from 1 to 0 when the over-current condition is removed. For host/OTG implementations, the user can provide over-current detection to the USBn_PWRFAULT signal for this condition. For device-only implementations, this bit must always be cleared. 0 Port not in over-current condition 1 Port currently in over-current condition
3 PEC	Port Enable/disable Change For the root hub, this bit gets set only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a 1 to it. In device mode, the device port is always enabled. (This bit is zero). This bit is cleared if the PP bit is cleared. 0 No change 1 Port disabled
2 PE	Port Enabled/disabled Host mode: Ports can only be enabled by the controller as a part of the reset and enable sequence. Software cannot enable a port by setting this bit. A fault condition (disconnect event or other fault condition) or host software can disable ports. The bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host and bus events. When the port is disabled, downstream propagation of data is blocked except for reset. This field is cleared if the PP bit is cleared in host mode. Device mode: The device port is always enabled. (This bit is set).
1 CSC	Connect Change Status Host mode: This bit indicates a change occurred in the port's current connect status. The controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition; hub hardware is setting an already-set bit (i.e., the bit remains set). Software clears this bit by writing a 1 to it. This field is cleared if the PP bit is cleared. Device mode: In device mode, this bit is undefined. 0 No change 1 Connect status has changed
0 CCS	Current Connect Status Indicates that a device successfully attaches and operates in high speed or full speed as indicated by the PSPD bit. If clear, the device did not attach successfully or forcibly disconnects by the software clearing the USBCMD[RUN] bit. It does not state the device disconnected or suspended. This bit is cleared if the PP bit is cleared in host mode. 0 No device present (host mode) or attached (device mode) 1 Device is present (host mode) or attached (device mode)

54.3.30 On-the-Go Status and Control Register (USBHS_OTGSC)

This register is not defined in the EHCI specification. The host controller implements one OTGSC register corresponding to port 0 of the host controller.

The OTGSC register has four sections:

OTG interrupt enables (read/write)

OTG interrupt status (read/write to clear)

OTG status inputs (read-only)

OTG controls (read/write)

The status inputs de-bounce using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status inputs or an OTG interrupt.

Address: 400A_1000h base + 1A4h offset = 400A_11A4h

111	17																
11–5 Reserved	Reserved																

Table continues on the next page...

USBHS_USBMODE field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
4 SDIS	Stream DISable Host mode: Setting this bit ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency fills to capacity before the packet launches onto the USB. Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING to characterize the adjustments needed for the scheduler when using this feature. Also, in systems with high system bus utilization, setting this bit ensures no overruns or underruns during operation at the expense of link utilization. SDIS can be left clear and the rules under the description of the TXFILLTUNING register can limit underruns/overruns for those who desire optimal link performance. Device mode: Setting this bit disables double priming on RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. In high-speed mode, all packets received are responded to with a NYET handshake when stream disable is active. 0 Inactive 1 Active
3 SLOM	Setup Lock-Out Mode For the module in device mode, this bit controls behavior of the setup lock mechanism. See section "Control Endpoint Operation."
2 ES	Endian Select Controls the byte ordering of the transfer buffers to match the host microprocessor bus architecture. The bit fields in the register interface and the DMA data structures (including the setup buffer within the device QH) are unaffected by the value of this bit, because they are based upon 32-bit words. 0 Little endian. First byte referenced in least significant byte of 32-bit word. 1 Big endian. First byte referenced in most significant byte of 32-bit word.
CM	Controller Mode This register can be written only once after reset. If necessary to switch modes, software must reset the controller by writing to the USBCMD[RST] bit before reprogramming this register. NOTE: The USBHS module must be initialized to the desired operating mode after reset. 00 Idle (default for the USBHS module) 01 Reserved 10 Device controller 11 Host controller

54.3.32 Endpoint Setup Status Register (USBHS_EPSETUPSR)

This register is not defined in the EHCI specification. This register contains the endpoint setup status and is used only in device mode.

Address: 400A_1000h base + 1ACh offset = 400A_11ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBHS_EPPRIME field descriptions

Field	Description
31–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19–16 PETB	Prime Endpoint tTransmit Buffer For each endpoint, a corresponding bit requests that a buffer be prepared for a transmit operation to respond to a USB IN/INTERRUPT transaction. Software must write a 1 to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when associated endpoint(s) is (are) successfully primed. NOTE: These bits are momentarily set by hardware during hardware re-priming operations when a dTD retires, and the dQH updates.
15–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
PERB	Prime Endpoint Receive Buffer For each endpoint, a corresponding bit requests that a buffer be prepared for a receive operation to respond to a USB OUT transaction. Software must write a 1 to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when associated endpoint(s) is (are) successfully primed. NOTE: These bits are momentarily set by hardware during hardware re-priming operations when a dTD retires, and the dQH updates.

54.3.34 Endpoint Flush Register (USBHS_EPFLUSH)

This register is not defined in the EHCI specification. This register used only in device mode.

Address: 400A_1000h base + 1B4h offset = 400A_11B4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
19–16 FETB	Flush Endpoint Transmit Buffer Writing a 1 to a bit in this field causes the associated endpoint to clear any primed buffers. If a packet is in progress for an associated endpoint, that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful.
15–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
FERB	Flush Endpoint Receive Buffer Writing a 1 to a bit in this field causes the associated endpoint to clear any primed buffers. If a packet is in progress for an associated endpoint, that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[3] corresponds to endpoint 3.

54.3.35 Endpoint Status Register (USBHS_EPSR)

This register is not defined in the EHCI specification. This register is only used in device mode.

Address: 400A_1000h base + 1B8h offset = 400A_11B8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_EPSR field descriptions

Field	Description
31–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19–16 ETBR	Endpoint Transmit Buffer Ready One bit for each endpoint indicates status of the respective endpoint buffer. The hardware sets this bit in response to receiving a command from a corresponding bit in the EPPRIME register. A constant delay exists between setting a bit in the EPPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the EPPRIME register. USB reset, USB DMA system, or EPFLUSH register clears the buffer ready. ETBR[3] (bit 19) corresponds to endpoint 3. NOTE: Hardware momentarily clears these bits during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated.
15–4 Reserved	Reserved This field is reserved.

Table continues on the next page...

USBHS_EPSR field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
ERBR	Endpoint Receive Buffer Ready One bit for each endpoint indicates status of the respective endpoint buffer. The hardware sets this bit in response to receiving a command from a corresponding bit in the EPPRIME register. A constant delay exists between setting a bit in the EPPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the EPPRIME register. USB reset, USB DMA system, or EPFLUSH register clears the buffer ready. ERBR[3] (bit 19) corresponds to endpoint 3. NOTE: Hardware momentarily clears these bits during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated.

54.3.36 Endpoint Complete Register (USBHS_EPCOMPLETE)

This register is not defined in the EHCI specification. This register is used only in device mode.

Address: 400A_1000h base + 1BCh offset = 400A_11BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBHS_EPCOMPLETE field descriptions

Field	Description
31–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19–16 ETCE	Endpoint Transmit Complete Event Each bit indicates a transmit event (IN/INTERRUPT) occurs and software must read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the transfer descriptor, this bit is set simultaneously with the USBINT. Writing a 1 clears the corresponding bit in this register. ETCE[3] (bit 19) corresponds to endpoint 3.
15–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
ERCE	Endpoint Receive Complete Event Each bit indicates a received event (OUT/SETUP) occurs and software must read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the transfer descriptor, this bit is set simultaneously with the USBINT. Writing a 1 clears the corresponding bit in this register. ERCE[3] corresponds to endpoint 3.

54.3.37 Endpoint Control Register 0 (USBHS_EPCR0)

This register is not defined in the EHCI specification. Every device implements endpoint 0 as a control endpoint.

Address: 400A_1000h base + 1C0h offset = 400A_11C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBHS_EPCR0 field descriptions

Field	Description
31–24 Reserved	This register is not defined in the EHCI specification. Every device implements endpoint 0 as a control endpoint. This field is reserved. This read-only field is reserved and always has the value 0.
23 TXE	TX Endpoint Enable Endpoint zero is always enabled. 1 Enable
22–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19–18 TXT	TX Endpoint Type Endpoint zero is always a control endpoint. 00 Control
17 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
16 TXS	TX Endpoint Stall Software can write a 1 to this bit to force the endpoint to return a STALL handshake to the host. It continues returning STALL until software clears the bit or it automatically clears upon receipt of a new SETUP request.

Table continues on the next page...

USBHS_EPCR0 field descriptions (continued)

Field	Description
	0 Endpoint OK 1 Endpoint stalled
15–8 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
7 RXE	RX endpoint Enable Endpoint zero is always enabled. 1 Enabled
6–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
3–2 RXT	RX endpoint Type Endpoint zero is always a control endpoint. 00 Control
1 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
0 RXS	RX endpoint Stall Software can write a 1 to this bit to force the endpoint to return a STALL handshake to the host. It continues returning STALL until software clears the bit or it automatically clears upon receipt of a new SETUP request. 0 Endpoint OK 1 Endpoint stalled

54.3.38 Endpoint Control Register n (USBHS_EPCRn)

These registers are not defined in the EHCI specification. There is an EPCRn register for each endpoint in a device.

Address: 400A_1000h base + 1C4h offset + (4d × i), where i=0d to 6d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBHS_EPCRn field descriptions

Field	Description
31–24 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
23 TXE	TX endpoint Enable 0 Disabled 1 Enabled
22 TXR	TX data toggle Reset When a configuration event is received for this Endpoint, software must write a 1 to this bit to synchronize the data PID's between the host and device. This bit is self-clearing.
21 TXI	TX data toggle Inhibit This bit is used only for test and should always be written as 0. Writing a 1 to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0 PID sequencing enabled 1 PID sequencing disabled
20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
19–18 TXT	TX endpoint Type NOTE: When only one endpoint (RX or TX, but not both) of an endpoint pair is used, the unused endpoint should be configured as a bulk type endpoint.

Table continues on the next page...

USBHS_EPCRN field descriptions (continued)

Field	Description
	00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX endpoint Data source This bit should always be written as 0, which selects the dual port memory/DMA engine as the source.
16 TXS	TX endpoint Stall This bit sets automatically upon receipt of a SETUP request if this endpoint is not configured as a control endpoint. It clears automatically upon receipt of a SETUP request if this endpoint is configured as a control endpoint. Software can write a 1 to this bit to force the endpoint to return a STALL handshake to the host. It continues returning STALL until software clears this bit clears or automatically clears as above. 0 Endpoint OK 1 Endpoint stalled
15–8 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
7 RXE	RX endpoint Enable 0 Disabled 1 Enabled
6 RXR	RX data toggle Reset When a configuration event is received for this endpoint, software must write a 1 to this bit to synchronize the data PIDs between the host and device. This bit is self-clearing.
5 RXI	RX data toggle Inhibit This bit is only for testing and should always be written as 0. Writing a 1 to this bit causes this endpoint to ignore the data toggle sequence and always accept data packets regardless of their data PID. 0 PID sequencing enabled 1 PID sequencing disabled
4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
3–2 RXT	RX endpoint Type NOTE: When only one endpoint (RX or TX, but not both) of an endpoint pair is used, the unused endpoint should be configured as a bulk type endpoint. 00 Control 01 Isochronous 10 Bulk 11 Interrupt
1 RXD	RX endpoint Data sink

Table continues on the next page...

USBHS_EPCR_n field descriptions (continued)

Field	Description
	This bit should always be written as 0, which selects the dual port memory/DMA engine as the sink.
0 RXS	RX endpoint Stall This bit sets automatically upon receipt of a SETUP request if this endpoint is not configured as a control endpoint. It clears automatically upon receipt of a SETUP request if this endpoint is configured as a control endpoint. Software can write a 1 to this bit to force the endpoint to return a STALL handshake to the host. It continues returning STALL until software clears this bit or automatically clears as above. 0 Endpoint OK 1 Endpoint stalled

54.3.39 USB General Control Register (USBHS_USBGENCTRL)

This register is not defined in the EHCI specification.

Address: 400A_1000h base + 200h offset = 400A_1200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	This field is reserved.
1 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
0 WU_IE	Wakeup Interrupt Enable This bit is used to enable the low power wakeup interrupt. 0 Disabled 1 Enabled

54.4 Functional Description

This module can be broken down into functional sub-blocks as described below.

54.4.1 System Interface

The system interface block contains all the control and status registers to allow a core to interface to the module. These registers allow the processor to control the configuration and ascertain the capabilities of the module and, they control the module's operation.

54.4.2 DMA Engine

The USBHS module contains a local DMA engine. It is responsible for moving all of the data transferred over the USB between the module and system memory.

The DMA controllers must access control information and packet data from system memory. Control information is contained in link list based queue structures. The DMA controllers have state machines able to parse data structures defined in the EHCI specification. In host mode, the data structures are EHCI compliant and represent queues of transfers performed by the host controller, including the split-transaction requests that allow an EHCI controller to direct packets to FS and LS speed devices. In device mode, data structures are similar to those in the EHCI specification and used to allow device responses to be queued for each of the active pipes in the device.

54.4.3 FIFO RAM Controller

The FIFO RAM controller is used for context information and to control FIFOs between the protocol engine and the DMA controller. These FIFOs decouple the system processor/memory bus requests from the extremely tight timing required by USB.

The use of the FIFO buffers differs between host and device mode operation. In host mode, a single data channel is maintained in each direction through the buffer memory. In device mode, multiple FIFO channels are maintained for each of the active endpoints in the system.

In host mode, the USB OTG modules use 16-byte transmit buffers and 16-byte receive buffers. For the USB OTG module, device operation uses a single 16-byte receive buffer and a 16-byte transmit buffer for each endpoint.

54.5 Initialization/Application Information

This section discusses host operation, device data structures, device operation, and servicing interrupts.

54.5.1 Host Operation

Enhanced Host Controller Interface (EHCI) Specification defines the general operational model for a USB module in host mode. The EHCI specification describes the register-level interface for a host controller for USB Revision 2.0. It includes a description of the hardware/software interface between system software and host controller hardware. The next section has information about the initialization of the USB modules; however, full details of the EHCI specification are beyond the scope of this document.

54.5.2 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between device controller driver (DCD) software and the device controller. The interface consists of device queue heads and transfer descriptors.

Note

Software must ensure that data structures do not span a 4K-page boundary.

The USB OTG uses an array of device endpoint queue heads to organize device transfers. As shown in the next figure, there are two endpoint queue heads in the array for each device endpoint—one for IN and one for OUT. The EPLISTADDR provides a pointer to the first entry in the array.

Figure 54-1. End Point Queue Head Organization

54.5.2.1 Endpoint Queue Head

All transfers are managed in the device endpoint queue head (dQH). The dQH is a 48-byte data structure, but must align on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) copies into the overlay area of the dQH, which starts at the nextTD pointer and continues through the end of the buffer pointers. After a transfer is complete, the dTD status updates in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH acts as a staging area for the dTD so the device controller can access needed information with minimal latency.

The next figure shows the endpoint queue head structure.

Table 54-4. Endpoint Queue Head Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

Table 54-4. Endpoint Queue Head Layout (continued)

	Buffer Pointer (Page 4)	Reserved	0x20 ¹
	Reserved		0x24
	Setup Buffer Bytes 3–0		0x28
	Setup Buffer Bytes 7–4		0x2C
	Device controller read/write; all others read-only.		

1. Offsets 0x08 through 0x20 contain the transfer overlay.

54.5.2.1.1 Endpoint Capabilities/Characteristics (Offset = 0x0)

This entry specifies static information about the endpoint. In other words, this information does not change over the lifetime of the endpoint. DCD software must not attempt to modify this information while the corresponding endpoint is enabled.

Table 54-5. Endpoint Capabilities/Characteristics

Field	Description
31–30 Mult	Mult. This field indicates the number of packets executed per transaction description as given by: 00 Execute N Transactions as demonstrated by the USB variable length packet protocol where N computes using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. Note: Non-ISO endpoints must set Mult equal to 00. ISO endpoints must set Mult equal to 01, 10, or 11 as needed.
29 ZLT	Zero length termination select. This bit is ignored in isochronous transfers. Clearing this bit enables the hardware to automatically append a zero length packet when the following conditions are true: - The packet transmitted equals maximum packet length - The dTD has exhausted the field Total Bytes After this the dTD retires. When the device is receiving, if the last packet length received equals the maximum packet length and the total bytes is zero, it waits for a zero length packet from the host to retire the current dTD. Setting this bit disables the zero length packet. When the device is transmitting, the hardware does not append any zero length packet. When receiving, it does not require a zero length packet to retire a dTD whose last packet was equal to the maximum packet length packet. The dTD is retired as soon as Total Bytes field goes to zero, or a short packet is received. 0 Enable zero length packet (default). 1 Disable the zero length packet. Note: Each transfer is defined by one dTD, so the zero length termination is for each dTD. In some software application cases, the logic transfer does not fit into only one dTD, so it does not make sense to add a zero length termination packet each time a dTD is consumed. On those cases we recommend to disable the ZLT feature, and use software to generate the zero length termination.

Table continues on the next page...

Table 54-5. Endpoint Capabilities/Characteristics (continued)

Field	Description
28–27	Reserved. Reserved for future use and must be cleared.
26–16 Maximum Packet Length	Maximum packet length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15 IOS	Interrupt on setup (IOS). This bit used on control type endpoints indicates if USBSTS[UI] is set in response to a setup being received.
14–0	Reserved. Reserved for future use and must be cleared.

54.5.2.1.2 Current dTD Pointer (Offset = 0x4)

The device controller uses the current dTD pointer to locate transfer in progress. This word is for USB OTG (hardware) use only and should not be modified by DCD software.

Table 54-6. Current dTD Pointer

Field	Description
31–5 Current dtd	Current dtd. This field is a pointer to the dTD represented in the transfer overlay area. This field is modified by the device controller to next dTD pointer during endpoint priming or queue advance.
4–0	Reserved. Reserved for future use and must be cleared.

54.5.2.1.3 Transfer Overlay (Offset = 0x8–0x20)

The seven entries in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, it does not read the associated endpoint.

After an endpoint is readied, the dTD is copied into this queue head overlay area by the device controller. Until a transfer expires, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller writes the results back to the original transfer descriptor and advance the queue.

54.5.2.1.4 Setup Buffer (Offset = 0x28–0x2C)

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID. Refer to [Control Endpoint Operation](#) for information on the procedure for reading the setup buffer

Note

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head receives setup data packets.

Table 54-7. Multiple Mode Control

Offset	Field	Description
0x28	31–0 Setup Buffer 0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller software reads.
0x2C	31–0 Setup Buffer 1	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller software reads.

54.5.2.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data sent/received for a given transfer. The DCD software should not attempt to modify any field in an active dTD except the next dTD pointer.

Table 54-8. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

Buffer Pointer (Page 4)															0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0x18		
Device controller read/write; all others read-only.																																	

54.5.2.2.1 Next dTD Pointer (Offset = 0x0)

The next dTD pointer is used to point the device controller to the next dTD in the linked list.

Table 54-9. Next dTD Pointer

Field	Description
31–5 Next dTD pointer	Next dTD pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4–1	Reserved. Reserved for future use and must be cleared.
0	Terminate. This bit indicates to the device controller no more valid entries exist in the queue.
T	0=Pointer is valid (points to a valid transfer element descriptor). 1=pointer is invalid.

54.5.2.2.2 dTD Token (Offset = 0x4)

The dTD token is used to specify attributes for the transfer including the number of bytes to read or write and the status of the transaction.

Table 54-10. dTD Token

Field	Description
31	Reserved. Reserved for future use and must be cleared.
30–16 Total Bytes	Total bytes. This field specifies the total number of bytes moved with this transfer descriptor. This field decrements by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K(0x5000). This is the maximum number of bytes 5 page pointers can access. Although possible to create a transfer up to 20K, this assumes the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (0x4000). Note: Larger transfer sizes can be supported, but require disabling ZLT and using multiple dTDs. If the value of the field is 0 when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. For IN transfers it is not a requirement for total bytes to transfer be an even multiple of the maximum packet length. If software builds such a transfer descriptor for an IN transfer, the last transaction is always less than maximum packet length. For OUT transfers the total bytes must be evenly divisible by the maximum packet length.
15 IOC	Interrupt on complete. Indicates if USBSTS[UI] is set in response to device controller finished with this dTD.
14–12	Reserved. Reserved for future use and must be cleared.
11–10 MultO	Multiplier Override. This field can possibly transmit-ISOs (ISO-IN) to override the multiplier in the QH. This field must be 0 for all packet types not transmit-ISO.

Table continues on the next page...

Table 54-10. dTD Token (continued)

Field	Description														
	For example, if QH.MULT equals 3; Maximum packet size equals 8; Total Bytes equals 15; MultiO equals 0 [default], then three packets are sent: {Data2(8); Data1(7); Data0(0)}. If QH.MULT equals 3; Maximum packet size equals 8; Total Bytes equals 15; MultiO equals 2, then two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software must compute MultiO equals greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes equals 0; then MultiO must be 1. Note: Non-ISO and Non-TX endpoints must set MultiO equals 00.														
9–8	Reserved. Reserved for future use and must be cleared.														
7–0 Status	Status. Device controller communicates individual command execution states back to the DCD software. This field contains the status of the last transaction performed on this dTD. The bit encodings are: <table> <tr> <th>Bit</th><th>Status Field Description</th></tr> <tr> <td>7</td><td>Active. Set by software to enable the execution of transactions by the device controller.</td></tr> <tr> <td>6</td><td>Halted. Set by the device controller during status updates to indicate a serious error has occurred at the device/endpoint addressed by this dTD. Any time a transaction results in the halted bit being set, the active bit is also cleared.</td></tr> <tr> <td>5</td><td>Data Buffer Error. Set by the device controller during status update to indicate the device controller is unable to maintain the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run).</td></tr> <tr> <td>4</td><td>Reserved.</td></tr> <tr> <td>3</td><td>Transaction Error. Set by the device controller during status update in case the device did not receive a valid response from the host (time-out, CRC, bad PID).</td></tr> <tr> <td>2–0</td><td>Reserved.</td></tr> </table>	Bit	Status Field Description	7	Active. Set by software to enable the execution of transactions by the device controller.	6	Halted. Set by the device controller during status updates to indicate a serious error has occurred at the device/endpoint addressed by this dTD. Any time a transaction results in the halted bit being set, the active bit is also cleared.	5	Data Buffer Error. Set by the device controller during status update to indicate the device controller is unable to maintain the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run).	4	Reserved.	3	Transaction Error. Set by the device controller during status update in case the device did not receive a valid response from the host (time-out, CRC, bad PID).	2–0	Reserved.
Bit	Status Field Description														
7	Active. Set by software to enable the execution of transactions by the device controller.														
6	Halted. Set by the device controller during status updates to indicate a serious error has occurred at the device/endpoint addressed by this dTD. Any time a transaction results in the halted bit being set, the active bit is also cleared.														
5	Data Buffer Error. Set by the device controller during status update to indicate the device controller is unable to maintain the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run).														
4	Reserved.														
3	Transaction Error. Set by the device controller during status update in case the device did not receive a valid response from the host (time-out, CRC, bad PID).														
2–0	Reserved.														

54.5.2.2.3 dTD Buffer Page Pointer List (Offset = 0x8–0x18)

The buffer page pointer list of a device element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

Table 54-11. Buffer Page Pointer List

Field	Description
31–12 Buffer Pointer	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems typically set the buffer pointers to a series of incrementing integers.
0;11–0 Current Offset	Current Offset. Offset into the 4kB buffer where the packet begins.
1;10–0 Frame Number	Frame Number. Written by the device controller to indicate the frame number a packet finishes in. Typically correlates relative completion times of packets on an ISO endpoint.

54.5.3 Device Operation

The device controller performs data transfers using a set of linked list transfer descriptors pointed to by a queue head. The next sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

54.5.3.1 Port State and Control

From a chip or system reset, the USB OTG module enters the powered state. A transition from the powered state to the attach state occurs when the USBCMD[RS] bit is set. After receiving a reset on the bus, the port enters the defaultFS or defaultHS state in accordance with the protocol reset described in Appendix C.2 of the *Universal Serial Bus Specification, Revision 2.0*. The next figure depicts the state of a USB 2.0 device.

Figure 54-2. USB 2.0 Device States

States powered, attach, defaultFS/HS, suspendFS/HS are implemented in the USB OTG, and they are communicated to the DCD using these status bits:

Table 54-12. Device Controller State Information Bits

Bit	Register
DC Suspend (SLI)	USBSTS
USB Reset Received (URI)	USBSTS
Port Change Detect (PCI)	USBSTS
High-Speed Port (PSPD)	PORTSCn

DCD software must maintain a state variable to differentiate between the defaultFS/HS state and the address/configured states. Change of state from default to the address and configured states is part of the enumeration process described in the device framework section of the USB 2.0 specification.

As a result of entering the address state, the DCD must program the device address register (DEVICEADDR).

Entry into the configured state indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the EPCR_n registers and initializing the associated queue heads.

54.5.3.1.1 Bus Reset

The host uses a bus reset to initialize downstream devices. When a bus reset is detected, USB OTG controller renegotiates its attachment speed, resets the device address to 0, and notifies the DCD by interrupt (assuming the USB reset interrupt enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and the device controller cancels any primed transactions. The concept of priming is clarified below, but when a reset is received, the DCD must perform:

1. Clear all setup token semaphores by reading the EPSETUPSR register and writing the same value back to the EPSETUPSR register.
2. Clear all the endpoint complete status bits by reading the EPCOMPLETE register and writing the same value back to the EPCOMPLETE register.
3. Cancel all primed status by waiting until all bits in the EPPRIME are 0 and then writing 0x000F_000F to EPFLUSH.
4. Read the reset bit in the PORTSC_n register and make sure it remains active. A USB reset occurs for a minimum of 3 ms and the DCD must reach this point in the reset clean-up before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare).
 - a. Setting USBCMD[RST] bit can perform a hardware reset.

Note

A hardware reset causes the device to detach from the bus by clearing the USBCMD[RS] bit. Therefore, the DCD must completely re-initialize the USB OTG after a hardware reset.

5. Free all allocated dTDs because the device controller no longer executes them. If this is the first time the DCD processes a USB reset event, it is likely no dTDs have been allocated.
6. At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a port change detect is indicated.
7. After a port change detect, the device has reached the default state and the DCD can read the `PORTSCn` register to determine if the device operates in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the chapter 9 Device Framework of the USB specification.

54.5.3.1.2 Suspend/Resume

To conserve power, USB OTG module automatically enters the suspended state when no bus traffic is observed for a specified period. When suspended, the module maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend any time they are powered, regardless if they are assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

The USB OTG module exits suspend mode when there is bus activity. It may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. The USB OTG is capable of remote wake-up signaling. When the USB OTG is reset, remote wake-up signaling must be disabled.

54.5.3.1.2.1 Suspend Operational Model

The USB OTG moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, an interrupt notifies the DCD (assuming device controller suspend interrupt is enabled, `USBINTR[SLE]` is set). When the `PORTSCn[SUSP]` is set, the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation. Find information on the bus power limits in suspend state in USB 2.0 specification.

54.5.3.1.2.2 Resume

If the USB OTG is suspended, its operation resumes when any non-idle signaling is received on its upstream facing port. In addition, the USB OTG can signal the system to resume operation by forcing resume signaling to the upstream port. Setting the `PORTSCn[FPR]` bit while the device is in suspend state sends resume signaling upstream. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

Note

Before use of resume signaling, the host must enable it by using the set feature command defined in chapter 9 Device Framework of the USB 2.0 specification.

54.5.3.2 Managing Endpoints

The USB 2.0 specification defines an endpoint (also called a device endpoint or an address endpoint) as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. Combination of the endpoint number and the endpoint direction specifies endpoint address.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints are supported by USB include bulk, interrupt, and isochronous. Each endpoint type has specific behavior related to packet response and error managing. Find more detail on endpoint operation in the USB 2.0 specification.

The USB OTG supports up to four endpoint specified numbers. The DCD can enable, disable, and configure each endpoint.

Each endpoint direction is essentially independent and can have differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0, for example, is always a control endpoint and uses both directions.

Each endpoint direction requires a queue head allocated in memory. If the maximum is four endpoint numbers (one for each endpoint direction used by the device controller), eight queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

54.5.3.2.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint 0 are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to the appropriate $EPCR_n$ register. Each $EPCR_n$ is split into an upper and lower half. The lower half of $EPCR_n$ configures the receive or OUT endpoint, and the upper half configures the corresponding transmit or IN endpoint. Control endpoints must be configured the same in the upper and lower half of the $EPCR_n$ register; otherwise, behavior is undefined. The next table shows how to construct a configuration word for endpoint initialization.

Table 54-13. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset (TXR, RXR)	1 Synchronize the data PIDs
Data Toggle Inhibit (TXI, RXI)	0 PID sequencing disabled
Endpoint Type (TXT, RXT)	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall (TXS, RXS)	0 Not stalled

54.5.3.2.2 Stalling

There USB OTG has two occasions it may need to return to the host a STALL:

- The first is the functional stall, a condition set by the DCD as described in the USB 2.0 Device Framework chapter. A functional stall is used only on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the $EPCR_n$ register associated with the given endpoint and the given direction. In a functional stall condition, the device controller continues to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.
- A protocol stall, unlike a function stall, is used on control endpoints and automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, DCD must enable the stall bits as a pair (TXS and RXS bits). A single write to the $EPCR_n$ register can ensure both stall bits are set at the same instant.

Note

Any write to the EPCR $_n$ register during operational mode must preserve the endpoint type field (perform a read-modify-write).

Table 54-14. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit	Effect on Stall bit	USB Response
SETUP packet received by a non-control endpoint.	N/A	None	STALL
IN/OUT/PING packet received by a non-control endpoint.	1	None	STALL
IN/OUT/PING packet received by a non-control endpoint.	0	None	ACK/NAK/NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	1	None	STALL
IN/OUT/PING packet received by a control endpoint.	0	None	ACK/NAK/NYET

54.5.3.2.3 Data Toggle

Data toggle maintains data coherency between host and device for any given data pipe. For more information on data toggle, refer to the USB 2.0 specification.

54.5.3.2.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by setting the data toggle reset bit in the EPCR $_n$ register. This should only happen when configuring/initializing an endpoint or returning from a STALL condition.

54.5.3.2.3.2 Data Toggle Inhibit

This feature is for test purposes only and must never be used during normal device controller operation.

Setting the data toggle inhibit bit causes the USB OTG module to ignore the data toggle pattern normally sent and accepts all incoming data packets regardless of the data toggle state.

In normal operation, the USB OTG checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If the data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the USB OTG from re-sending the same packet, the device controller responds to the error packet by acknowledging it with an ACK or NYET response.

54.5.3.3 Packet Transfers

The host initiates all transactions on the USB bus and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 specification.

A USB host sends requests to the USB OTG in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, expect the host to send IN requests to that endpoint. This USB OTG module prepares packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as priming the endpoint. This term appears throughout the documentation to describe the USB OTG operation so the DCD is built properly. Further, the term flushing describes the action of clearing a packet queued for execution.

54.5.3.3.1 Priming Transmit Endpoints

Priming a transmit endpoint causes the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to manage a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO splits into virtual channels so the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the EPSR register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of high-speed USB.

54.5.3.3.2 Priming Receive Endpoints

Priming receives endpoints identical to priming of transmit endpoints from the point of view of the DCD. The major difference in the operational model at the device controller is no data movement of the leading packet data because the data is to be received from the host.

As part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

54.5.3.3.3 Interrupt/Bulk Endpoint Operation

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes handshake with a NAK unless the endpoint is primed. After the endpoint is primed, data delivery commences.

A dTD is retired by the device controller when the packets described in the transfer descriptor are completed. Each dTD describes N packets to transfer according to the USB variable length transfer protocol. The formula below and the next table describe how the device controller computes the number and length of the packets sent/received by the USB vary according to the total number of bytes and maximum packet length. See [Endpoint Capabilities/Characteristics \(Offset = 0x0\)](#) for details on the ZLT bit.

With zero-length termination (ZLT) cleared:

$$N = \text{INT}(\text{number of bytes}/\text{max. packet length}) + 1$$

With zero-length termination (ZLT) set:

$$N = \text{MAXINT}(\text{number of bytes}/\text{max. packet length})$$

Table 54-15. Variable Length Transfer Protocol Example (ZLT=0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	3	256	256	0
512	512	2	512	0	—

Table 54-16. Variable Length Transfer Protocol Example (ZLT=1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	2	256	256	—
512	512	1	512	—	—

Note

The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described in the dTD successfully transmit. Total bytes in dTD equal 0 when this occurs.

RX-dTD is complete when:

- All packets described in the dTD are successfully received. Total bytes in dTD equal 0 when this occurs.
- A short packet (number of bytes < maximum packet length) was received.

This is a successful transfer completion; DCD must check the total bytes field in the dTD to determine the number of bytes remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.

- A long packet was received (number of bytes > maximum packet size) or (total bytes received > total bytes specified).

This is an error condition. The device controller discards the remaining packet and set the buffer error bit in the dTD. In addition, the endpoint flushes and the USBERR interrupt becomes active.

Note

Disabling zero-length packet termination allows transfers larger than the total bytes field spanning across two or more dTDs.

Upon successful completion of the packet(s) described by the dTD, the active bit in the dTD is cleared and the next pointer is followed when the terminate bit is clear. When the terminate bit is set, USB OTG flushes the endpoint/direction and ceases operations for that endpoint/direction.

Upon unsuccessful completion of a packet (see long packet above), the dQH is left pointing to the dTD in error. To recover from this error condition, DCD must properly re-initialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

Note

All packet level errors, such as a missing handshake or CRC error, are retried automatically by the device controller. There is no required interaction with the DCD for managing such errors.

Table 54-17. Interrupt/Bulk Endpoint Bus Response Matrix

Token Type	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error ¹	N/A
Out	STALL	NAK	Receive + NYET/ACK ²	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. Force bit stuff error

2. NYET/ACK — NYET unless the transfer descriptor has packets remaining according to the USB variable length protocol then ACK.

54.5.3.3.4 Control Endpoint Operation

54.5.3.3.4.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase.

Setup packet managing:

- Disable setup lockout by setting the setup lockout mode bit (USBMODE[SLOM]), once at initialization. Setup lockout is not necessary when using the tripwire as described below.

Note

Leaving the setup lockout mode cleared results in a potential compliance issue.

- After receiving an interrupt and inspecting EPSETUPSR to determine a setup packet was received on a particular pipe:

1. Write 1 to clear corresponding bit in EPSETUPSR.
2. Set the setup tripwire bit (USBCMD[SUTW]).
3. Duplicate contents of dQH.SetupBuffer into local software byte array.
4. Read the USBCMD[SUTW] bit. If set, continue; if cleared, goto 2)
5. Clear the USBCMD[SUTW] bit.
6. Poll until the EPSETUPSR bit clears.

7. Process setup packet using the local software byte array copy and execute status/handshake phases.

Note

After receiving a new setup packet, status and/or handshake phases may remain pending from a previous control sequence. These should be flushed and de-allocated before linking a new status and/or handshake dTD for the most recent setup packet.

54.5.3.3.4.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet is not received by reading the EPSETUPSR register immediately verifying that the prime had completed. A prime completes when the associated bit in the EPPRIME register is cleared and the associated bit in the EPSR register is set. If the EPPRIME bit goes to 0 and the EPSR bit is not set, the prime fails. This can only happen because of improper setup of the dQH, dTD, or a setup arriving during the prime operation. If a new setup packet is indicated after the EPPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must re-interpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller automatically clears the prime status (EPSR) to enforce data coherency with the setup packet.

Note

Error managing of data phase packets is the same as bulk packets described previously.

54.5.3.3.4.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the EPSETUPSR as described above in the data phase.

Note

Error managing of status phase packets is the same as bulk packets described previously.

54.5.3.3.4.4 Control Endpoint Bus Response Matrix

The next table shows the device controller response to packets on a control endpoint according to the device controller state.

Table 54-18. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR ¹	
In	STALL	NAK	Transmit	BS Error ²	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK ³	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

1. SYSERR — System error must never occur when the latency FIFOs are correctly sized and the DCD is responsive.
2. Force bit stuff error.
3. NYET/ACK — NYET unless the transfer descriptor has packets remaining according to the USB variable length protocol then ACK.

54.5.3.3.5 Isochronous Endpoint Operation

Isochronous endpoints used for real-time scheduled delivery of data, and their operational model is significantly different than the host throttled bulk, interrupt, and control data pipes. Real time delivery by the USB OTG is accomplished by:

- Exactly MULT packets per (micro)frame are transmitted/received.

Note

MULT is a two-bit field in the device queue head.
Isochronous endpoints do not use the variable length packet protocol.

- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If ISO-dTD remains active after that frame, ISO-dTD holds ready until executed or canceled by the DCD.

The USB OTG in host mode uses the periodic frame list to schedule data exchanges to isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for control/bulk/interrupt endpoints is also used for isochronous endpoints. The difference is in the managing of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint becomes primed only after a SOF is received. After the DCD writes the prime bit, the prime bit clears as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD, but occurs so the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. After an ISO transaction is started in a (micro)frame, it retires the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, and the device controller retires the current ISO-dTD and move to the next ISO-dTD.

Fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction stays primed indefinitely. This means it is up to software must discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error managing. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the transaction error bit and the data is stored as usual for the application software to sort out.

- TX packet retired:
 - MULT counter reaches zero.
 - Fulfillment error (transaction error bit is set):
 - # packets occurred > 0 AND # packets occurred < MULT

Note

For TX-ISO, MULT counter can be loaded with a lesser value in the dTD multiplier override field. If the multiplier override field is zero, the MULT counter initializes to the multiplier in the QH.

- RX packet retired:
 - MULT counter reaches zero.
 - Non-MDATA data PID is received
 - Overflow error:
 - Packet received is > maximum packet length. (Buffer Error bit is set)
 - Packet received exceeds total bytes allocated in dTD. (Buffer Error bit is set)
 - Fulfillment error (Transaction Error bit is set):
 - # packets occurred > 0 AND # packets occurred < MULT
 - CRC error (Transaction Error bit is set)

Note

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation, DCD must ensure the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

54.5.3.3.5.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro)frame number (FRINDEX register) can act as a marker. To cause a packet transfer to occur at a specific (micro)frame number (N), the DCD must interrupt on SOF during frame N-1. When the FRINDEX equals N-1, the DCD must write the prime bit. The USB OTG primes the isochronous endpoint in (micro)frame N-1 so the device controller executes delivery during (micro)frame N.

CAUTION

Priming an endpoint towards the end of (micro)frame N-1 does not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if the device controller does not have enough time to complete the prime before the SOF for packet N is received.

54.5.3.3.5.2 Isochronous Endpoint Bus Response Matrix

Table 54-19. Isochronous Endpoint Bus Response Matrix

Token Type	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL ¹ Packet	NULL Packet	Transmit	BS Error ²	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. Zero length packet
2. Force bit stuff error

54.5.3.4 Managing Queue Heads

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device transfer descriptor (dTDD). An area of memory pointed to by EPLISTADDR contains a group of all dQH's in a sequential list (see the next figure). The even elements in the list of dQH's receive endpoints (OUT/SETUP) and the odd elements transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. After the dTD retires, it is no longer part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers no longer exist within the queue head after the dTD is retired (see [Software Link Pointers](#)).

Figure 54-3. Endpoint Queue Head Diagram

In addition to current and next pointers and the dTD overlay examined in [Packet Transfers](#) the dQH also contains the following parameters for the associated endpoint: multiplier, maximum packet length, and interrupt on setup. The next section includes demonstration of complete initialization of the dQH including these fields.

54.5.3.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB specification chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required for bandwidth with the USB specification chapter 9 protocol. In FS mode, the multiplier field can only be 1 for ISO endpoints.
- Set the next dTD terminate bit field.
- Clear the active bit in the status field.
- Clear the halt bit in the status field.

Note

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

54.5.3.4.2 Setup Transfers Operation

As discussed in [Control Endpoint Operation](#) setup transfers require special treatment by the DCD. A setup transfer does not use a dTD, but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should manage the setup transfer by:

1. Copying setup buffer contents from dQH-RX to software buffer.
2. Acknowledging setup backup by writing a 1 to the corresponding bit in the EPSETUPSR register.

Note

The acknowledge must occur before continuing to process the setup packet. After acknowledge occurs, DCD must not attempt to access the setup buffer in dQH-RX. Only local software copy should be examined.

3. Checking for pending data or status dTD's from previous control transfers and flushing if any exist as discussed in [Flushing/De-priming an Endpoint](#).

Note

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

4. Decoding setup packet and prepare data phase (optional) and status phase transfer as required by the USB specification chapter 9 or application specific protocol.

54.5.3.5 Managing Transfers with Transfer Descriptors

54.5.3.5.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD executed. The operations described in the next section for managing dTDs assumes DCD can reference the head and tail of the dTD linked list.

Note

To conserve memory, the reserved fields at the end of the dQH can be used to store the head and tail pointers, but DCD must continue maintaining the pointers.

Figure 54-4. Software Link Pointers

Note

Check the status of each dTD to determine completed status.

54.5.3.5.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate a 32-byte dTD block of memory aligned to 32-byte boundaries. The last 5 bits of the address must equal 00000.

Write the following fields:

1. Initialize the first 7 entries (28 bytes) to 0.
2. Set the terminate bit.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete bit if desired.
5. Initialize the status field with the active bit set, and all remaining status bits cleared.

6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointers.

54.5.3.5.3 Executing a Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure that manages the event where the device controller reaches the end of the dTD list. At the same time, a new dTD is added to the end of the list.

Determine whether the linked list is empty:

Check the DCD driver to see if the pipe is empty (internal representation of the linked list should indicate if any packets are outstanding)

Case 1: Link list is empty

1. Write dQH next pointer AND dQH terminate bit to 0 as a single 32-bit operation.
2. Clear active and halt bit in dQH (in case set from a previous error).
3. Prime endpoint by writing 1 to the correct bit position in the EPPRIME register.

Case 2: Link list is not empty

1. Add dTD to end of the linked list.
2. Read correct prime bit in EPPRIME - if set, DONE.
3. Set the USBCMD[ATDTW] bit.
4. Read correct status bit in EPSR, and store in a temporary variable for later.
5. Read the USBCMD[ATDTW] bit:
 - If clear, go to 3.
 - If set, continue to 6.
6. Clear the USBCMD[ATDTW] bit.
7. If status bit read in step 4 is 1 DONE.
8. If status bit read in step 4 is 0 then go to case 1, step 1.

54.5.3.5.4 Transfer Completion

After a dTD is initialized and the associated endpoint is primed, the device controller executes the transfer upon the host-initiated request. The DCD is notified with a USB interrupt if the interrupt-on-complete bit was set, or alternatively, the DCD can poll the endpoint complete register to determine when the dTD had been executed. After a dTD is executed, DCD can check the status bits to determine success or failure.

CAUTION

Multiple dTDs can be completed in a single endpoint complete notification. After clearing the notification, the DCD must search the dTD linked list and retire all finished (active bit cleared) dTDs.

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0, Halted = 0, Transaction error = 0, Data buffer error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in [Device Error Matrix](#).

In addition to checking the status bit, the DCD must read the transfer bytes field to determine the actual bytes transferred. When a transfer is complete, the total bytes transferred decrements by the actual bytes transferred. For transmit packets, a packet is only complete after the actual bytes reaches zero. However, for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

54.5.3.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush or de-prime endpoints during a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The DCD can use this procedure to stop a transfer in progress:

1. Set the corresponding bit(s) in the EPFLUSH register.
2. Wait until all bits in the EPFLUSH register are cleared.

Note

This operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.

3. Read the EPSR register to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now cleared. If the corresponding bits are set after step #2 has finished, flush failed as described below:

In very rare cases, a packet is in progress to the particular endpoint when commanded to flush using EPFLUSH. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint successfully flushes.

54.5.3.5.6 Device Error Matrix

The following table summarizes packet errors not automatically managed by the USB OTG module.

Table 54-20. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Data Buffer Overflow	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

The device controller manages all errors on bulk/control/interrupt endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated.

Table 54-21. Error Descriptions

Overflow	Number of bytes received exceeded max. packet size or total buffer length. Note: This error also sets the halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, those are not executed.
ISO Packet Error	CRC error on received ISO packet. Contents not guaranteed correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery, DCD may need to readjust the data queue because a fulfillment error causes the device controller to cease data transfers on the pipe for one (micro)frame. During the dead (micro)frame, the device controller reports error on the pipe and primes for the following frame.

54.5.4 Servicing Interrupts

The interrupt service routine must understand there are high frequency, low frequency, and error operations to order accordingly.

54.5.4.1 High Frequency Interrupts

In particular, high frequency interrupts must be managed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 54-22. Interrupt Managing Order

Execution Order	Interrupt	Action
1a	USB Interrupt ¹ EPSETUPSR	Copy contents of setup buffer and acknowledge setup packet (as indicated in Managing Queue Heads). Process setup packet according to USB specification chapter 9 or application specific protocol.
1b	USB Interrupt EPCOMPLETE	Manage completion of dTD as indicated in Managing Queue Heads .
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely multiple interrupts stack up on any call to the interrupt service routine and during interrupt service routine.

54.5.4.1.1 Low Frequency Interrupts

The low frequency events include the following interrupts. These interrupts can be managed in any order because they do not occur often in comparison to the high-frequency interrupts.

Table 54-23. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power managing as necessary.
Reset Received	Change software state information. Abort pending transfers.

54.5.4.1.2 Error Interrupts

Error interrupts are least frequent and should be placed last in the interrupt service routine.

Table 54-24. Error Interrupt Events

Interrupt	Action
USB Error Interrupt.	This error is redundant because it combines USB interrupt and an error status in the dTD. The DCD more aptly manages packet-level errors by checking the dTD status field upon receipt of USB interrupt (w/ EPCOMPLETE).

Table continues on the next page...

Table 54-24. Error Interrupt Events (continued)

Interrupt	Action
System Error	Unrecoverable error. Immediate reset of module; free transfers buffers in progress and restart the DCD.

54.5.5 Deviations from the EHCI Specifications

The host mode operation of the USB OTG module is nearly EHCI-compatible with a few minor differences. For the most part, the modules conform to the data structures and operations described in Section 3, "Data Structures," and Section 4, "Operational Model," in the EHCI specification. The particulars of the deviations occur in the following areas:

- Embedded transaction translator—Allows direct attachment of HS, FS and LS devices in host mode without the need for a companion controller.
- Device operation—In host mode, the device operational registers are generally disabled; therefore, device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface—The module does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.

For the purposes of the USB OTG implementing a dual-role host/device controller with support for OTG applications, it is necessary to deviate from the EHCI specification. Device and OTG operation are not specified in the EHCI specification, and thus the implementation supported in the USB OTG module is proprietary.

54.5.5.1 Embedded Transaction Translator Function

The USB host mode supports directly connected high-, full- and low-speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high-speed hub transaction translator. Although there is no separate transaction translator block in the system, the transaction translator function normally associated with a high-speed hub is implemented within the DMA and protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models existing in the EHCI specification to support full- and low-speed devices.

54.5.5.1.1 Capability Registers

These additions to the capability registers support the embedded Transaction translator function:

- N_TT added to HSCPARAMS - Host Controller Structural Parameters
- N_PTT added to HSCPARAMS - Host Controller Structural Parameters

Refer to the section for the HSCPARAMS register for usage information.

54.5.5.1.2 Operational Registers

These additions to the operational registers support the embedded TT:

- Addition of the TTCTRL register.
- Addition of a two-bit port speed (PSPD) field to the PORTSC_n register.

54.5.5.1.3 Discovery

In a standard EHCI controller design, the EHCI host controller driver detects a full-speed (FS) or low-speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable is set only in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a high-speed connection (chirp completes successfully).

The module always sets the port enable bit after the port reset operation regardless of the result of the host device chirp result, and the resulting port speed is indicated by the PORTSC_n[PSPD] field. Therefore, the standard EHCI host controller driver requires an alteration to manage directly connected full- and low-speed devices or hubs. The change is a fundamental one summarized in the next table.

Table 54-25. Functional Differences Between EHCI and EHCI with Embedded TT

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from PORTSC _n .
FS and LS devices are assumed to be downstream from a HS hub. Therefore, all port-level control performs through the hub class to the nearest hub.	FS and LS device can be downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, port-level control acts using the hub class through the nearest hub. When a FS/LS device is directly attached, then port-level control is accomplished using PORTSC _n .

Table continues on the next page...

Table 54-25. Functional Differences Between EHCI and EHCI with Embedded TT (continued)

Standard EHCI	EHCI with embedded Transaction Translator
FS and LS devices are assumed to be downstream from a HS hub with HubAddr equal to X. [where HubAddr > 0 and HubAddr is the address of the hub where the bus transitions from HS to FS/LS (split target hub)]	FS and LS device can be downstream from a HS hub with HubAddr equal to X [HubAddr > 0] or directly attached [where HubAddr equals 0 and HubAddr is the address of the root hub where the bus transitions from HS to FS/LS (split target hub is the root hub)]

54.5.5.1.4 Data Structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the root hub. It is demonstrated here how hub address and endpoint speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) – asynchronous (bulk/control endpoints) periodic (interrupt)
 - Hub address equals 0
 - Transactions to direct attached device/hub.
 - QH.EPS equals port speed
 - Transactions to a device downstream from direct attached FS hub.
 - QH.EPS equals downstream device speed

Note

When QH.EPS equals 01 (LS) and PORTSC_n[PSPD] equals 00 (FS), a LS-pre-PID is sent before transmitting LS traffic.

Maximum packet size must equal 64 or less to prevent undefined behavior.

2. siTD (for direct attach FS) – Periodic (ISO endpoint)
 - All FS ISO transactions:
 - Hub address equals 0
 - siTD.EPS equals 00 (full speed)

Maximum packet size must equal to 1023 or less to prevent undefined behavior.

54.5.5.1.5 Operational Model

The operational models are well defined for the behavior of the transaction translator (see USB 2.0 specification) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded transaction translator exists within the USB host controller, no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections briefly discuss the operational model for how the EHCI and transaction translator operational models combine without the physical bus between. The following sections assume the reader is familiar with the EHCI and USB 2.0 transaction translator operational models.

54.5.5.1.5.1 Microframe Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B). The embedded transaction translator uses the same pipeline algorithms specified in the USB 2.0 specification for a hub-based transaction translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 are ready to execute on the bus in B-frame 0.

When programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream hub-based transaction translators.

After periodic transfers are exhausted, any stored asynchronous transfer is moved. Asynchronous transfers are opportunistic because they execute when possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer cannot babble through the SOF (start of B-frame 0.)

54.5.5.1.5.2 Split State Machines

The start and complete-split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete-split operation is simple an internal operation to the embedded transaction translator. The next table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 54-26. Emulated Handshakes

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full	NAK
Start-Split: All periodic buffers full	ERR
Start-Split: Success for start of async. transaction	ACK
Start-Split: Start periodic transaction	No handshake (Ok)
Complete-Split: Failed to find transaction in queue	Bus time-out
Complete-Split: Transaction in queue is busy	NYET
Complete-Split: Transaction in queue is complete	Actual handshake from FS/LS device

54.5.5.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- USB 2.0 – 11.17.3
 - Sequencing is provided and a packet length estimator ensures no full-/low-speed packet babbles into SOF time.
- USB 2.0 – 11.17.4
 - Transaction tracking for 2 data pipes.
- USB 2.0 – 11.17.5
 - Clear_TT_Buffer capability provided through the use of the TTCTRL register.

54.5.5.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded transaction translator:

- USB 2.0 – 11.18.6.[1-2]
 - Abort of pending start-splits
 - EOF (and not started in microframes 6)
 - Idle for more than 4 microframes
 - Abort of pending complete-splits

- EOF
- Idle for more than 4 microframes
- USB 2.0 - 11.18.[7-8]
 - Transaction tracking for up to four data pipes.
 - No more than 4 periodic transactions (interrupt/isochronous) can be scheduled through the embedded TT per frame.
- Complete-split transaction searching.

Note

There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

54.5.5.2 Device Operation

The co-existence of a device operational controller within the USB OTG module has little effect on EHCI compatibility for host operation. However, given that the USB OTG controller initializes in neither host nor device mode, the USBMODE register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

54.5.5.3 Non-Zero Fields in the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational registers have use in device mode. Adhere to these steps:

- Write operations to all EHCI reserved fields (some of which are device fields in the USB OTG module) in the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the module must properly mask EHCI reserved fields (some of which are device fields in the USB OTG module registers).

54.5.5.4 SOF Interrupt

The SOF interrupt is a free running 125 μ s or 1 ms interrupt for host mode. EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. The free running interrupt is shared with the device mode start-of-frame interrupt. See the sections for the USBSTS and USBINTR registers for more information.

54.5.5.5 Embedded Design

This is an embedded USB host controller as defined by the EHCI specification; therefore, it does not implement the PCI configuration registers.

54.5.5.5.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like those provided by the frame adjust register in the PCI configuration registers. Starts of microframes are timed precisely to 125 μ s using the transceiver clock as a reference clock or a 60 Mhz transceiver clock for 8-bit physical interfaces and full-speed serial interfaces.

54.5.5.6 Miscellaneous Variations from EHCI

54.5.5.6.1 Programmable Physical Interface Behavior

The modules support multiple physical interfaces that can operate in different modes when the module is configured with the software programmable physical interface modes. The control bits for selecting the PHY operating mode are added to the PORTSC_n register providing a capability not defined by the EHCI specification.

54.5.5.6.2 Discovery

54.5.5.6.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the $PORTSCn$ register for a duration of 10 ms. Due to the complexity required to support the attachment of devices not high speed, a counter is present in the design that can count the 10 ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is summarized as:

- Port change interrupt—Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall set the $PORTSCn[PR]$ bit to reset the device.
- Software shall clear the $PORTSCn[PR]$ bit after 10 ms.
 - This step, necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a 0 to the reset bit while a reset is in progress, the write is ignored and the reset continues until completion.
- Port change interrupt—Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed is determined.

54.5.5.6.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which re-assigns the port owner for any device that does not connect at high speed, this host controller supports direct attach of non-HS devices. Therefore, the following differences are important regarding port speed detection:

- Port owner hand-off is not implemented. Therefore, $PORTSCn[PO]$ bit is read-only and always reads 0.
- A 2-bit port speed indicator field has been added to $PORTSCn$ to provide the current operating speed of the port to the host controller driver.
- A 1-bit high-speed indicator bit has been added to $PORTSCn$ to signify that the port is in HS vs. FS/LS.
 - This information is redundant with the 2-bit port speed indicator field above.

Chapter 55

Universal Serial Bus 2.0 Integrated PHY (USB-PHY)

55.1 Chip-specific USBHS Phy information

55.1.1 USBHS Phy Overview

The USBHS Phy is shut off in LLSx and VLLSx modes and must be reconfigured on exit from these low power modes.

55.2 USB PHY Overview

The chip contains one integrated USB 2.0 PHY macrocell capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, the full-speed (FS) rate of 12 Mbits/s, or the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

See [Figure 55-1](#) for a block diagram of the PHY. The integrated PHY provides a standard UTMI+ interface. It has an integrated 480MHz PLL and DCD (Device Charger Detector) analog circuits, with an IP bus interface for configurations. For this product the Device Charger Detector functions are detailed in the separate USB Device Charger Detection Module (USBDCD) chapter in this Reference Manual. The USB_DP and USB_DM pins connect directly to a USB connector.

Figure 55-1. USB 2.0 PHY Block Diagram

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 High-Speed PHY.

55.3 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in [Figure 55-3](#).

55.3.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL in the USB PHY supplies a 480MHz clock to UTMI digital. The UTMI block will divide the clock to generate the 30MHz clock used in the interface. This 480MHz clock is also the input to the Phase Fractional Divider (PFD) block. The PFD can generate $\text{pfd\_clk} = 480\text{MHz} * 18/N$ ($N=18\sim35$), and it also has a mux to select pfd_clk , $\text{pfd\_clk}/2$ or $\text{pfd\_clk}/4$ (see the PFD_FRAC and PFD_CLK_SEL descriptions in the USBPHY_ANACTRL register in this chapter).

Please note, the PFD output clock should not be programmed to be more than 180 MHz in Run or HSRun modes.

Figure 55-2. USB1PFDCLK generation diagram

55.3.2 Initialization and application information

In order to bring up the internal 480MHz USB PLL clock, five external conditions should be met as shown below.

- 32kHz IRC clock enable by setting IRCLKEN bit in MCG_C1 register
- External reference clock enable on XTAL by setting ERCLKEN bit in OSC_CR register
- USB PHY 1.2V PLL regulator enabled by setting USBREGEN bit in SIM_SOPT2 register

- 3.3V USB regulator has valid 3.3V output, which means either VREGIN0 or VREGIN1 should be connected with 5V input
- The system oscillator on EXTAL0 and XTAL0 is either of the following values, 12MHz, 16MHz or 24MHz.

Sample code for bringing up the 480MHz USB PLL clock:

```

MCG_C1 |= MCG_C1_IRCLKEN_MASK; //32kHz IRC enable
OSC_CR |= OSC_CR_ERCLKEN_MASK; //external reference clock enable
SIM_SOPT2 |= SIM_SOPT2_USBREGEN_MASK; //enable USB PHY PLL regulator
SIM_SCGC3 |= SIM_SCGC3_USBHSPHY_MASK; //open USB PHY clock gate

USBPHY_CTRL &= ~USBPHY_CTRL_SFTRST_MASK; //release PHY from reset
USBPHY_CTRL &= ~USBPHY_CTRL_CLKGATE_MASK; //Clear to 0 to run clocks

USBPHY_PLL_SIC |= USBPHY_PLL_SIC_PLL_POWER_MASK; //power up PLL if(crystal_val == 24000000)
    USBPHY_PLL_SIC |= USBPHY_PLL_SIC_PLL_DIV_SEL(0);
else if(crystal_val == 16000000)
    USBPHY_PLL_SIC |= USBPHY_PLL_SIC_PLL_DIV_SEL(1);
else if(crystal_val == 12000000)
    USBPHY_PLL_SIC |= USBPHY_PLL_SIC_PLL_DIV_SEL(2);

```

55.3.3 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

55.3.4 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and 480 MHz, 9X oversampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffers restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

55.3.5 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module, as shown in the figure below and described further in this section.

Figure 55-3. USB 2.0 PHY Analog Transceiver Block Diagram

55.3.5.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is high (1'b1) if the differential signal is greater than a 0-V threshold.

Otherwise, its output is low (1'b0). Its purpose is to discriminate the ± 400 -mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

55.3.5.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is high (1'b1) if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is low (1'b0).

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

55.3.5.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB_DP line is above the crossover point and the USB_DM line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

55.3.5.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

55.3.5.5 USB Plugged-In (Cable Attach) Detection

The USB HS PHY when operating in device mode provides three different methods for the local USB device to detect the attachment of a cable also attached to a remote USB host or hub. Only one of these methods should be enabled at a time when waiting to identify the cable attachment event, and all of them must be disabled during USB data communication.

The preferred standards-based method is to use the Data Contact Detect function per the *USB Battery Charging Specification, Revision 1.2*. The use of this method is described in the USB Device Charger Detection Module (USBDCD) chapter in this Reference Manual.

The second method, called the USB plugged-in detector, looks for both USB_DP and USB_DM to be high. There is a pair of large on-chip switchable pullup resistors (200 K Ω) that hold both USB_DP and USB_DM high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case. When operating in device mode, the upstream port in the remote host/hub interface contains a 15 K Ω pulldown resistor which could easily override the 200 K Ω pullup resistor. When the cable attachment event occurs, at least one signal in the pair will be low, which will force the plugged-in detector output high. The USB plugged-in detector is controlled through the USBPHY_CTRL[ENVPLUGINDET] bit field and results are observable through the USBPHY_STATUS[DEVPLUGIN_STATUS] bit field.

The final method is a legacy resistive detection function described in the now-obsolete *USB Battery Charging Specification, Revision 1.0*. This method enables a 125 K Ω pullup resistor on the USB_DP pin and a 375 K Ω pulldown resistor on the USB_DM pin. When no cable is plugged in, the USB_DP pin will be high and the USB_DM pin will be low. If the local device has a cable attached to a remote host or hub, due to the host 15 K Ω pulldowns both the USB_DP and USB_DM pins will be low. If the local device has a cable attached to a dedicated charger with no pullup/pulldown resistors, both the USB_DP and USB_DM pins will be high. This method is enabled through the USBPHY_USB1_VBUS_DETECT[EN_CHARGER_RESISTOR] bit field. Results can be observed using the single ended receiver status in the USBPHY_CHRG_DET_STAT[DP_STATE, DM_STATE] bit fields.

55.3.5.6 Single-Ended USB_DP Receiver

The single-ended USB_DP receiver output is high whenever the USB_DP input is above its nominal 1.8 V threshold.

55.3.5.7 Single-Ended USB_DM Receiver

The single-ended USB_DM receiver output is high whenever the USB_DM input is above its nominal 1.8 V threshold.

55.3.5.8 9X Oversample Module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

55.3.6 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 K Ω pullup resistor.

See [Figure 55-4](#).

55.3.6.1 Switchable High-Speed 45 Ω Termination Resistors

High-speed current mode differential signaling requires good 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in [Figure 55-4](#). The HW_USBPHY_TX_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45 Ω terminator on the USB_DP signal.

55.3.6.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially a pair of low-impedance pullup/pulldown devices that are switched in a differential mode for most low-speed or full-speed signaling. One output is driven high while the other output is driven low to signal the "J" state or the "K" state. Both outputs are driven low for the low-speed/full-speed "SE0" state.

55.3.6.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB_DP signal or the USB_DM signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit.

55.3.6.4 Switchable 1.5K Ω USB_DP Pullup Resistor

This product contains a switchable 1.5 K Ω pullup resistor on the USB_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

55.3.6.5 Switchable 15K Ω USB_DP and USB_DM Pulldown Resistors

This product contains switchable 15 K Ω pulldown resistors on both USB_DP and USB_DM signals. They are enabled in host mode to indicate to the device controller on the far end of the USB connection that a host is present. These resistors are also used during certain Battery Charging detector functions.

Figure 55-4. USB 2.0 PHY Transmitter Block Diagram

55.3.7 Recommended Register Configuration for USB Certification

The USB HS PHY has programmability to adjust several transceiver parameters.

- The TX HS driver termination impedance/FS driver output impedance and HS driver output currents can be adjusted through bit fields of the USBPHY_TX register. The ability to override the default parametric trim bit fields using the USBPHY_TX register has to be enabled by setting bit fields in the USBPHY_TRIM_OVERRIDE register.
- The TX HS driver optional pre-emphasis feature can be enabled and configured through bit fields of the USBPHY_ANACTRL register.
- The HS RX thresholds for the Envelope Detector/Squelch comparator and the Host Disconnect comparator can be adjusted through bit fields of the USBPHY_RX register.

The default values of the bit fields for the transceiver parametric trims are centered with no changes needed for USB Certification testing when the product is used with boards optimized for signal integrity on the HS USB port.

In other cases, such as when external components are inserted between the USB DP/DM pins and the USB connector or other compromises are made on USB DP/DM signal routing, changes to the parametric trim bit fields may be useful.

55.4 USB PHY Memory Map/Register Definition

USBPHY Hardware Register Format Summary

Information for using the Set, Clear, Toggle register features is located in the **Register Macro Usage** section later in this chapter.

USBPHY memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
400A_2000	USB PHY Power-Down Register (USBPHY_PWD)	32	R/W	001E_1C00h	55.4.1/1700

55.4.1 USB PHY Power-Down Register (USBPHY_PWDn)

The USB PHY Power-Down Register provides overall control of the PHY power state.

Before programming this register, the PHY clocks must be enabled in the USBPHY_CTRL and USBPHY_PLL_SIC registers.

Address: 400A_2000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBPHY_PWDn field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 RXPWDRX	This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation 1 Power-down the entire USB PHY receiver block except for the full-speed differential receiver
19 RXPWDDIFF	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation. 1 Power-down the USB high-speed differential receiver
18 RXPWD1PT1	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation 1 Power-down the USB full-speed differential receiver.
17 RXPWDENV	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation. 1 Power-down the USB high-speed receiver envelope detector (squelch signal)
16–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 TXPWDV2I	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. Note that these circuits are shared with the battery charge circuit. Setting this to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. 0 Normal operation. 1 Power-down the USB PHY transmit V-to-I converter and the current mirror

Table continues on the next page...

USBPHY_PWD_n field descriptions (continued)

Field	Description
11 TXPWDIBIAS	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. Note that these circuits are shared with the battery charge circuit. Setting this bit to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. 0 Normal operation 1 Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path
10 TXPWDFS	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation. 1 Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.2 USB PHY Transmitter Control Register (USBPHY_TX_n)

The USB PHY Transmitter Control Register allows adjustment of transmit parametric values. Some bit fields only have effect if they are enabled with the USBPHY_TRIM_OVERRIDE_EN register.

Address: 400A_2000h base + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

USBPHY_TX_n field descriptions (continued)

Field	Description
28–26 USBPHY_TX_EDGECTRL	Controls the edge-rate of the current sensing transistors used in HS transmit. NOT FOR CUSTOMER USE.
25 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
24 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 TXCAL45DP	Decode to trim the nominal 45Ω series termination resistance to the USB_DP output pin. Maximum resistance = 0000. Resistance is centered by design at 0110. Trimming this resistance will impact both the overshoot/undershoot of the Full Speed TX output and the amplitude of the High Speed TX output. This bit field only has effect if it is enabled by the USBPHY_TRIM_OVERRIDE_EN[TRIM_TX_CAL45DP_OVERRIDE] bit.
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	Reserved This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 TXCAL45DM	Decode to trim the nominal 45Ω series termination resistance to the USB_DM output pin. Maximum resistance = 0000. Resistance is centered by design at 0110. Trimming this resistance will impact both the overshoot/undershoot of the Full Speed TX output and the amplitude of the High Speed TX output. This bit field only has effect if it is enabled by the USBPHY_TRIM_OVERRIDE_EN[TRIM_TX_CAL45DM_OVERRIDE] bit.
7–4 Reserved	This field is reserved. Reserved. Note: This bit should remain clear.
D_CAL	Decode to trim the nominal 17.78mA current source for the High Speed TX drivers on USB_DP and USB_DM. This current is directly proportional to the amplitude of the High Speed TX eye diagram. This bit field only has effect if it is enabled by the USBPHY_TRIM_OVERRIDE_EN[TRIM_TX_D_CAL_OVERRIDE] bit. 0000 Maximum current, approximately 19% above nominal.

Table continues on the next page...

USBPHY_TXn field descriptions (continued)

Field	Description
0111	Nominal
1111	Minimum current, approximately 19% below nominal.

55.4.3 USB PHY Receiver Control Register (USBPHY_RXn)

The USB PHY Receiver Control Register allows adjustment of receive parametric values.

Address: 400A_2000h base + 20h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBPHY_RXn field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RXDBYPASS	This test mode is intended for lab use only, replace FS differential receiver with DP single ended receiver. 0 Normal operation. 1 Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver
21–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 DISCONADJ	The DISCONADJ field adjusts the trip point for the disconnect detector. 000 Trip-Level Voltage is 0.56875 V 001 Trip-Level Voltage is 0.55000 V 010 Trip-Level Voltage is 0.58125 V 011 Trip-Level Voltage is 0.60000 V 1XX Reserved

Table continues on the next page...

USBPHY_RX n field descriptions (continued)

Field	Description
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ENVADJ	The ENVADJ field adjusts the trip point for the envelope detector. Values shown below are nominal DC settings to indicate effect of changing these bits. AC values measured during compliance testing will be somewhat higher. 000 Trip-Level Voltage is 0.1000 V 001 Trip-Level Voltage is 0.1125 V 010 Trip-Level Voltage is 0.1250 V 011 Trip-Level Voltage is 0.0875 V 1XX Reserved

55.4.4 USB PHY General Control Register (USBPHY_CTRLn)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

Address: 400A_2000h base + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBPHY_CTRLn field descriptions

Field	Description
31 SFTRST	Writing a 1 to this bit will soft-reset the USBPHY_PWD, USBPHY_TX, USBPHY_RX, and USBPHY_CTRL registers. Set to 0 to release the PHY from reset.
30 CLKGATE	Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated. Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHY_CTRL is enabled.
29 UTMI_SUSPENDM	Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHY_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1 when USB controller entering into Suspend mode. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	Forces the next FS packet that is transmitted to have a EOP with low-speed timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHY_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHY_DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	Indicates the results of USB_ID pin while monitoring the cable plugged into the Micro- or Mini-AB receptacle. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side. Similar to the function of the OTGID_STATUS bit in the USBPHY_STATUS register, but OTG_ID_VALUE has debounce and system clock synchronization logic to filter the glitches on the USB_ID pad.
26 Reserved	Reserved This field is reserved. This bit field has no effect for this module.
25 Reserved	Reserved This field is reserved. This bit field has no effect for this module.
24 FSDLL_RST_EN	Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 Reserved	This field is reserved. This bit field has no effect for this module. This bit field must remain at value 1'b0.
22 Reserved	This field is reserved. This bit field has no effect for this module. This bit field must remain at value 1'b0.
21 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
20 ENAUTOCLR_PHY_PWD	Enables the feature to auto-clear the PWD register bits in USBPHY_PWD if there is wakeup event while USB is suspended. This should be enabled if needed to support auto wakeup without software interaction.
19 ENAUTOCLR_CLKGATE	Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needed to support auto wakeup without software interaction.

Table continues on the next page...

USBPHY_CTRLn field descriptions (continued)

Field	Description
18 AUTORESUME_EN	Enable the auto resume feature, when set, HW will use 32KHz clock to send Resume to respond to the device remote wakeup(for host mode only). It's useful when PLL is off and reference clock is also powered down.
17 Reserved	This field is reserved. This bit field has no effect for this module.
16 Reserved	This field is reserved. This bit field has no effect for this module.
15 ENUTMILEVEL3	Enables UTMI+ Level 3 operation for the USB HS PHY. This should be enabled if an Embedded Host use case needs to support an external FS Hub with a LS device connected.
14 ENUTMILEVEL2	Enables UTMI+ Level 2 operation for the USB HS PHY. This should be enabled if an Embedded Host use case needs to support a LS device.
13 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
12 DEVPLUGIN_IRQ	Indicates that the device is connected. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
11 Reserved	This field is reserved. This bit field has no effect for this module.
10 Reserved	This field is reserved. This bit field has no effect for this module.
9 Reserved	This field is reserved. This bit field has no effect for this module.
8 Reserved	This field is reserved. This bit field has no effect for this module.
7 Reserved	This field is reserved. This bit field has no effect for this module. This bit field must remain at value 1'b0.
6 Reserved	This field is reserved. This bit field has no effect for this module.
5 Reserved	This field is reserved. This bit field has no effect for this module.
4 ENDEVPLUGINDET	Enables non-standard resistive plugged-in detection This bit field controls connection of nominal 200kΩ resistors to both the USB_DP and USB_DM pins as one method of detecting when a USB cable is attached in device mode. This bit field must remain at a value of 1'b0 for normal USB data communication, or when using the USBHSDCD module for battery charger detection per the <i>USB Battery Charger Specification Revision 1.2</i> or any other detection mechanism for USB cable plugin. The results of this detection method are reported in USBPHY_STATUS[6]. 0 Disables 200kΩ pullup resistors on USB_DP and USB_DM pins (Default) 1 Enables 200kΩ pullup resistors on USB_DP and USB_DM pins
3 HOSTDISCONDETECT_IRQ	Indicates that the device has disconnected in High-Speed mode. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
2 Reserved	This field is reserved. This bit field has no effect for this module.

Table continues on the next page...

USBPHY_CTRL_n field descriptions (continued)

Field	Description
1 ENHOSTDISCONDETECT	For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. It shall be set after HS device is connected.
0 Reserved	This field is reserved. This bit field has no effect for this module.

55.4.5 USB PHY Status Register (USBPHY_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: 400A_2000h base + 40h offset = 400A_2040h

USBPHY_STATUS field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 RESUME_STATUS	Indicates that the host is sending a wake-up after Suspend and has triggered an interrupt.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 OTGID_STATUS	Indicates the results of USB_ID pin on the USB cable plugged into the local Micro- or Mini-AB receptacle. False (0) is when ID resistance to ground is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 DEVPLUGIN_STATUS	Status indicator for non-standard resistive plugged-in detection Indicates that the device has been connected on the USB_DP and USB_DM lines using the non-standard resistive plugged-in detection method controlled by USBPHY_CTRL[4]. When a USB cable attached to a remote host is attached to the local device, the 15kΩ host pulldowns will override the high value resistors used in this detection method.

Table continues on the next page...

USBPHY_STATUS field descriptions (continued)

Field	Description
	0 No attachment to a USB host is detected 1 Cable attachment to a USB host is detected
5–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
3 HOSTDISCONDETECT_ STATUS	Indicates at the local host (downstream) port that the remote device has disconnected while in High-Speed mode. 0 USB cable disconnect has not been detected at the local host 1 USB cable disconnect has been detected at the local host
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.6 USB PHY Debug Register (USBPHY_DEBUGn)

This register is used to debug the USB PHY.

Address: 400A_2000h base + 50h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								0							
W		CLKGATE	HOST_RESUME_ DEBUG					ENSQUELCHRESE T

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R		0							0							
W				ENTX2RXCOUNT				TX2RXCOUNT			ENHSTPULLDOWN N		HSTPULLDOWN		DEBUG_ INTERFACE_ HOLD	OTGIDPIOLOCK
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY_DEBUGn field descriptions

Field	Description
31 Reserved	Reserved This field is reserved.

Table continues on the next page...

USBPHY_DEBUGn field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
30 CLKGATE	Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28–25 SQUELCHRESETLENGTH	Duration of RESET in terms of the number of 480-MHz cycles.
24 ENSQUELCHRESET	Set bit to allow squelch to reset high-speed receive.
23–21 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–16 SQUELCHRESETCOUNT	Delay in between the detection of squelch to the reset of high-speed RX.
15–13 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
12 ENTX2RXCOUNT	Set this bit to allow a countdown to transition in between TX and RX.
11–8 TX2RXCOUNT	Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7–6 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
5–4 ENHSTPULLDOWN	This bit field selects host pulldown overdrive mode. Set bit 5 to value 1'b1 to override the control of the USB_DP 15kΩ pulldown. Set bit 4 to value 1'b1 to override the control of the USB_DM 15Ω pulldown. Clear both bits to value 2'b00 to disable the host pulldown overdrive mode. When in host pulldown overdrive mode, the connection of the individual pulldown resistors is further controlled by the USBPHY_DEBUG[3:2] bit field.
3–2 HSTPULLDOWN	This bit field selects whether to connect pulldown resistors on the USB_DP/USB_DM pins if the corresponding pulldown overdrive mode is enabled through USBPHY_DEBUG[5:4] Set bit 3 to value 1'b1 to connect the 15Ω pulldown on USB_DP line. Set bit 2 to value 1'b1 to connect the 15Ω pulldown on the USB_DM line. Clear both bits to value 2'b00 to disconnect the pulldowns in override mode.
1 DEBUG_INTERFACE_HOLD	Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	Once OTG ID from USBPHY_STATUS_OTGID_STATUS is sampled, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

55.4.7 UTMI Debug Status Register 0 (USBPHY_DEBUG0_STATUS)

The UTMI Debug Status Register 0 holds multiple views for counters and status of state machines. This is used in conjunction with the USBPHY_x_DEBUG1_DBG_ADDRESS field to choose which function to view. The default is described in the bit fields below and is used to count errors.

Address: 400A_2000h base + 60h offset = 400A_2060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SQUELCH_COUNT						UTMI_RXERROR_FAIL_COUNT										LOOP_BACK_FAIL_COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY_DEBUG0_STATUS field descriptions

Field	Description
31–26 SQUELCH_COUNT	Running count of the squelch reset instead of normal end for HS RX.
25–16 UTMI_RXERROR_FAIL_COUNT	Running count of the UTMI_RXERROR.
LOOP_BACK_FAIL_COUNT	Running count of the failed pseudo-random generator loopback. Each time entering testmode, counter goes to 900D and will count up for every detected packet failure in digital/analog loopback tests.

55.4.8 UTMI Debug Status Register 1 (USBPHY_DEBUG1n)

Chooses the muxing of the debug register to be shown in USBPHY_x_DEBUG0_STATUS.

Address: 400A_2000h base + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	Reserved		PLL_ENABLE	PLL_POWER	PLL_HOLD_RING_OFF	Reserved	Reserved	Reserved	Reserved	PLL_EN_USB_CLKS	Reserved	Reserved			PLL_DIV_SEL		
W																	
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	

USBPHY_PLL_SICn field descriptions

Field	Description
31 PLL_LOCK	USB PLL lock status indicator 0 PLL is not currently locked 1 PLL is currently locked
30–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
16 PLL_BYPASS	Bypass the USB PLL.
15–14 Reserved	This field is reserved. This bit field has no effect for this module.
13 PLL_ENABLE	Enable the clock output from the USB PLL.
12 PLL_POWER	Power up the USB PLL.
11 PLL_HOLD_ RING_OFF	Analog debug bit. Not for customer use. This bit field must remain at value 1'b0 for normal operation.
10 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
9 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
8 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
7 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
6 PLL_EN_USB_ CLKS	Enable the USB clock output from the USB PHY PLL.
5 Reserved	This field is reserved. Not for customer use. This bit field must remain at value 1'b0.
4–2 Reserved	This field is reserved. This bit field has no effect for this module.
PLL_DIV_SEL	This field controls the USB PLL feedback loop divider. The USB PLL is designed to produce a 480MHz output clock. This bit field allows use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator. When override is enabled through USBPHY_TRIM_OVERRIDE_EN[0], the USB PLL will use this register value.

Table continues on the next page...

USBPHY_PLL_SIC_n field descriptions (continued)

Field	Description
00	PLL reference frequency = 24MHz
01	PLL reference frequency = 16MHz
1X	PLL reference frequency = 12MHz

55.4.11 USB PHY VBUS Detect Control Register (USBPHY_USB1_VBUS_DETECT_n)

This register defines controls for USB VBUS detect and some additional out of band signaling functions.

Address: 400A_2000h base + C0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBPHY_USB1_VBUS_DETECT n field descriptions

Field	Description
31 EN_CHARGER_RESISTOR	Enables resistors used for an older method of resistive battery charger detection This bit field enables a nominal 125kΩ pullup on USB_DP and a nominal 375kΩ pulldown on USB_DM. This allows resistive battery charger detection per the <i>USB Battery Charging Specification Revision 1.0</i> which is now obsolete. Detection of USB_DP and USB_DM pin states using this method is done with the USBPHY_CHRG_DET_STAT[3:2] bit fields. This bit field must remain at a value of 1'b0 for normal USB data communication, or when using the USBHSDCD module for battery charger detection per the <i>USB Battery Charger Specification Revision 1.2</i> or any other detection mechanism for USB cable plugin. 0 Disable resistive charger detection resistors on USB_DP and USB_DP 1 Enable resistive charger detection resistors on USB_DP and USB_DP
30–28 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This bit field has no effect for this module.
26 DISCHARGE_VBUS	Controls VBUS discharge resistor This bit field controls a nominal 22kΩ resistor between the USB1_VBUS pin and ground. It can be used to accelerate the fall of the VBUS signal at the end of a session. 0 VBUS discharge resistor is disabled (Default) 1 VBUS discharge resistor is enabled
25–23 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
22–21 Reserved	This field is reserved. This bit field has no effect for this module.

Table continues on the next page...

USBPHY_USB1_VBUS_DETECT_n field descriptions (continued)

Field	Description
20 PWRUP_CMPS	Enables the VBUS_VALID comparator Powers up the comparator used for the VBUS_VALID detector. This bit field can be reset to value 1'b0 to save power if the internal VBUS_VALID comparator is not used. 0 Powers down the VBUS_VALID comparator 1 Enables the VBUS_VALID comparator (default)
19 Reserved	Reserved This field is reserved. This bit field has no effect for this module.
18 VBUSVALID_ TO_SESSVALID	Selects the comparator used for VBUS_VALID This bit field controls the comparator used to report the VBUS_VALID results in USBPHY_USB1_VBUS_DETECT[3] between the VBUS_VALID comparator and the Session Valid comparator. The VBUS_VALID comparator is the most accurate and has a programmable threshold set by USBPHY_USB_VBUS_DETECT[2:0]. The Session Valid comparator may be useful in systems using non-standard VBUS voltages. The mux selection in this bit field happens before any VBUS_VALID selection controlled by the USBPHY_USB1_VBUS_DETECT[10:8] bits. 0 Use the VBUS_VALID comparator for VBUS_VALID results 1 Use the Session End comparator for VBUS_VALID results. The Session End threshold is >0.8V and <4.0V.
17–11 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
10–9 VBUS_ SOURCE_SEL	Selects the source of the VBUS_VALID signal reported to the USB controller This is one of the bit fields that selects the source of the VBUS_VALID signal reported to the USB controller. The VBUS_VALID source selections in this bit field only take effect if both USBPHY_USB1_VBUS_DETECT[8] and USBPHY_USB1_VBUS_DETECT[3] each have the value 1'b0. This bit field does not impact the VBUS_VALID value reported in USBPHY_USB1_VBUS_DET_STAT[3]. 00 Use the VBUS_VALID comparator results for signal reported to the USB controller (Default) 01 Use the Session Valid comparator results for signal reported to the USB controller 10 Use the Session Valid comparator results for signal reported to the USB controller 11 Reserved, do not use
8 VBUSVALID_ SEL	Selects the source of the VBUS_VALID signal reported to the USB controller This is one of the bit fields that selects the source of the VBUS_VALID signal reported to the USB controller. The VBUS_VALID source selection in this bit field only takes effect if USBPHY_USB1_VBUS_DETECT[3] has the value 1'b0. This bit field does not impact the VBUS_VALID value reported in USBPHY_USB1_VBUS_DET_STAT[3].

Table continues on the next page...

USBPHY_USB1_VBUS_DETECT n field descriptions (continued)

Field	Description
	0 Use the VBUS_VALID comparator results for signal reported to the USB controller (Default) 1 Use the VBUS_VALID_3V detector results for signal reported to the USB controller
7 VBUSVALID_ OVERRIDE	Override value for VBUS_VALID signal sent to USB controller The bit field provides the value for VBUS_VALID reported to the USB controller if the value of USBPHY_USB1_VBUS_DETECT[3] is set to 1'b1. The value of this bit field does not affect the value of USBPHY_USB1_VBUS_DET_STAT[3].
6 AVALID_ OVERRIDE	Override value for A-Device Session Valid The bit field provides the value for USBPHY_USB1_VBUS_DET_STAT[2] if USBPHY_USB1_VBUS_DETECT[3] is set to value 1'b1.
5 BVALID_ OVERRIDE	Override value for B-Device Session Valid The bit field provides the value for USBPHY_USB1_VBUS_DET_STAT[1] if USBPHY_USB1_VBUS_DETECT[3] is set to value 1'b1.
4 SESSEND_ OVERRIDE	Override value for SESSEND The bit field provides the value for USBPHY_USB1_VBUS_DET_STAT[0] if USBPHY_USB1_VBUS_DETECT[3] is set to value 1'b1.
3 VBUS_ OVERRIDE_EN	VBUS detect signal override enable This bit field allows SW to override the results from the VBUS_VALID and Session Valid comparators using the values in USBPHY_USB1_VBUS_DETECT[7:4]. The VBUS_VALID, AVALID, BVALID, and SESSEND signals sent to the USB controller are each affected by these bit selections. The values reported for AVALID, BVALID, and SESSEND in USBPHY_USB1_VBUS_DET_STAT[2:0] are also affected but the value reported for VBUS_VALID in USBPHY_USB1_VBUS_DET_STAT[3] is not affected. This override method may be useful if VBUS detection is not done with the internal VBUS_VALID or Session End comparators. 0 Use the results of the internal VBUS_VALID and Session Valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND (Default) 1 Use the override values for VBUS_VALID, AVALID, BVALID, and SESSEND
VBUSVALID_ THRESH	Sets the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50mV of hysteresis to prevent chattering at the comparator trip point. 000 4.0 V 001 4.1 V 010 4.2 V 011 4.3 V 100 4.4 V (Default) 101 4.5 V 110 4.6 V 111 4.7 V

55.4.12 USB PHY VBUS Detector Status Register (USBPHY_USB1_VBUS_DET_STAT)

This register allows observation of status for USB VBUS detect functions.

The values reported in this register are synchronized by the `apb_clk`.

Address: 400A_2000h base + D0h offset = 400A_20D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY_USB1_VBUS_DET_STAT field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 VBUS_VALID_3V	VBUS_VALID_3V detector status The VBUS_VALID_3V detector has a lower threshold for the voltage on the USB1_VBUS pin than either the Session Valid or VBUS_VALID comparators. This signal may be useful for applications using a non-standard VBUS voltage. 0 VBUS voltage is below VBUS_VALID_3V threshold 1 VBUS voltage is above VBUS_VALID_3V threshold
3 VBUS_VALID	VBUS voltage status This bit field shows the result of VBUS_VALID detection for the USB1_VBUS pin. The VBUS_VALID comparator used is selected by USBPHY_USB1_VBUS_DETECT[18]. The VBUS_VALID source is not affected by the values of USBPHY_USB1_VBUS_DETECT[7, 3] and cannot be overwritten by SW. 0 VBUS is below the comparator threshold 1 VBUS is above the comparator threshold
2 AVALID	A-Device Session Valid status A-Device Session Valid status, determined by the Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the USBPHY_VBUS_DETECT[6, 3] bit fields. 0 The VBUS voltage is below the Session Valid threshold 1 The VBUS voltage is above the Session Valid threshold
1 BVALID	B-Device Session Valid status B-Device Session Valid status, determined by the Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the USBPHY_VBUS_DETECT[5, 3] bit fields. 0 The VBUS voltage is below the Session Valid threshold 1 The VBUS voltage is above the Session Valid threshold
0 SESSEND	Session End indicator Session End status, value inverted from Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the USBPHY_VBUS_DETECT[4, 3] bit fields. 0 The VBUS voltage is above the Session Valid threshold 1 The VBUS voltage is below the Session Valid threshold

55.4.13 USB PHY Charger Detect Status Register (USBPHY_USB1_CHRG_DET_STAT)

The control of the USB Battery Charging detection functions has been moved to the USBHSDCD instantiation of the USBDCD module for this product.

For standards-based charger detection purposes, the USBHSDCD registers should be used rather than this register. However, the status values in this register may be useful for debugging or in case other detection methods are used.

Address: 400A_2000h base + F0h offset = 400A_20F0h

USBPHY_USB1_CHRG_DET_STAT field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 SECDET_DCP	Battery Charging Secondary Detection phase output During the USB Battery Charging Secondary Detection phase using the USBHSDCD module, this bit field indicates which kind of Charging Port was detected. 0 Charging Downstream Port (CDP) has been detected 1 Downstream Charging Port (DCP) has been detected
3 DP_STATE	Single ended receiver output for the USB_DP pin, from charger detection circuits. 0 USB_DP pin voltage is < 0.8V 1 USB_DP pin voltage is > 2.0V
2 DM_STATE	Single ended receiver output for the USB_DM pin, from charger detection circuits. 0 USB_DM pin voltage is < 0.8V 1 USB_DM pin voltage is > 2.0V
1 CHRG_DETECTED	Battery Charging Primary Detection phase output During the USB Battery Charging Primary Detection phase using the USBHSDCD module, this bit field indicates whether a Standard Downstream Port or Charging Port was detected. 0 Standard Downstream Port (SDP) has been detected 1 Charging Port has been detected
0 PLUG_CONTACT	Battery Charging Data Contact Detection phase output During the Data Contact Detection phase per the <i>USB Battery Charging Specification Revision 1.2</i> using the USBHSDCD module, this bit field indicates whether a USB cable has been attached between the remote host and the local device. 0 No USB cable attachment has been detected 1 A USB cable attachment between the device and host has been detected

55.4.14 USB PHY Analog Control Register (USBPHY_ANACTRLn)

The USBPHY_ANACTRL register has bit fields for the Phase Fractional Divider (PFD) clock output along with controls for adding pre-emphasis to the USB High-Speed TX output drivers.

The PFD input clock comes from the 480MHz USB PLL, and the PFD output clock (pfd_clk) is used to generate the USB1PFDCLK for use outside the USB HS PHY.

Address: 400A_2000h base + 100h offset + (4d × i), where i=0d to 3d

**USBPHY_ANACTRL_n field descriptions**

Field	Description
31 PFD_STABLE	PFD stable signal from the Phase Fractional Divider.
30–23 Reserved	This field is reserved. Not for customer use. For normal USB operation this bit field must remain cleared at value 8'h00.
22–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–14 EMPH_CUR_CTRL	Controls the amount of pre-emphasis current added for the High-Speed TX drivers after each data transition when the USBPHY_ANACTRL[EMPH_EN] bit is set high to 1'b1. Each unit of pre-emphasis current adds approximately 3% to the nominal HS TX output current. 00 No pre-emphasis current is enabled for the HS TX drivers

Table continues on the next page...

USBPHY_ANACTRLn field descriptions (continued)

Field	Description
	01 One unit of pre-emphasis current is enabled for the HS TX drivers 10 Two units of pre-emphasis current are enabled for the HS TX drivers 11 Three units of pre-emphasis current are enabled for the HS TX drivers
13 EMPH_EN	Enables pre-emphasis for the High-Speed TX drivers. Pre-emphasis adds additional output drive current for a brief period after each data transition. Use of pre-emphasis may be useful to optimize signal integrity depending on board design choices. 0 No pre-emphasis is used on HS TX output drivers 1 Enables pre-emphasis for HS TX output drivers
12–11 EMPH_PULSE_CTRL	Controls pre-emphasis time duration for the High Speed TX drivers after each data transition when the USBPHY_ANACTRL[EMPH_EN] bit is set high to 1'b1. The time duration for the pre-emphasis current increases as the value written to this bit field increases. 00 Minimum duration of pre-emphasis current after each data transition 01 10 11 Maximum duration of pre-emphasis current after each data transition
10 DEV_PULLDOWN	Setting this field to 1'b1 will enable the 15kΩ pulldown resistors on both USB_DP and USB_DM pins. This feature can be used in device mode while the USB cable is disconnected to keep the data pins at known values, avoiding unnecessary interrupts from the single ended receivers. This bit must be reset to 1'b0 during normal USB data communication in device mode, or while battery charger detection using the USBHSDCD module is used. 0 The 15kΩ nominal pulldowns on the USB_DP and USB_DM pins are disabled in device mode. 1 The 15kΩ nominal pulldowns on the USB_DP and USB_DM pins are enabled in device mode.
9–4 PFD_FRAC	PFD fractional divider setting used to select the pfd_clk output frequency. Changing this bit field will cause pfd_update to be toggled. The pfd_clk output frequency is 480MHz*18/N where N=18–35. Valid values of PFD_FRAC are from 6'd18 to 6'd35, other values may cause undefined results.
3–2 PFD_CLK_SEL	This bit field for the PFD selects the frequency relationship between the local pfd_clk output and the exported USB1PFDCLK. 00 USB1PFDCLK is the same frequency as the xtal clock (Default) 01 USB1PFDCLK frequency is pfd_clk divided by 4 10 USB1PFDCLK frequency is pfd_clk divided by 2 11 USB1PFDCLK frequency is the same as pfd_clk frequency
1 PFD_CLKGATE	This bit field controls clock gating (disabling) for the PFD pfd_clk output for power savings when the PFD is not used. Setting the bit to value 1'b1 will gate the output of PFD. This gating will also be enabled if the PFD reference clock is not stable, the USB PLL is not locked, or the USB PLL is not enabled. This bit field must be reset to value 1'b0 to enable the pfd_clk output. 0 PFD clock output is enabled 1 PFD clock output is gated (Default)
0 TESTCLK_SEL	Test clock selection to analog test. Not for customer use. The value of this bit field must remain at 1'b0 for normal operation.

55.4.15 USB PHY Loopback Control/Status Register (USBPHY_USB1_LOOPBACK_n)

This register controls loopback testing of the USB PHY. Loopback mode is for test purposes only; it cannot be used during normal USB data communication.

Address: 400A_2000h base + 110h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBPHY_USB1_LOOPBACK_n field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 TSTPKT	Selects the packet data byte used for USB loopback testing in Pulse mode. Pulse mode is selected by setting USBPHY_USB1_LOOPBACK[2:1] to a value of 2'b01. Default value produces a data inversion at each unit interval.
15 TSTI_HSFS_ MODE_EN	Setting this bit field to value 1'b1 will enable the loopback test to dynamically change the packet speed. It will send a number of High Speed packets determined by USBPHY_USB1_LOOPBACK_HSFSCNT[TSTI_HS_NUMBER], followed by a number of Full Speed packets determined by USBPHY_USB1_LOOPBACK_HSFSCNT[TSTI_FS_NUMBER].
14–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UTMO_DIG_ TST1	This read-only bit is a status bit for USB loopback test. Value = 1'b1 indicates a passing result. Test results are only valid while UTMI_TESTSTART is set to value 1'b1.
7 UTMO_DIG_ TST0	This read-only bit is a status bit for USB loopback test results. Value = 1'b0 indicates a passing result. Test results are only valid while UTMI_TESTSTART is set to value 1'b1.
6 TSTI_TX_HIZ	Sets TX Hi-Z for USB loopback test.
5 TSTI_TX_EN	Enable TX for USB loopback test.
4 TSTI_TX_LS_ MODE	Set to value 1'b1 to choose LS for USB loopback testing, set to value 1'b0 to choose HS or FS mode which is defined by TSTI1_TX_HS.
3 TSTI_TX_HS_ MODE	Select HS or FS mode for USB loopback testing. Set to value 1'b1 to choose HS for USB loopback testing, set to value 1'b0 to choose FS mode.
2 UTMI_DIG_TST1	Mode control for USB loopback test. Setting this bit to a value of 1'b1 while UTMI_DIG_TST0 remains at a value of 1'b0 selects Psuedorandom modes for the loopback test.
1 UTMI_DIG_TST0	Mode control for USB loopback test. Setting this bit to a value of 1'b1 while UTMI_DIG_TST1 remains at a value of 1'b0 selects Pulse mode for the loopback test.
0 UTMI_ TESTSTART	This bit enables the USB loopback test.

55.4.16 USB PHY Loopback Packet Number Select Register (USBPHY_USB1_LOOPBACK_HSFSCNT_n)

Address: 400A_2000h base + 120h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBPHY_USB1_LOOPBACK_HSFSCNT_n field descriptions

Field	Description
31–16 TSTI_FS_NUMBER	Full speed packet number, used when USBPHY_USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is set to value 1'b1.
TSTI_HS_NUMBER	High speed packet number, used when USBPHY_USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is set to value 1'b1.

55.4.17 USB PHY Trim Override Enable Register (USBPHY_TRIM_OVERRIDE_EN_n)

The bit fields in this register allow observation of the default IFR settings of Phy parameters for TX_CAL45DM, TX_CAL45DP, TX_D_CAL, ENV_TAIL_ADJ, and PLL_DIV_SEL.

Additional bit fields also determine whether those values can be overridden by settings in the USBPHY_TX, USBPHY_DEBUG1, and USBPHY_PLL_SIC registers.

27–24 TRIM_USBPHY_TX_CAL45DP	IFR value of TX_CAL45DP.
23–20 TRIM_USBPHY_TX_D_CAL	IFR value of TX_D_CAL.

Table continues on the next page...

USBPHY_TRIM_OVERRIDE_ENn field descriptions (continued)

Field	Description
19–18 TRIM_USB_ REG_ENV_ TAIL_ADJ_VD	IFR value of ENV_TAIL_ADJ.
17–16 TRIM_PLL_ CTRL0_DIV_SEL	IFR value of PLL_DIV_SEL.
15–5 Reserved	Reserved This field is reserved.
4 TRIM_TX_ CAL45DM_ OVERRIDE	Override enable for TX_CAL45DM, when set, the register value in USBPHY_TX[11:8] will be used.
3 TRIM_TX_ CAL45DP_ OVERRIDE	Override enable for TX_CAL45DP, when set, the register value in USBPHY_TX[19:16] will be used.
2 TRIM_TX_D_ CAL_OVERRIDE	Override enable for TX_D_CAL, when set, the register value in USBPHY_TX[3:0] will be used.
1 TRIM_ENV_ TAIL_ADJ_VD_ OVERRIDE	Override enable for ENV_TAIL_ADJ, when set, the register value in USBPHY_DEBUG1[14:13] will be used.
0 TRIM_DIV_SEL_ OVERRIDE	Override enable for PLL_DIV_SEL, when set, the register value in USBPHY_PLL_SIC[1:0] will be used.

55.5 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all bits set to 1 perform the associated operation on the primary register, while all bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read/modify/write operations. When atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

Chapter 56

Serial Peripheral Interface (SPI)

56.1 Chip-specific SPI information

56.1.1 SPI Modules Configuration

This device contains 4 SPI modules.

56.1.2 SPI clocking

The SPI module is clocked by the internal bus clock (the DSPI refers to it as system clock). The module has an internal divider, with a minimum divide is two. So, the SPI can run at a maximum frequency of bus clock/2.

NOTE

This device has 4 SPIs. SPI0, SPI1, and SPI2's input clock is fed from the bus clock, SPI3's input clock is fed from system clock.

56.1.3 Number of CTARs

SPI CTAR registers define different transfer attribute configurations. The SPI module supports up to eight CTAR registers. This device supports two CTARs on all instances of the SPI.

In master mode, the CTAR registers define combinations of transfer attributes, such as frame size, clock phase, clock polarity, data bit ordering, baud rate, and various delays. In slave mode only CTAR0 is used, and a subset of its bitfields sets the slave transfer attributes.

56.1.4 TX FIFO size

Table 56-1. SPI transmit FIFO size

SPI Module	Transmit FIFO size
SPI0	4 words
SPI1	4 words
SPI2	4 words
SPI3	4 words

56.1.5 RX FIFO Size

SPI supports up to 16-bit frame size during reception.

Table 56-2. SPI receive FIFO size

SPI Module	Receive FIFO size
SPI0	4 words
SPI1	4 words
SPI2	4 words
SPI3	4 words

56.1.6 Number of PCS signals

The following table shows the maximum number of peripheral chip select signals available per SPI module. Note that not all chip select signals are available in all device packages. Refer to [Pinouts](#) for additional information.

Table 56-3. SPI PCS signals

SPI Module	PCS Signals
SPI0	SPI0_PCS5
	SPI0_PCS4
	SPI0_PCS3
	SPI0_PCS2
	SPI0_PCS1
	SPI0_PCS0
SPI1	SPI1_PCS3

Table continues on the next page...

**Table 56-3. SPI PCS signals
(continued)**

SPI Module	PCS Signals
	SPI1_PCS2
	SPI1_PCS1
	SPI1_PCS0
SPI2	SPI2_PCS1
	SPI2_PCS0
SPI3	SPI3_PCS0

56.1.7 SPI Operation in Low Power Modes

In VLPR and VLPW modes the SPI is functional; however, the reduced system frequency also reduces the max frequency of operation for the SPI. In VLPR and VLPW modes the max SPI_CLK frequency is 4 MHz

In stop and VLPS modes, the clocks to the SPI module are disabled. The module is not functional, but it is powered so that it retains state.

There is one way to wake from stop mode via the SPI, which is explained in the following section.

56.1.7.1 Using GPIO Interrupt to Wake from stop mode

Here are the steps to use a GPIO to create a wakeup upon reception of SPI data in slave mode:

1. Point the GPIO interrupt vector to the desired interrupt handler.
2. Enable the GPIO input to generate an interrupt on either the rising or falling edge (depending on the polarity of the chip select signal).
3. Enter Stop or VLPS mode and Wait for the GPIO interrupt.

NOTE

It is likely that in using this approach the first word of data from the SPI host might not be received correctly. This is dependent on the transfer rate used for the SPI, the delay between chip select assertion and presentation of data, and the system interrupt latency.

56.1.8 SPI Doze Mode

The Doze mode for the SPI module is the same as the Wait and VLPW modes for the chip.

56.1.9 SPI Interrupts

The SPI has multiple sources of interrupt requests. However, these sources are OR'd together to generate a single interrupt request per SPI module to the interrupt controller. When an SPI interrupt occurs, read the SPI_SR to determine the exact interrupt source.

56.1.10 SPI clocks

This table shows the SPI module clocks and the corresponding chip clocks.

Table 56-4. SPI clock connections

Module clock	Chip clock
System Clock	Bus Clock

56.1.11 Writing SPI Transmit FIFO

The SPI supports 8-bit or 16-bit writes to the PUSH TX FIFO, allowing a single write to the command word followed by multiple writes to the transmit word. The TX FIFO will save the last command word written, and convert a 8-bit/16-bit write to the transmit word into a 32-bit write that pushes both the command word and transmit word into the SPI_PUSHR ([PUSH TX FIFO Register In Master Mode](#))

A 32-bit write to the SPI_PUSH register will push all 32-bits to the TX FIFO. An 8-bit or 16-bit write to the 16-bit transmit data field will push the data together with the last written command word. An 8-bit or 16-bit write to the command word does not push data onto the FIFO, but that command word is pushed to the TX FIFO on all subsequent 8-bit or 16-bit writes to the transmit data field. This allows a single 16-bit write to the command word to be used for all subsequent 8-bit or 16-bit writes to the transmit data word. Writing a different 16-bit command word will cause all subsequent 8-bit or 16-bit writes to the transmit data word to be pushed to the TX FIFO with the new command word.

56.2 Introduction

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device.

56.2.1 Block Diagram

The block diagram of this module is as follows:

NOTE

SPI is used for both SPI Mode and DSI mode in this diagram.

Figure 56-1. SPI Block Diagram

56.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues

- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
 - two transfer attribute registers
 - Serial clock (SCK) with programmable polarity and phase
 - Various programmable delays
 - Programmable serial frame size: 4 to 16
 - SPI frames longer than 16 bits can be supported using the continuous selection format.
 - Continuously held chip select capability
- 6 peripheral chip selects (PCSeS), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSeS) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
 - TX FIFO is not full (TFFF)
 - RX FIFO is not empty (RFDF)
- Interrupt conditions:
 - End of Queue reached (EOQF)
 - TX FIFO is not full (TFFF)
 - Transfer of current frame complete (TCF)
 - Attempt to transmit with an empty Transmit FIFO (TFUF)
 - RX FIFO is not empty (RFDF)
 - Frame received while Receive FIFO is full (RFOF)
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
 - Support for Stop mode
 - Support for Doze mode

56.2.3 Interface configurations

56.2.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

NOTE

SPI is used for both SPI Mode and DSI mode in this diagram.

Figure 56-2. SPI with queues and DMA

56.2.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:

- Master mode
- Slave mode
- Module Disable mode
- Chip-specific modes:
 - External Stop mode
 - Debug mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

56.2.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- SOUT
- PCS[x]

56.2.4.2 Slave Mode

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{\text{SS}}$ signals are configured as inputs and driven by an SPI bus master.

56.2.4.3 Module Disable Mode

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

56.2.4.4 External Stop Mode

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

NOTE

In master mode, if a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. In slave mode, this module waits until its chip select input signal goes high before it is ready to have its clocks shut off. It should be noted that the CS0 pad must be correctly configured to allow it to return to high when no transfer is occurring. If the pad is tied low then this could prevent the module from being correctly disabled.

56.2.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the chip is in debug mode.
- If the bit is cleared, the chip debug mode has no effect on the module.

56.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

Table 56-5. Module signal descriptions

Signal	Master mode	Slave mode	I/O
PCS0/ $\overline{SS}$	Peripheral Chip Select 0 (O)	Slave Select (I)	I/O
PCS[1:3]	Peripheral Chip Selects 1–3	(Unused)	O
PCS4	Peripheral Chip Select 4	(Unused)	O
PCS5/ $\overline{PCSS}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	(Unused)	O
SCK	Serial Clock (O)	Serial Clock (I)	I/O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O

56.3.1 PCS0/ $\overline{\text{SS}}$ —Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

NOTE

Do not tie the SPI slave select pin to ground. Otherwise, SPI cannot function properly.

56.3.2 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

56.3.3 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

56.3.4 PCS5/ $\overline{\text{PCSS}}$ —Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

56.3.5 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

56.3.6 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

56.3.7 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

56.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

SPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4002_C000	Module Configuration Register (SPI0_MCR)	32	R/W	0000_4001h	56.4.1/1750
4002_C008	Transfer Count Register (SPI0_TCR)	32	R/W	0000_0000h	56.4.2/1753
4002_C00C	Clock and Transfer Attributes Register (In Master Mode) (SPI0_CTAR0)	32	R/W	7800_0000h	56.4.3/1754

56.4.1 Module Configuration Register (SPIx_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: Base address + 0h offset

SPIx_MCR field descriptions

Field	Description
31 MSTR	Master/Slave Mode Select Enables either Master mode (if supported) or Slave mode (if supported) operation. 0 Enables Slave mode 1 Enables Master mode
30 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously.

Table continues on the next page...

SPIx_MCR field descriptions (continued)

Field	Description
	0 Continuous SCK disabled. 1 Continuous SCK enabled.
29–28 DCONF	SPI Configuration. Selects among the different configurations of the module. 00 SPI 01 Reserved 10 Reserved 11 Reserved
27 FRZ	Freeze Enables transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in Debug mode. 1 Halt serial transfers in Debug mode.
26 MTFE	Modified Transfer Format Enable Enables a modified transfer format to be used. NOTE: When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSH[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
25 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
24 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
23–22 Reserved	Always write the reset value to this field. This field is reserved.
21–16 PCSiS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx. Refer to the chip-specific SPI information for the number of PCS signals used in this chip. NOTE: The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the SPI interface.

Table continues on the next page...

SPIx_MCR field descriptions (continued)

Field	Description
	0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
15 DOZE	Doze Enable Provides support for an externally controlled Doze mode power-saving mechanism. 0 Doze mode has no effect on the module. 1 Doze mode disables the module.
14 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 1. When the module is used in Slave Mode, it is recommended to leave this bit 0, because a slave doesn't have control over master transactions. 0 Enables the module clocks. 1 Allows external logic to disable the module clocks.
13 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared. 0 TX FIFO is enabled. 1 TX FIFO is disabled.
12 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 RX FIFO is enabled. 1 RX FIFO is disabled.
11 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero. 0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.
10 CLR_RXF	Clear RX FIFO Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. NOTE: After every RX FIFO clear operation (MCR [CLR_RXF] = 0b1) following a RX FIFO overflow (SR [RFOF] = 0b1) scenario, perform a single POP from the RX FIFO and discard the read data. The POP and discard operation must be completed before receiving a new incoming frame. 0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.
9–8 SMPL_PT	Sample Point Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0.

Table continues on the next page...

SPIx_MCR field descriptions (continued)

Field	Description
	00 0 protocol clock cycles between SCK edge and SIN sample 01 1 protocol clock cycle between SCK edge and SIN sample 10 2 protocol clock cycles between SCK edge and SIN sample 11 Reserved
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved.
1 Reserved	This field is reserved.
0 HALT	Halt The HALT bit starts and stops frame transfers. See Start and Stop of Module transfers 0 Start transfers. 1 Stop transfers.

56.4.2 Transfer Count Register (SPIx_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SPIx_TCR field descriptions

Field	Description
31–16 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.4.3 Clock and Transfer Attributes Register (In Master Mode) (SPIx_CTARn)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

When the module is configured as a SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

Address: Base address + Ch offset + (4d × i), where i=0d to 1d

SPIx_CTARn field descriptions

Field	Description																				
31 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate. Table 56-6. SPI SCK Duty Cycle <table><tr><th>DBR</th><th>CPHA</th><th>PBR</th><th>SCK Duty Cycle</th></tr><tr><td>0</td><td>any</td><td>any</td><td>50/50</td></tr><tr><td>1</td><td>0</td><td>00</td><td>50/50</td></tr><tr><td>1</td><td>0</td><td>01</td><td>33/66</td></tr><tr><td>1</td><td>0</td><td>10</td><td>40/60</td></tr></table>	DBR	CPHA	PBR	SCK Duty Cycle	0	any	any	50/50	1	0	00	50/50	1	0	01	33/66	1	0	10	40/60

1	0	11	43/57																						
1	1	00	50/50																						
1	1	01	66/33																						
1	1	10	60/40																						
1	1	11	57/43																						
30–27 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4.																								
26 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. NOTE: In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.																								
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.																								
24 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. 0 Data is transferred MSB first. 1 Data is transferred LSB first.																								
23–22 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer PCS to SCK Delay (t_{csc}) for more details.																								

Table continues on the next page...

SPIx_CTARn field descriptions (continued)

Field	Description								
	00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.								
21–20 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. Refer After SCK Delay (t_{ASC}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.								
19–18 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer Delay after Transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.								
17–16 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.								
15–12 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK.$ The following table lists the delay scaler values. Table 56-7. Delay Scaler Encoding <table border="1"> <thead> <tr> <th>Field Value</th><th>Delay Scaler Value</th></tr> </thead> <tbody> <tr> <td>0000</td><td>2</td></tr> <tr> <td>0001</td><td>4</td></tr> <tr> <td>0010</td><td>8</td></tr> </tbody> </table>	Field Value	Delay Scaler Value	0000	2	0001	4	0010	8

	Refer PCS to SCK Delay (t_{CSC}) for more details.																														
11–8 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer After SCK Delay (t_{ASC}) for more details.																														
7–4 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values.																														
BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: $SCK \text{ baud rate} = (f_P / PBR) \times [(1+DBR)/BR]$ The following table lists the baud rate scaler values.

SPIx_CTARn_SLAVE field descriptions

Field	Description
31 Reserved	Always write the reset value to this field. This field is reserved.
30–27 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.
26 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). NOTE: In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
24–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 Reserved	This field is reserved.
Reserved	This field is reserved.

56.4.5 Status Register (SPIx_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: Base address + 2Ch offset

SPIx_SR field descriptions

Field	Description
31 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it. 0 Transfer not complete. 1 Transfer complete.

Table continues on the next page...

SPIx_SR field descriptions (continued)

Field	Description
30 TXRXS	TX and RX Status Reflects the run status of the module. 0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
27 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for SPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it. 0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 TFFF	Transmit FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request. NOTE: The reset value of this bit is 0 when the module is disabled, (MCR[MDIS]=1). 0 TX FIFO is full. 1 TX FIFO is not full.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 RFOF	Receive FIFO Overflow Flag

Table continues on the next page...

SPIx_SR field descriptions (continued)

Field	Description
	Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 RFDF	Receive FIFO Drain Flag Indicates whether there is an available location to be drained from the FIFO. Either a DMA request or an interrupt indication can be used to read from the FIFO. Note that this bit is set if at least one location can be read from the FIFO. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 RX FIFO is empty. 1 RX FIFO is not empty.
16 Reserved	This field is reserved.
15–12 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHX is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
11–8 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register. NOTE: When TX FIFO is cleared by setting SPI_MCR[CLR_TXF] to 1, this field does not update immediately to 0. Only when the next transfer starts, this field reflects the latest value TXNXTPTR = 1.
7–4 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
POPNTXPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNTXPTR is updated when the POPR is read.

56.4.6 DMA/Interrupt Request Select and Enable Register (SPIx_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: Base address + 30h offset

18 Reserved	Always write the reset value to this field. This field is reserved.
17 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled. 1 RFDF interrupt or DMA requests are enabled.
16 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select

Table continues on the next page...

SPIx_RSER field descriptions (continued)

Field	Description
	Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
15 Reserved	Always write the reset value to this field. This field is reserved.
14 Reserved	Always write the reset value to this field. This field is reserved.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.4.7 PUSH TX FIFO Register In Master Mode (SPIx_PUSHR)

Specifies data to be transferred to the TX FIFO. An 8- or 16-bit write access transfers all 32 bits to the TX FIFO. In Master mode, the register transfers 16 bits of data and 16 bits of command information. A read access of PUSHR returns the topmost TX FIFO entry.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: Base address + 34h offset

SPIx_RXFR_n field descriptions (continued)

Field	Description
	Contains the received SPI data.

56.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module has the following configuration

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPIx_MCR is 0b00.

The CTAR_n registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See [Clock and Transfer Attributes Register \(In Master Mode\) \(SPI_CTAR_n\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

Figure 56-3. Serial protocol overview

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The SPI configuration shares transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

56.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

56.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

56.5.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(SPI_PUSHR\)](#) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

56.5.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

56.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS_TXF] bit disables the TX FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO is disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

56.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

56.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO by writing to the PUSHHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller

indicates that a write to PUSHHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

56.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

56.5.2.5 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

56.5.2.5.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

56.5.2.5.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

56.5.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

Figure 56-4. Communications clock prescalers and scalers

56.5.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 56-9. Baud rate computation example

f_p	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

56.5.3.2 PCS to SCK Delay (t_{csc})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 56-6](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR_x registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 56-10. PCS to SCK delay computation example

f_{sys}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 μ s

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

56.5.3.3 After SCK Delay (t_{ASC})

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 56-6](#) and [Figure 56-7](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR_x registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 56-11. After SCK Delay computation example

f_p	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 μ s

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

56.5.3.4 Delay after Transfer (t_{DT})

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 56-6](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR_x registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

Table 56-12. Delay after Transfer computation example

f_p	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

56.5.3.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The $\overline{\text{PCSS}}$ signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

Figure 56-5. Peripheral Chip Select Strobe timing

The delay between the assertion of the PCS signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_P} \times \text{PCSSCK}$$

At the end of the transfer, the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_P} \times \text{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 56-13. Peripheral Chip Select Strobe Assert computation example

f_P	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 56-14. Peripheral Chip Select Strobe Negate computation example

f_P	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The $\overline{\text{PCSS}}$ signal is not supported when Continuous Serial Communication SCK mode is enabled.

NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

56.5.4 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

56.5.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 56-6. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

56.5.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

Figure 56-7. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

56.5.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The SPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The SPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the SPI operation with MTFE=1. Timing delays shown are:

- T_{csc} - PCS to SCK assertion delay
- T_{acs} - After SCK PCS negation delay
- $T_{su_{ms}}$ - master SIN setup time
- $T_{hd_{ms}}$ - master SIN hold time
- $T_{vd_{sl}}$ - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$ - data setup time on slave data input
- $T_{hd_{sl}}$ - data hold time on slave data input
- T_{sys} - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and $F_{sys}/F_{sck} = 4$. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

Functional description

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of SPI Slave", presents SPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show SPI SIN input as being driven by a regular external SPI slave, configured according SPI master CPHA programming.

Note

In the following diagrams, f_{sys} represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

NOTE

SPI is used for both SPI Mode and DSI mode in the following diagrams.

Figure 56-8. SPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{\text{sck}} = f_{\text{sys}}/4$)

Figure 56-9. SPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/2$)

Figure 56-10. SPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/3$)

56.5.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the SPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK

NOTE

SPI is used for both SPI Mode and DSI mode in this diagram.

. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

Figure 56-11. SPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/2$)

Figure 56-12. SPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/3$)

Figure 56-13. SPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/4$)

56.5.4.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

Figure 56-14. Example of non-continuous format (CPHA=1, CONT=0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

Figure 56-15. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

56.5.5 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 56-16. Continuous SCK Timing Diagram (CONT=0)

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 56-17. Continuous SCK timing diagram (CONT=1)

56.5.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and $\overline{SS}$ signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

56.5.7 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 56-15. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
Transfer Complete	TCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-

Table continues on the next page...

Table 56-15. Interrupt and DMA request conditions (continued)

Condition	Flag	Interrupt	DMA
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

56.5.7.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

56.5.7.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

56.5.7.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

56.5.7.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

56.5.7.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated. Configure the DMA to drain only one FIFO location per transfer.

56.5.7.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

56.5.8 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

56.5.8.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

56.5.8.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSH Register does not change the state of the TX FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

56.6 Initialization/application information

This section describes how to initialize the module.

56.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO by writing a 1 to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

56.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

56.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling its Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

56.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

Table 56-16. Baud rate values (bps)

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

56.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

Table 56-17. Delay values

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 μ s
	32	320.0 ns	960.0 ns	1.6 μ s	2.2 μ s
	64	640.0 ns	1.9 μ s	3.2 μ s	4.5 μ s
	128	1.3 μ s	3.8 μ s	6.4 μ s	9.0 μ s
	256	2.6 μ s	7.7 μ s	12.8 μ s	17.9 μ s
	512	5.1 μ s	15.4 μ s	25.6 μ s	35.8 μ s
	1024	10.2 μ s	30.7 μ s	51.2 μ s	71.7 μ s
	2048	20.5 μ s	61.4 μ s	102.4 μ s	143.4 μ s
	4096	41.0 μ s	122.9 μ s	204.8 μ s	286.7 μ s
	8192	81.9 μ s	245.8 μ s	409.6 μ s	573.4 μ s
	16384	163.8 μ s	491.5 μ s	819.2 μ s	1.1 ms
	32768	327.7 μ s	983.0 μ s	1.6 ms	2.3 ms
	65536	655.4 μ s	2.0 ms	3.3 ms	4.6 ms

56.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 56-18. TX FIFO pointers and counter

56.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXTPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

56.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

Chapter 57

Inter-Integrated Circuit (I2C)

57.1 Chip-specific I2C information

57.1.1 Number of I2C modules

This device has 4 I²C module(s).

The I2C module includes SMBus support and DMA support. It also has optional address match wakeup in Stop/VLPS mode. The digital glitch filter implemented in the IIC module, controlled by the I2Cx_FLT[FLT] registers, is clocked from the bus clock and thus has filter granularity in bus clock cycle counts.

57.2 Introduction

The inter-integrated circuit (I²C, I2C, or IIC) module provides a method of communication between a number of devices.

The interface is designed to operate up to at least 400 kbit/s with maximum bus loading and timing. The I2C device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF. The I2C module also complies with the *System Management Bus (SMBus) Specification, version 2*.

57.2.1 Features

The I2C module has the following features:

- Compatible with *The I²C-Bus Specification*
- Multimaster operation
- Software programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- START and STOP signal generation and detection
- Repeated START signal generation and detection
- Acknowledge bit generation and detection
- Bus busy detection
- General call recognition
- 10-bit address extension
- Support for *System Management Bus (SMBus) Specification, version 2*
- Programmable input glitch filter
- Low power mode wakeup on slave address match
- Range slave address support
- DMA support
- Double buffering support to achieve higher baud rate

57.2.2 Modes of operation

The I2C module's operation in various low power modes is as follows:

- Run mode: This is the basic mode of operation. To conserve power in this mode, disable the module.
- Wait mode: The module continues to operate when the core is in Wait mode and can provide a wakeup interrupt.
- Stop mode: The module is inactive in Stop mode for reduced power consumption, except that address matching is enabled in Stop mode. The STOP instruction does not affect the I2C module's register states.

57.2.3 Block diagram

The following figure is a functional block diagram of the I2C module.

Figure 57-1. I2C Functional block diagram

57.3 I²C signal descriptions

The signal properties of I²C are shown in the table found here.

Table 57-1. I²C signal descriptions

Signal	Description	I/O
SCL	Bidirectional serial clock line of the I ² C system.	I/O
SDA	Bidirectional serial data line of the I ² C system.	I/O

57.4 Memory map/register definition

This section describes in detail all I2C registers accessible to the end user.

I2C memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4006_6000	I2C Address Register 1 (I2C0_A1)	8	R/W	00h	57.4.1/1804
4006_6001	I2C Frequency Divider register (I2C0_F)	8	R/W	00h	57.4.2/1804
4006_6002	I2C Control Register 1 (I2C0_C1)	8	R/W	00h	57.4.3/1805
4006_6003	I2C Status register (I2C0_S)	8	R/W	80h	57.4.4/1807
4006_6004	I2C Data I/O register (I2C0_D)	8	R/W	00h	57.4.5/1809
4006_6005	I2C Control Register 2 (I2C0_C2)	8	R/W	00h	57.4.6/1809
4006_6006	I2C Programmable Input Glitch Filter Register (I2C0_FLT)	8	R/W	00h	57.4.7/1810
4006_6007	I2C Range Address register (I2C0_RA)	8	R/W	00h	57.4.8/1812
4006_6008	I2C SMBus Control and Status register (I2C0_SMB)	8	R/W	00h	57.4.9/1812
4006_6009	I2C Address Register 2 (I2C0_A2)	8	R/W	C2h	57.4.10/1814
4006_600A	I2C SCL Low Timeout Register High (I2C0_SLTH)	8	R/W	00h	57.4.11/1814
4006_600B	I2C SCL Low Timeout Register Low (I2C0_SLTL)	8	R/W	00h	57.4.12/1815
4006_600C	I2C Status register 2 (I2C0_S2)	8	R/W	01h	57.4.13/1815
4006_7000	I2C Address Register 1 (I2C1_A1)	8	R/W	00h	57.4.1/1804
4006_7001	I2C Frequency Divider register (I2C1_F)	8	R/W	00h	57.4.2/1804
4006_7002	I2C Control Register 1 (I2C1_C1)	8	R/W	00h	57.4.3/1805
4006_7003	I2C Status register (I2C1_S)	8	R/W	80h	57.4.4/1807

400E_700A	I2C SCL Low Timeout Register High (I2C3_SLTH)	8	R/W	00h	57.4.11/1814
400E_700B	I2C SCL Low Timeout Register Low (I2C3_SLTL)	8	R/W	00h	57.4.12/1815
400E_700C	I2C Status register 2 (I2C3_S2)	8	R/W	01h	57.4.13/1815

57.4.1 I2C Address Register 1 (I2Cx_A1)

This register contains the slave address to be used by the I2C module.

Address: Base address + 0h offset

Bit	7	6	5	4	3	2	1	0
Read	AD[7:1]							0
Write								0
Reset	0	0	0	0	0	0	0	0

I2Cx_A1 field descriptions

Field	Description
7–1 AD[7:1]	Address Contains the primary slave address used by the I2C module when it is addressed as a slave. This field is used in the 7-bit address scheme and the lower seven bits in the 10-bit address scheme.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.2 I2C Frequency Divider register (I2Cx_F)

Address: Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read	MULT		ICR					
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_F field descriptions

Field	Description
7–6 MULT	Multiplier Factor Defines the multiplier factor (mul). This factor is used along with the SCL divider to generate the I2C baud rate. 00 mul = 1 01 mul = 2 10 mul = 4 11 Reserved
ICR	ClockRate Prescales the I2C module clock for bit rate selection. This field and the MULT field determine the I2C baud rate, the SDA hold time, the SCL start hold time, and the SCL stop hold time. For a list of values corresponding to each ICR setting, see I2C divider and hold values . The SCL divider multiplied by multiplier factor (mul) determines the I2C baud rate. $\text{I2C baud rate} = \text{I2C module clock speed (Hz)} / (\text{mul} \times \text{SCL divider})$

Table continues on the next page...

I2Cx_F field descriptions (continued)

Field	Description																																	
	The SDA hold time is the delay from the falling edge of SCL (I2C clock) to the changing of SDA (I2C data). $\text{SDA hold time} = \text{I2C module clock period (s)} \times \text{mul} \times \text{SDA hold value}$ The SCL start hold time is the delay from the falling edge of SDA (I2C data) while SCL is high (start condition) to the falling edge of SCL (I2C clock). $\text{SCL start hold time} = \text{I2C module clock period (s)} \times \text{mul} \times \text{SCL start hold value}$ The SCL stop hold time is the delay from the rising edge of SCL (I2C clock) to the rising edge of SDA (I2C data) while SCL is high (stop condition). $\text{SCL stop hold time} = \text{I2C module clock period (s)} \times \text{mul} \times \text{SCL stop hold value}$ For example, if the I2C module clock speed is 8 MHz, the following table shows the possible hold time values with different ICR and MULT selections to achieve an I²C baud rate of 100 kbit/s. <table><tr><th rowspan="2">MULT</th><th rowspan="2">ICR</th><th colspan="3">Hold times (μs)</th></tr><tr><th>SDA</th><th>SCL Start</th><th>SCL Stop</th></tr><tr><td>2h</td><td>00h</td><td>3.500</td><td>3.000</td><td>5.500</td></tr><tr><td>1h</td><td>07h</td><td>2.500</td><td>4.000</td><td>5.250</td></tr><tr><td>1h</td><td>0Bh</td><td>2.250</td><td>4.000</td><td>5.250</td></tr><tr><td>0h</td><td>14h</td><td>2.125</td><td>4.250</td><td>5.125</td></tr><tr><td>0h</td><td>18h</td><td>1.125</td><td>4.750</td><td>5.125</td></tr></table>	MULT	ICR	Hold times (μs)			SDA	SCL Start	SCL Stop	2h	00h	3.500	3.000	5.500	1h	07h	2.500	4.000	5.250	1h	0Bh	2.250	4.000	5.250	0h	14h	2.125	4.250	5.125	0h	18h	1.125	4.750	5.125

0h	18h	1.125	4.750	5.125																														

57.4.3 I2C Control Register 1 (I2Cx_C1)

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	IICEN	IICIE	MST	TX	TXAK	0	WUEN	DMAEN
Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_C1 field descriptions

Field	Description
7 IICEN	I2C Enable Enables I2C module operation. 0 Disabled 1 Enabled
6 IICIE	I2C Interrupt Enable Enables I2C interrupt requests.

Table continues on the next page...

I2Cx_C1 field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
5 MST	Master Mode Select When MST is changed from 0 to 1, a START signal is generated on the bus and master mode is selected. When this bit changes from 1 to 0, a STOP signal is generated and the mode of operation changes from master to slave. 0 Slave mode 1 Master mode
4 TX	Transmit Mode Select Selects the direction of master and slave transfers. In master mode this bit must be set according to the type of transfer required. Therefore, for address cycles, this bit is always set. When addressed as a slave this bit must be set by software according to the SRW bit in the status register. 0 Receive 1 Transmit
3 TXAK	Transmit Acknowledge Enable Specifies the value driven onto the SDA during data acknowledge cycles for both master and slave receivers. The value of SMB[FACK] affects NACK/ACK generation. NOTE: SCL is held low until TXAK is written. 0 An acknowledge signal is sent to the bus on the following receiving byte (if FACK is cleared) or the current receiving byte (if FACK is set). 1 No acknowledge signal is sent to the bus on the following receiving data byte (if FACK is cleared) or the current receiving data byte (if FACK is set).
2 RSTA	Repeat START Writing 1 to this bit generates a repeated START condition provided it is the current master. This bit will always be read as 0. Attempting a repeat at the wrong time results in loss of arbitration.
1 WUEN	Wakeup Enable The I2C module can wake the MCU from low power mode with no peripheral bus running when slave address matching occurs. 0 Normal operation. No interrupt generated when address matching in low power mode. 1 Enables the wakeup function in low power mode.
0 DMAEN	DMA Enable Enables or disables the DMA function. 0 All DMA signalling disabled. 1 DMA transfer is enabled. While SMB[FACK] = 0, the following conditions trigger the DMA request: - a data byte is received, and either address or data is transmitted. (ACK/NACK is automatic) - the first byte received matches the A1 register or is a general call address.

Table continues on the next page...

I2Cx_C1 field descriptions (continued)

Field	Description
	If any address matching occurs, S[IAAS] and S[TCF] are set. If the direction of transfer is known from master to slave, then it is not required to check S[SRW]. With this assumption, DMA can also be used in this case. In other cases, if the master reads data from the slave, then it is required to rewrite the C1 register operation. With this assumption, DMA cannot be used. When FACK = 1, an address or a data byte is transmitted.

57.4.4 I2C Status register (I2Cx_S)

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0
Read	TCF	IAAS	BUSY	ARBL	RAM	SRW	IICIF	RXAK
Write				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

I2Cx_S field descriptions

Field	Description
7 TCF	Transfer Complete Flag Acknowledges a byte transfer; TCF is set on the completion of a byte transfer. This bit is valid only during or immediately following a transfer to or from the I2C module. TCF is cleared by reading the I2C data register in receive mode or by writing to the I2C data register in transmit mode. NOTE: In the buffer mode, TCF is cleared automatically by internal reading or writing the data register I2C_D, with no need waiting for manually reading/writing the I2C data register in Rx/Tx mode. 0 Transfer in progress 1 Transfer complete
6 IAAS	Addressed As A Slave This bit is set by one of the following conditions: - The calling address matches the programmed primary slave address in the A1 register, or matches the range address in the RA register (which must be set to a nonzero value and under the condition I2C_C2[RMEN] = 1). - C2[GCAEN] is set and a general call is received. - SMB[SIICAEN] is set and the calling address matches the second programmed slave address. - ALERTEN is set and an SMBus alert response address is received - RMEN is set and an address is received that is within the range between the values of the A1 and RA registers. IAAS sets before the ACK bit. The CPU must check the SRW bit and set TX/RX accordingly. Writing the C1 register with any value clears this bit. 0 Not addressed 1 Addressed as a slave
5 BUSY	Bus Busy

Table continues on the next page...

I2Cx_S field descriptions (continued)

Field	Description
	Indicates the status of the bus regardless of slave or master mode. This bit is set when a START signal is detected and cleared when a STOP signal is detected. 0 Bus is idle 1 Bus is busy
4 ARBL	Arbitration Lost This bit is set by hardware when the arbitration procedure is lost. The ARBL bit must be cleared by software, by writing 1 to it. 0 Standard bus operation. 1 Loss of arbitration.
3 RAM	Range Address Match This bit is set to 1 by any of the following conditions, if I2C_C2[RMEN] = 1: - Any nonzero calling address is received that matches the address in the RA register. - The calling address is within the range of values of the A1 and RA registers. NOTE: For the RAM bit to be set to 1 correctly, C1[IICIE] must be set to 1. Writing the C1 register with any value clears this bit to 0. 0 Not addressed 1 Addressed as a slave
2 SRW	Slave Read/Write When addressed as a slave, SRW indicates the value of the R/W command bit of the calling address sent to the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IICIF	Interrupt Flag This bit sets when an interrupt is pending. This bit must be cleared by software by writing 1 to it, such as in the interrupt routine. One of the following events can set this bit: - One byte transfer, including ACK/NACK bit, completes if FACK is 0. An ACK or NACK is sent on the bus by writing 0 or 1 to TXAK after this bit is set in receive mode. - One byte transfer, excluding ACK/NACK bit, completes if FACK is 1. - Match of slave address to calling address including primary slave address, range slave address, alert response address, second slave address, or general call address. - Arbitration lost - In SMBus mode, any timeouts except SCL and SDA high timeouts - I2C bus stop or start detection if the SSIE bit in the Input Glitch Filter register is 1 NOTE: To clear the I2C bus stop or start detection interrupt: In the interrupt service routine, first clear the STOPF or STARTF bit in the Input Glitch Filter register by writing 1 to it, and then clear the IICIF bit. If this sequence is reversed, the IICIF bit is asserted again. 0 No interrupt pending 1 Interrupt pending
0 RXAK	Receive Acknowledge

Table continues on the next page...

I2Cx_S field descriptions (continued)

Field	Description
0	Acknowledge signal was received after the completion of one byte of data transmission on the bus
1	No acknowledge signal detected

57.4.5 I2C Data I/O register (I2Cx_D)

Address: Base address + 4h offset

Bit	7	6	5	4	3	2	1	0
Read	DATA							
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_D field descriptions

Field	Description
DATA	Data In master transmit mode, when data is written to this register, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates receiving of the next byte of data. NOTE: When making the transition out of master receive mode, switch the I2C mode before reading the Data register to prevent an inadvertent initiation of a master receive data transfer. In slave mode, the same functions are available after an address match occurs. The C1[TX] bit must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For example, if the I2C module is configured for master transmit but a master receive is desired, reading the Data register does not initiate the receive. Reading the Data register returns the last byte received while the I2C module is configured in master receive or slave receive mode. The Data register does not reflect every byte that is transmitted on the I2C bus, and neither can software verify that a byte has been written to the Data register correctly by reading it back. In master transmit mode, the first byte of data written to the Data register following assertion of MST (start bit) or assertion of RSTA (repeated start bit) is used for the address transfer and must consist of the calling address (in bits 7-1) concatenated with the required R/W bit (in position bit 0).

57.4.6 I2C Control Register 2 (I2Cx_C2)

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	GCAEN	ADEXT	HDRS	SBRC	RMEN	AD[10:8]		
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_C2 field descriptions

Field	Description
7 GCAEN	General Call Address Enable Enables general call address. 0 Disabled 1 Enabled
6 ADEXT	Address Extension Controls the number of bits used for the slave address. 0 7-bit address scheme 1 10-bit address scheme
5 HDRS	High Drive Select Controls the drive capability of the I2C pads. 0 Normal drive mode 1 High drive mode
4 SBRC	Slave Baud Rate Control Enables independent slave mode baud rate at maximum frequency, which forces clock stretching on SCL in very fast I2C modes. To a slave, an example of a "very fast" mode is when the master transfers at 40 kbit/s but the slave can capture the master's data at only 10 kbit/s. 0 The slave baud rate follows the master baud rate and clock stretching may occur 1 Slave baud rate is independent of the master baud rate
3 RMEN	Range Address Matching Enable This bit controls the slave address matching for addresses between the values of the A1 and RA registers. When this bit is set, a slave address matching occurs for any address greater than the value of the A1 register and less than or equal to the value of the RA register. 0 Range mode disabled. No address matching occurs for an address within the range of values of the A1 and RA registers. 1 Range mode enabled. Address matching occurs when a slave receives an address within the range of values of the A1 and RA registers.
AD[10:8]	Slave Address Contains the upper three bits of the slave address in the 10-bit address scheme. This field is valid only while the ADEXT bit is set.

57.4.7 I2C Programmable Input Glitch Filter Register (I2Cx_FLT)

Address: Base address + 6h offset

Bit	7	6	5	4	3	2	1	0
Read	SHEN	STOPF	SSIE	STARTF	FLT			
Write		w1c		w1c				
Reset	0	0	0	0	0	0	0	0

I2Cx_FLT field descriptions

Field	Description
7 SHEN	Stop Hold Enable Set this bit to hold off entry to stop mode when any data transmission or reception is occurring. The following scenario explains the holdoff functionality: 1. The I2C module is configured for a basic transfer, and the SHEN bit is set to 1. 2. A transfer begins. 3. The MCU signals the I2C module to enter stop mode. 4. The byte currently being transferred, including both address and data, completes its transfer. 5. The I2C slave or master acknowledges that the in-transfer byte completed its transfer and acknowledges the request to enter stop mode. 6. After receiving the I2C module's acknowledgment of the request to enter stop mode, the MCU determines whether to shut off the I2C module's clock. If the SHEN bit is set to 1 and the I2C module is in an idle or disabled state when the MCU signals to enter stop mode, the module immediately acknowledges the request to enter stop mode. If SHEN is cleared to 0 and the overall data transmission or reception that was suspended by stop mode entry was incomplete: To resume the overall transmission or reception after the MCU exits stop mode, software must reinitialize the transfer by resending the address of the slave. If the I2C Control Register 1's IICIE bit was set to 1 before the MCU entered stop mode, system software will receive the interrupt triggered by the I2C Status Register's TCF bit after the MCU wakes from the stop mode. 0 Stop holdoff is disabled. The MCU's entry to stop mode is not gated. 1 Stop holdoff is enabled.
6 STOPF	I2C Bus Stop Detect Flag Hardware sets this bit when the I2C bus's stop status is detected. The STOPF bit must be cleared by writing 1 to it. NOTE: The stop flag is only for the matched slave devices, therefore the master will not respond for it. 0 No stop happens on I2C bus 1 Stop detected on I2C bus
5 SSIE	I2C Bus Stop or Start Interrupt Enable This bit enables the interrupt for I2C bus stop or start detection. NOTE: To clear the I2C bus stop or start detection interrupt: In the interrupt service routine, first clear the STOPF or STARTF bit by writing 1 to it, and then clear the IICIF bit in the status register. If this sequence is reversed, the IICIF bit is asserted again. 0 Stop or start detection interrupt is disabled 1 Stop or start detection interrupt is enabled
4 STARTF	I2C Bus Start Detect Flag Hardware sets this bit when the I2C bus's start status is detected. The STARTF bit must be cleared by writing 1 to it. 0 No start happens on I2C bus 1 Start detected on I2C bus
FLT	I2C Programmable Filter Factor

Table continues on the next page...

I2Cx_FLT field descriptions (continued)

Field	Description
	Controls the width of the glitch, in terms of I2C module clock cycles, that the filter must absorb. For any glitch whose size is less than or equal to this width setting, the filter does not allow the glitch to pass.
0h	No filter/bypass
1-Fh	Filter glitches up to width of n I2C module clock cycles, where $n=1-15d$

57.4.8 I2C Range Address register (I2Cx_RA)

Address: Base address + 7h offset

Bit	7	6	5	4	3	2	1	0
Read	RAD							0
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_RA field descriptions

Field	Description
7–1 RAD	Range Slave Address This field contains the slave address to be used by the I2C module. The field is used in the 7-bit address scheme. If I2C_C2[RMEN] is set to 1, any nonzero value write enables this register. This register value can be considered as a maximum boundary in the range matching mode.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.9 I2C SMBus Control and Status register (I2Cx_SMB)**NOTE**

When the SCL and SDA signals are held high for a length of time greater than the high timeout period, the SHTF1 flag sets. Before reaching this threshold, while the system is detecting how long these signals are being held high, a master assumes that the bus is free. However, the SHTF1 bit is set to 1 in the bus transmission process with the idle bus state.

NOTE

When the TCKSEL bit is set, there is no need to monitor the SHTF1 bit because the bus speed is too high to match the protocol of SMBus.

Address: Base address + 8h offset

Bit	7	6	5	4	3	2	1	0
Read	FAACK	ALERTEN	SIICAEN	TCKSEL	SLTF	SHTF1	SHTF2	SHTF2IE
Write					w1c		w1c	
Reset	0	0	0	0	0	0	0	0

I2Cx_SMB field descriptions

Field	Description
7 FAACK	Fast NACK/ACK Enable For SMBus packet error checking, the CPU must be able to issue an ACK or NACK according to the result of receiving data byte. 0 An ACK or NACK is sent on the following receiving data byte 1 Writing 0 to TXAK after receiving a data byte generates an ACK. Writing 1 to TXAK after receiving a data byte generates a NACK.
6 ALERTEN	SMBus Alert Response Address Enable Enables or disables SMBus alert response address matching. NOTE: After the host responds to a device that used the alert response address, you must use software to put the device's address on the bus. The alert protocol is described in the SMBus specification. 0 SMBus alert response address matching is disabled 1 SMBus alert response address matching is enabled
5 SIICAEN	Second I2C Address Enable Enables or disables SMBus device default address. 0 I2C address register 2 matching is disabled 1 I2C address register 2 matching is enabled
4 TCKSEL	Timeout Counter Clock Select Selects the clock source of the timeout counter. 0 Timeout counter counts at the frequency of the I2C module clock / 64 1 Timeout counter counts at the frequency of the I2C module clock
3 SLTF	SCL Low Timeout Flag This bit is set when the SLT register (consisting of the SLTH and SLTL registers) is loaded with a non-zero value (LoValue) and an SCL low timeout occurs. Software clears this bit by writing a logic 1 to it. NOTE: The low timeout function is disabled when the SLT register's value is 0. 0 No low timeout occurs 1 Low timeout occurs
2 SHTF1	SCL High Timeout Flag 1 This read-only bit sets when SCL and SDA are held high more than clock × LoValue / 512, which indicates the bus is free. This bit is cleared automatically. 0 No SCL high and SDA high timeout occurs 1 SCL high and SDA high timeout occurs

Table continues on the next page...

I2Cx_SMB field descriptions (continued)

Field	Description
1 SHTF2	SCL High Timeout Flag 2 This bit sets when SCL is held high and SDA is held low more than $\text{clock} \times \text{LoValue} / 512$. Software clears this bit by writing 1 to it. 0 No SCL high and SDA low timeout occurs 1 SCL high and SDA low timeout occurs
0 SHTF2IE	SHTF2 Interrupt Enable Enables SCL high and SDA low timeout interrupt. 0 SHTF2 interrupt is disabled 1 SHTF2 interrupt is enabled

57.4.10 I2C Address Register 2 (I2Cx_A2)

Address: Base address + 9h offset

Bit	7	6	5	4	3	2	1	0
Read	SAD							0
Write								
Reset	1	1	0	0	0	0	1	0

I2Cx_A2 field descriptions

Field	Description
7–1 SAD	SMBus Address Contains the slave address used by the SMBus. This field is used on the device default address or other related addresses.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.11 I2C SCL Low Timeout Register High (I2Cx_SLTH)

Address: Base address + Ah offset

Bit	7	6	5	4	3	2	1	0
Read	SSLT[15:8]							
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_SLTH field descriptions

Field	Description
SSLT[15:8]	SSLT[15:8] Most significant byte of SCL low timeout value that determines the timeout period of SCL low.

57.4.12 I2C SCL Low Timeout Register Low (I2Cx_SLTL)

Address: Base address + Bh offset

Bit	7	6	5	4	3	2	1	0
Read	SSLT[7:0]							
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_SLTL field descriptions

Field	Description
SSLT[7:0]	SSLT[7:0] Least significant byte of SCL low timeout value that determines the timeout period of SCL low.

57.4.13 I2C Status register 2 (I2Cx_S2)

Address: Base address + Ch offset

Bit	7	6	5	4	3	2	1	0

7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 ERROR	Error flag Indicates if there are read or write errors with the Tx and Rx buffers. 0 The buffer is not full and all write/read operations have no errors. 1 There are 3 or more write/read errors during the data transfer phase (when the Empty flag is not set and the buffer is busy).

Table continues on the next page...

I2Cx_S2 field descriptions (continued)

Field	Description
0 EMPTY	Empty flag Indicates if the Tx or Rx buffer is empty. 0 Tx or Rx buffer is not empty and cannot be written to, that is new data cannot be loaded into the buffer. 1 Tx or Rx buffer is empty and can be written to, that is new data can be loaded into the buffer.

57.5 Functional description

This section provides a comprehensive functional description of the I2C module.

57.5.1 I2C protocol

The I2C bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfers.

All devices connected to it must have open drain or open collector outputs. A logic AND function is exercised on both lines with external pull-up resistors. The value of these resistors depends on the system.

Normally, a standard instance of communication is composed of four parts:

1. START signal
2. Slave address transmission
3. Data transfer
4. STOP signal

The STOP signal should not be confused with the CPU STOP instruction. The following figure illustrates I2C bus system communication.

Figure 57-2. I2C bus transmission signals

57.5.1.1 START signal

The bus is free when no master device is engaging the bus (both SCL and SDA are high). When the bus is free, a master may initiate communication by sending a START signal. A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer—each data transfer might contain several bytes of data—and brings all slaves out of their idle states.

57.5.1.2 Slave address transmission

Immediately after the START signal, the first byte of a data transfer is the slave address transmitted by the master. This address is a 7-bit calling address followed by an $R/\overline{W}$ bit. The $R/\overline{W}$ bit tells the slave the desired direction of data transfer.

- 1 = Read transfer: The slave transmits data to the master
- 0 = Write transfer: The master transmits data to the slave

Only the slave with a calling address that matches the one transmitted by the master responds by sending an acknowledge bit. The slave sends the acknowledge bit by pulling SDA low at the ninth clock.

No two slaves in the system can have the same address. If the I2C module is the master, it must not transmit an address that is equal to its own slave address. The I2C module cannot be master and slave at the same time. However, if arbitration is lost during an address cycle, the I2C module reverts to slave mode and operates correctly even if it is being addressed by another master.

57.5.1.3 Data transfers

When successful slave addressing is achieved, data transfer can proceed on a byte-by-byte basis in the direction specified by the $\overline{R/W}$ bit sent by the calling master.

All transfers that follow an address cycle are referred to as data transfers, even if they carry subaddress information for the slave device.

Each data byte is 8 bits long. Data may be changed only while SCL is low. Data must be held stable while SCL is high. There is one clock pulse on SCL for each data bit, and the MSB is transferred first. Each data byte is followed by a ninth (acknowledge) bit, which is signaled from the receiving device by pulling SDA low at the ninth clock. In summary, one complete data transfer needs nine clock pulses.

If the slave receiver does not acknowledge the master in the ninth bit, the slave must leave SDA high. The master interprets the failed acknowledgement as an unsuccessful data transfer.

If the master receiver does not acknowledge the slave transmitter after a data byte transmission, the slave interprets it as an end to data transfer and releases the SDA line.

In the case of a failed acknowledgement by either the slave or master, the data transfer is aborted and the master does one of two things:

- Relinquishes the bus by generating a STOP signal.
- Commences a new call by generating a repeated START signal.

57.5.1.4 STOP signal

The master can terminate the communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is asserted.

57.5.1.5 Repeated START signal

The master may generate a START signal followed by a calling command without generating a STOP signal first. This action is called a repeated START. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus. The master needs to send a NACK signal before sending repeated-START in the buffering mode.

57.5.1.6 Arbitration procedure

The I2C bus is a true multimaster bus that allows more than one master to be connected on it.

If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock. The bus clock's low period is equal to the longest clock low period, and the high period is equal to the shortest one among the masters.

The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic level 1 while another master transmits logic level 0. The losing masters immediately switch to slave receive mode and stop driving SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets a status bit to indicate the loss of arbitration.

57.5.1.7 Clock synchronization

Because wire AND logic is performed on SCL, a high-to-low transition on SCL affects all devices connected on the bus. The devices start counting their low period and, after a device's clock has gone low, that device holds SCL low until the clock reaches its high state. However, the change of low to high in this device clock might not change the state of SCL if another device clock is still within its low period. Therefore, the synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time; see the following diagram. When all applicable devices have counted off their low period, the synchronized clock SCL is released and pulled high. Afterward there is no difference between the device clocks and the state of SCL, and all devices start counting their high periods. The first device to complete its high period pulls SCL low again.

Figure 57-3. I2C clock synchronization

57.5.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. A slave device may hold SCL low after completing a single byte transfer (9 bits). In this case, it halts the bus clock and forces the master clock into wait states until the slave releases SCL.

57.5.1.9 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master drives SCL low, a slave can drive SCL low for the required period and then release it. If the slave's SCL low period is greater than the master's SCL low period, the resulting SCL bus signal's low period is stretched. In other words, the SCL bus signal's low period is increased to be the same length as the slave's SCL low period.

57.5.1.10 I2C divider and hold values

NOTE

For some cases on some devices, the SCL divider value may vary by ± 2 or ± 4 when ICR's value ranges from 00h to 0Fh. These potentially varying SCL divider values are highlighted in the following table.

Table 57-2. I2C divider and hold values

ICR (hex)	SCL divider	SDA hold value	SCL hold (start) value	SCL hold (stop) value	ICR (hex)	SCL divider (clocks)	SDA hold (clocks)	SCL hold (start) value	SCL hold (stop) value
00	20	7	6	11	20	160	17	78	81

57.5.2 10-bit address

For 10-bit addressing, 0x11110 is used for the first 5 bits of the first address byte. Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing.

57.5.2.1 Master-transmitter addresses a slave-receiver

The transfer direction is not changed. When a 10-bit address follows a START condition, each slave compares the first 7 bits of the first byte of the slave address (11110XX) with its own address and tests whether the eighth bit ($R/\overline{W}$ direction bit) is 0. It is possible that more than one device finds a match and generates an acknowledge (A1). Each slave that finds a match compares the 8 bits of the second byte of the slave address with its own address, but only one slave finds a match and generates an acknowledge (A2). The matching slave remains addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

Table 57-3. Master-transmitter addresses slave-receiver with a 10-bit address

S	Slave address first 7 bits 11110 + AD10 + AD9	R/W 0	A1	Slave address second byte AD[8:1]	A2	Data	A	...	Data	A/A	P

After the master-transmitter has sent the first byte of the 10-bit address, the slave-receiver sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

57.5.2.2 Master-receiver addresses a slave-transmitter

The transfer direction is changed after the second $R/\overline{W}$ bit. Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks whether the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and it tests whether the eighth ($R/\overline{W}$) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

After a repeated START condition (Sr), all other slave devices also compare the first seven bits of the first byte of the slave address with their own addresses and test the eighth ($R/\overline{W}$) bit. However, none of them are addressed because $R/\overline{W} = 1$ (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match.

Table 57-4. Master-receiver addresses a slave-transmitter with a 10-bit address

S	Slave address first 7 bits 11110 + AD10 + AD9	R/ $\overline{W}$ 0	A1	Slave address second byte AD[8:1]	A2	Sr	Slave address first 7 bits 11110 + AD10 + AD9	R/ $\overline{W}$ 1	A3	Data	A	...	Data	A	P

After the master-receiver has sent the first byte of the 10-bit address, the slave-transmitter sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

57.5.3 Address matching

All received addresses can be requested in 7-bit or 10-bit address format.

- AD[7:1] in Address Register 1, which contains the I2C primary slave address, always participates in the address matching process. It provides a 7-bit address.
- If the ADEXT bit is set, AD[10:8] in Control Register 2 participates in the address matching process. It extends the I2C primary slave address to a 10-bit address.

Additional conditions that affect address matching include:

- If the GCAEN bit is set, general call participates the address matching process.
- If the ALERTEN bit is set, alert response participates the address matching process.
- If the SIICAEN bit is set, Address Register 2 participates in the address matching process.
- If the RMEN bit is set, when the Range Address register is programmed to a nonzero value, any address within the range of values of Address Register 1 (excluded) and the Range Address register (included) participates in the address matching process. The Range Address register must be programmed to a value greater than the value of Address Register 1.

When the I2C module responds to one of these addresses, it acts as a slave-receiver and the IAAS bit is set after the address cycle. Software must read the Data register after the first byte transfer to determine that the address is matched.

57.5.4 System management bus specification

SMBus provides a control bus for system and power management related tasks. A system can use SMBus to pass messages to and from devices instead of tripping individual control lines.

Removing the individual control lines reduces pin count. Accepting messages ensures future expandability. With the system management bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status.

57.5.4.1 Timeouts

The $T_{\text{TIMEOUT},\text{MIN}}$ parameter allows a master or slave to conclude that a defective device is holding the clock low indefinitely or a master is intentionally trying to drive devices off the bus. The slave device must release the bus (stop driving the bus and let SCL and SDA float high) when it detects any single clock held low longer than $T_{\text{TIMEOUT},\text{MIN}}$. Devices that have detected this condition must reset their communication and be able to receive a new START condition within the timeframe of $T_{\text{TIMEOUT},\text{MAX}}$.

SMBus defines a clock low timeout, T_{TIMEOUT} , of 35 ms, specifies $T_{\text{LOW}:\text{SEXT}}$ as the cumulative clock low extend time for a slave device, and specifies $T_{\text{LOW}:\text{MEXT}}$ as the cumulative clock low extend time for a master device.

57.5.4.1.1 SCL low timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than a timeout value condition. Devices that have detected the timeout condition must reset the communication. When the I2C module is an active master, if it detects that SMBCLK low has exceeded the value of $T_{\text{TIMEOUT},\text{MIN}}$, it must generate a stop condition within or after the current data byte in the transfer process. When the I2C module is a slave, if it detects the $T_{\text{TIMEOUT},\text{MIN}}$ condition, it resets its communication and is then able to receive a new START condition.

57.5.4.1.2 SCL high timeout

When the I2C module has determined that the SMBCLK and SMBDAT signals have been high for at least $T_{\text{HIGH:MAX}}$, it assumes that the bus is idle.

A HIGH timeout occurs after a START condition appears on the bus but before a STOP condition appears on the bus. Any master detecting this scenario can assume the bus is free when either of the following occurs:

- SHTF1 rises.
- The BUSY bit is high and SHTF1 is high.

When the SMBDAT signal is low and the SMBCLK signal is high for a period of time, another kind of timeout occurs. The time period must be defined in software. SHTF2 is used as the flag when the time limit is reached. This flag is also an interrupt resource, so it triggers IICIF.

57.5.4.1.3 CSMBCLK TIMEOUT MEXT and CSMBCLK TIMEOUT SEXT

The following figure illustrates the definition of the timeout intervals $T_{\text{LOW:SEXT}}$ and $T_{\text{LOW:MEXT}}$. When in master mode, the I2C module must not cumulatively extend its clock cycles for a period greater than $T_{\text{LOW:MEXT}}$ within a byte, where each byte is defined as START-to-ACK, ACK-to-ACK, or ACK-to-STOP. When CSMBCLK TIMEOUT MEXT occurs, SMBus MEXT rises and also triggers the SLTF.

Figure 57-4. Timeout measurement intervals

A master is allowed to abort the transaction in progress to any slave that violates the $T_{\text{LOW:SEXT}}$ or $T_{\text{TIMEOUT,MIN}}$ specifications. To abort the transaction, the master issues a STOP condition at the conclusion of the byte transfer in progress. When a slave, the I2C module must not cumulatively extend its clock cycles for a period greater than $T_{\text{LOW:SEXT}}$ during any message from the initial START to the STOP. When CSMBCLK TIMEOUT SEXT occurs, SEXT rises and also triggers SLTF.

NOTE

CSMBCLK TIMEOUT SEXT and CSMBCLK TIMEOUT MEXT are optional functions that are implemented in the second step.

57.5.4.2 FAST ACK and NACK

To improve reliability and communication robustness, implementation of packet error checking (PEC) by SMBus devices is optional for SMBus devices but required for devices participating in and only during the address resolution protocol (ARP) process. The PEC is a CRC-8 error checking byte, calculated on all the message bytes. The PEC is appended to the message by the device that supplied the last data byte. If the PEC is present but not correct, a NACK is issued by the receiver. Otherwise an ACK is issued. To calculate the CRC-8 by software, this module can hold the SCL line low after receiving the eighth SCL (8th bit) if this byte is a data byte. So software can determine whether an ACK or NACK should be sent to the bus by setting or clearing the TXAK bit if the FACK (fast ACK/NACK enable) bit is enabled.

SMBus requires a device always to acknowledge its own address, as a mechanism to detect the presence of a removable device (such as a battery or docking station) on the bus. In addition to indicating a slave device busy condition, SMBus uses the NACK mechanism to indicate the reception of an invalid command or invalid data. Because such a condition may occur on the last byte of the transfer, SMBus devices are required to have the ability to generate the not acknowledge after the transfer of each byte and before the completion of the transaction. This requirement is important because SMBus does not provide any other resend signaling. This difference in the use of the NACK signaling has implications on the specific implementation of the SMBus port, especially in devices that handle critical system data such as the SMBus host and the SBS components.

NOTE

In the last byte of master receive slave transmit mode, the master must send a NACK to the bus, so FACK must be switched off before the last byte transmits.

57.5.5 Resets

The I2C module is disabled after a reset. The I2C module cannot cause a core reset.

57.5.6 Interrupts

The I2C module generates an interrupt when any of the events in the table found here occur, provided that the IICIE bit is set.

The interrupt is driven by the IICIF bit (of the I2C Status Register) and masked with the IICIE bit (of the I2C Control Register 1). The IICIF bit must be cleared (by software) by writing 1 to it in the interrupt routine. The SMBus timeouts interrupt is driven by SLTF and masked with the IICIE bit. The SLTF bit must be cleared by software by writing 1 to it in the interrupt routine. You can determine the interrupt type by reading the Status Register.

NOTE

In master receive mode, the FACK bit must be set to zero before the last byte transfer.

Table 57-5. Interrupt summary

Interrupt source	Status	Flag	Local enable
Complete 1-byte transfer	TCF	IICIF	IICIE
Match of received calling address	IAAS	IICIF	IICIE
Arbitration lost	ARBL	IICIF	IICIE
I ² C bus stop detection	STOPF	IICIF	IICIE & SSIE
I ² C bus start detection	STARTF	IICIF	IICIE & SSIE
SMBus SCL low timeout	SLTF	IICIF	IICIE
SMBus SCL high SDA low timeout	SHTF2	IICIF	IICIE & SHTF2IE
Wakeup from stop or wait mode	IAAS	IICIF	IICIE & WUEN

57.5.6.1 Byte transfer interrupt

The Transfer Complete Flag (TCF) bit is set at the falling edge of the ninth clock to indicate the completion of a byte and acknowledgement transfer. When FACK is enabled, TCF is then set at the falling edge of eighth clock to indicate the completion of byte.

57.5.6.2 Address detect interrupt

When the calling address matches the programmed slave address (I2C Address Register) or when the GCAEN bit is set and a general call is received, the IAAS bit in the Status Register is set. The CPU is interrupted, provided the IICIE bit is set. The CPU must check the SRW bit and set its Tx mode accordingly.

57.5.6.3 Stop Detect Interrupt

When the stop status is detected on the I²C bus, the STOPF bit is set to 1. The CPU is interrupted, provided the IICIE and SSIE bits are both set to 1.

57.5.6.4 Exit from low-power/stop modes

The slave receive input detect circuit and address matching feature are still active on low power modes (wait and stop). An asynchronous input matching slave address or general call address brings the CPU out of low power/stop mode if the interrupt is not masked. Therefore, TCF and IAAS both can trigger this interrupt.

57.5.6.5 Arbitration lost interrupt

The I2C is a true multimaster bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, the relative priority of the contending masters is determined by a data arbitration procedure. The I2C module asserts the arbitration-lost interrupt when it loses the data arbitration process and the ARBL bit in the Status Register is set.

Arbitration is lost in the following circumstances:

1. SDA is sampled as low when the master drives high during an address or data transmit cycle.
2. SDA is sampled as low when the master drives high during the acknowledge bit of a data receive cycle.
3. A START cycle is attempted when the bus is busy.
4. A repeated START cycle is requested in slave mode.
5. A STOP condition is detected when the master did not request it.

The ARBL bit must be cleared (by software) by writing 1 to it.

57.5.6.6 Timeout interrupt in SMBus

When the IICIE bit is set, the I2C module asserts a timeout interrupt (outputs SLTF and SHTF2) upon detection of any of the mentioned timeout conditions, with one exception. The SCL high and SDA high TIMEOUT mechanism must not be used to influence the timeout interrupt output, because this timeout indicates an idle condition on the bus. SHTF1 rises when it matches the SCL high and SDA high TIMEOUT and falls automatically just to indicate the bus status. The SHTF2's timeout period is the same as that of SHTF1, which is short compared to that of SLTF, so another control bit, SHTF2IE, is added to enable or disable it.

57.5.7 Programmable input glitch filter

An I2C glitch filter has been added outside legacy I2C modules but within the I2C package. This filter can absorb glitches on the I2C clock and data lines for the I2C module.

The width of the glitch to absorb can be specified in terms of the number of (half) I2C module clock cycles. A single Programmable Input Glitch Filter control register is provided. Effectively, any down-up-down or up-down-up transition on the data line that occurs within the number of clock cycles programmed in this register is ignored by the I2C module. The programmer must specify the size of the glitch (in terms of I2C module clock cycles) for the filter to absorb and not pass.

Figure 57-5. Programmable input glitch filter diagram

57.5.8 Address matching wake-up

When a primary, range, or general call address match occurs when the I2C module is in slave receive mode, the MCU wakes from a low power mode where no peripheral bus is running.

Data sent on the bus that is the same as a target device address might also wake the target MCU.

After the address matching IAAS bit is set, an interrupt is sent at the end of address matching to wake the core. The IAAS bit must be cleared after the clock recovery.

NOTE

After the system recovers and is in Run mode, restart the I2C module if it is needed to transfer packets. To avoid I2C transfer problems resulting from the situation, firmware should prevent the MCU execution of a STOP instruction when the I2C module is in the middle of a transfer unless the Stop mode holdoff feature is used during this period (set FLT[SHEN] to 1).

NOTE

After I2C address matching wake-up, the master must wait a time long enough for the slave ISR to finish running and resend start or repeat start signals.

For the SRW bit to function properly, it only supports Address+Write to wake up by I2C address matching. Before entering the next low power mode, Address+Write must be sent to change the SRW status.

57.5.9 DMA support

If the DMAEN bit is cleared and the IICIE bit is set, an interrupt condition generates an interrupt request.

If the DMAEN bit is set and the IICIE bit is set, an interrupt condition generates a DMA request instead. DMA requests are generated by the transfer complete flag (TCF).

If the DMAEN bit is set, only the TCF initiates a DMA request. All other events generate CPU interrupts.

NOTE

Before the last byte of master receive mode, TXAK must be set to send a NACK after the last byte's transfer. Therefore, the DMA must be disabled before the last byte's transfer.

NOTE

In 10-bit address mode transmission, the addresses to send occupy 2–3 bytes. During this transfer period, the DMA must be disabled because the C1 register is written to send a repeat start or to change the transfer direction.

57.5.10 Double buffering mode

In the double buffering mode, the data transfer is processed byte by byte. However, the data can be transferred without waiting for the interrupt or the polling to finish. This means the write/read I2C_D operation will not block the data transfer, as the hardware has already finished the internal write or read. The benefit is that the baud rate is able to achieve higher speed.

There are several items to consider as follows:

- When initiating a double buffering transfer at Tx side, the user can write 2 values to the I2C_D buffer before transfer. However, that is allowed only at one time per package frame (due to the buffer depth, and because two-times writes in each ISR are not allowed). The second write to the I2C_D buffer must wait for the Empty flag. On the other hand, at Rx side the user can read twice in a one-byte transfer (if needed).

NOTE

Check Empty flag before write to I2C_D.

Write twice to the I2C_D buffer ONLY after the address matching byte. Do not write twice (Address+Data) before START or at the beginning of I2C transfer, especially when the baud rate is very slow.

- To write twice in one frame, during the next-to-last ISR, do a dummy read from the I2C_D buffer at Tx side (or the TCF will stay high, because the TCF is cleared by write/read operation). In the next-to-last ISR, do not send data again (the buffer data will be under running).
- To keep new ISRs software-compatible with previous ISRs, the write/read I2C_D operation will not block the internal-hardware-released SCL/SDA signals. At the ACK phase, the bus is released to accept the next byte if the master can send the clock immediately.
- On the slave side, two-times writes to the I2C_D buffer may be limited by the master's clock and START/repeated-START signal. This is not currently supported, and the master's START/repeated-START signal will break data transfers. To release the bus, do a dummy read or write to the I2C_D buffer again. It is suggested to send repeated-START/START during intervals as before.
- The master receive should send a NACK in the next-to-last ISR, if it wants to do the STOP or the repeated-START work. The transmitting slave which receives the NACK, will switch to receive mode, and do a dummy read to release SCL and SDA signals.

57.6 Initialization/application information

Module Initialization (Slave)

1. Write: Control Register 2
 - to enable or disable general call
 - to select 10-bit or 7-bit addressing mode
2. Write: Address Register 1 to set the slave address
3. Write: Control Register 1 to enable the I2C module and interrupts
4. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
5. Initialize RAM variables used to achieve the routine shown in the following figure

Module Initialization (Master)

1. Write: Frequency Divider register to set the I2C baud rate (see example in description of [ICR](#))
2. Write: Control Register 1 to enable the I2C module and interrupts
3. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
4. Initialize RAM variables used to achieve the routine shown in the following figure
5. Write: Control Register 1 to enable TX
6. Write: Control Register 1 to enable MST (master mode)
7. Write: Data register with the address of the target slave (the LSB of this byte determines whether the communication is master receive or transmit)

The routine shown in the following figure encompasses both master and slave I2C operations. For slave operation, an incoming I2C message that contains the proper address begins I2C communication. For master operation, communication must be initiated by writing the Data register. An example of an I2C driver which implements many of the steps described here is available in [AN4342: Using the Inter-Integrated Circuit on ColdFire+ and Kinetis](#) .

Notes:

1. If general call is enabled, check to determine if the received address is a general call address (0x00).
If the received address is a general call address, the general call must be handled by user software.
2. When 10-bit addressing addresses a slave, the slave sees an interrupt following the first byte of the extended address.
Ensure that for this interrupt, the contents of the Data register are ignored and not treated as a valid data transfer.

Figure 57-6. Typical I2C interrupt routine

Notes:

1. If general call or SIICAEN is enabled, check to determine if the received address is a general call address (0x00) or an SMBus device default address. In either case, they must be handled by user software.
2. In receive mode, one bit time delay may be needed before the stop signal generation, to wait for the possible longest time period (in worst case) of the 9th SCL cycle.

Figure 57-7. Typical I2C SMBus interrupt routine

Chapter 58

Low Power Universal asynchronous receiver/transmitter (LPUART)

58.1 Chip-specific LPUART information

58.1.1 LPUART overview

The LPUART module supports basic UART with DMA interface function and x4 to x32 oversampling of baud-rate.

The module can remain functional in Stop and VLPS mode provided the clock it is using remains enabled.

This module supports LIN slave operation.

NOTE

LPUART2 pins can be muxed over USB. See USB chapter for more detail.

58.1.2 LPUART Instantiation

This device contains 5 LPUART modules. This section describes how each module is configured on this device.

Table 58-1. LPUART instantiations

Feature	Receive Buffer Size
LPUARTs instantiated	5
LPUART0 FIFO (RX & TX)	8 Words
LPUART1 FIFO (RX & TX)	8 Words

Table continues on the next page...

Table 58-1. LPUART instantiations (continued)

Feature	Receive Buffer Size
LPUART2 FIFO (RX & TX)	8 Words
LPUART3 FIFO (RX & TX)	8 Words
LPUART4 FIFO (RX & TX)	8 Words

58.2 Introduction

58.2.1 Features

Features of the LPUART module include:

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Transmit and receive baud rate can operate asynchronous to the bus clock:
 - Baud rate can be configured independently of the bus clock frequency
 - Supports operation in Stop modes
- Interrupt, DMA or polled operation:
 - Transmit data register empty and transmission complete
 - Receive data register full
 - Receive overrun, parity error, framing error, and noise error
 - Idle receiver detect
 - Active edge on receive pin
 - Break detect supporting LIN
 - Receive data match
- Hardware parity generation and checking
- Programmable 8-bit, 9-bit or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Three receiver wakeup methods:
 - Idle line wakeup
 - Address mark wakeup
 - Receive data match
- Automatic address matching to reduce ISR overhead:
 - Address mark matching
 - Idle line address matching
 - Address match start, address match end
- Optional 13-bit break character generation / 11-bit break character detection

- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64 or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
 - Separate configurable watermark for receive and transmit requests
 - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

58.2.2 Modes of operation

58.2.2.1 Stop mode

The LPUART will remain functional during Stop mode, provided the asynchronous transmit and receive clock remains enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from Stop mode.

58.2.2.2 Wait mode

The LPUART can be configured to Stop in Wait modes, when the DOZEEN bit is set. The transmitter and receiver will finish transmitting/receiving the current word.

58.2.2.3 Debug mode

The LPUART remains functional in debug mode.

58.2.3 Signal Descriptions

Signal	Description	I/O
LPUART_TX	Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data.	I/O

Table continues on the next page...

Signal	Description	I/O
LPUART_RX	Receive data.	I
LPUART_CTS	Clear to send.	I
LPUART_RTS	Request to send.	O

58.2.4 Block diagram

The following figure shows the transmitter portion of the LPUART.

Figure 58-1. LPUART transmitter block diagram

The following figure shows the receiver portion of the LPUART.

Figure 58-2. LPUART receiver block diagram

58.3 Register definition

The LPUART includes registers to control baud rate, select LPUART options, report LPUART status, and for transmit/receive data. Access to an address outside the valid memory map will generate a bus error.

LPUART memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400C_4000	LPUART Baud Rate Register (LPUART0_BAUD)	32	R/W	0F00_0004h	58.3.1/1841

LPUARTx_BAUD field descriptions

Field	Description
31 MAEN1	Match Address Mode Enable 1 0 Normal operation. 1 Enables automatic address matching or data matching mode for MATCH[MA1].
30 MAEN2	Match Address Mode Enable 2 0 Normal operation. 1 Enables automatic address matching or data matching mode for MATCH[MA2].
29 M10	10-bit Mode select The M10 bit causes a tenth bit to be part of the serial transmission. This bit should only be changed when the transmitter and receiver are both disabled. 0 Receiver and transmitter use 8-bit or 9-bit data characters. 1 Receiver and transmitter use 10-bit data characters.
28–24 OSR	Oversampling Ratio This field configures the oversampling ratio for the receiver between 4x (00011) and 32x (11111). Writing an invalid oversampling ratio (for example, a value not between 4x and 32x) will default to an oversampling ratio of 16 (01111). The OSR field should only be changed when the transmitter and receiver are both disabled. Note that the oversampling ratio = OSR + 1.
23 TDMAE	Transmitter DMA Enable TDMAE configures the transmit data register empty flag, LPUART_STAT[TDRE], to generate a DMA request. 0 DMA request disabled. 1 DMA request enabled.

Table continues on the next page...

LPUARTx_BAUD field descriptions (continued)

Field	Description
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 RDMAE	Receiver Full DMA Enable RDMAE configures the receiver data register full flag, LPUART_STAT[RDRF], to generate a DMA request. 0 DMA request disabled. 1 DMA request enabled.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–18 MATCFG	Match Configuration Configures the match addressing mode used. 00 Address Match Wakeup 01 Idle Match Wakeup 10 Match On and Match Off 11 Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled. 0 Receiver samples input data using the rising edge of the baud rate clock. 1 Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	Resynchronization Disable When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled. 0 Resynchronization during received data word is supported 1 Resynchronization during received data word is disabled
15 LBKDIE	LIN Break Detect Interrupt Enable LBKDIE enables the LIN break detect flag, LBKDIF, to generate interrupt requests. 0 Hardware interrupts from LPUART_STAT[LBKDIF] disabled (use polling). 1 Hardware interrupt requested when LPUART_STAT[LBKDIF] flag is 1.
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables the receive input active edge, RXEDGIF, to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the RXEDGIF to set. 0 Hardware interrupts from LPUART_STAT[RXEDGIF] disabled (use polling). 1 Hardware interrupt requested when LPUART_STAT[RXEDGIF] flag is 1.
13 SBNS	Stop Bit Number Select SBNS determines whether data characters are one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled.

Table continues on the next page...

LPUARTx_BAUD field descriptions (continued)

Field	Description
	0 One stop bit. 1 Two stop bits.
SBR	Baud Rate Modulo Divisor. The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must only be updated when the transmitter and receiver are both disabled (LPUART_CTRL[RE] and LPUART_CTRL[TE] are both 0).

58.3.2 LPUART Status Register (LPUARTx_STAT)

Address: Base address + 4h offset

LPUARTx_STAT field descriptions

Field	Description
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.

Table continues on the next page...

LPUARTx_STAT field descriptions (continued)

Field	Description
	0 No LIN break character has been detected. 1 LIN break character has been detected.
30 RXEDGIF	LPUART_RX Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the LPUART_RX pin occurs. RXEDGIF is cleared by writing a 1 to it. 0 No active edge on the receive pin has occurred. 1 An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled. 0 LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1 MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE].
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. NOTE: Setting RXINV inverts the LPUART_RX input for all cases: data bits, start and stop bits, break, and idle. 0 Receive data not inverted. 1 Receive data inverted.
27 RWUID	Receive Wake Up Idle Detect For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled. 0 During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not get set when an address does not match. 1 During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does get set when an address does not match.
26 BRK13	Break Character Generation Length BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. 0 Break character is transmitted with length of 10 bit times (if M = 0, SBNS = 0) or 11 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 12 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 13 (if M10 = 1, SNBS = 1). 1 Break character is transmitted with length of 13 bit times (if M = 0, SBNS = 0) or 14 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 15 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 16 (if M10 = 1, SNBS = 1).
25 LBKDE	LIN Break Detection Enable LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer.

Table continues on the next page...

LPUARTx_STAT field descriptions (continued)

Field	Description
	0 Break character is detected at length 10 bit times (if M = 0, SBNS = 0) or 11 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 12 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 13 (if M10 = 1, SNBS = 1). 1 Break character is detected at length of 11 bit times (if M = 0, SBNS = 0) or 12 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 14 (if M = 1, SBNS = 1 or M10 = 1, SNBS = 0) or 15 (if M10 = 1, SNBS = 1).
24 RAF	Receiver Active Flag RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. 0 LPUART receiver idle waiting for a start bit. 1 LPUART receiver active (LPUART_RX input not idle).
23 TDRE	Transmit Data Register Empty Flag When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (LPUART_DATA) is equal to or less than the number indicated by LPUART_WATER[TXWATER]. To clear TDRE, write to the LPUART data register (LPUART_DATA) until the number of words in the transmit FIFO is greater than the number indicated by LPUART_WATER[TXWATER]. When the transmit FIFO is disabled, TDRE will set when the transmit data register (LPUART_DATA) is empty. To clear TDRE, write to the LPUART data register (LPUART_DATA). TDRE is not affected by a character that is in the process of being transmitted, it is updated at the start of each transmitted character. 0 Transmit data buffer full. 1 Transmit data buffer empty.
22 TC	Transmission Complete Flag TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to LPUART_DATA to transmit new data, queuing a preamble by clearing and then setting LPUART_CTRL[TE], queuing a break character by writing 1 to LPUART_CTRL[SBK]. 0 Transmitter active (sending data, a preamble, or a break). 1 Transmitter idle (transmission activity complete).
21 RDRF	Receive Data Register Full Flag When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by LPUART_WATER[RXWATER]. To clear RDRF, read LPUART_DATA until the number of datawords in the receive data buffer is equal to or less than the number indicated by LPUART_WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (LPUART_DATA) is full. To clear RDRF, read the LPUART_DATA register. A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received. 0 Receive data buffer empty. 1 Receive data buffer full.
20 IDLE	Idle Line Flag IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When ILT is set, the receiver doesn't start counting

Table continues on the next page...

LPUARTx_STAT field descriptions (continued)

Field	Description
	idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line. To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot become set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag. IDLE is set only once even if the receive line remains idle for an extended period. 0 No idle line detected. 1 Idle line was detected.
19 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received. While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag. 0 No overrun. 1 Receive overrun (new LPUART data lost).
18 NF	Noise Flag The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from LPUART_DATA was received with noise detected within the character. To clear NF, write logic one to the NF. 0 No noise detected. 1 Noise detected in the received character in LPUART_DATA.
17 FE	Framing Error Flag FE is set whenever the next character to be read from LPUART_DATA was received with logic 0 detected where a stop bit was expected. To clear FE, write logic one to the FE. 0 No framing error detected. This does not guarantee the framing is correct. 1 Framing error.
16 PF	Parity Error Flag PF is set whenever the next character to be read from LPUART_DATA was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic one to the PF. 0 No parity error. 1 Parity error.
15 MA1F	Match 1 Flag MA1F is set whenever the next character to be read from LPUART_DATA matches MA1. To clear MA1F, write a logic one to the MA1F. 0 Received data is not equal to MA1 1 Received data is equal to MA1

Table continues on the next page...

LPUARTx_STAT field descriptions (continued)

Field	Description
14 MA2F	Match 2 Flag MA2F is set whenever the next character to be read from LPUART_DATA matches MA2. To clear MA2F, write a logic one to the MA2F. 0 Received data is not equal to MA2 1 Received data is equal to MA2
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.3.3 LPUART Control Register (LPUARTx_CTRL)

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LPUARTx_CTRL field descriptions

Field	Description
31 R8T9	Receive Bit 8 / Transmit Bit 9 R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading LPUART_DATA. T9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing LPUART_DATA. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.
30 R9T8	Receive Bit 9 / Transmit Bit 8

Table continues on the next page...

LPUARTx_CTRL field descriptions (continued)

Field	Description
	R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading LPUART_DATA T8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing LPUART_DATA. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.
29 TXDIR	LPUART_TX Pin Direction in Single-Wire Mode When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the LPUART_TX pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the LPUART_TX pin. 0 LPUART_TX pin is an input in single-wire mode. 1 LPUART_TX pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion Setting this bit reverses the polarity of the transmitted data output. NOTE: Setting TXINV inverts the LPUART_TX output for all cases: data bits, start and stop bits, break, and idle. 0 Transmit data not inverted. 1 Transmit data inverted.
27 ORIE	Overrun Interrupt Enable This bit enables the overrun flag (OR) to generate hardware interrupt requests. 0 OR interrupts disabled; use polling. 1 Hardware interrupt requested when OR is set.
26 NEIE	Noise Error Interrupt Enable This bit enables the noise flag (NF) to generate hardware interrupt requests. 0 NF interrupts disabled; use polling. 1 Hardware interrupt requested when NF is set.
25 FEIE	Framing Error Interrupt Enable This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0 FE interrupts disabled; use polling. 1 Hardware interrupt requested when FE is set.
24 PEIE	Parity Error Interrupt Enable This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0 PF interrupts disabled; use polling). 1 Hardware interrupt requested when PF is set.
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests.

Table continues on the next page...

LPUARTx_CTRL field descriptions (continued)

Field	Description
	0 Hardware interrupts from TDRE disabled; use polling. 1 Hardware interrupt requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0 Hardware interrupts from TC disabled; use polling. 1 Hardware interrupt requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate interrupt requests. 0 Hardware interrupts from RDRF disabled; use polling. 1 Hardware interrupt requested when RDRF flag is 1.
20 ILIE	Idle Line Interrupt Enable ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0 Hardware interrupts from IDLE disabled; use polling. 1 Hardware interrupt requested when IDLE flag is 1.
19 TE	Transmitter Enable Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the LPUART_TX pin is tristated. 0 Transmitter disabled. 1 Transmitter enabled.
18 RE	Receiver Enable Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any). 0 Receiver disabled. 1 Receiver enabled.
17 RWU	Receiver Wakeup Control This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear. NOTE: RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted. 0 Normal receiver operation. 1 LPUART receiver in standby waiting for wakeup condition.
16 SBK	Send Break Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 10 to 13, or 13 to 16 if LPUART_STATBRK13 is set, bit times of logic 0 are queued as long

Table continues on the next page...

LPUARTx_CTRL field descriptions (continued)

Field	Description
	as SBK is set. Depending on the timing of the set and clear of SBK relative to the information currently being transmitted, a second break character may be queued before software clears SBK. 0 Normal transmitter operation. 1 Queue break character(s) to be sent.
15 MA1IE	Match 1 Interrupt Enable 0 MA1F interrupt disabled 1 MA1F interrupt enabled
14 MA2IE	Match 2 Interrupt Enable 0 MA2F interrupt disabled 1 MA2F interrupt enabled
13–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before the IDLE flag is set. 000 1 idle character 001 2 idle characters 010 4 idle characters 011 8 idle characters 100 16 idle characters 101 32 idle characters 110 64 idle characters 111 128 idle characters
7 LOOPS	Loop Mode Select When LOOPS is set, the LPUART_RX pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function. 0 Normal operation - LPUART_RX and LPUART_TX use separate pins. 1 Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0 LPUART is enabled in Doze mode. 1 LPUART is disabled in Doze mode.
5 RSRC	Receiver Source Select This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0 Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the LPUART_RX pin. 1 Single-wire LPUART mode where the LPUART_TX pin is connected to the transmitter output and receiver input.
4 M	9-Bit or 8-Bit Mode Select

Table continues on the next page...

LPUARTx_CTRL field descriptions (continued)

Field	Description
	0 Receiver and transmitter use 8-bit data characters. 1 Receiver and transmitter use 9-bit data characters.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the LPUART when RWU=1: • Address mark in the most significant bit position of a received data character, or • An idle condition on the receive pin input signal. 0 Configures RWU for idle-line wakeup. 1 Configures RWU with address-mark wakeup.
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. NOTE: In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0 Idle character bit count starts after start bit. 1 Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0 No hardware parity generation or checking. 1 Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even. 0 Even parity. 1 Odd parity.

58.3.4 LPUART Data Register (LPUARTx_DATA)

This register is actually two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer. Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

Address: Base address + Ch offset

LPUARTx_DATA field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 NOISY	The current received dataword contained in DATA[R9:R0] was received with noise. 0 The dataword was received without noise. 1 The data was received with noise.
14 PARITYE	The current received dataword contained in DATA[R9:R0] was received with a parity error.

Table continues on the next page...

LPUARTx_DATA field descriptions (continued)

Field	Description
	0 The dataword was received without a parity error. 1 The dataword was received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0 The dataword was received without a frame error on read, transmit a normal character on write. 1 The dataword was received with a frame error, transmit an idle or break character on transmit.
12 RXEMPT	Receive Buffer Empty Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0 Receive buffer contains valid data. 1 Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0 Receiver was not idle before receiving this character. 1 Receiver was idle before receiving this character.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 R9T9	Read receive data buffer 9 or write transmit data buffer 9.
8 R8T8	Read receive data buffer 8 or write transmit data buffer 8.
7 R7T7	Read receive data buffer 7 or write transmit data buffer 7.
6 R6T6	Read receive data buffer 6 or write transmit data buffer 6.
5 R5T5	Read receive data buffer 5 or write transmit data buffer 5.
4 R4T4	Read receive data buffer 4 or write transmit data buffer 4.
3 R3T3	Read receive data buffer 3 or write transmit data buffer 3.
2 R2T2	Read receive data buffer 2 or write transmit data buffer 2.
1 R1T1	Read receive data buffer 1 or write transmit data buffer 1.
0 R0T0	Read receive data buffer 0 or write transmit data buffer 0.

58.3.5 LPUART Match Address Register (LPUARTx_MATCH)

Address: Base address + 10h offset

LPUARTx_MATCH field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–16 MA2	Match Address 2 The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MA1	Match Address 1 The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear.

58.3.6 LPUART Modem IrDA Register (LPUARTx_MODIR)

The MODEM register controls options for setting the modem configuration.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LPUARTx_MODIR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. 0 IR disabled. 1 IR enabled.
17–16 TNP	Transmitter narrow pulse Enables whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse. 00 1/OSR. 01 2/OSR. 10 3/OSR. 11 4/OSR.
15–8 RTSWATER	Receive RTS Configuration Configures the point at which the RX RTS output negates based on the number of additional characters that can be stored in the Receive FIFO. When configured to 0, RTS negates when the the start bit is detected for the character that will cause the FIFO to become full. 0 RTS asserts when the receiver FIFO is full or receiving a character that causes the FIFO to become full. 1 RTS asserts when the receive FIFO is less than or equal to the RXWATER configuration and negates when the receive FIFO is greater than the RXWATER configuration.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0 CTS input is the LPUART_CTS pin. 1 CTS input is the inverted Receiver Match result.
4 TXCTSC	Transmit CTS Configuration Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0 CTS input is sampled at the start of each character. 1 CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. NOTE: Do not set both RXRTSE and TXRTSE. 0 The receiver has no effect on RTS. 1 RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full. RTS assertion is configured by the RTSWATER field

Table continues on the next page...

LPUARTx_MODIR field descriptions (continued)

Field	Description
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. 0 Transmitter RTS is active low. 1 Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission. 0 The transmitter has no effect on RTS. 1 When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0 CTS has no effect on the transmitter. 1 Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

58.3.7 LPUART FIFO Register (LPUARTx_FIFO)

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

LPUARTx_FIFO field descriptions (continued)

Field	Description
22 RXEMPT	Receive Buffer/FIFO Empty Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0 Receive buffer is not empty. 1 Receive buffer is empty.
21–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 TXOF	Transmitter Buffer Overflow Flag Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of TXOFE. However, an interrupt will be issued to the host only if TXOFE is set. This flag is cleared by writing a 1. 0 No transmit buffer overflow has occurred since the last time the flag was cleared. 1 At least one transmit buffer overflow has occurred since the last time the flag was cleared.
16 RXUF	Receiver Buffer Underflow Flag Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of RXUFE. However, an interrupt will be issued to the host only if RXUFE is set. This flag is cleared by writing a 1. 0 No receive buffer underflow has occurred since the last time the flag was cleared. 1 At least one receive buffer underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO/Buffer Flush Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register. 0 No flush operation occurs. 1 All data in the transmit FIFO/Buffer is cleared out.
14 RXFLUSH	Receive FIFO/Buffer Flush Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register. 0 No flush operation occurs. 1 All data in the receive FIFO/buffer is cleared out.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–10 RXIDEN	Receiver Idle Empty Enable When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. 000 Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters.

Table continues on the next page...

LPUARTx_FIFO field descriptions (continued)

Field	Description
	110 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111 Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0 TXOF flag does not generate an interrupt to the host. 1 TXOF flag generates an interrupt to the host.
8 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0 RXUF flag does not generate an interrupt to the host. 1 RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0 Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support). 1 Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.
6–4 TXFIFOSIZE	Transmit FIFO. Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only. 000 Transmit FIFO/Buffer depth = 1 dataword. 001 Transmit FIFO/Buffer depth = 4 datawords. 010 Transmit FIFO/Buffer depth = 8 datawords. 011 Transmit FIFO/Buffer depth = 16 datawords. 100 Transmit FIFO/Buffer depth = 32 datawords. 101 Transmit FIFO/Buffer depth = 64 datawords. 110 Transmit FIFO/Buffer depth = 128 datawords. 111 Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	Receive FIFO Enable When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0 Receive FIFO is not enabled. Buffer is depth 1. (Legacy support) 1 Receive FIFO is enabled. Buffer is depth indicated by RXFIFOSIZE.
RXFIFOSIZE	Receive FIFO. Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only. 000 Receive FIFO/Buffer depth = 1 dataword.

Table continues on the next page...

LPUARTx_FIFO field descriptions (continued)

Field	Description
001	Receive FIFO/Buffer depth = 4 datawords.
010	Receive FIFO/Buffer depth = 8 datawords.
011	Receive FIFO/Buffer depth = 16 datawords.
100	Receive FIFO/Buffer depth = 32 datawords.
101	Receive FIFO/Buffer depth = 64 datawords.
110	Receive FIFO/Buffer depth = 128 datawords.
111	Receive FIFO/Buffer depth = 256 datawords.

58.3.8 LPUART Watermark Register (LPUARTx_WATER)

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LPUARTx_WATER field descriptions

Field	Description
31–24 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.
23–16 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE] and must be greater than 0.
15–8 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.
TXWATER	Transmit Watermark When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

LPUARTx_WATER field descriptions (continued)

Field	Description

58.4 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

58.4.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derive the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to SBR[12:0] determines the baud clock divisor for the asynchronous LPUART baud clock. The SBR bits are in the LPUART baud rate registers, BDH and BDL. The baud rate clock drives the receiver, while the transmitter is driven by the baud rate clock divided by the over sampling ratio. Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

Figure 58-3. LPUART baud rate generation

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

58.4.2 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (LPUART_TX) idle state defaults to logic high, CTRL[TXINV] is cleared following reset. The transmitter output is inverted by setting CTRL[TXINV]. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the LPUART data register.

The central element of the LPUART transmitter is the transmit shift register that is 10-bit to 13 bits long depending on the setting in the CTRL[M], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit data buffer at LPUART_DATA.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the LPUART_TX pin, the transmitter sets the transmit complete flag and enters an idle mode, with LPUART_TX high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter will not start transmitting another character.

58.4.2.1 Send break and queued idle

The LPUART_CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 10-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting LPUART_STAT[BRK13]. Normally, a program would wait for LPUART_STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the LPUART_CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If LPUART_CTRL[SBK] remains 1 when the queued break moves into the shifter,

synchronized to the baud rate clock, an additional break character is queued. If the receiving device is another LPUART, the break characters are received as 0s in all data bits and a framing error (LPUART_STAT[FE] = 1) occurs.

A break character can also be transmitted by writing to the LPUART_DATA register with bit 13 set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for LPUART_STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the LPUART_CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while LPUART_CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the LPUART_TX pin.

An idle character can also be transmitted by writing to the LPUART_DATA register with bit 13 set and the data bits also set. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a break character.

The length of the break character is affected by the LPUART_STAT[BRK13], LPUART_CTRL[M], LPUART_BAUD[M10] and LPUART_BAUD[SNBS] bits as shown below.

Table 58-2. Break character length

BRK13	M	M10	SNBS	Break character length
0	0	0	0	10 bit times
0	0	0	1	11 bit times
0	1	0	0	11 bit times
0	1	0	1	12 bit times
0	X	1	0	12 bit times
0	X	1	1	13 bit times
1	0	0	0	13 bit times
1	0	0	1	13 bit times
1	1	0	0	14 bit times
1	1	0	1	14 bit times
1	X	1	0	15 bit times
1	X	1	1	15 bit times

58.4.2.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS. If the clear-to-send operation is enabled, the character is transmitted when CTS is asserted. If CTS is deasserted in the middle of a transmission with characters remaining in the receiver data buffer, the character in the shift register is sent and LPUART_TX remains in the mark state until CTS is reasserted.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS.

The transmitter's CTS signal can also be enabled even if the same LPUART receiver's RTS signal is disabled.

58.4.2.3 Transceiver driver enable

The transmitter can use LPUART_RTS as an enable signal for the driver of an external transceiver. See [Transceiver driver enable using LPUART_RTS](#) for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, LPUART_RTS asserts one bit time before the start bit is transmitted. LPUART_RTS remains asserted for the whole time that the transmitter data buffer has any characters. LPUART_RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts LPUART_RTS, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's LPUART_RTS signal asserts only when the transmitter is enabled. However, the transmitter's LPUART_RTS signal is unaffected by its LPUART_CTS signal. LPUART_RTS will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

58.4.2.4 Transceiver driver enable using LPUART_RTS

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the UART is driving. The LPUART_RTS signal can be used by the transmitter to enable the driver of a transceiver. The polarity of LPUART_RTS can be matched to the polarity of the transceiver's driver enable signal.

Figure 58-4. Transceiver driver enable using LPUART_RTS

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect LPUART_RTS to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull LPUART_RX to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the LPUART_RX pin for other uses.

58.4.3 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting LPUART_STAT[RXINV]. The receiver is enabled by setting the LPUART_CTRL[RE] bit. Character frames consist of a start bit of logic 0, eight to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 9-bit or 10-bit data mode, refer to [8-bit, 9-bit and 10-bit data modes](#). For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (LPUART_STAT[RDRF]) status flag is set. If LPUART_STAT[RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost. Because the LPUART receiver is double-buffered, the program has one full character time after LPUART_STAT[RDRF] is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full (LPUART_STAT[RDRF] = 1), it gets the data from the receive data register by reading LPUART_DATA. Refer to [Interrupts and status flags](#) for details about flag clearing.

58.4.3.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between $4\times$ and $32\times$ of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the LPUART_RX serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at $(OSR/2)$, $(OSR/2)+1$, and $(OSR/2)+2$ to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at $(OSR/2)$, $(OSR/2)+1$, and $(OSR/2)+2$ to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (LPUART_STAT[NF]) is set when the received character is transferred to the receive data buffer.

When the LPUART receiver is configured to sample on both edges of the baud rate clock, the number of segments in each received bit is effectively doubled (from 1 to $OSR\times 2$). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of $4\times$ to $7\times$ and is optional for higher oversampling rates.

The falling edge detection logic continuously looks for falling edges. If an edge is detected, the sample clock is resynchronized to bit times (unless resynchronization has been disabled). This improves the reliability of the receiver in the presence of noise or mismatched baud rates. It does not improve worst case analysis because some characters do not have any extra falling edges anywhere in the character frame.

In the case of a framing error, provided the received character was not a break character, the sampling logic that searches for a falling edge is filled with three logic 1 samples so that a new start bit can be detected almost immediately.

58.4.3.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (LPUART_CTRL[RWU]). When RWU bit and LPUART_S2[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, IDLE, are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, or at the beginning of the next message, all receivers automatically force LPUART_CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver will ignore all characters that do not meet the address match requirements.

Table 58-3. Receiver Wakeup Options

RWU	MA1 MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
0	0	X	X	Normal operation
1	0	00	00	Receiver wakeup on idle line, IDLE flag not set
1	0	00	01	Receiver wakeup on idle line, IDLE flag set
1	0	00	10	Receiver wakeup on address mark
1	1	11	X0	Receiver wakeup on data match
0	1	00	X0	Address mark address match, IDLE flag not set for discarded characters
0	1	00	X1	Address mark address match, IDLE flag set for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Address match on and address match off, IDLE flag not set for discarded characters
0	1	10	X1	Address match on and address match off, IDLE flag set for discarded characters

58.4.3.2.1 Idle-line wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, LPUART_CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The LPUART_CTRL[M] and LPUART_BAUD[M10] control bit selects 8-bit to 10-bit data mode and the LPUART_BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 10 to 13 bit times because of the start and stop bits.

When LPUART_CTRL[RWU] is one and LPUART_STAT[RWUID] is zero, the idle condition that wakes up the receiver does not set the LPUART_STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the LPUART_STAT[RDRF] flag and generates an interrupt if enabled. When LPUART_STAT[RWUID] is one, any idle condition sets the LPUART_STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether LPUART_CTRL[RWU] is zero or one.

The idle-line type (LPUART_CTRL[ILT]) control bit selects one of two ways to detect an idle line. When LPUART_CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When LPUART_CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

58.4.3.2.2 Address-mark wakeup

When LPUART_CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, LPUART_CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of a received character.

Address-mark wakeup allows messages to contain idle characters, but requires the MSB be reserved for use in address frames. The logic 1 in the MSB of an address frame clears the LPUART_CTRL[RWU] bit before the stop bits are received and sets the LPUART_STAT[RDRF] flag. In this case, the character with the MSB set is received even though the receiver was sleeping during most of this character time.

58.4.3.2.3 Data match wakeup

When LPUART_CTRL[RWU] is set and LPUART_BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, LPUART_CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

58.4.3.2.4 Address Match operation

Address match operation is enabled when the LPUART_BAUD[MAEN1] or LPUART_BAUD[MAEN2] bit is set and LPUART_BAUD[MATCFG] is equal to 00. In this function, a character received by the LPUART_RX pin with a logic 1 in the bit position immediately preceding the stop bit is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and LPUART_STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the bit position immediately preceding the stop bit are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs then no transfer is made to the receive data buffer, and all following characters with logic zero in the bit position immediately preceding the stop bit are also discarded. If both the LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either register.

58.4.3.2.5 Idle Match operation

Idle match operation is enabled when the LPUART_BAUD[MAEN1] or LPUART_BAUD[MAEN2] bit is set and LPUART_BAUD[MATCFG] is equal to 01. In this function, the first character received by the LPUART_RX pin after an idle line condition is considered an address and is compared with the associated MA1 or MA2 register. The character is only transferred to the receive buffer, and LPUART_STAT[RDRF] is set, if the comparison matches. All subsequent characters are

considered to be data associated with the address and are transferred to the receive data buffer until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive data buffer, and all following frames until the next idle condition are also discarded. If both the LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Idle match operation functions in the same way for both MA1 and MA2 registers.

- If only one of LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] are asserted, the first character after an idle line is compared with both match registers and data is transferred only on a match with either register.

58.4.3.2.6 Match On Match Off operation

Match on, match off operation is enabled when both LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] are set and LPUART_BAUD[MATCFG] is equal to 10. In this function, a character received by the LPUART_RX pin that matches MATCH[MA1] is received and transferred to the receive buffer, and LPUART_STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive data buffer, until a character is received that matches MATCH[MA2] register. The character that matches MATCH[MA2] and all following characters are discarded, this continues until another character that matches MATCH[MA1] is received. If both the LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

NOTE

Match on, match off operation requires both LPUART_BAUD[MAEN1] and LPUART_BAUD[MAEN2] to be asserted.

58.4.3.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert LPUART_RTS.

- LPUART_RTS remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See [Transceiver driver enable using LPUART_RTS](#) for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts LPUART_RTS if the number of characters in the receiver data register is full or a start bit is detected that will cause the receiver data register to be full.
- The receiver asserts LPUART_RTS when the number of characters in the receiver data register is not full and has not detected a start bit that will cause the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if LPUART_RTS is deasserted, the receiver continues to receive characters until the receiver data buffer is overrun.
- If the receiver request-to-send functionality is disabled, the receiver LPUART_RTS remains deasserted.

58.4.3.4 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received.

58.4.3.4.1 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

58.4.3.4.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

58.4.3.4.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

58.4.3.4.4 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to [Low-bit detection](#). The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

58.4.4 Additional LPUART functions

The following sections describe additional LPUART functions.

58.4.4.1 8-bit, 9-bit and 10-bit data modes

The LPUART transmitter and receiver can be configured to operate in 9-bit data mode by setting the LPUART_CTRL[M] or 10-bit data mode by setting LPUART_CTRL[M10]. In 9-bit mode, there is a ninth data bit in 10-bit mode there is a tenth data bit. For the transmit data buffer, these bits are stored in LPUART_CTRL[T8] and LPUART_CTRL[T9]. For the receiver, these bits are held in LPUART_CTRL[R8] and LPUART_CTRL[R9]. They are also accessible via 16-bit or 32-bit accesses to the LPUART_DATA register.

For coherent 8-bit writes to the transmit data buffer, write to LPUART_CTRL[T8] and LPUART_CTRL[T9] before writing to LPUART_DATA[7:0]. For 16-bit and 32-bit writes to the LPUART_DATA register all 10 transmit bits are written to the transmit data buffer at the same time.

If the bit values to be transmitted as the ninth and tenth bit of a new character are the same as for the previous character, it is not necessary to write to LPUART_CTRL[T8] and LPUART_CTRL[T9] again. When data is transferred from the transmit data buffer to the transmit shifter, the value in LPUART_CTRL[T8] and LPUART_CTRL[T9] is copied at the same time data is transferred from LPUART_DATA[7:0] to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

58.4.4.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position. The CTRL[ILT] register can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit will cause any discarded characters to be treated as if they were idle characters.

58.4.4.3 Loop mode

When LPUART_CTRL[LOOPS] is set, the LPUART_CTRL[RSRC] bit in the same register chooses between loop mode (LPUART_CTRL[RSRC] = 0) or single-wire mode (LPUART_CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the LPUART_RX pin is not used by the LPUART.

58.4.4.4 Single-wire operation

When LPUART_CTRL[LOOPS] is set, the RSRC bit in the same register chooses between loop mode (LPUART_CTRL[RSRC] = 0) or single-wire mode (LPUART_CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the LPUART_TX pin (the LPUART_RX pin is not used).

In single-wire mode, the LPUART_CTRL[TXDIR] bit controls the direction of serial data on the LPUART_TX pin. When LPUART_CTRL[TXDIR] is cleared, the LPUART_TX pin is an input to the receiver and the transmitter is temporarily disconnected from the LPUART_TX pin so an external device can send serial data to the

receiver. When LPUART_CTRL[TXDIR] is set, the LPUART_TX pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

58.4.5 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This design covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the LPUART. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

58.4.5.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the LPUART_TX signal. A narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a zero bit when LPUART_CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a zero bit when LPUART_CTRL[TXINV] is set.

58.4.5.2 Infrared receive decoder

The infrared receive block converts data from the LPUART_RX signal to the receive shift register. A narrow pulse is expected for each zero received and no pulse is expected for each one received. A narrow low pulse is expected for a zero bit when

LPUART_STAT[RXINV] is cleared, while a narrow high pulse is expected for a zero bit when LPUART_STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

58.4.6 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty LPUART_STAT[TDRE]) indicates when there is room in the transmit data buffer to write another transmit character to LPUART_DATA. If the transmit interrupt enable LPUART_CTRL[TIE]) bit is set, a hardware interrupt is requested when LPUART_STAT[TDRE] is set. Transmit complete (LPUART_STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with LPUART_TX at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (LPUART_CTRL[TCIE]) bit is set, a hardware interrupt is requested when LPUART_STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the LPUART_STAT[TDRE] and LPUART_STAT[TC] status flags if the corresponding LPUART_CTRL[TIE] or LPUART_CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (LPUART_STAT[RDRF] = 1), it gets the data from the receive data register by reading LPUART_DATA. The LPUART_STAT[RDRF] flag is cleared by reading LPUART_DATA.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the LPUART_RX line remains idle for an extended period of time. IDLE is cleared by writing 1 to the LPUART_STAT[IDLE] flag. After LPUART_STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set LPUART_STAT[RDRF].

If the associated error was detected in the received character that caused LPUART_STAT[RDRF] to be set, the error flags - noise flag (LPUART_STAT[NF]), framing error (LPUART_STAT[FE]), and parity error flag (LPUART_STAT[PF]) - are set at the same time as LPUART_STAT[RDRF]. These flags are not set in overrun cases.

If LPUART_STAT[RDRF] was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (LPUART_STAT[OR]) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the LPUART_STAT[MA1F] and/or LPUART_STAT[MA2F] flags are set at the same time that LPUART_STAT[RDRF] is set.

Functional description

At any time, an active edge on the LPUART_RX serial data input pin causes the LPUART_STAT[RXEDGIF] flag to set. The LPUART_STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (LPUART_CTRL[RE] = 1).

Chapter 59

Flexible I/O (FlexIO)

59.1 Chip-specific FlexIO information

59.1.1 FlexIO Instantiation

This section summarize the features and module configurations of FlexIO

Amongst other features, the FlexIO module in this device supports:

1. Emulation in serial/parallel communication protocols
2. Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules

59.1.2 FlexIO Trigger options

FlexIO has a selectable trigger input source controlled by FlexIO_TIMCTLn[TRGSEL] (4-bit field) to use for starting the counter and/or reloading the counter. The options available are shown in the following table

Table 59-1. FlexIO Trigger Options

FlexIO_TIMCTLn[TRGSEL] (4-bit field)	Selected source
0000	External trigger pin input (EXTRG_IN)
0001	CMP0 output
0010	CMP1 output
0011	Reserved
0100	PIT trigger 0
0101	PIT trigger 1
0110	PIT trigger 2

Table continues on the next page...

Table 59-1. FlexIO Trigger Options (continued)

FlexIO_TIMCTLn[TRGSEL] (4-bit field)	Selected source
0111	PIT trigger 3
1000	FTM0 trigger
1001	FTM1 trigger
1010	FTM2 trigger
1011	FTM3 trigger
1100	RTC alarm
1101	RTC seconds
1110	LPTMR0 trigger
1111	Reserved

59.2 Introduction

59.2.1 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

These functions are provided by the FlexIO while adhering to the following key objectives:

- Low software/CPU overhead: less overhead than software bit-banging, more overhead than dedicated peripheral IP.
- Area/Power efficient implementation: more efficient than integrating multiple peripherals for each desired protocol or adding external board-level discrete logic.

59.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive and data match modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state

59.2.3 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

Figure 59-1. FlexIO block diagram

59.2.4 Modes of operation

The FlexIO module supports the chip modes described in the following table.

Table 59-2. Chip modes supported by the FlexIO module

Chip mode	FlexIO Operation
Run	Normal operation
Stop/Wait	Can continue operating provided the Doze Enable bit (CTRL[DOZEN]) is set and the FlexIO is using an external or internal clock source which remains operating during stop/wait modes.
Low Leakage Stop	The Doze Enable (CTRL[DOZEN]) bit is ignored and the FlexIO will wait for all Timers to complete any pending operation before acknowledging low leakage mode entry.
Debug	Can continue operating provided the Debug Enable bit (CTRL[DBGEE]) is set.

59.2.5 FlexIO Signal Descriptions

Signal	Description	I/O
FXIO_Dn (n=0...31)	Bidirectional FlexIO Shifter and Timer pin inputs/outputs	I/O

59.3 Memory Map/Register Definition

This section includes the memory map and register definition.

NOTE

The FlexIO functional clock must be enabled before accessing any FlexIO registers. Accessing FlexIO registers with FlexIO functional clock disabled will result in transfer error.

FLEXIOx_VERID field descriptions

Field	Description
31–24 MAJOR	Major Version Number This read only field returns the major version number for the module specification.
23–16 MINOR	Minor Version Number This read only field returns the minor version number for the module specification.
FEATURE	Feature Specification Number This read only field returns the feature set number. 0x0000 Standard features implemented. 0x0001 Supports state, logic and parallel modes.

59.3.2 Parameter Register (FLEXIOx_PARAM)

Address: 400D_F000h base + 4h offset = 400D_F004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	0													FASTACC	SWRST	FLEXEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FLEXIOx_CTRL field descriptions

Field	Description
31 DOZEN	Doze Enable Disables FlexIO operation in Doze modes. This field is ignored and the FlexIO always disabled in low-leakage stop modes. 0 FlexIO enabled in Doze modes. 1 FlexIO disabled in Doze modes.
30 DBGE	Debug Enable Enables FlexIO operation in Debug mode. 0 FlexIO is disabled in debug modes. 1 FlexIO is enabled in debug modes
29–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 FASTACC	Fast Access Enables fast register accesses to FlexIO registers, but requires the FlexIO clock to be at least twice the frequency of the bus clock. 0 Configures for normal register accesses to FlexIO 1 Configures for fast register accesses to FlexIO
1 SWRST	Software Reset The FlexIO Control Register is not affected by the software reset, all other logic in the FlexIO is affected by the software reset and register accesses are ignored until this bit is cleared. This register bit will remain set until cleared by software, and the reset has cleared in the FlexIO clock domain. 0 Software reset is disabled 1 Software reset is enabled, all FlexIO registers except the Control Register are reset.
0 FLEXEN	FlexIO Enable 0 FlexIO module is disabled. 1 FlexIO module is enabled.

59.3.4 Pin State Register (FLEXIOx_PIN)

Address: 400D_F000h base + Ch offset = 400D_F00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXIOx_SHIFTSTAT field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: For SMOD=Receive, the status flag is set when SHIFTBUF has been loaded with data from Shifter (SHIFTBUF is full), and the status flag is cleared when SHIFTBUF register is read. For SMOD=Transmit, the status flag is set when SHIFTBUF data has been transferred to the Shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit, and the status flag is cleared when the SHIFTBUF register is written. For SMOD=Match Store, the status flag is set when a match has occurred between SHIFTBUF and Shifter, and the status flag is cleared when the SHIFTBUF register is read. For SMOD=Match Continuous, returns the current match result between the SHIFTBUF and Shifter. For SMOD=State, the status flag for a shifter will set when it is selected by the current state pointer. For SMOD=Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/State/Logic. 0 Status flag is clear 1 Status flag is set

59.3.6 Shifter Error Register (FLEXIOx_SHIFTErr)

Address: 400D_F000h base + 14h offset = 400D_F014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXIOx_SHIFTErr field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: For SMOD=Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value. For SMOD=Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun). For SMOD=Match Store, indicates a match event occurred before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun). For SMOD=Match Continuous, the error flag is set when a match has occurred between SHIFTBUF and Shifter. For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted. Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read. 0 Shifter Error Flag is clear 1 Shifter Error Flag is set

59.3.7 Timer Status Register (FLEXIOx_TIMSTAT)

Address: 400D_F000h base + 18h offset = 400D_F018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXIOx_TIMSTAT field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TSF	Timer Status Flags The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. In 8-bit counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements, this also causes the counter to reload with the value in the compare register. In 8-bit PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements, this also causes the counter to reload with the value in the compare register.. In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements, this also causes the counter to reload with the value in the compare register.. 0 Timer Status Flag is clear 1 Timer Status Flag is set

59.3.8 Shifter Status Interrupt Enable (FLEXIOx_SHIFTSIEN)

FLEXIOx_SHIFTCFGn field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 PWIDTH	Parallel Width For all Shifters, this register field configures the number of bits to be shifted on each Shift clock as follows: 1-bit shift for PWIDTH=0 4-bit shift for PWIDTH=1...3

Table continues on the next page...

FLEXIOx_SHIFTCFGn field descriptions (continued)

Field	Description
	8-bit shift for PWIDTH=4...7 16-bit shift for PWIDTH=8...15 32-bit shift for PWIDTH=16...31 For Shifters which support parallel transmit (SHIFTER0, SHIFTER4) or parallel receive (SHIFTER3, SHIFTER7), this register field, together with PSEL, also selects the pins to be driven or sampled on each Shift clock as follows: FXIO_D[PSEL+PWIDTH]:FXIO_D[PSEL] For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 INSRC	Input Source Selects the input source for the shifter. 0 Pin 1 Shifter N+1 Output
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 SSTOP	Shifter Stop bit For SMOD=Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit. For SMOD=Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00 Stop bit disabled for transmitter/receiver/match store 01 Reserved for transmitter/receiver/match store 10 Transmitter outputs stop bit value 0 on store, receiver/match store sets error flag if stop bit is not 0 11 Transmitter outputs stop bit value 1 on store, receiver/match store sets error flag if stop bit is not 1
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SSTART	Shifter Start bit For SMOD=Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit. For SMOD=Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00 Start bit disabled for transmitter/receiver/match store, transmitter loads data on enable 01 Start bit disabled for transmitter/receiver/match store, transmitter loads data on first shift

Table continues on the next page...

FLEXIOx_SHIFTCFGn field descriptions (continued)

Field	Description
10	Transmitter outputs start bit value 0 before loading data on first shift, receiver/match store sets error flag if start bit is not 0
11	Transmitter outputs start bit value 1 before loading data on first shift, receiver/match store sets error flag if start bit is not 1

59.3.15 Shifter Buffer N Register (FLEXIOx_SHIFTBUFn)

Address: 400D_F000h base + 200h offset + (4d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXIOx_SHIFTBUFn field descriptions

Field	Description
SHIFTBUF	Shift Buffer Shift buffer data is used for a variety of functions depending on the SMOD setting: For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins. For SMOD=Match Store/Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents. The Match is checked either continuously (Match Continuous mode) or when the Timer expires (Match Store mode). SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). In Match Store mode, Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See 'Logic Mode' section for more detail. For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See 'State Mode' section for more detail.

59.3.16 Shifter Buffer N Bit Swapped Register (FLEXIOx_SHIFTBUFBISn)

FLEXIOx_TIMCFGn field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 TIMOUT	Timer Output Configures the initial state of the Timer Output and whether it is affected by the Timer reset. 00 Timer output is logic one when enabled and is not affected by timer reset 01 Timer output is logic zero when enabled and is not affected by timer reset 10 Timer output is logic one when enabled and on timer reset 11 Timer output is logic zero when enabled and on timer reset
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–20 TIMDEC	Timer Decrement Configures the source of the Timer decrement and the source of the Shift clock. 00 Decrement counter on FlexIO clock, Shift clock equals Timer output. 01 Decrement counter on Trigger input (both edges), Shift clock equals Timer output. 10 Decrement counter on Pin input (both edges), Shift clock equals Pin input. 11 Decrement counter on Trigger input (both edges), Shift clock equals Trigger input.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 TIMRST	Timer Reset

Table continues on the next page...

FLEXIOx_TIMCFGn field descriptions (continued)

Field	Description
	Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset will only reset the lower 8-bits that configure the baud rate. In all other modes, the timer reset will reset the full 16-bits of the counter. 000 Timer never reset 001 Reserved 010 Timer reset on Timer Pin equal to Timer Output 011 Timer reset on Timer Trigger equal to Timer Output 100 Timer reset on Timer Pin rising edge 101 Reserved 110 Timer reset on Trigger rising edge 111 Timer reset on Trigger rising or falling edge
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–12 TIMDIS	Timer Disable Configures the condition that causes the Timer to be disabled and stop decrementing. 000 Timer never disabled 001 Timer disabled on Timer N-1 disable 010 Timer disabled on Timer compare 011 Timer disabled on Timer compare and Trigger Low 100 Timer disabled on Pin rising or falling edge 101 Timer disabled on Pin rising or falling edge provided Trigger is high 110 Timer disabled on Trigger falling edge 111 Reserved
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 TIMENA	Timer Enable Configures the condition that causes the Timer to be enabled and start decrementing. 000 Timer always enabled 001 Timer enabled on Timer N-1 enable 010 Timer enabled on Trigger high 011 Timer enabled on Trigger high and Pin high 100 Timer enabled on Pin rising edge 101 Timer enabled on Pin rising edge and Trigger high 110 Timer enabled on Trigger rising edge 111 Timer enabled on Trigger rising or falling edge
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 TSTOP	Timer Stop Bit The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters will output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00 Stop bit disabled

Table continues on the next page...

FLEXIOx_TIMCFGn field descriptions (continued)

Field	Description
	01 Stop bit is enabled on timer compare 10 Stop bit is enabled on timer disable 11 Stop bit is enabled on timer compare and timer disable
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 TSTART	Timer Start Bit When start bit is enabled, configured shifters will output the contents of the start bit when the timer is enabled and the timer counter will reload from the compare register on the first rising edge of the shift clock. 0 Start bit disabled 1 Start bit enabled
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

59.3.21 Timer Compare N Register (FLEXIOx_TIMCMPn)

Address: 400D_F000h base + 500h offset + (4d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																CMP															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FLEXIOx_TIMCMPn field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CMP	Timer Compare Value The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset and when the timer decrements down to zero. In dual 8-bit counters baud/bit mode, the lower 8-bits configures the baud rate divider equal to (CMP[7:0] + 1) * 2. The upper 8-bits configure the number of bits in each word equal to (CMP[15:8] + 1) / 2. In dual 8-bit counters PWM mode, the lower 8-bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2.

59.3.22 Shifter Buffer N Nibble Byte Swapped Register (FLEXIOx_SHIFTBUFNBSn)

59.4 Functional description

59.4.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

Figure 59-2. Shifter Microarchitecture

59.4.1.1 Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter will load data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/after SHIFTBUF data by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Note that the shifter will immediately load a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag will clear when new data has been written into the SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

59.4.1.2 Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter will shift data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

59.4.1.3 Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter will shift data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the matched data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

59.4.1.4 Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter will shift data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs. The flag will clear automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when a match occurs. The flag will clear when there is a read from the SHIFTBUF register or it is written with logic 1.

59.4.1.5 State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU using FlexIO hardware.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

Figure 59-3. State Microarchitecture

When Shifter *i* has been selected by the current state pointer, output pins FXIO_D[7:0] will be driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTL[PINCFG]. When set, {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCFG[PSEL] together with SHIFTBUFi[23:0]. Note that each state could potentially use a different set of 3 input pins. The following table details how the next state value is computed when the current state pointer is pointing to Shifter *i*.

Table 59-3. Next State computation for SHIFTSTATE[STATE]=i

FXIO_D[PSEL+2]	FXIO_D[PSEL+1]	FXIO_D[PSEL]	Next State Value
0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by `SHIFTCTL[TIMSEL]` with polarity controlled by `SHIFTCTL[TIMPOL]`. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs will not be driven and a next state transition is never triggered.

The Shifter Status Flag (`SHIFTSTAT[SSF]`) and any enabled interrupts or DMA requests will set whenever the Shifter has been selected by the current state pointer. The flag will clear when the current state pointer is updated to a different Shifter.

59.4.1.6 Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter. This feature allows board-level glue logic to be integrated on-chip using FlexIO hardware.

When configured for Logic mode (`SHIFTCTL[SMOD]=Logic`), the `SHIFTBUF` register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

Figure 59-4. Logic Microarchitecture

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHFITCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

Table 59-4. Logic Look-up table for Shifter 'i'

SHIFTERi[0]	FXIO_D[x+3] ¹	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUFi[0]
0	0	0	0	1	SHIFTBUFi[1]
0	0	0	1	0	SHIFTBUFi[2]
0	0	0	1	1	SHIFTBUFi[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUFi[31]

- ```

1. for Shifter i=0...3, x=i
 for Shifter i=4...7, x=i+4

```

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} will mask FXIO\_D[x+3]...FXIO\_D[x] inputs respectively, so that any transitions on these pins will not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table (without synchronization), allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] will control the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter will introduce a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter will introduce a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag will clear when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when the output pin allocated to the logic look-up table has a value of 1. The flag can be cleared by writing it with logic 1.

## 59.4.2 Timer operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip configuration section for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD). Once the TIMOD is configured for the desired mode, when the condition configured by timer enable (TIMENA) is detected then the following events occur.

- Timer counter will load the current value of the Compare Register and start decrementing as configured by TIMDEC.

- Timer output will set depending on the TIMOUT configuration.
- Transmit shifters controlled by this timer will either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

The Timer will then generate the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC=00 or 01) or equal to the decrement clock (when TIMDEC=10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer will decrement on both rising and falling edges.

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter will load the current value of the Compare Register again, the timer output may also be affected by the reset as configured in TIMOUT.

If the Timer start bit is enabled, the timer counter will reload with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift will not load correctly.

When configured for 8-bit counter mode, whenever the lower 8-bit counter decrements to zero the timer output will toggle, the lower 8-bit counter register will reload from the compare register and the upper 8-bit counter will decrement. For 8-bit PWM mode, the lower 8-bit counter will only decrement when the output is high and the upper 8-bit counter will only decrement when the output is low. The timer output will toggle whenever either lower or upper 8-bit counter decrements to zero.

When the timer decrements to zero, a compare event occurs depending on the timer mode. For 8-bit counter or PWM modes, both halves of the counter must equal zero and the upper half must decrement for the timer compare event to occur, while in 16-bit mode the entire counter must equal zero and decrement. The timer compare event will cause the timer status flag to set, the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load and any configured receive shift registers to store .

When the is Timer is configured to add a stop bit on each compare, the following additional events will occur.

- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter will reload the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter will reload the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output will clear.
- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter will continue decrementing until the next rising edge of the shift clock is detected, at which point it will finish. A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). Receive shift registers will stop bit enabled will store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

### 59.4.3 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

In addition, shifters can also be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter will be sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PSEL selecting the pins as follows: FXIO\_D[PSEL+PWIDTH]:FXIO\_D[PSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits will be masked with 0 e.g. if PSEL=7 and PWIDTH=6, then SHIFTER[31:24] will sample {0,0,FXIO\_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PSEL selecting the pins as follows: FXIO\_D[PSEL+PWIDTH]:FXIO\_D[PSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins will not be driven e.g. if PSEL=7 and PWIDTH=6, then SHIFTER[5:0] will drive only FXIO\_D[12:7] on each Shift clock.

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin will make an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 – 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

## 59.5 Application Information

This section provides examples for a variety of FlexIO module applications.

### 59.5.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUF<sub>n</sub> (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

**Table 59-5. UART Transmit Configuration**

| Register              | Value            | Comments                                                                                                                                                                                  |
|-----------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFG <sub>n</sub> | 0x0000_0032      | Configure start bit of 0 and stop bit of 1.                                                                                                                                               |
| SHIFTCTL <sub>n</sub> | 0x0003_0002      | Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1. |
| TIMCMP <sub>n</sub>   | 0x0000_0F01      | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.                   |
| TIMCFG <sub>n</sub>   | 0x0000_2222      | Configure start bit, stop bit, enable on trigger low and disable on compare. Can support CTS by configuring TIMEN=0x3.                                                                    |
| TIMCTL <sub>n</sub>   | 0x01C0_0001      | Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.                       |
| SHIFTBUF <sub>n</sub> | Data to transmit | Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit                                                                                                                        |

**Table 59-5. UART Transmit Configuration**

| Register | Value | Comments                                                                                                                                                                                  |
|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          |       | transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBS[7:0] register instead. |

## 59.5.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters will cause the error flag to set and the shifter buffer register will return 0x00.

FlexIO does not support automatic verification of parity bits.

**Table 59-6. UART Receiver Configuration**

| Register  | Value           | Comments                                                                                                                                                                |
|-----------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFGn | 0x0000_0032     | Configure start bit of 0 and stop bit of 1.                                                                                                                             |
| SHIFTCTLn | 0x0080_0001     | Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.                                                  |
| TIMCMPn   | 0x0000_0F01     | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFGn   | 0x0204_2422     | Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.                  |
| TIMCTLn   | 0x0000_0081     | Configure dual 8-bit counter using inverted Pin 0 input.                                                                                                                |
| SHIFTBUFn | Data to receive | Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be                                                               |

**Table 59-6. UART Receiver Configuration**

| Register | Value | Comments                                                                                                                  |
|----------|-------|---------------------------------------------------------------------------------------------------------------------------|
|          |       | read using interrupt or DMA request.<br>Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead. |

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS will assert when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit will be detected while the RTS is asserted, the received data is simply ignored.

**Table 59-7. UART Receiver with RTS Configuration**

| Register    | Value           | Comments                                                                                                                                                                                                                            |
|-------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFGn   | 0x0000_0032     | Configure start bit of 0 and stop bit of 1.                                                                                                                                                                                         |
| SHIFTCTLn   | 0x0080_0001     | Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.                                                                                                              |
| TIMCMPn     | 0x0000_0F01     | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.                                                             |
| TIMCFGn     | 0x0204_2522     | Configure start bit, stop bit, enable on pin posedge with trigger low and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.                                                             |
| TIMCTLn     | 0x03C0_0081     | Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.                                                                                                                            |
| TIMCMP(n+1) | 0x0000_FFFF     | Never compare.                                                                                                                                                                                                                      |
| TIMCFG(n+1) | 0x0030_6100     | Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.                                                                                                                            |
| TIMCTL(n+1) | 0x0143_0083     | Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.                                                                                                                                             |
| SHIFTBUFn   | Data to receive | Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.<br>Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead. |

### 59.5.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 59-8. SPI Master (CPHA=0) Configuration**

| Register      | Value            | Comments                                                                                                                                                                 |
|---------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFGn     | 0x0000_0000      | Start and stop bit disabled.                                                                                                                                             |
| SHIFTCTLn     | 0x0083_0002      | Configure transmit using Timer 0 on negedge of clock with output data on Pin 0.                                                                                          |
| SHIFTCFG(n+1) | 0x0000_0000      | Start and stop bit disabled.                                                                                                                                             |
| SHIFTCTL(n+1) | 0x0000_0101      | Configure receive using Timer 0 on posedge of clock with input data on Pin 1.                                                                                            |
| TIMCMPn       | 0x0000_3F01      | Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFGn       | 0x0100_2222      | Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0. Set PINPOL to invert the output shift clock.               |
| TIMCTLn       | 0x01C3_0201      | Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger.                                                              |
| TIMCMP(n+1)   | 0x0000_FFFF      | Never compare.                                                                                                                                                           |
| TIMCFG(n+1)   | 0x0000_1100      | Enable when Timer 0 is enabled and disable when Timer 0 is disabled.                                                                                                     |
| TIMCTL(n+1)   | 0x0003_0383      | Configure 16-bit counter (never compare) using inverted Pin 3 output (as slave select).                                                                                  |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to SHIFTBUF, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can                           |

### 59.5.4 SPI Slave

SPI slave mode can be supported using one Timer, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external slave select asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

## 59.5.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter will load 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register will assert an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

| TIMCMPn       | 0x0000_2501      | Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set $TIMCMP[15:8] = (\text{number of words} \times 18) + 1$ . Set $TIMCMP[7:0] = (\text{baud rate divider} / 2) - 1$ . |
| TIMCFGn       | 0x0102_2222      | Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.                                 |
| TIMCTLn       | 0x01C1_0101      | Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.                                                                               |
| TIMCMP(n+1)   | 0x0000_000F      | Configure 8-bit transfer. Set $TIMCMP[15:0] = (\text{number of bits} \times 2) - 1$ .                                                                                                               |
| TIMCFG(n+1)   | 0x0020_1112      | Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.                                                        |
| TIMCTL(n+1)   | 0x01C0_0183      | Configure 16-bit counter using inverted Pin 1 input (SCL).                                                                                                                                          |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to $SHIFTBUFBBS[7:0]$ , use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.                                               |
| SHIFTBUF(n+1) | Data to receive  | Received data can be read from $SHIFTBUFBIS[7:0]$ , use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.                                                   |

### 59.5.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before

enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 59-13. I2S Master Configuration**

### 59.5.7 I2S Slave

I2S slave mode can be supported using two Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

**Table 59-14. I2S Slave Configuration**

| Register      | Value       | Comments                                                                                                                                                     |

| TIMCTL(n+1)   | 0x0340_0203      | Configure 16-bit counter using Pin 2 input (bit clock), with Timer 0 output as the trigger.                                                                                                                           |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead. |
| SHIFTBUF(n+1) | Data to receive  | Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.   |

## 59.5.8 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

**Table 59-15. Camera Interface Configuration for 8-bit CMOS sensor**

| Register                     | Value       | Comments                                                          |

## 59.5.9 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

**Table 59-16. Motorola 68K/Intel 8080 Write Configuration**

Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.                          |
| TIMCFG0       | 0x0000_2220                                                                                                                                          | Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable.                                                                                                          |
| TIMCTL0       | 0x1DC3_1001 (Motorola 68K, 1 beat)<br>0x01C3_1001 (Motorola 68K, 16 beats)<br>0x1DC3_1181 (Intel 8080, 1 beat)<br>0x01C3_1181 (Intel 8080, 16 beats) | Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger. |
| SHIFTBUF0...7 | Data received                                                                                                                                        | Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.                             |

In general, any operation to a 68K/8080 bus slave will begin with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

### 59.5.10 State Machine Example

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode. In this example, FlexIO waits for the FXIO\_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO\_CLK/131072 on the FXIO\_D[1:0] pins while the comparator output is asserted (assumes comparator is connected to external trigger 15). The state diagram below shows the states and transitions implemented by this example.

**Figure 59-5. Example State Diagram**

**Table 59-18. State Machine Configuration**

| Register      | Value       | Comments                                                                                                                |
|---------------|-------------|-------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFG0...2 | 0x0000_0003 | Enable FXIO_D[1:0] as outputs.                                                                                          |
| SHIFTCTL0     | 0x0080_0206 | Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.  |
| SHIFTBUF0     | 0x0020_8208 | State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.                               |
| SHIFTCTL1     | 0x0000_0206 | Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state. |
| SHIFTBUF1     | 0x0140_8408 | State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)       |
| SHIFTCTL2     | 0x0080_0206 | Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.  |
| SHIFTBUF2     | 0x0224_9249 | State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low                                               |
| TIMCMP0       | 0x0000_FFFF | Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.             |
| TIMCFG0       | 0x0000_0000 | Configure timer always enabled.                                                                                         |
| TIMCTL0       | 0x0000_0003 | Configure single 16-bit counter.                                                                                        |
| TIMCFG1       | 0x0010_7600 | Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.            |
| TIMCTL1       | 0x0F03_0303 | Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.                          |

## Chapter 60

# Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)

## 60.1 Chip-specific I2S/SAI information

### 60.1.1 Instantiation information

This device contains 2 I<sup>2</sup>S module.

As configured on the device, module features include:

- TX data lines: 2
- RX data lines: 2
- FIFO size (words): 8 Words
- Maximum words per frame: 32
- Maximum bit clock divider: 512

### 60.1.2 Features

- I2S, TDM, AC97, CODEC, DSP interfaces
- Transmit and Receive can operate asynchronously or synchronously
- Multiple SAI can be synchronized
- Asynchronous FIFO design eliminates Bit Clock / Bus Clock restrictions
- Supports operation in back-biased run mode with 1 MHz Bus Clock
- Supports operation in Stop mode from external bit clock or audio clock
- Asynchronous interrupt can generate wakeup for CPU from Stop mode
- Graceful shut-down when not configured to operate in Stop mode
- Supports 8-bit to 32-bit data word
- Bits per Word configured separately for first word in frame (AC97)

- Supports MSB or LSB first plus word alignment in FIFO is configurable
- Double-buffered word mask register can mask any word in the frame
- Configurable width and data alignment (one bit early or with first bit)
- Frame Sync Error flag and interrupt supported with external frame sync
- Word Start flag and interrupt can trigger at start of any word in frame
- Fully configurable FIFO Watermark generates Interrupt or DMA request
- Stereo 16-bit data can be packed into one 32-bit FIFO word
- Graceful restart on Frame boundary after FIFO overflow/underflow

### **60.1.3 I<sup>2</sup>S/SAI clocking**

#### **60.1.3.1 Audio Master Clock**

The audio master clock (MCLK) is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The audio master clock can also be output to or input from a pin. The transmitter and receiver have the same audio master clock inputs.

#### **60.1.3.2 Bit Clock**

The I<sup>2</sup>S/SAI transmitter and receiver support asynchronous bit clocks (BCLKs) that can be generated internally from the audio master clock or supplied externally. The module also supports the option for synchronous operation between the receiver and transmitter product or between two separate I<sup>2</sup>S/SAI peripherals.

#### **60.1.3.3 Bus Clock**

The bus clock is used by the control registers and to generate synchronous interrupts and DMA requests.

#### **60.1.3.4 I<sup>2</sup>S/SAI clock generation**

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock.

The MCLK Input Clock Select bit of the MCLK Control Register (MCR[MICS]) selects the clock input to the I<sup>2</sup>S/SAI module's MCLK divider.

The following table shows the input clock selection options on this device.

**Table 60-1. I2S0/1 MCLK input clock selection**

| MCR[MICS] | Clock Selection        |
|-----------|------------------------|
| 00        | System clock           |
| 01        | OSC0ERCLK              |
| 10        | Not supported          |
| 11        | MCGPLLCLK or MCGFLLCLK |

The module's MCLK Divide Register (MDR) configures the MCLK divide ratio.

The module's MCLK Output Enable bit of the MCLK Control Register (MCR[MOE]) controls the direction of the MCLK pin. The pin is the input from the pin when MOE is 0, and the pin is the output from the clock divider when MOE is 1.

The transmitter and receiver can independently select between the bus clock and the audio master clocks to generate the bit clock. Each module's Clocking Mode field of the Transmit Configuration 2 Register and Receive Configuration 2 Register (TCR2[MSEL] and RCR2[MSEL]) selects the master clock.

The following table shows the TCR2[MSEL] and RCR2[MSEL] field settings for this device.

**Table 60-2. I2S0 master clock settings**

| TCR2[MSEL], RCR2[MSEL] | Master Clock  |
|------------------------|---------------|
| 00                     | Bus Clock     |
| 01                     | I2S0_MCLK     |
| 10                     | Not supported |
| 11                     | Not supported |

**Table 60-3. I2S1 master clock settings**

| TCR2[MSEL], RCR2[MSEL] | Master Clock  |
|------------------------|---------------|
| 00                     | Bus Clock     |
| 01                     | I2S1_MCLK     |
| 10                     | Not supported |
| 11                     | Not supported |

### 60.1.3.5 Clock gating and I<sup>2</sup>S/SAI initialization

The clock to the I<sup>2</sup>S/SAI module can be gated using a bit in the SIM. To minimize power consumption, these bits are cleared after any reset, which disables the clock to the corresponding module. The clock enable bit should be set by software at the beginning of the module initialization routine to enable the module clock before initialization of any of the I<sup>2</sup>S/SAI registers.

## 60.1.4 I<sup>2</sup>S/SAI operation in low power modes

### 60.1.4.1 Stop and very low power modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In VLPS mode, the module behaves as it does in stop mode if VLPS mode is entered from run mode. However, if VLPS mode is entered from VLPR mode, the FIFO might underflow or overflow before wakeup from stop mode due to the limits in bus bandwidth. In VLPW and VLPR modes, the module is limited by the maximum bus clock frequencies.

When operating from an internally generated bit clock or Audio Master Clock that is disabled in stop modes:

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 60.1.4.2 Low-leakage modes

When entering low-leakage modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored, and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

## 60.2 Introduction

The I<sup>2</sup>S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I<sup>2</sup>S, AC97, TDM, and codec/DSP interfaces.

### 60.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 2 data lines
- Receiver with independent bit clock and frame sync supporting 2 data lines
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 8 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data channel FIFOs into single data channel FIFO

### 60.2.2 Block diagram

The following block diagram also shows the module clocks.

Figure 60-1. I²S/SAI block diagram

### 60.2.3 Modes of operation

Available power modes include: Run mode, Stop mode, low-leakage modes, and Debug mode.

#### 60.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

#### 60.2.3.2 Stop mode

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 60.2.3.3 Low-leakage modes

When entering low-leakage modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored, and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 60.2.3.4 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

## 60.3 External signals

| Name             | Function                                                                                                                                                                                           | I/O |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| SAI_TX_BCLK      | Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.                                                                                   | I/O |
| SAI_TX_SYNC      | Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |
| SAI_TX_DATA[1:0] | Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.                                                                    | O   |
| SAI_RX_BCLK      | Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.                                                                                    | I/O |
| SAI_RX_SYNC      | Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.  | I/O |
| SAI_RX_DATA[1:0] | Receive Data. The receive data is sampled synchronously by the bit clock.                                                                                                                          | I   |
| SAI_MCLK         | Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.                                                                                | I/O |

## 60.4 Memory map and register definition

A read or write access to an address from offset 0x108 and above will result in a bus error.

**I2S memory map**

| Absolute address (hex) | Register name                                     | Width (in bits) | Access                | Reset value | Section/ page                |
|------------------------|---------------------------------------------------|-----------------|-----------------------|-------------|------------------------------|
| 4002_F000              | SAI Transmit Control Register (I2S0_TCSR)         | 32              | R/W                   | 0000_0000h  | <a href="#">60.4.1/1940</a>  |

#### I2Sx\_TCR2 field descriptions

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–30<br>SYNC | <p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation.</p> <p>00 Asynchronous mode.<br/>01 Synchronous with receiver.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 29<br>BCS     | <p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC).</p> <p>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC).</p> <p>0 Use the normal bit clock source.<br/>1 Swap the bit clock source.</p>                                                                                                |
| 28<br>BCI     | <p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock.</p> <p>0 No effect.<br/>1 Internal logic is clocked as if bit clock was externally generated.</p> |
| 27–26<br>MSEL | MCLK Select                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 28<br>FCONT       | FIFO Continue on Error<br><br>Configures when the SAI will continue transmitting after a FIFO error has been detected.<br><br>0 On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.<br>1 On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 27–26<br>FCOMB    | FIFO Combine Mode<br><br>When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel.<br><br>When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.<br><br>00 FIFO combine mode disabled.<br>01 FIFO combine mode enabled on FIFO reads (from transmit shift registers).<br>10 FIFO combine mode enabled on FIFO writes (by software).<br>11 FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software). |
| 25–24<br>FPACK    | FIFO Packing Mode<br><br>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software.<br><br>00 FIFO packing is disabled<br>01 Reserved<br>10 8-bit FIFO packing is enabled<br>11 16-bit FIFO packing is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TDR   | Transmit Data Register<br><br>The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored. |

## 60.4.8 SAI Transmit FIFO Register (I2Sx\_TFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

## 60.4.9 SAI Transmit Mask Register (I2Sx\_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–30<br>SYNC | <p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation.</p> <p>00 Asynchronous mode.<br/>01 Synchronous with transmitter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 29<br>BCS     | <p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (SAI_TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (SAI_RX_SYNC).</p> <p>When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (SAI_RX_BCLK) but use the transmitter frame sync (SAI_TX_SYNC).</p> <p>0 Use the normal bit clock source.<br/>1 Swap the bit clock source.</p>                                                                                                   |
| 28<br>BCI     | <p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock.</p> <p>0 No effect.<br/>1 Internal logic is clocked as if bit clock was externally generated.</p> |

| WDFL              | Word Flag Configuration<br><br>Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.                                                                                                                                                                                                                                                                                                                                                                                                                                |

**60.4.14 SAI Receive Configuration 4 Register (I2Sx\_RCR4)**

This register must not be altered when RCSR[RE] is set.

Address: Base address + 90h offset

| 28<br>FCONT       | FIFO Continue on Error<br><br>Configures when the SAI will continue receiving after a FIFO error has been detected.<br><br>0 On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.<br>1 On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 27–26<br>FCOMB    | FIFO Combine Mode<br><br>When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.<br><br>When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.<br><br>00 FIFO combine mode disabled.<br>01 FIFO combine mode enabled on FIFO writes (from receive shift registers).<br>10 FIFO combine mode enabled on FIFO reads (by software).<br>11 FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software). |
| 25–24<br>FPACK    | FIFO Packing Mode<br><br>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.<br><br>00 FIFO packing is disabled<br>01 Reserved.<br>10 8-bit FIFO packing is enabled<br>11 16-bit FIFO packing is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**I2Sx\_RDRn field descriptions**

| Field | Description                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RDR   | Receive Data Register<br><br>The corresponding RCR3[RCE] bit must be set before accessing the channel's receive data register. Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored. |

### 60.4.17 SAI Receive FIFO Register (I2Sx\_RFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + C0h offset + (4d × i), where i=0d to 1d

### 60.4.18 SAI Receive Mask Register (I2Sx\_RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

## Memory map and register definition

Address: Base address + E0h offset

**60.4.20 SAI MCLK Divide Register (I2Sx\_MDR)**

The MCLK Divide Register (MDR) configures the MCLK divide ratio. Although the MDR can be changed when the MCLK divider clock is enabled, additional writes to the MDR are blocked while MCR[DUF] is set. Writes to the MDR when the MCLK divided clock is disabled do not set MCR[DUF].

## 60.5 Functional description

This section provides a complete functional description of the block.

### 60.5.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

#### 60.5.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock. The input clock selection and pin direction cannot be altered if an SAI module using that audio master clock has been enabled. The MCLK divide ratio can be altered while an SAI is using that master clock, although the change in the divide ratio takes several cycles. MCR[DUF] can be polled to determine when the divide ratio change has completed.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated. A typical implementation appears in the following figure.

**Figure 60-2. SAI master clock generation**

The MCLK fractional clock divider uses both clock edges from the input clock to generate a divided down clock that will approximate the output frequency, but without creating any new clock edges. Configuring FRACT and DIVIDE to the same value will result in a divide by 1 clock, while configuring FRACT higher than DIVIDE is not supported. The duty cycle can range from 66/33 when FRACT is set to one less than DIVIDE down to 50/50 for integer divide ratios, and will approach 50/50 for large non-integer divide ratios. There is no cycle to cycle jitter or duty cycle variance when the divide ratio is an integer or half integer, otherwise the divider output will oscillate between the two divided frequencies that are the closest integer or half integer divisors of the divider input clock frequency. The maximum jitter is therefore equal to half the divider input clock period, since both edges of the input clock are used in generating the divided clock.

### 60.5.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

### **60.5.1.3 Bus clock**

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

#### **NOTE**

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

## **60.5.2 SAI resets**

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

### **60.5.2.1 Software reset**

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

### 60.5.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

## 60.5.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

### 60.5.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.

- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

### **60.5.4 Frame sync configuration**

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

### **60.5.5 Data FIFO**

Each transmit and receive channel includes a FIFO of size  $8 \times 32$ -bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

### 60.5.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 60-3](#) for LSB First configurations and [Figure 60-4](#) for MSB First configurations.

Figure 60-3. SAI first bit shifted, LSB first

Figure 60-4. SAI first bit shifted, MSB first

### 60.5.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

### 60.5.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset \$0 (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset \$2 (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset \$0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset \$2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset \$0, second word in byte offset \$1, third word in byte offset \$2 and fourth word in byte offset \$3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset \$0.

#### 60.5.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

### **60.5.6 Word mask register**

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

### **60.5.7 Interrupts and DMA requests**

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts are generated to wake up the CPU from stop mode.

#### **60.5.7.1 FIFO request flag**

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

### 60.5.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

### 60.5.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCNT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

#### **60.5.7.4 Sync error flag**

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

#### **60.5.7.5 Word start flag**

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

# Chapter 61

## Secured digital host controller (SDHC)

### 61.1 Chip-specific SDHC information

#### 61.1.1 SDHC clocking

In addition to the system clock, the SDHC needs a clock for the base for the external card clock. There are four possible clock sources for this clock, selected by the SIM\_SOPT2 register:

- Core/system clock
- MCGPLLCLK or MCGFLLCLK
- OSCERCLK
- Bypass clock from off-chip (SDHC0\_CLKIN) when available

#### NOTE

SDHC0\_CLKIN is not available on all packages. See the [Pinout](#) section for more information.

#### 61.1.2 SD bus pullup/pulldown constraints

The SD standard requires the SD bus signals (except the SD clock) to be pulled up during data transfers. The SDHC also provides a feature of detecting card insertion/removal, by detecting voltage level changes on DAT[3] of the SD bus. To support this DAT[3] must be pulled down. To avoid a situation where the SDHC detects voltage changes due to normal data transfers on the SD bus as card insertion/removal, the interrupt relating to this event must be disabled after the card has been inserted and detected. It can be re-enabled after the card is removed.

## 61.2 Introduction

The chapter is intended for a module driver software developer. It describes module-level operation and programming.

## 61.3 Overview

### 61.3.1 Supported types of cards

Different types of cards supported by the SDHC are described briefly as follows:

The multimedia card (MMC) is a universal low-cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high-speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

The secure digital card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC with some additions.

Under the SD protocol, it can be categorized into memory card, I/O card and combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the figure does not show cards with reduced size or mini cards.

Figure 61-1. System connection of the SDHC

### 61.3.2 SDHC block diagram

Figure 61-2. Enhanced secure digital host controller block diagram

### 61.3.3 Features

The features of the SDHC module include:

- Conforms to the SD Host Controller Standard Specification version 2.0 including test event register support
- Compatible with the MMC System Specification version 4.2/4.3
- Compatible with the SD Memory Card Specification version 2.0 and supports the high capacity SD memory card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD memory, miniSD memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 52 MHz
- Supports 1-bit/4-bit SD and SDIO modes, 1-bit/4-bit / 8-bit MMC modes devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in Single Data Rate (SDR) mode
- Supports single block, multiblock read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort (both hardware and software CMD12)
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports auto CMD12 for multiblock transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data

- Supports internal DMA capabilities
- Supports advanced DMA to perform linked memory access

### NOTE

External SDHC DMA request is not supported.

## 61.3.4 Modes and operations

The SDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification mode up to 400 kHz
- MMC Full Speed mode up to 20 MHz
- MMC High Speed mode up to 52 MHz
- SD/SDIO Full Speed mode up to 25 MHz
- SD/SDIO High Speed mode up to 50 MHz

## 61.4 SDHC signal descriptions

Table 61-1. SDHC signal descriptions

| Signal    | Description                                                                                        | I/O |
|-----------|----------------------------------------------------------------------------------------------------|-----|
| SDHC_DCLK | Generated clock used to drive the MMC, SD, SDIO or CE-ATA cards.                                   | O   |
| SDHC_CMD  | Send commands to and receive responses from the card.                                              | I/O |
| SDHC_D0   | DAT0 line or busy-state detect                                                                     | I/O |
| SDHC_D1   | 8-bit mode: DAT1 line<br>4-bit mode: DAT1 line or interrupt detect<br>1-bit mode: Interrupt detect | I/O |

*Table continues on the next page...*

| Field    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | <p>return an invalid value. The host driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver shall wait, until PRSSTAT[DLA] is cleared, before writing to this register.</p> <p>The SDHC internal DMA does not support a virtual memory system. It supports only continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, SDHC will automatically change SEQ burst type to NSEQ.</p> <p>Because this register supports dynamic address reflecting, when IRQSTAT[TC] bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when IRQSTAT[TC] is set.</p> |
| Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**61.5.2 Block Attributes register (SDHC\_BLKATTR)**

This register is used to configure the number of data blocks and the number of bytes in each block.

**SDHC\_BLKATTR field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–16<br>BLKCNT | <p>Blocks Count For Current Transfer</p> <p>This register is enabled when XFERTYP[BCEN] is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The host driver shall set this register to a value between 1 and the maximum block count. The SDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register must be accessed only when no transaction is executing, that is, after transactions are stopped. During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p> <p>When saving transfer content as a result of a suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register must be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when suspend command is sent out, SDHC will regard the current transfer as aborted and change BLKCNT back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a resume command, the host driver shall restore the previously saved block count.</p> <p><b>NOTE:</b> Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when XFERTYP[MSBSEL] is 0, indicating a single block transfer, the read value of BLKCNT is always 1.</p> |

Table continues on the next page...

| Field  | Description                                                                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMDARG | Command Argument<br><br>The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This register is write protected when PRSSTAT[CDIHB0] is set. |

## 61.5.4 Transfer Type register (SDHC\_XFERTYP)

This register is used to control the operation of data transfers. The host driver shall set this register before issuing a command followed by a data transfer, or before issuing a resume command. To prevent data loss, the SDHC prevents writing to the bits that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver shall check PRSSTAT[CDIHB] and PRSSTAT[CIHB] before writing to this register. When PRSSTAT[CDIHB] is set, any attempt to send a command with data by writing to this register is ignored; when PRSSTAT[CIHB] bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is nonzero. Besides, block count must also be nonzero, or indicated as single block transfer (bit 5 of this register is 0 when written), or block count is disabled (bit 1 of this register is 0 when written), otherwise SDHC will ignore the sending of this command and do nothing.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, SDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver must issue the command again to retry the transfer. It is also possible that, for some reason, the card responds to the command but SDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The following table shows the summary of how register settings determine the type of data transfer.

**Table 61-2. Transfer Type register setting for various transfer types**

| Multi/Single block select | Block count enable | Block count     | Function          |
|---------------------------|--------------------|-----------------|-------------------|
| 0                         | Don't care         | Don't care      | Single transfer   |
| 1                         | 0                  | Don't care      | Infinite transfer |
| 1                         | 1                  | Positive number | Multiple transfer |
| 1                         | 1                  | Zero            | No data transfer  |

The following table shows the relationship between XFERTYP[CICEN] and XFERTYP[CCCEN], in regards to XFERTYP[RSPTYP] as well as the name of the response type.

**Table 61-3. Relationship between parameters and the name of the response type**

| Response type (RSPTYP) | Index check enable (CICEN) | CRC check enable (CCCEN) | Name of response type |
|------------------------|----------------------------|--------------------------|-----------------------|
| 00                     | 0                          | 0                        | No Response           |
| 01                     | 0                          | 1                        | IR2                   |
| 10                     | 0                          | 0                        | R3,R4                 |
| 10                     | 1                          | 1                        | R1,R5,R6              |
| 11                     | 1                          | 1                        | R1b,R5b               |

**NOTE**

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the SDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Address: 400B\_1000h base + Ch offset = 400B\_100Ch

## SDHC\_XFERTYP field descriptions (continued)

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23–22<br>CMDTYP | <p>Command Type</p> <p>There are three types of special commands: suspend, resume, and abort. These bits shall be set to 00b for all other commands.</p> <ul style="list-style-type: none"> <li>• Suspend command: If the suspend command succeeds, the SDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DAT line. Because the SDHC does not monitor the content of command response, it does not know if the suspend command succeeded or not. It is the host driver's responsibility to check the status of the suspend command and send another command marked as suspend to inform the SDHC that a suspend command was successfully issued. After the end bit of command is sent, the SDHC deasserts read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the suspend command fails, the SDHC will maintain its current state, and the host driver shall restart the transfer by setting PROCTL[CREQ].</li> <li>• Resume command: The host driver restarts the data transfer by restoring the registers saved before sending the suspend command and then sends the resume command. The SDHC will check for a pending busy state before starting write transfers.</li> <li>• Abort command: If this command is set when executing a read transfer, the SDHC will stop reads to the buffer. If this command is set when executing a write transfer, the SDHC will stop driving the DAT line. After issuing the abort command, the host driver must issue a software reset (abort transaction).</li> </ul> <p>00b Normal other commands.<br/> 01b Suspend CMD52 for writing bus suspend in CCCR.<br/> 10b Resume CMD52 for writing function select in CCCR.<br/> 11b Abort CMD12, CMD52 for writing I/O abort in CCCR.</p> |
| 21<br>DPSEL     | <p>Data Present Select</p> <p>This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following:</p> <ul style="list-style-type: none"> <li>• Commands using only the CMD line, for example: CMD52.</li> <li>• Commands with no data transfer, but using the busy signal on DAT[0] line, R1b or R5b, for example: CMD38.</li> </ul> <p><b>NOTE:</b> In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>0b No data present.<br/> 1b Data present.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 20<br>CICEN     | <p>Command Index Check Enable</p> <p>If this bit is set to 1, the SDHC will check the index field in the response to see if it has the same value as the command index. If it is not, it is reported as a command index error. If this bit is set to 0, the index field is not checked.</p> <p>0b Disable<br/> 1b Enable</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 19<br>CCEN      | <p>Command CRC Check Enable</p> <p>If this bit is set to 1, the SDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Field   | Description        |
|---------|--------------------|
| CMDRSP1 | Command Response 1 |

### 61.5.7 Command Response 2 (SDHC\_CMDRSP2)

This register is used to store part 2 of the response bits from the card.

Address: 400B\_1000h base + 18h offset = 400B\_1018h

#### SDHC\_CMDRSP2 field descriptions

| Field   | Description        |
|---------|--------------------|
| CMDRSP2 | Command Response 2 |

### 61.5.8 Command Response 3 (SDHC\_CMDRSP3)

This register is used to store part 3 of the response bits from the card.

The following table describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

**Table 61-4. Response bit definition for each response type**

| Response type             | Meaning of response                               | Response field | Response register                          |
|---------------------------|---------------------------------------------------|----------------|--------------------------------------------|
| R1,R1b (normal response)  | Card status                                       | R[39:8]        | CMDRSP0                                    |
| R1b (Auto CMD12 response) | Card status for auto CMD12                        | R[39:8]        | CMDRSP3                                    |
| R2 (CID, CSD register)    | CID/CSD register [127:8]                          | R[127:8]       | {CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0} |
| R3 (OCR register)         | OCR register for memory                           | R[39:8]        | CMDRSP0                                    |
| R4 (OCR register)         | OCR register for I/O etc.                         | R[39:8]        | CMDRSP0                                    |
| R5, R5b                   | SDIO response                                     | R[39:8]        | CMDRSP0                                    |
| R6 (Publish RCA)          | New published RCA[31:16]<br>and card status[15:0] | R[39:9]        | CMDRSP0                                    |

This table shows that most responses with a length of 48 (R[47:0]) have 32-bit of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bit of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the SDHC stores only a part of the response data in the command response registers. This enables the host driver to efficiently read 32-bit of response data in one read cycle on a 32-bit bus system. Parts of the response, the index field and the CRC, are checked by the SDHC, as specified by XFERTYP[CICEN] and XFERTYP[CCCEN], and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the SDHC will check R[47:1], and if the response length is 136 the SDHC will check R[119:1].

Because the SDHC may have a multiple block data transfer executing concurrently with a CMD\_wo\_DAT command, the SDHC stores the auto CMD12 response in the CMDRSP3 register. The CMD\_wo\_DAT response is stored in CMDRSP0. This allows the SDHC to avoid overwriting the Auto CMD12 response with the CMD\_wo\_DAT and vice versa. When the SDHC modifies part of the command response registers, as shown in the table above, it preserves the unmodified bits.

|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATCONT | Data Content<br><br>The Buffer Data Port register is for 32-bit data access by the CPU or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s. |

### 61.5.10 Present State register (SDHC\_PRSTAT)

The host driver can get status of the SDHC from this 32-bit read-only register.

#### NOTE

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CIHB) is set to zero. Other commands shall be issued when Command Inhibit (CDIHB) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

| 3<br>SDSTB  | <p>SD Clock Stable</p> <p>Indicates that the internal card clock is stable. This bit is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear SYSCTL[SDCLKEN] to remove glitch on the card clock when the frequency is changing.</p> <p>0b Clock is changing frequency and not stable.</p> <p>1b Clock is stable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2<br>DLA    | <p>Data Line Active</p> <p>Indicates whether one of the DAT lines on the SD bus is in use.</p> <p><b>In the case of read transactions:</b></p> <p>This status indicates whether a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a block gap event interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to PROCTL[CREQ] to restart a read transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ol style="list-style-type: none"> <li>1. When the end bit of the last data block is sent from the SD bus to the SDHC.</li> <li>2. When the read wait state is stopped by a suspend command and the DAT2 line is released.</li> </ol> <p>The SDHC will wait at the next block gap by driving read wait at the start of the interrupt cycle. If the read wait signal is already driven (data buffer cannot receive data), the SDHC can wait for a current block gap by continuing to drive the read wait signal. It is necessary to support read wait to use the suspend / resume function. This bit will remain 1 during read wait.</p> <p><b>In the case of write transactions:</b></p> <p>This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a transfer complete interrupt in the interrupt status register.</p> |

## SDHC\_PRSTAT field descriptions (continued)

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>After the end bit of the write command.</li> <li>When writing to 1 to PROCTL[CREQ] to continue a write transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>When the SD card releases write busy of the last data block, the SDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the SDHC shall assume the card drive "Not busy".</li> <li>When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request.</li> </ul> <p><b>In the case of command with busy pending:</b></p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released.</p> <p>0b DAT line inactive.<br/>1b DAT line active.</p> |
| 1<br>CDIHB | <p>Command Inhibit (DAT)</p> <p>This status bit is generated if either the DLA or the RTA is set to 1. If this bit is 0, it indicates that the SDHC can issue the next SD/MMC Command. Commands with a busy signal belong to CDIHB, for example, R1b, R5b type. Except in the case when the command busy is finished, changing from 1 to 0 generates a transfer complete interrupt in the Interrupt Status register.</p> <p><b>NOTE:</b> The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>0b Can issue command which uses the DAT line.<br/>1b Cannot issue command which uses the DAT line.</p>                                                                                                                                                                                                                                                                                                                                                    |
| 0<br>CIHB  | <p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the SDHC can issue a SD/MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the CDIHB bit is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a command complete interrupt in the interrupt status register. If the SDHC cannot issue the command because of a command conflict error (see command CRC error) or because of a command not issued by auto CMD12 error, this bit will remain 1 and the command complete is not set. The status of issuing an auto CMD12 does not show on this bit.</p> <p>0b Can issue command using only CMD line.<br/>1b Cannot issue command.</p>                                                                                                                         |

### 61.5.11 Protocol Control register (SDHC\_PROCTL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the SDHC issues a suspend command or the SD card accepts the suspend command:

- If the host driver does not issue a suspend command, the continue request shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card accepts it, a resume command shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card does not accept it, the continue request shall be used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver shall wait for a transfer complete (in the interrupt status register), before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver shall clear the stop at block gap request before or simultaneously.

| 19<br>IABG        | <p>Interrupt At Block Gap</p> <p>Valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card can't signal an interrupt during a multiple block transfer, this bit must be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>0b Disabled<br/>1b Enabled</p>                                                                                                                                                                                                                                                                                                                       |
| 18<br>RWCTL       | <p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the SDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the SDHC will stop the SD Clock to pause reading operation.</p> <p>0b Disable read wait control, and stop SD clock at block gap when SABGREQ is set.<br/>1b Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set.</p> |
| 17<br>CREQ        | <p>Continue Request</p> <p>Used to restart a transaction which was stopped using the PROCTL[SABGREQ]. When a suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set PROCTL[SABGREQ] to 0 and set this bit to 1 to restart the transfer.</p> <p>The SDHC automatically clears this bit, therefore it is not necessary for the host driver to set this bit to 0. If both PROCTL[SABGREQ] and this bit are 1, the continue request is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                              |

| 16<br>SABGREQ     | <p>Stop At Block Gap Request</p> <p>Used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the IRQSTATEN[TCSSEN] is set to 1, indicating a transfer completion, the host driver shall leave this bit set to 1. Clearing both PROCTL[SABGREQ] and PROCTL[CREQ] does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The SDHC will honor the PROCTL[SABGREQ] for write transfers, but for read transfers it requires that SDIO card support read wait. Therefore, the host driver shall not set this bit during read transfers unless the SDIO card supports read wait and has set PROCTL[RWCTL] to 1, otherwise the SDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the data port register, the host driver shall set this bit after all block data is written. If this bit is set to 1, the host driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the host driver shall not clear this bit before IRQSTATEN[TCSSEN] is set, otherwise the SDHC's behavior is undefined.</p> <p>This bit effects PRSSTAT[RTA], PRSSTAT[WTB], and PRSSTAT[CDIHB].</p> 0b Transfer<br>1b Stop |

**SDHC\_PROCTL field descriptions (continued)**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3<br>D3CD  | <p>DAT3 As Card Detection Pin</p> <p>If this bit is set, DAT3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DAT3 is also a chip-select for the SPI mode. A pulldown on this pin and CMD0 may set the card into the SPI mode, which the SDHC does not support. Note: Keep this bit set if SDIO interrupt is used.</p> <p>0b DAT3 does not monitor card Insertion.<br/>1b DAT3 as card detection pin.</p>                                                                      |
| 2–1<br>DTW | <p>Data Transfer Width</p> <p>Selects the data width of the SD bus for a data transfer. The host driver shall set it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits.</p> <p>00b 1-bit mode<br/>01b 4-bit mode<br/>10b 8-bit mode<br/>11b Reserved</p>                                                                                                                                                                                                                               |
| 0<br>LCTL  | <p>LED Control</p> <p>This bit, fully controlled by the host driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands.</p> <p>0b LED off.<br/>1b LED on.</p> |

| 31–28<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 27<br>INITA       | Initialization Active<br><br>When this bit is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this bit is self-cleared. This bit is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the PRSSTAT[CIHB] and PRSSTAT[CIDIHB] bits are set, writing 1 to this bit is ignored, that is, when command line or data lines are active, write to this bit is not allowed. On the otherhand, when this bit is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self-cleared. |
| 26<br>RSTD        | Software Reset For DAT Line<br>Only part of the data circuit is reset. DMA circuit is also reset.<br>The following registers and bits are cleared by this bit: <ul style="list-style-type: none"> <li>• Data Port register</li> <li>• Buffer Is Cleared And Initialized.Present State register</li> <li>• Buffer Read Enable</li> <li>• Buffer Write Enable</li> <li>• Read Transfer Active</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 24<br>RSTA        | <p>Software Reset For ALL</p> <p>Effects the entire host controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the host driver shall set this bit to 1 to reset the SDHC. The SDHC shall reset this bit to 0 when the capabilities registers are valid and the host driver can read them. Additional use of software reset for all does not affect the value of the capabilities registers. After this bit is set, it is recommended that the host driver reset the external card and reinitialize it.</p> <p>0b No reset.<br/>1b Reset.</p> |
| 23–20<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 19–16<br>DTCV     | <p>Data Timeout Counter Value</p> <p>Determines the interval by which DAT line timeouts are detected. See IRQSTAT[DTOE] for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value.</p> <p>The host driver can clear IRQSTATEN[DTOESEN] to prevent inadvertent time-out events.</p> <p>0000b SDCLK x 2<sup>13</sup><br/>0001b SDCLK x 2<sup>14</sup><br/>...<br/>1110b SDCLK x 2<sup>27</sup><br/>1111b Reserved</p>                                                                                                     |
| 15–8<br>SDCLKFS   | <p>SDCLK Frequency Select</p> <p>Used to select the frequency of the SDCLK pin. The frequency is not programmed directly. Rather this register holds the prescaler (this register) and divisor (next register) of the base clock frequency register.</p> <p>Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of SDHC clock and the following divisor bits.</p>                                                                                               |

## SDHC\_SYSCTL field descriptions (continued)

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <p>The frequency of SDCLK is set by the following formula: Clock frequency = (Base clock) / (prescaler x divisor)</p> <p>For example, if the base clock frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input base clock ( SDHC clock ) is about 96 MHz, the default SD clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and shall never exceed this limit.</p> <p>Only the following settings are allowed:</p> <p>01h Base clock divided by 2.<br/> 02h Base clock divided by 4.<br/> 04h Base clock divided by 8.<br/> 08h Base clock divided by 16.<br/> 10h Base clock divided by 32.<br/> 20h Base clock divided by 64.<br/> 40h Base clock divided by 128.<br/> 80h Base clock divided by 256.</p> |
| 7-4<br>DVS   | <p>Divisor</p> <p>Used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisor without deterioration of duty cycle.</p> <p>The setting are as following:</p> <p>0h Divisor by 1.<br/> 1h Divisor by 2.<br/> ...<br/> Eh Divisor by 15.<br/> Fh Divisor by 16.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3<br>SDCLKEN | <p>SD Clock Enable</p> <p>The host controller shall stop SDCLK when writing this bit to 0. SDCLK frequency can be changed when this bit is 0. Then, the host controller shall maintain the same clock frequency until SDCLK is stopped (stop at SDCLK = 0). If the IRQSTAT[CINS] is cleared, this bit must be cleared by the host driver to save power.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 2<br>PEREN   | <p>Peripheral Clock Enable</p> <p>If this bit is set, SDHC clock will always be active and no automatic gating is applied. Thus the SDCLK is active except for when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the SDHC clock will be automatically off whenever there is no transaction on the SD bus. Because this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The SDHC clock will be internally gated off, if none of the following factors are met:</p> <ul style="list-style-type: none"> <li>• The cmd part is reset, or</li> <li>• Data part is reset, or</li> <li>• A soft reset, or</li> <li>• The cmd is about to send, or</li> <li>• Clock divisor is just updated, or</li> <li>• Continue request is just set, or</li> <li>• This bit is set, or</li> <li>• Card insertion is detected, or</li> <li>• Card removal is detected, or</li> </ul>                                                                                                                                                                                                                                    |

| 0<br>IPGEN | <p>IPG Clock Enable</p> <p>If this bit is set, bus clock will always be active and no automatic gating is applied. The bus clock will be internally gated off, if none of the following factors are met:</p> <ul style="list-style-type: none"> <li>The cmd part is reset, or</li> <li>Data part is reset, or</li> <li>Soft reset, or</li> <li>The cmd is about to send, or</li> <li>Clock divisor is just updated, or</li> <li>Continue request is just set, or</li> <li>This bit is set, or</li> <li>Card insertion is detected, or</li> <li>Card removal is detected, or</li> <li>Card external interrupt is detected, or</li> <li>The SDHC clock is not gated off</li> </ul> <p><b>NOTE:</b> The bus clock will not be auto gated off if the SDHC clock is not gated off. So clearing only this bit has no effect unless the PEREN bit is also cleared.</p> <p>0b Bus clock will be internally gated off.<br/>1b Bus clock will not be automatically gated off.</p> |

**61.5.13 Interrupt Status register (SDHC\_IRQSTAT)**

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the CTOE and the CC bits.

**Table 61-5. SDHC status for CTOE/CC bit combinations**

| Command complete | Command timeout error | Meaning of the status                        |
|------------------|-----------------------|----------------------------------------------|
| 0                | 0                     | X                                            |
| X                | 1                     | Response not received within 64 SDCLK cycles |
| 1                | 0                     | Response received                            |

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 61-6. SDHC status for data timeout error/transfer complete bit combinations**

| Transfer complete | Data timeout error | Meaning of the status            |
|-------------------|--------------------|----------------------------------|
| 0                 | 0                  | X                                |
| 0                 | 1                  | Timeout occurred during transfer |
| 1                 | X                  | Data transfer complete           |

The table below shows the relationship between the command CRC Error (CCE) and Command Timeout Error (CTOE).

**Table 61-7. SDHC status for CCE/CTOE Bit Combinations**

| Command complete | Command timeout error | Meaning of the status  |
|------------------|-----------------------|------------------------|
| 0                | 0                     | No error               |
| 0                | 1                     | Response timeout error |
| 1                | 0                     | Response CRC error     |
| 1                | 1                     | CMD line conflict      |

| 28<br>DMAE        | DMA Error<br><br>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver shall restart the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DSADDR value or from the remaining number of blocks and the block size.<br><br>0b No error.<br>1b Error. |

| 8<br>CINT        | <p>Card Interrupt</p> <p>This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the SDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this bit to 1 can clear this bit, but as the interrupt factor from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt factor from the external card followed by a writing 1 to this bit.</p> |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (it must reset the interrupt factors in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.</p> <p>0b No Card Interrupt.<br/>1b Generate Card Interrupt.</p>                                                                               |
| 7<br>CRM  | <p>Card Removal</p> <p>This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. To leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register.</p> <p>0b Card state unstable or inserted.<br/>1b Card removed.</p>   |
| 6<br>CINS | <p>Card Insertion</p> <p>This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. To leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.</p> <p>0b Card state unstable or removed.<br/>1b Card inserted.</p> |
| 5<br>BRR  | <p>Buffer Read Ready</p> <p>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. See the Buffer Read Enable bit in the Present State register for additional information.</p> <p>0b Not ready to read buffer.<br/>1b Ready to read buffer.</p>                                                                                                                                                                                                                                                                                                                                                          |
| 4<br>BWR  | <p>Buffer Write Ready</p> <p>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. See the Buffer Write Enable bit in the Present State register for additional information.</p> <p>0b Not ready to write buffer.<br/>1b Ready to write buffer.</p>                                                                                                                                                                                                                                                                                                                                                     |
| 3<br>DINT | <p>DMA Interrupt</p> <p>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set.</p> <p>0b No DMA Interrupt.<br/>1b DMA Interrupt is generated.</p>                                                                                                                                                                                                                                                                                                   |

|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2<br>BGE | <p>Block Gap Event</p> <p>If PROCTL[SABGREQ] is set, this bit is set when a read or write transaction is stopped at a block gap. If PROCTL[SABGREQ] is not set to 1, this bit is not set to 1.</p> <p>In the case of a read transaction: This bit is set at the falling edge of the DAT line active status, when the transaction is stopped at SD Bus timing. The read wait must be supported in order to use this function.</p> <p>In the case of write transaction: This bit is set at the falling edge of write transfer active status, after getting CRC status at SD bus timing.</p> <p>0b No block gap event.<br/>1b Transaction stopped at block gap.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 1<br>TC  | <p>Transfer Complete</p> <p>This bit is set when a read or write transfer is completed.</p> <p>In the case of a read transaction: This bit is set at the falling edge of the read transfer active status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length, after the last data has been read to the host system. The second is when data has stopped at the block gap and completed the data transfer by setting PROCTL[SABGREQ], after valid data has been read to the host system.</p> <p>In the case of a write transaction: This bit is set at the falling edge of the DAT line active status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting PROCTL[SABGREQ], and the data transfers are completed, after valid data is written to the SD card and the busy signal released.</p> <p>0b Transfer not complete.<br/>1b Transfer complete.</p> |
| 0<br>CC  | <p>Command Complete</p> <p>This bit is set when you receive the end bit of the command response, except Auto CMD12. See PRSSTAT[CIHB].</p> <p>0b Command not complete.<br/>1b Command complete.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**61.5.14 Interrupt Status Enable register (SDHC\_IRQSTATEN)**

Setting the bits in this register to 1 enables the corresponding interrupt status to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is also cleared, that is, when the bit in this register is cleared, the corresponding bit in interrupt status register is always 0.

**NOTE**

- Depending on PROCTL[IABG] bit setting, SDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the card interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both IRQSTATEN[CTOESEN] and IRQSTATEN[CCESEN] to 1.

Address: 400B\_1000h base + 34h offset = 400B\_1034h

**61.5.15 Interrupt Signal Enable register (SDHC\_IRQSIGEN)**

This register is used to select which interrupt status is indicated to the host system as the interrupt. All of these status bits share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Address: 400B\_1000h base + 38h offset = 400B\_1038h

**61.5.16 Auto CMD12 Error Status Register (SDHC\_AC12ERR)**

When the AC12ESEN bit in the Status register is set, the host driver shall check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

The following table shows the relationship between the Auto CMGD12 CRC error and the Auto CMD12 command timeout error.

**Table 61-8. Relationship between Command CRC Error and Command Timeout Error For Auto CMD12**

| Auto CMD12 CRC error | Auto CMD12 timeout error | Type of error          |
|----------------------|--------------------------|------------------------|
| 0                    | 0                        | No error               |
| 0                    | 1                        | Response timeout error |
| 1                    | 0                        | Response CRC error     |
| 1                    | 1                        | CMD line conflict      |

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the SDHC is going to issue an Auto CMD12:
  - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command.
  - Set bit 0 to 0 if the auto CMD12 is issued.
2. At the end bit of an auto CMD12 response:
  - Check errors corresponding to bits 1-4.
  - Set bits 1-4 corresponding to detected errors.
  - Clear bits 1-4 corresponding to detected errors.
3. Before reading the Auto CMD12 error status bit 7:
  - Set bit 7 to 1 if there is a command that can't be issued.
  - Clear bit 7 if there is no command to issue.

The timing for generating the auto CMD12 error and writing to the command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the command register. So it is suggested to read this register only when IRQSTAT[AC12E] is set. An Auto CMD12 error interrupt is generated when one of the error bits (0-4) is set to 1. The command not issued by auto CMD12 error does not generate an interrupt.

### 61.5.17 Host Controller Capabilities (SDHC\_HTCAPBLT)

This register provides the host driver with information specific to the SDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset. Any write to this register is ignored.

### 61.5.19 Force Event register (SDHC\_FEVT)

The Force Event (FEVT) register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding bit of the Interrupt Status Enable register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status register. A read from this register always results in 0's. To change the corresponding status bits in the interrupt status register, make sure to set SYSCTL[IPGEN] so that bus clock is always active.

## Memory map and register definition

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is selfcleared.

Address: 400B\_1000h base + 50h offset = 400B\_1050h

### 61.5.20 ADMA Error Status register (SDHC\_ADMAES)

When an ADMA error interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- **ST\_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST\_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST\_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST\_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver must use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data may exist in the host controller.

The host controller generates the ADMA error interrupt when it detects invalid descriptor data (valid = 0) in the ST\_FDS state. The host driver can distinguish this error by reading the valid bit of the error descriptor.

**Table 61-9. ADMA Error State coding**

| D01-D00 | ADMA Error State when error has occurred | Contents of ADMA System Address register                    |
|---------|------------------------------------------|-------------------------------------------------------------|
| 00      | ST_STOP (Stop DMA)                       | Holds the address of the next executable descriptor command |
| 01      | ST_FDS (fetch descriptor)                | Holds the valid descriptor address                          |
| 10      | ST_CADR (change address)                 | No ADMA error is generated                                  |
| 11      | ST_TFR (Transfer Data)                   | Holds the address of the next executable descriptor command |

Address: 400B\_1000h base + 54h offset = 400B\_1054h

**SDHC\_ADSADDR field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–2<br>ADSADDR | ADMA System Address<br><br>Holds the word address of the executing command in the descriptor table. At the start of ADMA, the host driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a descriptor command. When the ADMA is stopped at the block gap, this register indicates the address of the next executable descriptor command. When the ADMA error interrupt is generated, this register shall hold the valid descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word-aligned. Because this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. |
| Reserved        | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

61.5.22 Vendor Specific register (SDHC\_VENDOR)

This register contains the vendor-specific control/status register.

Address: 400B\_1000h base + C0h offset = 400B\_10C0h

## 61.6 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA crossbar switch interface, dual-port memory wrapper, data/command controller, clock & reset manager, and clock generator.

### 61.6.1 Data buffer

The SDHC uses one configurable data buffer, so that data can be transferred between the system bus and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). The following diagram illustrates the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

**Figure 61-3. SDHC buffer scheme**

There are 3 transfer modes to access the data buffer:

- CPU Polling mode:

- For a host read operation, when the number of words received in the buffer meets or exceeds the RDWML watermark value, then by polling IRQSTAT[BRR] the host driver can read the DATPORT register to fetch the amount of words set in the WML register from the buffer. The write operation is similar.
- Internal DMA mode (includes simple and advanced DMA access's):
  - The internal DMA access, either by simple or advanced DMA, is over the crossbar switch bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in WML, the internal DMA starts fetching data over the crossbar switch bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of WML
2. Watermark level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor if the ADMA is active
5. 1 KB address boundary

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software, as illustrated in the following diagrams. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

**Figure 61-4. Data swap between system bus and SDHC data buffer in byte little endian mode**

**Figure 61-5. Data swap between system bus and SDHC data buffer in half word big endian mode**

### 61.6.1.1 Write operation sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. Using external DMA through the SDHC DMA request signal.
2. Processor core polling through IRQSTAT[BWR] (interrupt or polling).
3. Using the internal DMA.

When the internal DMA is not used, that is, the XFERTYP[DMAEN] bit is not set when the command is sent, the SDHC asserts a DMA request when the amount of buffer space exceeds the value set in WML, and is ready for receiving new data. At the same time, the SDHC would set IRQSTAT[BWR]. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the contents of the DSADDR to get the starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the write operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

The SDHC will not start data transmission until the number of words set in WML can be held in the buffer. If the buffer is empty and the host system does not write data in time, the SDHC will stop the SD\_CLK to avoid the data buffer underrun situation.

### 61.6.1.2 Read operation sequence

There are three ways to read data from the buffer when the user transfers data to the card:

1. Processor core polling through IRQSTAT[BRR] (interrupt or polling)

## 2. Using the internal DMA

When internal DMA is not used, that is, XFERTYP[DMAEN] is not set when the command is sent, the SDHC asserts a DMA request when the amount of data exceeds the value set in WML, that is available and ready for system fetching data. At the same time, the SDHC would set IRQSTAT[BRR]. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block.

The host driver must read the content of the DMA system address register to get the starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

For any write transfer mode, the SDHC will not start data transmission until the number of words set in WML are in the buffer. If the buffer is full and the Host System does not read data in time, the SDHC will stop the SDHC\_DCLK to avoid the data buffer overrun situation.

### 61.6.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to use it in the most optimized way. In the SDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length can be from 1 word to the maximum of 31 words. The host driver may configure the value according to the system situation and requirement.

During a multiblock data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive, which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it doesn't support a partial block access, which is not the integer times of 512 bytes.

For block size not times of 4, that is, not word aligned, SDHC requires stuff bytes at the end of each block, because the SDHC treats each block individually. For example, the block size is 7 bytes, there are 12 blocks to write, the system side must write 2 times for

each block, and for each block, the ending byte would be abandoned by the SDHC because it sends only 7 bytes to the card and picks data from the following system write, so there would be 24 beats of write access in total.

#### 61.6.1.4 Dividing large data transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

The following diagram illustrates the dividing of large data transfers. Assuming a kind of WLAN SDIO card supports block size only up to 64 bytes. Although the SDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided. See the example below.

Figure 61-6. Example for dividing large data transfers

61.6.2 DMA crossbar switch interface

The internal DMA implements a DMA engine and the crossbar switch master. When the internal DMA is enabled (XFERTYP[DMAEN] is set), the interrupt status bits are set if they are enabled. To avoid setting them, clear IRQSTATEN[BWRSEN, BRRSEN]. The following diagram illustrates the DMA crossbar switch interface block.

Figure 61-7. DMA crossbar switch interface block

### 61.6.2.1 Internal DMA request

If the watermark level requirement is met in data transfer, and the internal DMA is enabled, the data buffer block sends a DMA request to the crossbar switch interface. Meanwhile, the external DMA request signal is disabled. The delay in response from the internal DMA engine depends on the system bus loading and the priority assigned to the SDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multiblock data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer, which might contain some data of the next block, another DMA request read is sent. This is because the remaining number of words to send for the current block is  $(31 - 6 * 4) / 4 = 2$ . The SDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

### 61.6.2.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in [Internal DMA request](#) again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block

starts, which is 31 bytes, more than 6 words. The host driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

### 61.6.2.3 Crossbar switch master interface

It is possible that the internal DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. IRQSTAT[DMAE] is set to inform the driver.

After the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read DSADDR[DSADDR] to get the starting address of the corrupted block. After the DMA error is fixed, the software must apply a data reset and restart the transfer from this address to recover the corrupted block.

### 61.6.2.4 ADMA engine

In the SDHC standard, the new DMA transfer algorithm called the advanced DMA (ADMA) is defined. For simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention would not be needed during long DMA-based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in host controller. ADMA1 can support data transfer of 4 KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of descriptor table are different.

ADMA can recognize all kinds of descriptors defined in the SDHC standard, and if end flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

#### 61.6.2.4.1 ADMA concept and descriptor format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor

- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor
- Rsv descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the Valid flag of descriptor is 0, it will ignore the high 32-bit. The address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before tran type descriptor. Every tran type will trigger a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous tran descriptor, the data length will be the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, tran type descriptor contains both the data length and transfer data address, so only a tran type descriptor can start a data transfer.

**Table 61-10. Format of the ADMA1 descriptor table**

| Address/page field     |    | Address/page field |   | Attribute field |      |                 |     |              |              |

| 0              |    | 1                                                                                                                   |    | rsv        |    | Reserved        |                 | Same as nop. Read this line and go to next one                    |     |     |       |
| 1              |    | 0                                                                                                                   |    | tran       |    | Transfer data   |                 | Transfer data with address and length set in this descriptor line |     |     |       |
| 1              |    | 1                                                                                                                   |    | link       |    | Link descriptor |                 | Link to another descriptor                                        |     |     |       |
| Valid          |    | Valid = 1 indicates this line of descriptor is effective. If valid = 0 generate ADMA error interrupt and stop ADMA. |    |            |    |                 |                 |                                                                   |     |     |       |
| End            |    | End = 1 indicates current descriptor is the ending one.                                                             |    |            |    |                 |                 |                                                                   |     |     |       |
| Int            |    | Int = 1 generates DMA interrupt when this descriptor is done.                                                       |    |            |    |                 |                 |                                                                   |     |     |       |

**Figure 61-9. Concept and access method of ADMA2 descriptor table**

#### 61.6.2.4.2 ADMA interrupt

If the interrupt flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

#### 61.6.2.4.3 ADMA error

The ADMA stops whenever any error is encountered. These errors include:

- Fetching descriptor error

- Transfer error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect the valid flag in the descriptor. If ADMA descriptor error occurs, the interrupt is not generated even if the interrupt flag of this descriptor is set.

When XFERTYP[BCEN] is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If XFERTYP[BCEN] is not set, the whole data length set in descriptor must be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

### **61.6.3 SD protocol unit**

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into the corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD transceiver
- SD clock and monitor
- Command agent
- Data agent

### 61.6.3.1 SD transceiver

In the SD protocol unit, the transceiver is the main control module. It consists of a FSM and control module, from which the control signals for all other three modules are generated.

### 61.6.3.2 SD clock & monitor

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the register bank. The driver can use this for debug purposes.

The module also detects the card detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when PROCTL[D3CD] is set.

The module detects the write protect (WP) line. With the information of the WP state, the register bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this module will open and the SD clock will be active again.

This module also drives the SDHC\_LCTL output signal when PROCTL[LCTL] is set by the driver.

### 61.6.3.3 Command agent

The command agent deals with the transactions on the CMD line. The following diagram illustrates the structure for the command CRC Shift Register.

## Functional description

**Figure 61-10. Command CRC Shift Register**

The CRC polynomials for the CMD line are as follows:

Generator polynomial:  $G(x) = x^7 + x^3 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

### 61.6.3.4 Data agent

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DAT[0] line, and generates the read wait state by the request from the transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial:  $G(x) = x^{16} + x^{12} + x^5 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

### 61.6.4 Clock and reset manager

This module controls all the reset signals within the SDHC.

There are four kinds of reset signals within the SDHC:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

There are three clocks inside the SDHC:

- Bus clock
- SDHC clock
- System clock

The module monitors the activities of all other modules, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

### 61.6.5 Clock generator

The clock generator generates the SDHC\_CLK by peripheral source clock in two stages. The following diagram illustrates the structure of the divider. The term "base" represents the frequency of peripheral source clock.

**Figure 61-11. Two stages of the clock divider**

The first stage outputs an intermediate clock (DIV), which can be base, base/2, base/3, ..., or base/16.

The second stage is a prescaler, and outputs the actual clock (SDHC\_CLK). This clock is the driving clock for all submodules of the SD protocol unit, and the sync FIFOs to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4,..., or DIV/256. Thus, the highest frequency of the SDHC\_CLK is base, and the next highest is base/2, while the lowest frequency is base/4096. If the base clock is of equal duty ratio (usually true), the duty cycle of SDHC\_CLK is also 50%, even when the compound divisor is an odd value.

### 61.6.6 SDIO card interrupt

This section discusses SDIO interrupt handling.

#### 61.6.6.1 Interrupts in 1-bit mode

In this case, the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

### 61.6.6.2 Interrupt in 4-bit mode

Because the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will be sent by the card and recognized by the host only during a specific time. This is known as the interrupt period. The SDHC will only sample the level on pin 8 during the interrupt period. At all other times, the host will ignore the level on pin 8, and treat it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the interrupt period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the interrupt period. In this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the SDHC\_D1 line will be held low for one clock cycle with the last clock cycle pulling SDHC\_D1 high. On completion of the Interrupt Period, the card releases the SDHC\_D1 line into the high Z state. The SDHC samples the SDHC\_D1] during the interrupt period when PROCTL[IABG] is set.

See the SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

### 61.6.6.3 Card interrupt handling

When IRQSIGEN[CINTIEN] is set to 0, the SDHC clears the interrupt request to the host system. The host driver must clear this bit before servicing the SDIO Interrupt and must set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the SDHC will detect the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the host system interrupt controller. When the SDIO status has been set, and the host driver needs to service this interrupt, so the SDIO bit in the interrupt control register of the SDIO card will be cleared. This is required to clear the

SDIO interrupt status latched in the SDHC and to stop driving the interrupt signal to the system interrupt controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the SDHC starts sampling the interrupt signal again.

The following diagram illustrates the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 61-12. Card interrupt scheme and card interrupt detection and handling procedure**

### 61.6.7 Card insertion and removal detection

The SDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the SDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card

detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the SDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

### 61.6.8 Power management and wakeup events

When there is no operation between the SDHC and the card through the SD bus, the user can completely disable the bus clock and the SDHC clock in the chip-level clock control module to save power. When the user needs to use the SDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the SDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The SDHC can generate these interrupt even when there are no clocks enabled.

The three interrupts which can be used as wakeup events are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The SDHC offers a power management feature. By clearing the clock enabled bits in the system control register, the clocks are gated in the low position to the SDHC. For maximum power saving, the user can disable all the clocks to the SDHC when there is no operation in progress.

These three wakeup events, or wakeup interrupts, can also be used to wake up the system from low-power modes.

#### Note

To make the interrupt a wakeup event, when all the clocks to the SDHC are disabled or when the whole system is in low-power mode, the corresponding wakeup enabled bit needs to be set. See Protocol Control register for more information.

### 61.6.8.1 Setting wakeup events

For the SDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters Sleep mode. Before the software disables the host clock, it must ensure that all of the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

### 61.6.9 MMC fast boot

In Embedded MultiMediaCard(eMMC4.3) spec, add fast boot feature needs hardware support.

In Boot Operation mode, the master (multimediacard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

There are two types of Fast Boot mode, boot operation, and Alternative boot operation in eMMC4.3 spec. Each type also has with acknowledge and without acknowledge modes.

#### Note

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

#### 61.6.9.1 Boot operation

#### Note

In this block guide, this fast boot is called Normal Fast Boot mode.

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that Boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes low, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line low to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern 010 to the master within 50 ms after the CMD line goes low. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate Boot mode with the CMD line high.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 61-13. Multimediacard state diagram in Normal Boot mode**

### 61.6.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to 1, the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued, or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 61-14. MultiMediaCard state diagram in Alternative Boot mode**

## 61.7 Initialization/application of SDHC

All communication between system and cards are controlled by the host. The host sends commands of two types:

- Broadcast
- Addressed point-to-point

Broadcast commands are intended for all cards, such as GO\_IDLE\_STATE, SEND\_OP\_COND, ALL\_SEND\_CID, and so on. In Broadcast mode, all cards are in the Open-Drain mode to avoid bus contention. See [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter Standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to Push-Pull mode, to have the driving capability for maximum frequency operation. See [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

### 61.7.1 Command send and response receive basic operation

Assuming the data type WORD is an unsigned 32-bit integer, the following flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
 WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
 recommended to implement in a bit-field manner
 wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
 set CMDTYP, DPSEL, CICCEN, CCCEN, RSTTYP, DTDSEL according to the command index;
 if (internal DMA is used) wCmd |= 0x1;
```

## Initialization/application of SDHC

```
if (multi-block transfer) {
 set MSBSEL bit;
 if (finite block number) {
 set BCEN bit;
 if (auto12 command is to use) set AC12EN bit;
 }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
 while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
 read IRQ Status register and check if any error bits about Command are set
 if (any error bits are set) report error;
 write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the command complete interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

In some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the standby state, no response to the host when CMD2 is sent. The host driver shall deal with 'fake' errors like this with caution.

## 61.7.2 Card Identification mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the relative card address (RCA) or to set the RCA for the MMC cards.

### 61.7.2.1 Card detect

The following diagram illustrates the detection of MMC, SD, and SDIO cards using the SDHC.

**Figure 61-15. Flow diagram for card detection**

Here is the card detection sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the SDHC is received, check IRQSTAT[CINS] in the Interrupt Status register to see whether it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

### 61.7.2.2 Reset

The host consists of three types of resets:

- Hardware reset (card and host) which is driven by power on reset (POR)
- Software reset (host only) is initiated by the write operation of the SYSCTL[RSTD], SYSCTL[RSTC], or SYSCTL[RSTA] bits to reset the data part, command part, or all parts of the host controller, respectively
- Card reset (card only). The command, Go\_Idle\_State (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA = 0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. The following diagram illustrates the software flow to reset both the SDHC and the card.

**Figure 61-16. Flow chart for reset of the SDHC and SD I/O card**

```

software_reset()
{
 set_bit(SYSCTRL, RSTA); // software reset the Host
 set DTOCV and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
 configure IO pad to set the power voltage of external card to around 3.0V
 poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
 set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
 send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
 or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}

```

### 61.7.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for  $V_{DD}$  are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are able to communicate this information only under data transfer  $V_{DD}$  conditions. This means if the host and card have noncommon  $V_{DD}$  ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send\_Op\_Cont (CMD1 for MMC), SD\_Send\_Op\_Cont (ACMD41 for SD Memory) and IO\_Send\_Op\_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the  $V_{DD}$  range(s) desired by the host. This is accomplished by the host sending the desired  $V_{DD}$  voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before

sending out-of-range cards into the inactive state. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a nonusable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_arguement)
{
 label the card as UNKNOWN;
 send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
 operation voltage, command argument is zero
 if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
 if (0 < number of IO functions) {
 label the card as SDIO;
 IORDY = 0;
 while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
 send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
 wait_for_response(IO_SEND_OP_COND);
 } // end of while ...
 } // end of if (0 < ...
 if (memory part is present inside SDIO card) Label the card as SDCCombo; // this is an
 SD-Combo card
 } // end of if (RESP_TIMEOUT ...
 if (the card is labelled as SDIO card) return; // card type is identified and voltage range
 is
 set, so exit the function;
 send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
 CMD
 prefix
 if (no error calling wait_for_response(APP_CMD, <...>)) { // CMD55 is accepted
 send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
 for memory part or SD card
 wait_for_response(SD_APP_OP_COND); // voltage range is set
 if (card type is UNKNOWN) label the card as SD;
 return; //
 } // end of if (no error ...
 else if (errors other than time-out occur) { // command/response pair is corrupted
 deal with it by program specific manner;
 } // of else if (response time-out
 else { // CMD55 is refuse, it must be MMC card or CE-ATA card
 if (card is already labelled as SDCCombo) { // change label
 re-label the card as SDIO;
 ignore the error or report it;
 return; // card is identified as SDIO card
 } // of if (card is ...
 send_command(SEND_OP_COND, <voltage range>, <...>);
 if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
 label the card as UNKNOWN;
 return;
 } // of if (RESP_TIMEOUT ...
 if (check for CE-ATA signature succeeded) { // the card is CE-ATA
 store CE-ATA specific info from the signature;
 label the card as CE-ATA;
 } // of if (check for CE-ATA ...
 else label the card as MMC;
 } // of else
}

```

### 61.7.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different.

For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V, as defined by the card specification. At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the inactive state. The host then issues the command, All\_Send\_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified, in the ready state, send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send\_Relative\_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send\_Relative\_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in Open-Drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated, the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the wired OR operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state.

The host then issues the broadcast command All\_Send\_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards, the cards in ready state, simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Because the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the Identification state.

Thereafter, the host issues Set\_Relative\_Addr (CMD3) to assign to the card a relative card address (RCA). When the RCA is received the card state changes to the standby state, and the card does not react in further identification cycles, and its output driver

switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
 if (card is labelled as SDCCombo or SDIO) { // for SDIO card like device
 send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
 retrieve RCA from response;
 } // end if (card is labelled as SDCCombo ...
 else if (card is labelled as SD) { // for SD card
 send_command(ALL_SEND_CID, <...>);
 if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
 send_command(SET_RELATIVE_ADDR, <...>);
 retrieve RCA from response;
 } // else if (card is labelled as SD ...
 else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
 send_command(ALL_SEND_CID, <...>);
 rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also the
relative address to access the CE-ATA card
 send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
 } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

### 61.7.3 Card access

This section discusses the various card access methods.

#### 61.7.3.1 Block write

This section discusses the block write access methods.

##### 61.7.3.1.1 Normal write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the dat line. The transferred data will be discarded and not written, and all further transmitted blocks in Multiple Block Write mode will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS\_ERROR error bit in

the status register, and while ignoring all further data transfer, waits in the Receive-Data-state for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 to select a different card to place the card into the Standby state and release the DAT line without interrupting the write operation. When reselecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods, by means of external DMA or CPU polling status, with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC cards, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).

5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the eSDHC DMA when sending the command with data transfer. AC12EN should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 61.7.3.1.2 Write with pause

The write operation can be paused during the transfer. Instead of stopping the SD\_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set PROCTL[SABGREQ] to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to deassert to release the busy state, no suspend command is needed.

Like the flow described in [Normal write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the SDHC DMA when sending the command with data transfer. The XFERTYP[AC12EN] bit should also be set.
6. Set PROCTL[SABGREQ].
7. Wait for the transfer complete interrupt.
8. Clear PROCTL[SABGREQ].
9. Check the status bit to see whether a write CRC error occurred.

10. Set PROCTL[CREQ] to continue the write operation.
11. Wait for the transfer complete interrupt.
12. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKATTR[BLKCNT] . As the data transfer and the setting of the PROCTL[SABGREQ] bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The driver shall read the value of BLKATTR[BLKCNT] after the transfer is paused and the transfer complete interrupt is received.

It is also possible that the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the suspend command for the SDIO card. This is because when such a command is sent, the SDHC thinks the system will switch to another function on the SDIO card, and flush the data buffer. The SDHC takes the resume command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, XFERTYP[MSBSEL] and XFERTYP[BCEN] are set as well as XFERTYP[AC12EN]. However, the SDHC will automatically send a CMD12 to mark the end of the multiblock transfer.

### 61.7.3.2 Block read

This section discusses the block read access methods.

#### 61.7.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the SDHC DMA when sending the command with data transfer. XFERTYP[AC12EN] must also be set.
6. Wait for the transfer complete interrupt.
7. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

### 61.7.3.2.2 Read with pause

The read operation is not generally able to pause. Only the SDIO card and SDCombo card working under I/O mode supporting the read and wait feature can pause during the read operation. If the SDIO card support read wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the eSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. Set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Like the flow described in [Normal read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set RWCTL.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the SDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. AC12EN must also be set.
8. Set SABGREQ.
9. Wait for the Transfer Complete interrupt.
10. Clear SABGREQ.
11. Check the status bit to see whether read CRC error occurred.
12. Set CREQ to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the SDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. Whether the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the SDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the SDHC will automatically send the CMD12 to mark the end of multi-block transfer.

### 61.7.3.3 Suspend resume

The SDHC supports the suspend resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

#### 61.7.3.3.1 Suspend

After setting the PROCTL[SABGREQ] bit, the host driver may send a suspend command to switch to another function of the SDIO card. The SDHC does not monitor the content of the response, therefore it doesn't know whether the suspend command succeeded or not. Accordingly, it doesn't deassert read wait for read pause. To solve this problem, the driver shall not mark the suspend command as a suspend, that is, setting the XFERTYP[CMDTYP] bits to 01. Instead, the driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the driver send another command marked as suspend to inform the SDHC that the current transfer is suspended. As shown in the following sequence for suspend operation:

1. Set PROCTL[SABGREQ] to pause the current data transfer at block gap.
2. After IRQSTAT[BGE] is set, send the suspend command to suspend the active function. XFERTYP[CMDTYP] field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The XFERTYP[CMDTYP] of this command must be 2'b01, so the SDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the SDHC stops driving DAT2 and goes to the Idle state.
5. Save the context registers in the system memory for later use, including the DMA system address register for internal DMA operation, and the block attribute register.

6. Begin operation for another function on the SDIO card.

#### 61.7.3.3.2 Resume

To resume the data transfer, a resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step 5 of the suspend operation above.
2. Send the resume command. In the transfer type register, all fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume, except the CMDTYP is set to 2'b10.
3. If the resume command has responded, the data transfer will be resumed.

#### 61.7.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4 KB address aligned).
3. If necessary, create a link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1–3.
4. Repeat steps 1–3 until all descriptors are created.
5. In the last descriptor, set the end flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the BLKATTR register.
6. Set the DSADDR register to the address of the first descriptor and set the PROCTL[DMAS] field to 01 to select the ADMA.
7. Issue a write or read command with XFERTYP[DMAEN] set to 1.

Steps 1–5 are independent of step 6, so step 6 can finish before steps 1–5. Regarding the descriptor configuration, do not to use the link descriptor, as it requires extra system memory access.

### 61.7.3.5 Transfer error

This section discusses the handling of transfer errors.

#### 61.7.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. Discard the following data blocks and retransfer the block from the corrupted one.

For a multi-block transfer, the host driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the XFERTYP[AC12EN] and BCEND bits are set, the SDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an auto CMD12 will be sent by the SDHC. In this case, the driver shall re-send or re-obtain the last block with a single block transfer.

#### 61.7.3.5.2 Internal DMA error

During the data transfer with internal simple DMA, if the DMA engine encounters some error on the system bus, the DMA operation is aborted and DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Reading the DMA system address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Reading the BLKCNT field of the block attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the block attribute register does not change, so this method does not work.

When a DMA error occurs, abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

### 61.7.3.5.3 ADMA error

There are three kinds of possible ADMA errors: transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and retransfer from the place of interruption.

- **Transfer error:** May occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
- **Invalid descriptor error:** For such errors, retrieve the transfer context, reset for the data part, and recreate the descriptor chain from the invalid descriptor, and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- **Data-length mismatch error:** It is similar to recover from this error. The host driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

### 61.7.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and XFERTYP[AC12EN] is set when the data transfer is initiated by the data command, the SDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, the driver can deal with the situations in the following manner:

1. **Auto CMD12 response time-out:** It is not certain whether the command is accepted by the card or not. The driver should clear the IRQSTAT[AC12E] bits and resend the CMD12 until it is accepted by the card.
2. **Auto CMD12 response CRC error:** Because the card responds to the CMD12, the card will abort the transfer. The driver may ignore the error and clear the IRQSTAT[AC12E] bit.
3. **Auto CMD12 conflict error or not sent:** The command is not sent, so the driver shall send a CMD12 manually.

### 61.7.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The SDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the SDHC, and the host system is informed by the SDHC asserting the SDHC interrupt line, the interrupt service from the host driver is called.

Because the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before IRQSTAT[CINT] is cleared by written 1. See [Card interrupt handling](#) for the card interrupt handling flow.

### 61.7.4 Switch function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC specifications. The high-speed timing mode for all card devices was also recently defined in various card specifications. To enable these new features, a switch command shall be issued by the host driver.

For SDIO cards, the high-speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6, with the mnemonic symbol as SWITCH\_FUNC. For MMC cards, the high-speed mode is queried by a CMD8 and enabled by a CMD6, with the mnemonic symbol as SWITCH.

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

#### 61.7.4.1 Query, enable and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
```

```
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

### 61.7.4.2 Query, enable, and disable SD high-speed mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

### 61.7.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
```

```

card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}

```

#### 61.7.4.4 Set MMC bus width

```

change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}

```

### 61.7.5 ADMA operation

This section presents code examples for ADMA operation.

#### 61.7.5.1 ADMA1 operation

```

Set_adma1_descriptor
{
 if (to start data transfer) {
 // Make sure the address is 4KB align.
 Set 'Set' type descriptor;
 {
 Set Act bits to 01;
 Set [31:12] bits data length (byte unit);
 }
 Set 'Tran' type descriptor;
 {
 Set Act bits to 10;
 Set [31:12] bits address (4KB align);
 }
 }
 else if (to fetch descriptor at non-continuous address) {
 Set Act bits to 11;
 Set [31:12] bits the next descriptor address (4KB align);
 }
 else { // other types of descriptor
 Set Act bits accordingly
 }
}

```

```

 if (this descriptor is the last one) {
 Set End bit to 1;
 }
 if (to generate interrupt for this descriptor) {
 Set Int bit to 1;
 }
 Set Valid bit to 1;
}

```

## 61.7.5.2 ADMA2 operation

```

Set_adma2_descriptor
{
 if (to start data transfer) {
 // Make sure the address is 32-bit boundary (lower 2-bit are always '00').
 Set higher 32-bit of descriptor for this data transfer initial address;
 Set [31:16] bits data length (byte unit);
 Set Act bits to '10';
 }
 else if (to fetch descriptor at non-continuous address) {
 Set Act bits to '11';
 // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
 Set higher 32-bit of descriptor for the next descriptor address;
 }
 else { // other types of descriptor
 Set Act bits accordingly
 }
 if (this descriptor is the last one) {
 Set 'End' bit '1';
 }
 if (to generate interrupt for this descriptor) {
 Set 'Int' bit '1';
 }
 Set the 'Valid' bit to '1';
}

```

## 61.7.6 Fast boot operation

This section discusses fast boot operations.

### 61.7.6.1 Normal fast boot flow

1. Software needs to configure SYSCTL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1, MMCBOOT[BOOTMODE] to 0, and MMCBOOT[BOOTACK] to select the ack mode or not. If sending through DMA mode, software needs to configure MMCBOOT[AUTOSABGEN] to enable automatically stop at block gap feature, and MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequency.

3. Software then needs to configure BLKATTR register to set block size/no.
4. Software needs to configure PROCTL[DTW].
5. Software needs to configure CMDARG to set argument if needed (no need in normal fast boot).
6. Software needs to configure XFERTYP register to start the boot process. In Normal Boot mode, XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCEN], XFERTYP[AC12EN], XFERTYP[BCEN] and XFERTYP[DMAEN] are kept default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. Note XFERTYP[DMAEN] must be configured as 0 in polling mode. And if XFERTYP[BCEN] is configured as 1, better to configure BLKATTR[BLKSIZE] to the max value.
7. When the step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time-out happened (ack time out or the first data read time out), Interrupt will be triggered, and software need to configure MMCBOOT[BOOTEN] to 0 to disable boot. Thus will make CMD high, and then after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out, software needs to decide the data read is finished and then configure MMCBOOT[BOOTEN] to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

### 61.7.6.2 Alternative fast boot flow

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT [BOOTEN] to 1, MMCBOOT [BOOTMODE] to 1, and MMCBOOT [BOOTACK] to select the ack mode or not. If sending through DMA mode, it also needs to configure MMCBOOT [AUTOSABGEN] to enable automatically stop at block gap feature. And needs to configure MMCBOOT [DTCVACK] to select the ack timeout value according to the sd clk frequency.
3. Software then needs to configure BLKATTR register to set block size/no.

4. Software needs to configure PROCTL[DTW].
5. Software needs to configure CMDARG register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure XFERTYP register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, C ICEN, CCCEN, AC12EN, BCEN, and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in Polling mode, it is better to configure blk no in Bock Attributes Register to the max value.
7. When step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time out (ack data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMCBOOT[BOOTEN] to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after command completed, configure MMCBOOT[BOOTEN] to stop the process. After 8 clocks from command completed, slave(card) is ready for identification step.
9. Reset the host and then begin the normal process.

### 61.7.6.3 Fast boot application case in DMA mode

In the boot application case, because the image destination and the image size are contained in the beginning of the image, switching DMA parameters on the fly during MMC fast boot is required.

In fast boot, host can use ADMA2 (advanced DMA2) with two destinations.

The detail flow:

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1; and MMCBOOT[BOOTMODE] to 0 (normal fast boot), to 1(alternative boot); and MMCBOOT[BOOTACK] to select the ack mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] to set the VAULE1 (value of

block count that need to trans first time), so that host will stop at block gap when card block counter is equal to this value. And it needs to configure MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequency.

3. Software then needs to configure BLKATTR register to set block size/no. In DMA mode, it is better to set block number to the max value(16'hffff).
4. Software needs to configure PROCTL[DTW].
5. Software enables ADMA2 by configuring PROCTL[DMAS].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (that is, in IRAM, at least 6 words). The first pair descriptor define the start address (IRAM) and data length(512byte\*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writable), data length is suggest to set 1~2 word (record as VAULE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data\_length data transfer descriptor.
7. Software needs to configure CMDARG register to set argument to 0xFFFFFFFFFA in alternative fast boot, and doesn't need to be set in normal fast boot.
8. Software needs to configure XFERTYP register to start the boot process . XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCEN], XFERTYP[AC12EN], XFERTYP[BCEN], and XFERTYP[DMAEN] are kept at default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. XFERTYP[DMAEN] is configured as 1 in DMA mode. And if XFERTYP[BCEN] is configured as 1, better to configure blk no in BLKATTR register to the max value.
9. When step 8 is configured, boot process will begin, the first VAULE1 block number data has transfer. Software needs to poll IRQSTAT[TC] bit to determine first transfer is end. Also software needs to poll IRQSTAT[BGE] bit to determine if first transfer stop at block gap.
10. When IRQSTAT[TC] and IRQSTAT[BGE] bits are 1, . SW can analyzes the first code of VAULE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VAULE3 the remain boot code block). Remember set the last descriptor with END.
11. Software needs to configure MMCBOOT register (offset 0xc4) again. Set MMCBOOT[BOOTEN] bit to 1; and MMCBOOT[BOOTMODE] bit to 0 (normal fast boot), to 1 (alternative boot); and MMCBOOT[BOOTACK] bit to select the ack

mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] bit to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] bit to set the (VAULE1+1+VAULE3), so that host will stop at block gap when card block counter is equal to this value. And need to configure MMCBOOT[DTOCVACK] bit to select the ack timeout value according to the sd clk frequency.

12. Software needs to clear IRQSTAT[TC] and IRQSTAT[BGE] bit. And software need to clear PROCTL[SABGREQ], and set PROCTL[CREQ] to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software needs to poll IRQSTAT[BGE] bit to determine if the fast boot is over.

### Note

1. When ADMA boot flow is started, for SDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 words data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

## 61.7.7 Commands for MMC/SD/SDIO

The following table lists the commands for the MMC/SD/SDIO cards.

See the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the Multimediacard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DAT
- Addressed (point-to-point) data transfer commands (adtc)

**Table 61-12. Commands for MMC/SD/SDIO cards**

| CMD INDEX         | Type | Argument                                                                                                                                                                                                 | Resp            | Abbreviation                   | Description                                                                                                                                                                                                                                  |
|-------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD0              | bc   | [31:0] stuff bits                                                                                                                                                                                        | -               | GO_IDLE_STATE                  | Resets all MMC and SD memory cards to idle state.                                                                                                                                                                                            |
| CMD1              | bcr  | [31:0] OCR without busy                                                                                                                                                                                  | R3              | SEND_OP_COND                   | Asks all MMC and SD memory cards in idle state to send their operation conditions register contents in the response on the CMD line.                                                                                                         |
| CMD2              | bcr  | [31:0] stuff bits                                                                                                                                                                                        | R2              | ALL_SEND_CID                   | Asks all cards to send their CID numbers on the CMD line.                                                                                                                                                                                    |
| CMD3 <sup>1</sup> | ac   | [31:6] RCA<br>[15:0] stuff bits                                                                                                                                                                          | R1<br>R6 (SDIO) | SET/<br>SEND_RELATIVE_AD<br>DR | Assigns relative address to the card.                                                                                                                                                                                                        |
| CMD4              | bc   | [31:0] DSR<br>[15:0] stuff bits                                                                                                                                                                          | -               | SET_DSR                        | Programs the DSR of all cards.                                                                                                                                                                                                               |
| CMD5              | bc   | [31:0] OCR without busy                                                                                                                                                                                  | R4              | IO_SEND_OP_COND                | Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.                                                                                                                      |
| CMD6 <sup>2</sup> | adtc | [31] Mode<br>0: Check function<br>1: Switch function [30:8]<br>Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF)<br>[7:4] Function group1 for command system<br>[3:0] Function group2 for access mode | R1              | SWITCH_FUNC                    | Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.                                                                                                                |
| CMD6 <sup>3</sup> | ac   | [31:26] Set to 0<br>[25:24] Access<br>[23:16] Index<br>[15:8] Value<br>[7:3] Set to 0<br>[2:0] Cmd Set                                                                                                   | R1b             | SWITCH                         | Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.                                                        |
| CMD7              | ac   | [31:6] RCA<br>[15:0] stuff bits                                                                                                                                                                          | R1b             | SELECT/<br>DESELECT_CARD       | Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all. |

Table continues on the next page...

**Table 61-12. Commands for MMC/SD/SDIO cards (continued)**

| CMD INDEX | Type     | Argument                        | Resp | Abbreviation         | Description                                                                                                                       |
|-----------|----------|---------------------------------|------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| CMD8      | adtc     | [31:0] stuff bits               | R1   | SEND_EXT_CSD         | The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.                                           |
| CMD9      | ac       | [31:6] RCA<br>[15:0] stuff bits | R2   | SEND_CSD             | Addressed card sends its card-specific data (CSD) on the CMD line.                                                                |
| CMD10     | ac       | [31:6] RCA<br>[15:0] stuff bits | R2   | SEND_CID             | Addressed card sends its card-identification (CID) on the CMD line.                                                               |
| CMD11     | adtc     | [31:0] data address             | R1   | READ_DAT_UNTIL_STOP  | Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.                                |
| CMD12     | ac       | [31:0] stuff bits               | R1b  | STOP_TRANSMISSION    | Forces the card to stop transmission.                                                                                             |
| CMD13     | ac       | [31:6] RCA<br>[15:0] stuff bits | R1   | SEND_STATUS          | Addressed card sends its status register.                                                                                         |
| CMD14     | Reserved |                                 |      |                      |                                                                                                                                   |
| CMD15     | ac       | [31:6] RCA<br>[15:0] stuff bits | -    | GO_INACTIVE_STATE    | Sets the card to inactive state to protect the card stack against communication breakdowns.                                       |
| CMD16     | ac       | [31:0] block length             | R1   | SET_BLOCKLEN         | Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD. |
| CMD17     | adtc     | [31:0] data address             | R1   | READ_SINGLE_BLOCK    | Reads a block of the size selected by the SET_BLOCKLEN command.                                                                   |
| CMD18     | adtc     | [31:0] data address             | R1   | READ_MULTIPLE_BLOCK  | Continuously transfers data blocks from card to host until interrupted by a stop command.                                         |
| CMD19     | Reserved |                                 |      |                      |                                                                                                                                   |
| CMD20     | adtc     | [31:0] data address             | R1   | WRITE_DAT_UNTIL_STOP | Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.                               |
| CMD21-23  | Reserved |                                 |      |                      |                                                                                                                                   |
| CMD24     | adtc     | [31:0] data address             | R1   | WRITE_BLOCK          | Writes a block of the size selected by the SET_BLOCKLEN command.                                                                  |
| CMD25     | adtc     | [31:0] data address             | R1   | WRITE_MULTIPLE_BLOCK | Continuously writes blocks of data until a STOP_TRANSMISSION follows.                                                             |

**Table 61-12. Commands for MMC/SD/SDIO cards (continued)**

| CMD INDEX | Type     | Argument                          | Resp | Abbreviation          | Description                                                                                                                                                                                                                                 |
|-----------|----------|-----------------------------------|------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD26     | adtc     | [31:0] stuff bits                 | R1   | PROGRAM_CID           | Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer. |
| CMD27     | adtc     | [31:0] stuff bits                 | R1   | PROGRAM_CSD           | Programming of the programmable bits of the CSD.                                                                                                                                                                                            |
| CMD28     | ac       | [31:0] data address               | R1b  | SET_WRITE_PROT        | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).                                         |
| CMD29     | ac       | [31:0] data address               | R1b  | CLR_WRITE_PROT        | If the card provides write protection features, this command clears the write protection bit of the addressed group.                                                                                                                        |
| CMD30     | adtc     | [31:0] write protect data address | R1   | SEND_WRITE_PROT       | If the card provides write protection features, this command asks the card to send the status of the write protection bits.                                                                                                                 |
| CMD31     | Reserved |                                   |      |                       |                                                                                                                                                                                                                                             |
| CMD32     | ac       | [31:0] data address               | R1   | TAG_SECTOR_START      | Sets the address of the first sector of the erase group.                                                                                                                                                                                    |
| CMD33     | ac       | [31:0] data address               | R1   | TAG_SECTOR_END        | Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.                                                                                                                 |
| CMD34     | ac       | [31:0] data address               | R1   | UNTAG_SECTOR          | Removes one previously selected sector from the erase selection.                                                                                                                                                                            |
| CMD35     | ac       | [31:0] data address               | R1   | TAG_ERASE_GROUP_START | Sets the address of the first erase group within a range to be selected for erase.                                                                                                                                                          |
| CMD36     | ac       | [31:0] data address               | R1   | TAG_ERASE_GROUP_END   | Sets the address of the last erase group within a continuous range to be selected for erase.                                                                                                                                                |
| CMD37     | ac       | [31:0] data address               | R1   | UNTAG_ERASE_GROUP     | Removes one previously selected erase group from the erase selection.                                                                                                                                                                       |

**Table 61-12. Commands for MMC/SD/SDIO cards (continued)**

| CMD INDEX | Type     | Argument                                                                                 | Resp | Abbreviation             | Description                                                                                                                                                                                                                                                                                                                   |
|-----------|----------|------------------------------------------------------------------------------------------|------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD38     | ac       | [31:0] stuff bits                                                                        | R1b  | ERASE                    | Erase all previously selected sectors.                                                                                                                                                                                                                                                                                        |
| CMD39     | ac       | [31:0] RCA<br>[15] register write flag<br>[14:8] register address<br>[7:0] register data | R4   | FAST_IO                  | Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard. |
| CMD40     | bcr      | [31:0] stuff bits                                                                        | R5   | GO_IRQ_STATE             | Sets the system into interrupt mode.                                                                                                                                                                                                                                                                                          |
| CMD41     | Reserved |                                                                                          |      |                          |                                                                                                                                                                                                                                                                                                                               |
| CDM42     | adtc     | [31:0] stuff bits                                                                        | R1b  | LOCK_UNLOCK              | Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.                                                                                                                                                                                                       |
| CMD43~51  | Reserved |                                                                                          |      |                          |                                                                                                                                                                                                                                                                                                                               |
| CMD52     | ac       | [31:0] stuff bits                                                                        | R5   | IO_RW_DIRECT             | Access a single register within the total 128k of register space in any I/O function.                                                                                                                                                                                                                                         |
| CMD53     | ac       | [31:0] stuff bits                                                                        | R5   | IO_RW_EXTENDED           | Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.                                                                                                                                                                                                     |
| CMD54     | Reserved |                                                                                          |      |                          |                                                                                                                                                                                                                                                                                                                               |
| CMD55     | ac       | [31:16] RCA<br>[15:0] stuff bits                                                         | R1   | APP_CMD                  | Indicates to the card that the next command is an application specific command rather than a standard command.                                                                                                                                                                                                                |
| CMD56     | adtc     | [31:1] stuff bits<br>[0]: RD/WR                                                          | R1b  | GEN_CMD                  | Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.                                                                                                                    |
| CMD57~59  | Reserved |                                                                                          |      |                          |                                                                                                                                                                                                                                                                                                                               |

**Table 61-12. Commands for MMC/SD/SDIO cards (continued)**

| CMD INDEX           | Type     | Argument                                                | Resp | Abbreviation           | Description                                                                                                                                  |
|---------------------|----------|---------------------------------------------------------|------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
|                     |          | [7:0] byte count                                        |      |                        | Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.          |
| CMD61               | adtc     | [31] WR<br>[30:16] stuff bits<br>[15:0] data unit count | R1b  | RW_MULTIPLE_BLOCK      | The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.                                                                      |
| CMD62~63            | Reserved |                                                         |      |                        |                                                                                                                                              |
| ACMD6 <sup>4</sup>  | ac       | [31:2] stuff bits [1:0] bus width                       | R1   | SET_BUS_WIDTH          | Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register. |
| ACMD13 <sup>4</sup> | adtc     | [31:0] stuff bits                                       | R1   | SD_STATUS              | Send the SD memory card status.                                                                                                              |
| ACMD22 <sup>4</sup> | adtc     | [31:0] stuff bits                                       | R1   | SEND_NUM_WR_SECTORS    | Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.                                       |
| ACMD23 <sup>4</sup> | ac       |                                                         | R1   | SET_WR_BLK_ERASE_COUNT | -                                                                                                                                            |
| ACMD41 <sup>4</sup> | bcr      | [31:0] OCR                                              | R3   | SD_APP_OP_COND         | Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.                              |
| ACMD42 <sup>4</sup> | ac       |                                                         | R1   | SET_CLR_CARD_DETECT    | -                                                                                                                                            |
| ACMD51 <sup>4</sup> | adtc     | [31:0] stuff bits                                       | R1   | SEND_SCR               | Reads the SD Configuration Register (SCR).                                                                                                   |

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET\_RELATIVE\_ADDR, with a response type of R1. For SD cards, it is referred to as SEND\_RELATIVE\_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH\_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in EXT\_CSD Access Modes table.
4. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT\_CSD Access Modes are shown in the following table.

**Table 61-13. EXT\_CSD Access Modes**

| Bits | Access Name | Operation                                                                             |
|------|-------------|---------------------------------------------------------------------------------------|
| 00   | Command Set | The command set is changed according to the Cmd Set field of the argument             |
| 01   | Set Bits    | The bits in the pointed byte are set, according to the 1 bits in the Value field.     |
| 10   | Clear Bits  | The bits in the pointed byte are cleared, according to the 1 bits in the Value field. |

Table continues on the next page...

**Table 61-13. EXT\_CSD Access Modes (continued)**

| Bits | Access Name | Operation                                         |
|------|-------------|---------------------------------------------------|
| 11   | Write Byte  | The Value field is written into the pointed byte. |

## 61.8 Software restrictions

Software for the SDHC must observe the following restrictions.

### 61.8.1 Initialization active

The driver cannot set SYSCTL[INITA] when any of the command line or data lines is active, so the driver must ensure both PRSSTAT[CDIHB] and PRSSTAT[CIHB] bits are cleared. To auto clear SYSCTL[INITA], SYSCTL[SDCLKEN] must be 1, otherwise no clocks can go out to the card and SYSCTL[INITA] will never clear.

### 61.8.2 Software polling procedure

For polling read or write, when the software begins a buffer read or write, it must access exactly the number of times as the values set in the watermark level register. Moreover, if the block size is not the times of the value in watermark level register, read and write respectively, the software must access exactly the remained number of words at the end of each block.

For example, for read operation, if the WML[RDWML] is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 61.8.3 Suspend operation

To suspend the data transfer, the software must inform SDHC that the suspend command is successfully accepted. To achieve this, after the suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (XFERTYP[CMDTYP] bits set as 01) to inform SDHC that the transfer is suspended.

If software needs resume the suspended transfer, it should read the value in BLKATTR[BLKCNT] to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such suspend command, SDHC will regard the current transfer as aborted and change BLKATTR[BLKCNT] to its original value, instead of keeping the remained number of blocks.

### 61.8.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be times of 4.

### 61.8.5 (A)DMA address setting

To configure ADMA1/ADMA2/DMA address register, when TC[IRQSTAT] is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must ensure that TC[IRQSTAT] is cleared prior to configuring ADMA1/ADMA2/DMA address register.

### 61.8.6 Data port access

Data port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or external DMA. Otherwise the data would be corrupted inside the SDHC buffer.

### 61.8.7 Change clock frequency

SDHC does not automatically gates off the card clock when the host driver changes the clock frequency. To remove possible glitch on the card clock, clear SYSCTL[SDCLKEN] when changing clock divisor value and set SYSCTL[SDCLKEN] to 1 after PRSSTAT[SDSTB] is 1 again.

### 61.8.8 Multi-block read

For predefined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or predefined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an

abort command, either automatic or manual CMD12/CMD52, is still required by SDHC after the pre-defined number of blocks are done, to drive the internal start response timeout. Manually sending an abort command with XFERTYP[RSPTYP] both bits cleared is recommended.

## **Chapter 62**

# **General-Purpose Input/Output (GPIO)**

## **62.1 Chip-specific GPIO information**

### **62.1.1 GPIO access protection**

The GPIO module does not have access protection because it is not connected to a peripheral bridge slot and is not protected by the MPU.

### **62.1.2 Number of GPIO signals**

The number of GPIO signals available on the devices covered by this document are detailed in .

Eight GPIO pins support a high drive capability - PTB0, PTB1, PTD4, PTD5, PTD6, PTD7, PTC3, and PTC4. All other GPIO support normal drive option only.

PTA4 includes a passive input filter that is enabled or disabled by PORTA\_PCR4[PFE] control. This reset default is to have this function disabled.

## **62.2 Introduction**

The general-purpose input and output (GPIO) module is accessible via the peripheral bus. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

## 62.2.1 Features

Features of the GPIO module include:

- Port Data Input register visible in all digital pin-multiplexing modes
- Port Data Output register with corresponding set/clear/toggle registers
- Port Data Direction register

### NOTE

The GPIO module is clocked by system clock.

## 62.2.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

**Table 62-1. Modes of operation**

| Modes of operation | Description                        |
|--------------------|------------------------------------|
| Run                | The GPIO module operates normally. |
| Wait               | The GPIO module operates normally. |
| Stop               | The GPIO module is disabled.       |
| Debug              | The GPIO module operates normally. |

## 62.2.3 GPIO signal descriptions

**Table 62-2. GPIO signal descriptions**

| GPIO signal descriptions | Description                  | I/O |
|--------------------------|------------------------------|-----|
| PORTA31–PORTA0           | General-purpose input/output | I/O |
| PORTB31–PORTB0           | General-purpose input/output | I/O |
| PORTC31–PORTC0           | General-purpose input/output | I/O |
| PORTD31–PORTD0           | General-purpose input/output | I/O |
| PORTE31–PORTE0           | General-purpose input/output | I/O |

### NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

### 62.2.3.1 Detailed signal description

**Table 62-3. GPIO interface-detailed signal descriptions**

| Signal                                                                                 | I/O | Description                  |                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                        |     | State meaning                | Asserted: The pin is logic 1.<br>Deasserted: The pin is logic 0.                                                                                                                                                                                                                                                                                                                   |
|                                                                                        |     | Timing                       | Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.<br><br>Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. |

#### NOTE

Not all pins within each port are implemented on each device.  
See the chapter on signal multiplexing for the number of GPIO ports available in the device.

## 62.3 Memory map and register definition

Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

#### GPIO memory map

| Absolute address (hex) | Register name                           | Width (in bits) | Access                | Reset value | Section/page                |
|------------------------|-----------------------------------------|-----------------|-----------------------|-------------|-----------------------------|
| 400F_F000              | Port Data Output Register (GPIOA_PDOR)  | 32              | R/W                   | 0000_0000h  | <a href="#">62.3.1/2085</a> |
| 400F_F004              | Port Set Output Register (GPIOA_PSOR)   | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">62.3.2/2086</a> |
| 400F_F008              | Port Clear Output Register (GPIOA_PCOR) | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">62.3.3/2086</a> |

*Table continues on the next page...*

## GPIO memory map (continued)

## 62.4 Functional description

### 62.4.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The Port Data Input registers return the synchronized pin state after any enabled digital filter in the Port Control and Interrupt module. The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

### 62.4.2 General-purpose output

The logic state of each pin can be controlled via the port data output registers and port data direction registers, provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

|    |      |
|----|------|
| If | Then |
|----|------|

|                                                                                                            |                                                                                                                            |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| A pin is configured for the GPIO function and the corresponding port data direction register bit is clear. | The pin is configured as an input.                                                                                         |
| A pin is configured for the GPIO function and the corresponding port data direction register bit is set.   | The pin is configured as an output and the logic state of the pin is equal to the corresponding port data output register. |

To facilitate efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers exist to allow one or more outputs within one port to be set, cleared, or toggled from a single register write.

The corresponding Port Control and Interrupt module does not need to be enabled to update the state of the port data direction registers and port data output registers including the set/clear/toggle registers.

## Chapter 63

# JTAG Controller (JTAGC)

### 63.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

#### 63.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to [Register description](#) for more information about the JTAGC registers.

**Figure 63-1. JTAG (IEEE 1149.1) block diagram**

### 63.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 63-3](#) for a list of supported instructions.
- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

### 63.1.3 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

#### 63.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

### 63.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

### 63.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 63.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 63-1. JTAG signal properties**

| Name | I/O    | Function         | Reset State         |
|------|--------|------------------|---------------------|
| TCK  | Input  | Test Clock       | Weak pulldown       |
| TDI  | Input  | Test Data In     | Weak pullup         |
| TDO  | Output | Test Data Out    | High Z <sup>1</sup> |
| TMS  | Input  | Test Mode Select | Weak pullup         |

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 63.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 63.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 63.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

### 63.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

## 63.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 63.3.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the

Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                  |   |   |   |
|--------|------------------|---|---|---|
|        | 3                | 2 | 1 | 0 |
| R      | 0                | 0 | 0 | 1 |
| W      | Instruction Code |   |   |   |
| Reset: | 0                | 0 | 0 | 1 |

**Figure 63-2. Instruction register**

### 63.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 63.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

|       |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |    |
|-------|----------------------------|----|----|----|----------------------------|----|----|----|----|----|----------------------------|----|----|----|----|----|
|       | 31                         | 30 | 29 | 28 | 27                         | 26 | 25 | 24 | 23 | 22 | 21                         | 20 | 19 | 18 | 17 | 16 |
| R     | Part Revision Number       |    |    |    | Design Center              |    |    |    |    |    | Part Identification Number |    |    |    |    |    |
| W     |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |    |
| Reset | PRN                        |    |    |    | DC                         |    |    |    |    |    | PIN                        |    |    |    |    |    |
|       | 15                         | 14 | 13 | 12 | 11                         | 10 | 9  | 8  | 7  | 6  | 5                          | 4  | 3  | 2  | 1  | 0  |
| R     | Part Identification Number |    |    |    | Manufacturer Identity Code |    |    |    |    |    |                            |    |    |    |    | 1  |
| W     |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |    |
| Reset | PIN (contd.)               |    |    |    | MIC                        |    |    |    |    |    |                            |    |    |    |    | 1  |

The following table describes the device identification register functions.

**Table 63-2. Device identification register field descriptions**

| Field     | Description                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRN       | Part Revision Number. Contains the revision number of the part. Value is described in <a href="#">SIM_SDID register</a> . On this device, the PIN mirrors bits 15-12 of the SIM_SDID[REVID] field.                   |
| DC        | Design Center. Indicates the design center. Value is 0x2C.                                                                                                                                                           |
| PIN       | Part Identification Number. Contains the part number of the device. On this device, the PIN mirrors bits 9-0 of the SIM_SDID register. Please see the <a href="#">SIM_SDID register</a> description for more detail. |
| MIC       | Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.                                                                                               |
| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.                                                                                     |

### 63.3.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

## 63.4 Functional description

This section explains the JTAGC functional description.

### 63.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

### 63.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

**Figure 63-3. Shifting data through a register**

### 63.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 63-4. IEEE 1149.1-2001 TAP controller finite state machine**

### 63.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

### 63.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

### 63.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 63-3. 4-bit JTAG instructions**

| Instruction            | Code[3:0] | Instruction summary                                                                                                                                     |
|------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| IDCODE                 | 0000      | Selects device identification register for shift                                                                                                        |
| SAMPLE/PRELOAD         | 0010      | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation                                           |
| SAMPLE                 | 0011      | Selects boundary scan register for shifting and sampling without disturbing functional operation                                                        |
| EXTEST                 | 0100      | Selects boundary scan register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| Factory debug reserved | 0101      | Intended for factory debug only                                                                                                                         |
| Factory debug reserved | 0110      | Intended for factory debug only                                                                                                                         |
| Factory debug reserved | 0111      | Intended for factory debug only                                                                                                                         |

| CLAMP                | 1100      | Selects bypass register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| ARM JTAG-DP Reserved | 1110      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.                                        |
| BYPASS               | 1111      | Selects bypass register for data operations                                                                                                      |

#### 63.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

#### 63.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

### 63.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

### 63.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

### 63.4.4.5 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

### 63.4.4.6 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### **63.4.4.7 BYPASS instruction**

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

#### **63.4.5 Boundary scan**

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

### **63.5 Initialization/Application information**

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS
2. Load the appropriate instruction for the test or action to be performed

# Chapter 64

## Release Notes for Revision 2

### 64.1 General changes throughout document

- Added part numbers MK27FN2M0AVMI15 in the document

### 64.2 About This Manual changes

- No substantial content changes

### 64.3 Introduction changes

- Added Mask Set columns and new part numbers in Orderable part numbers summary table in [Orderable part numbers](#)

### 64.4 Core Overview changes

- No substantial content changes

### 64.5 Memories and Memory Interfaces changes

- Added new part numbers in SRAM Sizes for Orderable Part Numbers table in [SRAM sizes](#)

## 64.6 Memory Map changes

- No substantial content changes

## 64.7 Clock Distribution using MCG changes

- Added one more item that states "or QSPI select IRC48MHz clock -- enabled when QuadSPI\_SOCCR[2:0] = 100" in [IRC 48MHz clock](#)

## 64.8 Reset and Boot changes

- No substantial content changes

## 64.9 Power Management changes

- No substantial content changes

## 64.10 Flash Security Measures and Module Interactions changes

- No substantial content changes

## 64.11 Debug changes

- No substantial content changes

## 64.12 Signal Multiplexing and Signal Descriptions changes

- No substantial content changes

## 64.13 Port Control and Interrupts (PORT) changes

- No substantial content changes

## 64.14 System Integration Module (SIM) changes

- No substantial content changes

## 64.15 Kinetis ROM Bootloader changes

### 64.15.1 Kinetis ROM Bootloader chip-specific changes

- No substantial content changes

### 64.15.2 Kinetis ROM Bootloader changes

- Changed section title "CRC-32 Check on Application Data" to "Verifying the application in flash using CRC-32"; also reworded the section to be more clear.

## 64.16 Reset Control Module changes (RCM)

- No substantial content changes

## 64.17 System Mode Controller changes (SMC)

- No substantial content changes

## **64.18 Power Management Controller (PMC) changes**

### **64.18.1 PMC chip-specific changes**

- No substantial content changes

### **64.18.2 PMC changes**

- No substantial content changes

## **64.19 Low-Leakage Wakeup Unit (LLWU) changes**

### **64.19.1 LLWU chip-specific changes**

- No substantial content changes

### **64.19.2 LLWU changes**

- No substantial content changes

## **64.20 Miscellaneous Control Module (MCM) changes**

- No substantial content changes

## **64.21 Crossbar switch (AXBS) changes**

### **64.21.1 Crossbar switch chip-specific changes**

- No substantial content changes

## 64.21.2 Crossbar switch module changes

- [Priority Registers Slave \(AXBS\\_PRSn\)](#) : The two bullets in the first note about the  $Mn$  fields and the number of masters have changed.
- [Priority Registers Slave \(AXBS\\_PRSn\)](#) : In register description, added bullet to note about  $Mn$  priority fields: "If the chip contains fewer than three masters, only one bit is valid."

## 64.22 Peripheral Bridge (AIPS-Lite) changes

### 64.22.1 AIPS-Lite chip-specific changes

- No substantial content changes

### 64.22.2 AIPS-Lite module changes

- [Memory map/register definition](#) : MSB of each four-bit master field in MPRA is always ROZ.

## 64.23 Memory Protection Unit (MPU) changes

### 64.23.1 MPU chip-specific changes

- No substantial content changes

### 64.23.2 MPU module changes

- No substantial content changes

## 64.24 Bit Manipulation Engine2 (BME2) changes

- No substantial content changes

## 64.25 Direct Memory Access Multiplexer (DMAMUX) changes

### 64.25.1 DMAMUX chip-specific changes

- No substantial content changes

### 64.25.2 DMAMUX module changes

- No substantial content changes

## 64.26 eDMA module changes

- [DONE](#) : Added "The access of this field is W0C, write-zero-to-clear." to the field description.
- [Performance](#) : Added row for 48-MHz system speed to "eDMA peak transfer rates (Mbytes/sec)" table and "eDMA peak request rate (MReq/sec)" table.
- Added note beginning with "Disable a channel's hardware service request..." to [Enable Request Register \(DMA\\_ERQ\)](#) and [Clear Enable Request Register \(DMA\\_CERQ\)](#) descriptions.
- Added new section: [Suspend/resume a DMA channel with active hardware service requests](#).
- [SSIZE](#) : Added note about privileged data access to field description.

## 64.27 External Watchdog Monitor (EWM) changes

### 64.27.1 EWM chip-specific changes

- No substantial content changes

### 64.27.2 EWM changes

- No substantial content changes

## **64.28 Watchdog Timer (WDOG) changes**

### **64.28.1 WDOG chip-specific changes**

- No substantial content changes

### **64.28.2 WDOG changes**

- No substantial content changes

## **64.29 Multipurpose Clock Generator (MCG) changes**

### **64.29.1 MCG chip-specific changes**

- No substantial content changes

### **64.29.2 MCG changes**

- No substantial content changes

## **64.30 Oscillator (OSC) changes**

### **64.30.1 OSC chip-specific changes**

- No substantial content changes

### **64.30.2 OSC changes**

- No substantial content changes

## 64.31 RTC Oscillator (OSC32K) changes

- No substantial content changes

## 64.32 Local Memory Controller (LMEM) changes

### 64.32.1 LMEM chip-specific changes

- No substantial content changes

### 64.32.2 LMEM changes

The description for PSCLCR[LCWAY] and PCCLCR[LCWAY] is now:

If the command used cache address and way, then LCWAY will equal the way it was searched. If the command is a physical address search, then the LCWAY value is only valid if LCIVB=1.

## 64.33 Flash Memory Controller (FMC) changes

### 64.33.1 FMC chip-specific changes

- No substantial content changes

### 64.33.2 FMC changes

- No substantial content changes

## 64.34 FTFE changes

- Updated description of PGMSEC command related to the section program buffer contents being impacted if the swap indicator is targeted

## 64.35 Synchronous DRAM Controller Module (SDRAM) changes

### 64.35.1 SDRAM Controller chip-specific changes

- No substantial content changes

### 64.35.2 SDRAM Controller changes

- No substantial content changes

## 64.36 Quad Serial Peripheral Interface (QuadSPI) changes

### 64.36.1 QuadSPI chip-specific changes

- No substantial content changes

### 64.36.2 QuadSPI changes

- In [QuadSPI\\_BUF0IND](#), revised the register description from, "The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 gives 16 bytes etc. The size of buffer0 is the difference between BUF0IND+8 and 0." to "The register value should be set to the desired number of bytes. For example, setting BUF0IND[31:3] to 0 gives 0 bytes, 1 gives 8 bytes etc. The size of buffer0 is the difference between BUF0IND and 0".
- In [QuadSPI\\_RSER](#), updated the access of bits 30:29 from 'RU' to 'RW'.
- In [QuadSPI\\_MCR](#), added that SCLKCFG is writable only in disabled mode.

## 64.37 External Bus Interface (FlexBus) changes

### 64.37.1 FlexBus chip-specific changes

- No substantial content changes

## 64.37.2 FlexBus changes

- No substantial content changes

## 64.38 CRC changes

- No substantial content changes

## 64.39 CAU changes

- No substantial content changes

## 64.40 TRNG module changes

- No substantial content changes

## 64.41 Analog-to-Digital Converter (ADC) changes

### 64.41.1 ADC chip-specific changes

- No substantial content changes

### 64.41.2 ADC changes

- No substantial content changes

## 64.42 Comparator (CMP) changes

### 64.42.1 CMP chip-specific changes

- No substantial content changes

### 64.42.2 CMP changes

- No substantial content changes

## 64.43 Voltage Reference (VREFV1) changes

### 64.43.1 VREF chip-specific changes

- No substantial content changes

### 64.43.2 VREF changes

- No substantial content changes

## 64.44 12-bit Digital-to-Analog Converter (DAC) changes

### 64.44.1 DAC chip-specific changes

- No substantial content changes

### 64.44.2 DAC changes

- No substantial content changes

## 64.45 FlexTimer Module (FTM) changes

### 64.45.1 FTM chip-specific changes

- No substantial content changes

### 64.45.2 FTM changes

- No substantial content changes

## 64.46 Timer/PWM Module (TPM) changes

### 64.46.1 TPM chip-specific changes

- No substantial content changes

### 64.46.2 TPM changes

- No substantial content changes

## 64.47 Low-Power Timer (LPTMR) changes

### 64.47.1 LPTMR chip-specific changes

- No substantial content changes

### 64.47.2 LPTMR changes

- No substantial content changes

## 64.48 Carrier Modulator Transmitter (CMT) changes

### 64.48.1 CMT chip-specific changes

- No substantial content changes

### 64.48.2 CMT changes

- No substantial content changes

## 64.49 Programmable Delay Block (PDB) changes

### 64.49.1 PDB chip-specific changes

- No substantial content changes

### 64.49.2 PDB changes

- for CHC1[TOS] PDB Channel Pre-Trigger Output Select, changed SETRIG to SWTRIG (a correction)
- Added support for 3 PDB channels.

## 64.50 Periodic Interrupt Timer (PIT) changes

### 64.50.1 PIT chip-specific changes

- No substantial content changes

### 64.50.2 PIT module changes

- No substantial content changes

## 64.51 Real Time Clock (RTC) changes

### 64.51.1 RTC chip-specific changes

- No substantial content changes

### 64.51.2 RTC changes

- No substantial content changes

## 64.52 Universal Serial Bus Full Speed OTG Controller (USBFSOTG) changes

### 64.52.1 USB full speed OTG controller chip-specific changes

- No substantial content changes

### 64.52.2 USB full speed OTG controller changes

In "Introduction" section, in note regarding similarity of register names, corrected mention of register name 'USB\_CTRL' to 'USBCTRL'.

## 64.53 USB Device Charger Detection Module (USBDCD) changes

### 64.53.1 USBDCD chip-specific changes

- No substantial content changes

## **64.53.2 USBDCD changes**

- No substantial content changes

## **64.54 USB Voltage Regulator (USBVREG) changes**

### **64.54.1 USBVREG chip-specific changes**

- No substantial content changes

### **64.54.2 USBVREG changes**

- No substantial content changes

## **64.55 USB High Speed OTG Controller (USBHS) changes**

### **64.55.1 USB high speed OTG controller chip-specific changes**

- No substantial content changes

### **64.55.2 USB high speed OTG controller changes**

- No substantial content changes

## 64.56 Universal Serial Bus 2.0 Integrated PHY (USB-PHY) changes

### 64.56.1 Universal Serial Bus 2.0 Integrated PHY chip-specific changes changes

- No substantial content changes

### 64.56.2 Universal Serial Bus 2.0 Integrated PHY changes

- No substantial content changes

## 64.57 Serial Peripheral Interface (SPI) changes

### 64.57.1 SPI chip-specific changes changes

- No substantial content changes

### 64.57.2 SPI module changes

- In [MTFE](#), added note When MTFE=1 with continuous SCK enabled..
- In [Modified SPI Transfer Format \(MTFE = 1, CPHA = 1\)](#) removed note When MTFE=1 with continuous SCK enabled..
- In [MCR\[CLR\\_RXF\]](#), made editorial change.
- In [External Stop Mode](#), added Note about Module disable mode for Master and Slave under power saving features.
- Editorial fixes in [CLR\\_RXF](#)
- Added Note in DSPI\_SR[TXNXTPTR] bit field in [SPI](#).
- Editorial fix in [Status Register \(SPI\\_SR\)](#).
- Editorial fix in [Receive FIFO Registers \(SPI\\_RXFRn\)](#).
- Editorial fix in [Features](#).
- Editorial fix across chapter.
- Added note on diagrams "SPI is used for both SPI Mode and DSI mode in this diagram."

## 64.58 Inter-Integrated Circuit (I2C) changes

### 64.58.1 I2C chip-specific changes changes

- No substantial content changes

### 64.58.2 I2C changes

- No substantial content changes

## 64.59 Low Power Universal asynchronous receiver/transmitter (LPUART) changes

### 64.59.1 LPUART chip-specific changes changes

- No substantial content changes

### 64.59.2 LPUART changes

- Updated the bitfield definition of [RXEDGIF](#).

## 64.60 Flexible I/O (FlexIO) changes

### 64.60.1 FlexIO chip-specific changes changes

- No substantial content changes

### 64.60.2 FlexIO changes

- No substantial content changes

## 64.61 Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI) changes

### 64.61.1 I2S/SAI chip-specific changes changes

- No substantial content changes

### 64.61.2 I2S/SAI changes

- Updated SAI Transmit Configuration Register 3 TCR3[TCE] (Transmit Channel Enable), TCR3[CFR] (Channel FIFO Reset)
- Updated SAI Receive Configuration Register 3 RCR3[RCE] (Receive Channel Enable), RCR3[CFR] (Channel FIFO Reset)

## 64.62 Secured digital host controller (SDHC) changes

### 64.62.1 SDHC chip-specific changes changes

- No substantial content changes

### 64.62.2 SDHC changes

Editorial update in Block Diagram.

## 64.63 General-Purpose Input/Output (GPIO) changes

### 64.63.1 GPIO chip-specific changes changes

- No substantial content changes

## 64.63.2 GPIO changes

- No substantial content changes

## 64.64 JTAGC module changes

- No substantial content changes
