|                         |  |         |  |       |  |       |  | 0        |   |
|                         |  |         |  |       |  |       |  | XUNDRN   |   |
|                         |  |         |  |       |  |       |  | R/W-0    |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-41. Transmitter Status Register (XSTAT) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved | 0      | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                                                                                          |
| 8    | XERR     | 0<br>1 | XERR bit always returns a logic-OR of: XUNDRN   XSYNCERR   XCKFAIL   XDMAERR<br>Allows a single bit to be checked to determine if a transmitter error interrupt has occurred.<br>No errors have occurred.<br>An error has occurred.                                                                                                                                                                                                   |
| 7    | XDMAERR  | 0<br>1 | Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more serializers through the DMA port in a given time slot than were programmed as transmitters. Causes a transmit interrupt (XINT), if this bit is set and XDMAERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>Transmit DMA error did not occur.<br>Transmit DMA error did occur.                            |
| 6    | XSTAFRM  | 0<br>1 | Transmit start of frame flag. Causes a transmit interrupt (XINT), if this bit is set and XSTAFRM in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>No new transmit frame sync (AFSX) is detected.<br>A new transmit frame sync (AFSX) is detected.                                                                                                                                     |
| 5    | XDATA    | 0<br>1 | Transmit data ready flag. Causes a transmit interrupt (XINT), if this bit is set and XDATA in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>XBUF is written and is full.<br>Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT). |
| 4    | XLAST    | 0<br>1 | Transmit last slot flag. XLAST is set along with XDATA, if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT), if this bit is set and XLAST in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>Current slot is not the last slot in a frame.<br>Current slot is the last slot in a frame. XDATA is also set.                                              |
| 3    | XTDMSLOT | 0<br>1 | Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd.<br>Current TDM time slot is odd.<br>Current TDM time slot is even.                                                                                                                                                                                                                                             |
| 2    | XCKFAIL  | 0<br>1 | Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error (see <a href="#">Section 25.0.21.6.6</a> ). Causes a transmit interrupt (XINT), if this bit is set and XCKFAIL in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>Transmit clock failure did not occur.<br>Transmit clock failure did occur.                             |

**Table 25-41. Transmitter Status Register (XSTAT) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | XSYNCERR | 0<br>1 | Unexpected transmit frame sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT), if this bit is set and XSYNCERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>Unexpected transmit frame sync did not occur.<br>Unexpected transmit frame sync did occur.                                                                                                                                                  |
| 0   | XUNDRN   | 0<br>1 | Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT), if this bit is set and XUNDRN in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.<br>Transmitter underrun did not occur.<br>Transmitter underrun did occur. See <a href="#">Section 25.0.21.6.2</a> for details on McASP action upon underrun conditions. |

### 25.1.34 Current Transmit TDM Time Slot Register (XSLOT)

The current transmit TDM time slot register (XSLOT) indicates the current time slot for the transmit data frame. The XSLOT is shown in [Figure 25-67](#) and described in [Table 25-42](#).

**Figure 25-67. Current Transmit TDM Time Slot Register (XSLOT)**

|                         |  |   |          |  |    |
|-------------------------|--|---|----------|--|----|
| 31                      |  |   |          |  | 16 |
| Reserved <sup>(A)</sup> |  |   |          |  |    |
| R-0                     |  |   |          |  |    |
| 15                      |  | 9 | 8        |  | 0  |
| Reserved <sup>(A)</sup> |  |   | XSLOTCNT |  |    |
| R-0                     |  |   | R-17Fh   |  |    |

LEGEND: R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-42. Current Transmit TDM Time Slot Register (XSLOT) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                        |
|------|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved | 0      | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                       |
| 8-0  | XSLOTCNT | 0-17Fh | Current transmit time slot count. Legal values: 0 to 383 (17Fh). During reset, this counter value is 383 so the next count value, which is used to encode the first DIT group of data, will be 0 and encodes the B preamble. TDM function is not supported for > 32 time slots. However, TDM time slot counter may count to 383 when used to transmit a DIT block. |

### 25.1.35 Transmit Clock Check Control Register (XCLKCHK)

The transmit clock check control register (XCLKCHK) configures the transmit clock failure detection circuit. The XCLKCHK is shown in [Figure 25-68](#) and described in [Table 25-43](#).

**Figure 25-68. Transmit Clock Check Control Register (XCLKCHK)**

|       |    |                         |       |
|-------|----|-------------------------|-------|
| 31    | 24 | 23                      | 16    |
| XCNT  |    | XMAX                    |       |
| R-0   |    | R/W-0                   |       |
| 15    | 8  | 7                       | 0     |
| XMIN  |    | Reserved <sup>(A)</sup> | XPS   |
| R/W-0 |    | R-0                     | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-43. Transmit Clock Check Control Register (XCLKCHK) Field Descriptions**

| Bit   | Field    | Value                                                              | Description                                                                                                                                                                                                                                                                                                                                                                         |
|-------|----------|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | XCNT     | 0                                                                  | Transmit clock count value (from previous measurement). The clock circuit continually counts the number of DSP system clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken.                                                                                                                  |
| 23-16 | XMAX     | 0-FFh                                                              | Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.     |
| 15-8  | XMIN     | 0-FFh                                                              | Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.                             |
| 7-4   | Reserved | 0                                                                  | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                                        |
| 3-0   | XPS      | 0-Fh<br>0<br>1h<br>2h<br>3h<br>4h<br>5h<br>6h<br>7h<br>8h<br>9h-Fh | Transmit clock check prescaler value.<br>McASP system clock divided by 1<br>McASP system clock divided by 2<br>McASP system clock divided by 4<br>McASP system clock divided by 8<br>McASP system clock divided by 16<br>McASP system clock divided by 32<br>McASP system clock divided by 64<br>McASP system clock divided by 128<br>McASP system clock divided by 256<br>Reserved |

### 25.1.36 Transmitter DMA Event Control Register (XEVTCTL)

The transmitter DMA event control register (XEVTCTL) is shown in [Figure 25-69](#) and described in [Table 25-44](#).

#### CAUTION

DSP specific registers

Accessing XEVTCTL not implemented on a specific DSP may cause improper device operation.

**Figure 25-69. Transmitter DMA Event Control Register (XEVTCTL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-44. Transmitter DMA Event Control Register (XEVTCTL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                  |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility. |
| 0    | XDATDMA  | 0     | Transmit data DMA request enable bit. If writing to this field, always write the default value of 0.                                                                                                         |
|      |          | 1     | Reserved.                                                                                                                                                                                                    |

### 25.1.37 Serializer Control Registers (SRCTL<sub>n</sub>)

Each serializer on the McASP has a serializer control register (SRCTL). There are up to 16 serializers per McASP. The SRCTL is shown in [Figure 25-70](#) and described in [Table 25-45](#).

**CAUTION**

DSP specific registers

Accessing SRCTL<sub>n</sub> not implemented on a specific DSP may cause improper device operation.

**Figure 25-70. Serializer Control Registers (SRCTL<sub>n</sub>)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-45. Serializer Control Registers (SRCTL<sub>n</sub>) Field Descriptions**

| Bit  | Field    | Value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|----------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0                           | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5    | RRDY     | 0<br>1                      | Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSR to RBUF.<br>Receive buffer (RBUF) is empty.<br>Receive buffer (RBUF) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.                                                                                                                                                                                                    |
| 4    | XRDY     | 0<br>1                      | Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0).<br>Transmit buffer (XBUF) contains data.<br>Transmit buffer (XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs. |
| 3-2  | DISMOD   | 0-3h<br>0<br>1h<br>2h<br>3h | Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0).<br>Drive on pin is 3-state.<br>Reserved<br>Drive on pin is logic low.<br>Drive on pin is logic high.                                                                                                                                                                                                                                                                                                                         |
| 1-0  | SRMOD    | 0-3h<br>0<br>1h<br>2h<br>3h | Serializer mode bit.<br>Serializer is inactive.<br>Serializer is transmitter.<br>Serializer is receiver.<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 25.1.38 DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)

The DIT left channel status registers (DITCSRA) provide the status of each left channel (even TDM time slot). Each of the six 32-bit registers (Figure 25-71) can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

**Figure 25-71. DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)**

LEGEND: R/W = Read/Write; -n = value after reset

### 25.1.39 DIT Right Channel Status Registers (DITCSRB0-DITCSRB5)

The DIT right channel status registers (DITCSRB) provide the status of each right channel (odd TDM time slot). Each of the six 32-bit registers (Figure 25-72) can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

**Figure 25-72. DIT Right Channel Status Registers (DITCSRB0-DITCSRB5)**

LEGEND: R/W = Read/Write; -n = value after reset

### 25.1.40 DIT Left Channel User Data Registers (DITUDRA0-DITUDRA5)

The DIT left channel user data registers (DITUDRA) provides the user data of each left channel (even TDM time slot). Each of the six 32-bit registers (Figure 25-73) can store 192 bits of user data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register in time, if a different set of data need to be sent.

**Figure 25-73. DIT Left Channel User Data Registers (DITUDRA0-DITUDRA5)**

LEGEND: R/W = Read/Write; -n = value after reset

### 25.1.41 DIT Right Channel User Data Registers (DITUDRB0-DITUDRB5)

The DIT right channel user data registers (DITUDRB) provides the user data of each right channel (odd TDM time slot). Each of the six 32-bit registers (Figure 25-74) can store 192 bits of user data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register in time, if a different set of data need to be sent.

**Figure 25-74. DIT Right Channel User Data Registers (DITUDRB0-DITUDRB5)**

LEGEND: R/W = Read/Write; -n = value after reset

### 25.1.42 Transmit Buffer Registers (XBUF<sub>n</sub>)

The transmit buffers for the serializers (XBUF) hold data from the transmit format unit. For transmit operations, the XBUF ([Figure 25-75](#)) is an alias of the XRBUF in the serializer. The XBUF can be accessed through the peripheral configuration port ([Table 25-7](#)) or through the DMA port ([Table 25-8](#)).

#### CAUTION

DSP specific registers

Accessing XBUF registers not implemented on a specific DSP may cause improper device operation.

**Figure 25-75. Transmit Buffer Registers (XBUF<sub>n</sub>)**

|    |                   |   |
|----|-------------------|---|
| 31 |                   | 0 |
|    | XBUF <sub>n</sub> |   |
|    | R/W-0             |   |

LEGEND: R/W = Read/Write; -n = value after reset

### 25.1.43 Receive Buffer Registers (RBUF<sub>n</sub>)

The receive buffers for the serializers (RBUF) hold data from the serializer before the data goes to the receive format unit. For receive operations, the RBUF ([Figure 25-76](#)) is an alias of the XRBUF in the serializer. The RBUF can be accessed through the peripheral configuration port ([Table 25-7](#)) or through the DMA port ([Table 25-8](#)).

#### CAUTION

DSP specific registers

Accessing RBUF registers not implemented on a specific DSP may cause improper device operation.

**Figure 25-76. Receive Buffer Registers (RBUF<sub>n</sub>)**

|    | RBUF <sub>n</sub> |   |
|    | R/W-0             |   |

LEGEND: R/W = Read/Write; -n = value after reset

### 25.1.44 AFIFO Revision Identification Register (AFIFOREV)

The Audio FIFO (AFIFO) revision identification register (AFIFOREV) contains revision data for the Audio FIFO (AFIFO). The AFIFOREV is shown in [Figure 25-77](#) and described in [Table 25-46](#).

**Figure 25-77. AFIFO Revision Identification Register (AFIFOREV)**

LEGEND: R = Read only; -n = value after reset

**Table 25-46. AFIFO Revision Identification Register (AFIFOREV) Field Descriptions**

| Bit  | Field | Value      | Description                        |
|------|-------|------------|------------------------------------|
| 31-0 | REV   | 4431 1100h | Identifies revision of Audio FIFO. |

### 25.1.45 Write FIFO Control Register (WFIFOCTL)

The Write FIFO control register (WFIFOCTL) is shown in [Figure 25-78](#) and described in [Table 25-47](#).

**NOTE:** The WNUMEVT and WNUMDMA values must be set prior to enabling the Write FIFO.  
If the Write FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

**Figure 25-78. Write FIFO Control Register (WFIFOCTL)**

|          |   |  |  |  |         |  |  |  |  |  |       |    |

| 16    | WENA     | 0       | Write FIFO enable bit.<br>Write FIFO is disabled. The WLVL field in the Write FIFO status register (WFIFOSTS) is reset to 0 and pointers are initialized, that is, the Write FIFO is "flushed."                                                                                                                                                               |
|       |          | 1       | Write FIFO is enabled. If Write FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.                                                                                                                                                                                                                                                 |
| 15-8  | WNUMEVT  | 0-FFh   | Write word count per DMA event (32-bit). When the Write FIFO has space for at least WNUMEVT words of data, then an AXEVT (transmit DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as transmitters. This value must be set prior to enabling the Write FIFO. |
|       |          | 0       | 0 words                                                                                                                                                                                                                                                                                                                                                       |
|       |          | 1h      | 1 word                                                                                                                                                                                                                                                                                                                                                        |
|       |          | 2h      | 2 words                                                                                                                                                                                                                                                                                                                                                       |
|       |          | 3h-40h  | 3 to 64 words                                                                                                                                                                                                                                                                                                                                                 |
|       |          | 41h-FFh | Reserved                                                                                                                                                                                                                                                                                                                                                      |
| 7-0   | WNUMDMA  | 0-FFh   | Write word count per transfer (32-bit words). Upon a transmit DMA event from the McASP, WNUMDMA words are transferred from the Write FIFO to the McASP. This value must equal the number of McASP serializers (not the number of channels) used as transmitters. This value must be set prior to enabling the Write FIFO.                                     |
|       |          | 0       | 0 words                                                                                                                                                                                                                                                                                                                                                       |

### 25.1.46 Write FIFO Status Register (WFIFOSTS)

The Write FIFO status register (WFIFOSTS) is shown in [Figure 25-79](#) and described in [Table 25-48](#).

**Figure 25-79. Write FIFO Status Register (WFIFOSTS)**

LEGEND: R = Read only; -n = value after reset

**Table 25-48. Write FIFO Status Register (WFIFOSTS) Field Descriptions**

| Bit  | Field    | Value   | Description                                                                  |
|------|----------|---------|------------------------------------------------------------------------------|
| 31-8 | Reserved | 0       | Reserved                                                                     |
| 7-0  | WLVL     | 0-FFh   | Write level (read-only). Number of 32-bit words currently in the Write FIFO. |
|      |          | 0       | 0 words currently in Write FIFO.                                             |
|      |          | 1h      | 1 word currently in Write FIFO.                                              |
|      |          | 2h      | 2 words currently in Write FIFO.                                             |
|      |          | 3h-40h  | 3 to 64 words currently in Write FIFO.                                       |
|      |          | 41h-FFh | Reserved                                                                     |

### 25.1.47 Read FIFO Control Register (RFIFOCTL)

The Read FIFO control register (RFIFOCTL) is shown in [Figure 25-80](#) and described in [Table 25-49](#).

**NOTE:** The RNUMEVT and RNUMDMA values must be set prior to enabling the Read FIFO.  
If the Read FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

**Figure 25-80. Read FIFO Control Register (RFIFOCTL)**

|       |          | 11h-FFh | Reserved                                                                                                                                                                                                                                                                                                                                          |

### 25.1.48 Read FIFO Status Register (RFIFOSTS)

The Read FIFO status register (RFIFOSTS) is shown in [Figure 25-81](#) and described in [Table 25-50](#).

**Figure 25-81. Read FIFO Status Register (RFIFOSTS)**

LEGEND: R = Read only; -n = value after reset

**Table 25-50. Read FIFO Status Register (RFIFOSTS) Field Descriptions**

| Bit  | Field    | Value   | Description                                                                |
|------|----------|---------|----------------------------------------------------------------------------|
| 31-8 | Reserved | 0       | Reserved                                                                   |
| 7-0  | RLVL     | 0-FFh   | Read level (read-only). Number of 32-bit words currently in the Read FIFO. |
|      |          | 0       | 0 words currently in Read FIFO.                                            |
|      |          | 1h      | 1 word currently in Read FIFO.                                             |
|      |          | 2h      | 2 words currently in Read FIFO.                                            |
|      |          | 3h-40h  | 3 to 64 words currently in Read FIFO.                                      |
|      |          | 41h-FFh | Reserved                                                                   |

## ***Multichannel Buffered Serial Port (McBSP)***

---

---

This chapter describes the multichannel buffered serial port (McBSP). See your device-specific data manual to determine how many McBSPs are available on your device.

| <b>Topic</b>                   | <b>Page</b>                 |
|--------------------------------|-----------------------------|
| <b>26.1 Introduction .....</b> | <b><a href="#">1210</a></b> |
| <b>26.2 Architecture .....</b> | <b><a href="#">1212</a></b> |
| <b>26.3 Registers .....</b>    | <b><a href="#">1259</a></b> |

## 26.1 Introduction

### 26.1.1 Purpose of the Peripheral

The primary use for the multichannel buffered serial port (McBSP) is for audio interface purposes. The McBSP is a specialized version of the McBSP peripheral used on other TI DSPs. The primary audio modes that are supported are the AC97 and IIS modes. In addition to the primary audio modes, the McBSP can be programmed to support other serial formats but is not intended to be used as a high-speed interface.

The McBSP consists of a data path and a control path that connect to external devices. Separate pins for transmission and reception communicate data to these external devices. The CPU communicates to the McBSP using 32-bit-wide control registers accessible via the internal peripheral bus.

### 26.1.2 Features

The McBSP provides the following functions:

- Full-duplex communication
- Double-buffered data registers, which allow a continuous data stream
- Independent framing and clocking for receive and transmit
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected analog-to-digital (A/D) and digital-to-analog (D/A) devices
- External shift clock or an internal, programmable frequency shift clock for data transfer

In addition, the McBSP has the following capabilities:

- Direct interface to:
  - T1/E1 framers
  - MVIP switching compatible and ST-BUS compliant devices including:
    - MVIP framers
    - H.100 framers
    - SCSA framers
  - IOM-2 compliant devices
  - AC97 compliant devices (the necessary multiphase frame synchronization capability is provided)
  - IIS compliant devices
- Multichannel transmit and receive of up to 128 channels
- A wide selection of data sizes, including 8, 12, 16, 20, 24, and 32 bits
- $\mu$ -Law and A-Law companding
- 8-bit data transfers with the option of LSB or MSB first
- Programmable polarity for both frame synchronization and data clocks
- Highly programmable internal clock and frame generation
- Additional McBSP Buffer FIFO (BFIFO):
  - Provides additional data buffering
  - Provides added tolerance to variations in host/DMA controller response times
  - May be used as a DMA event pacer
  - Independent Read FIFO and Write FIFO
  - 256 bytes of RAM for each FIFO (read and write)
  - Option to bypass Write FIFO and/or Read FIFO, independently

### 26.1.3 Functional Block Diagram

The McBSP consists of a data path and control path, as shown in Figure 26-1

### 26.1.4 Industry Standard Compliance Statement

The McBSP supports the following industry standard interfaces:

**AC97**— The AC97 standard specifies a 5-wire digital serial link between an audio codec device and its digital controller.

**IIS**— IIS is a protocol for transmitting two channels of digital audio data over a single serial connection. The IIS bus is an industry standard three-wire interface for streaming stereo audio between devices, typically between a CPU/DSP and a DAC/ADC.

Figure 26-1. McBSP Block Diagram

## 26.2 Architecture

This section describes the architecture of the McBSP.

### 26.2.1 Clock Control

The McBSP can use an internal or external clock source. Either clock source can be divided-down inside the McBSP to generate the actual interface bit clock frequency. For detailed timing information, see the device-specific data manual. Detailed information about how the interface clock and frame synchronization signals are generated is provided in [Section 26.2.5](#).

### 26.2.2 Signal Descriptions

The signals used on the audio interface are listed in [Table 26-1](#).

**Table 26-1. McBSP Interface Signals**

| Pin  | I/O/Z | Description                                                                                                                             |
|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------|
| CLKR | I/O/Z | Receive clock - supplies or receives a reference clock for the receiver; or supplies a reference clock to the sample rate generator     |
| CLKS | I     | Supplies the input clock of the sample rate generator                                                                                   |
| CLKX | I/O/Z | Transmit clock - supplies or receives a reference clock for the transmitter; or supplies a reference clock to the sample rate generator |
| DR   | I     | Received serial data                                                                                                                    |
| DX   | O/Z   | Transmitted serial data                                                                                                                 |
| FSR  | I/O/Z | Receive frame synchronization - control signal to synchronize the start of received data                                                |
| FSX  | I/O/Z | Transmit frame synchronization - control signal to synchronize the start of transmitted data                                            |

### 26.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. Refer to the device-specific data manual to determine how pin multiplexing affects the McBSP.

### 26.2.4 Endianness Considerations

There are no endianness considerations for the McBSP.

## 26.2.5 Clock, Frames, and Data

The McBSP has several ways of selecting clocking and framing for both the receiver and transmitter. Clocking and framing can be sent to both portions by the sample rate generator. Each portion can select external clocking and/or framing independently. Figure 26-2 is a block diagram of the clock and frame selection circuitry.

Figure 26-2. Clock and Frame Generation

### 26.2.5.1 Frame and Clock Operation

Receive and transmit frame sync pulses (FSR/X), and clocks (CLKR/X), can either be generated internally by the sample rate generator (see Section 26.2.5.2) or be driven by an external source. The source of frame sync and clock is selected by programming the mode bits, FS(R/X)M and CLK(R/X)M respectively, in the pin control register (PCR). FSR is also affected by the GSYNC bit in the sample rate generator register (SRGR), see Section 26.2.5.4.2 for details.

When FSR and FSX are inputs (FSXM = FSRM = 0), the McBSP detects them on the internal falling edge of clock, CLKR\_int and CLKX\_int, respectively (see Figure 26-2). The receive data arriving at the DR pin is also sampled on the falling edge of CLKR\_int. These internal clock signals are either derived from an external source via the CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X)\_int. Similarly, data on DX is output on the rising edge of CLKX\_int.

The FSRP, FSXP, CLKRP, and CLKXP bits in PCR configure the polarities of FSR, FSX, CLKR, and CLKX. All frame sync signals (FSR\_int and FSX\_int) internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to the McBSP) and FSRP = FSXP = 1, the external active (low) frame sync signals are inverted before being sent to the receiver signal (FSR\_int) and transmitter signal (FSX\_int). Similarly, if internal synchronization is selected (FSR/FSX are outputs and GSYNC = 0), the internal active (high) sync signals are inverted if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin. Figure 26-2 shows this inversion using XOR gates.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of CLKX\_int (see [Figure 26-3](#)). If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge-triggered input clock on CLKX is inverted to a rising-edge-triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge-triggered) clock, CLKX\_int, is inverted before being sent out on the CLKX pin.

Similarly, the receiver can reliably sample data that is clocked (by the transmitter) with a rising-edge clock. The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of CLKR\_int (see [Figure 26-4](#)). Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge-triggered clock is inverted to a rising edge before being sent out on the CLKR pin.

In a system where the same clock (internal or external) is used to clock the receiver and transmitter, CLKRP = CLKXP. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold times of data around this edge. [Figure 26-4](#) shows how data clocked by an external serial device using a rising-edge clock can be sampled by the McBSP receiver with the falling edge of the same clock.

**Figure 26-3. Transmit Data Clocking**

**Figure 26-4. Receive Data Clocking**

### 26.2.5.2 Sample Rate Generator Clocking and Framing

The sample rate generator is composed of a 3-stage clock divider that provides a programmable data clock (CLKG) and framing signal (FSG), as shown in [Figure 26-5](#). CLKG and FSG are McBSP internal signals that can be programmed to drive receive and/or transmit clocking, CLK(R/X), and framing, FS(R/X). The sample rate generator can be programmed to be driven by an internal clock source or an internal clock derived from an external clock source.

The sample rate generator is not used when CLKX, FSX, CLKR, and FSR are driven by an external source. Therefore, the GRST bit in the serial port control register (SPCR) does not need to be enabled (GRST = 1) for this setup. The three stages of the sample rate generator circuit compute:

- Clock divide-down (CLKGDV): The number of input clocks per data bit clock
- Frame period (FPER): The frame period in data bit clocks
- Frame width (FWID): The width of an active frame pulse in data bit clocks

In addition, a frame pulse detection and clock synchronization module allows synchronization of the clock divide-down with an incoming frame pulse. The operation of the sample rate generator during device reset is described in [Section 26.2.11](#).

**Figure 26-5. Sample Rate Generator Block Diagram**

### 26.2.5.3 Data Clock Generation

When the receive/transmit clock mode is set to 1 (CLK(R/X)M = 1 in the pin control register (PCR)), the data clocks (CLK(R/X)) are driven by the internal sample rate generator output clock, CLKG. You can select for the receiver and transmitter from a variety of data bit clocks including:

- The input clock to the sample rate generator, which can be either the internal clock source or a dedicated external clock source via the CLKX, CLKR, or CLKS pins. Internally, the McBSP clock is selected to be either PLL0\_SYSCLK2 or PLL1\_SYSCLK2 by configuring the ASYNC3\_CLKSRC bit in the chip configuration 3 register (CFGCHIP3) of the System Configuration Module. See [Section 26.2.5.3.1](#) for details on the source of the McBSP internal clock.
- The input clock source (internal clock source or external clock CLKX/CLKR/CLKS) to the sample rate generator can be divided-down by a programmable value (CLKGDV bit in the sample rate generator register (SRGR)) to drive CLKG.

Regardless of the source to the sample rate generator, the rising edge of CLKSRG (see [Figure 26-5](#)) generates CLKG and FSG.

#### 26.2.5.3.1 Input Clock Source Mode: CLKSM and SCLKME

The sample rate generator input clock signal can be driven from one of four sources selectable with the SCLKME bit in the pin control register (PCR) and the CLKSM bit in the sample rate generator register (SRGR), see [Table 26-2](#).

**Table 26-2. Choosing an Input Clock for the Sample Rate Generator With the SCLKME and CLKSM Bits**

| SCLKME Bit<br>in PCR | CLKSM Bit<br>in SRGR | Input Clock for Sample Rate Generator |
|----------------------|----------------------|---------------------------------------|
| 0                    | 0                    | Signal on CLKS pin                    |
| 0                    | 1                    | McBSP internal input clock            |
| 1                    | 0                    | Signal on CLKR pin                    |
| 1                    | 1                    | Signal on CLKX pin                    |

#### 26.2.5.3.2 Sample Rate Generator Data Bit Clock Rate: CLKGDV

The first divider stage generates the serial data bit clock from the input clock. This divider stage uses a counter that is preloaded by the CLKGDV bit in the sample rate generator register (SRGR) and that contains the divide ratio value. The output of this stage is the data bit clock that is output on the sample rate generator output, CLKG, and that serves as the input for the second and third divider stages.

CLKG has a frequency equal to  $1/(\text{CLKGDV} + 1)$  of the sample rate generator input clock. Thus, the sample rate generator input clock frequency is divided by a value between 1 to 256. The CLKGDV value chosen must result in a clock that meets the timing requirements/limitations specified in the device-specific data manual.

When CLKGDV is an odd value or equal to 0, the CLKG duty cycle is 50%. Note that an odd CLKGDV value means an even divide down of the source clock and an even CLKGDV value means an odd divide down of the source clock. When CLKGDV is an even value (2p), the high state duration is p + 1 cycles and the low state duration is p cycles. This is illustrated in [Example 26-1](#), [Example 26-2](#), and [Example 26-3](#).

In the following examples:

$S_{IN}$  = sample generator input clock period

$f_{IN}$  = sample generator input clock frequency

$S_G$  = CLKG period

$f_G$  = CLKG frequency

The following equation is given above:  $f_G = f_{IN}/(\text{CLKGDV} + 1)$ ; therefore,  $S_G = (\text{CLKGDV} + 1) \times S_{IN}$ .

**Example 26-1. CLKGDV = 0**

$$\text{CLKGDV} = 0$$

$$S_G = (\text{CLKGDV} + 1) \times S_{\text{IN}} = (0 + 1) \times S_{\text{IN}} = S_{\text{IN}}$$

$$\text{Pulse width high} = S_{\text{IN}} \times (\text{CLKGDV} + 1)/2 = S_{\text{IN}} \times (0 + 1)/2 = 0.5 \times S_{\text{IN}}$$

$$\text{Pulse width low} = S_{\text{IN}} \times (\text{CLKGDV} + 1)/2 = S_{\text{IN}} \times (0 + 1)/2 = 0.5 \times S_{\text{IN}}$$

**Example 26-2. CLKGDV = 1**

$$\text{CLKGDV} = 1$$

$$S_G = (\text{CLKGDV} + 1) \times S_{\text{IN}} = (1 + 1) \times S_{\text{IN}} = 2 \times S_{\text{IN}}$$

$$\text{Pulse width high} = S_{\text{IN}} \times (\text{CLKGDV} + 1)/2 = S_{\text{IN}} \times (1 + 1)/2 = S_{\text{IN}}$$

$$\text{Pulse width low} = S_{\text{IN}} \times (\text{CLKGDV} + 1)/2 = S_{\text{IN}} \times (1 + 1)/2 = S_{\text{IN}}$$

**Example 26-3. CLKGDV = 2**

$$\text{CLKGDV} = 2$$

$$S_G = (\text{CLKGDV} + 1) \times S_{\text{IN}} = (2 + 1) \times S_{\text{IN}} = 3 \times S_{\text{IN}}$$

$$\text{Pulse width high} = S_{\text{IN}} \times (\text{CLKGDV}/2 + 1) = S_{\text{IN}} \times (2/2 + 1) = 2 \times S_{\text{IN}}$$

$$\text{Pulse width low} = S_{\text{IN}} \times \text{CLKGDV}/2 = S_{\text{IN}} \times 2/2 = 1 \times S_{\text{IN}}$$

**26.2.5.3.3 Bit Clock Polarity: CLKSP**

The external clock (CLKS) is selected to drive the sample rate generator clock divider by selecting CLKSM = 0 in the sample rate generator register (SRGR) and SCLKME = 0 in the pin control register (PCR). In this case, the CLKSP bit in SRGR selects the edge of CLKS on which sample rate generator data bit clock (CLKG) and frame sync signal (FSG) are generated. Since the rising edge of CLKSRG generates CLKG and FSG, the rising edge of CLKS when CLKSP = 0 or the falling edge of CLKS when CLKSP = 1 causes the transition on CLKG and FSG.

**26.2.5.3.4 Bit Clock and Frame Synchronization**

When the external clock (CLKS) is selected to drive the sample rate generator (CLKSM = 0 in SRGR and SCLKME = 0 in PCR), the GSYNC bit in SRGR can be used to configure the timing of CLKG relative to CLKS. GSYNC = 1 ensures that the McBSP and the external device to which it is communicating are dividing down the CLKS with the same phase relationship. If GSYNC = 0, this feature is disabled and CLKG runs freely and is not resynchronized. If GSYNC = 1, an inactive-to-active transition on FSR triggers a resynchronization of CLKG and the generation of FSG. CLKG always begins at a high state after synchronization. Also, FSR is always detected at the same edge of CLKS that generates CLKG, regardless of the length the FSR pulse. Although an external FSR is provided, FSG can still drive internal receive frame synchronization when GSYNC = 1. When GSYNC = 1, FPER does not matter, because the frame period is determined by the arrival of the external frame sync pulse.

Figure 26-6 and Figure 26-7 show this operation with various polarities of CLKS and FSR. These figures assume that FWID is 0, for a FSG = 1 CLKG wide.

These figures show what happens to CLKG when it is initially in sync and GSYNC = 1, as well as when it is not in sync with the frame synchronization and GSYNC = 1.

**Figure 26-6. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 1**

**Figure 26-7. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 3**

When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that the following conditions are met:

- FSX is programmed to be driven by the sample rate generator frame sync, FSG (FSGM = 1 in SRGR and FSXM = 1 in PCR).
- The sample-rate generator clock should drive the transmit and receive bit clock (CLK(R/X)M = 1 in SPCR). Therefore, the CLK(R/X) pin should not be driven by any other source.

#### 26.2.5.3.5 Digital Loopback Mode: DLB

The DLB mode cannot be used when the McBSP is in clock stop mode (CLKSTP = 2h or 3h in the serial port control register (SPCR)). Setting DLB = 1 in SPCR enables digital loopback mode. In DLB mode, DR, FSR, and CLKR are internally connected through multiplexers to DX, FSX, and CLKX, respectively, as shown in Figure 26-2 and Figure 33-4. DLB mode allows testing of serial port code without using the external interface of the McBSP. CLKX and FSX must be enabled as outputs (CLKXM = FSXM = 1) in DLB mode.

Figure 26-8. Digital Loopback Mode

#### 26.2.5.3.6 Receive Clock Selection: DLB, CLKRM

Table 26-3 shows how the digital loopback bit (DLB) in the serial port control register (SPCR) and the CLKRM bit in the pin control register (PCR) select the receiver clock. In digital loopback mode (DLB = 1), the transmitter clock drives the receiver. CLKRM determines whether the CLKR pin is an input or an output.

Table 26-3. Receive Clock Selection

| DLB Bit in SPCR | CLKRM Bit in PCR | Source of Receive Clock                                                                                   | CLKR Function                                                                           |
|-----------------|------------------|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 0               | 0                | CLKR acts as an input driven by the external clock and inverted as determined by CLKRP before being used. | Input.                                                                                  |
| 0               | 1                | The sample rate generator clock (CLKG) drives CLKR.                                                       | Output. CLKG inverted as determined by CLKRP before being driven out on CLKR.           |
| 1               | 0                | CLKX_int drives the receive clock CLKR_int as selected and is inverted.                                   | High impedance.                                                                         |
| 1               | 1                | CLKX_int drives CLKR_int as selected and is inverted.                                                     | Output. CLKR (same as CLKX) is inverted as determined by CLKRP before being driven out. |

### 26.2.5.3.7 Transmit Clock Selection: CLKXM

Table 26-4 shows how the CLKXM bit in the pin control register (PCR) selects the transmit clock and whether the CLKX pin is an input or output.

**Table 26-4. Transmit Clock Selection**

| CLKXM Bit in PCR | Source of Transmit Clock                                                                                 | CLKX Function                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| 0                | The external clock drives the CLKX input pin. CLKX is inverted as determined by CLKXP before being used. | Input.                                                                           |
| 1                | The sample rate generator clock (CLKG) drives the transmit clock.                                        | Output. CLKG is inverted as determined by CLKXP before being driven out on CLKX. |

### 26.2.5.3.8 Stopping Clocks

Two methods can be used to stop serial clocks between data transfers:

- The SPI™ CLKSTP mode where clocks are stopped between single-element transfers. This mode is not supported on this device.
- The clocks are inputs to the McBSP (CLKXM or CLKRM = 0 in the pin control register (PCR)) and the McBSP operates in non-SPI mode (the clocks can be stopped between data transfers). If the external device stops the serial clock between data transfers, the McBSP interprets it as a slowed-down serial clock. Ensure that there are no glitches on the CLK(R/X) lines as the McBSP may interpret them as clock-edge transitions. Restarting the serial clock is equivalent to a normal clock transition after a slow CLK(R/X) cycle. Note that just as in normal operations, transmit under flow (XEMPTY) may occur if the DXR is not properly serviced at least three CLKX cycles before the next frame sync. Therefore, if the serial clock is stopped before DXR is properly serviced, the external device needs to restart the clock at least three CLKX cycles before the next frame sync to allow the DXR write to be properly synchronized. See Figure 26-29 for a graphical explanation on when DXR needs to be written to avoid underflow.

### 26.2.5.4 Frame Sync Generation

Data frame synchronization is independently programmable for the receiver and the transmitter for all data delay values. When the FRST bit in the serial port control register (SPCR) is set to 1 the frame generation logic is activated to generate frame sync signals, provided that FSGM = 1 in the sample rate generator register (SRGR). The frame sync programming options are:

- A frame pulse with a programmable period between sync pulses and a programmable active width specified in SRGR.
- The transmitter can trigger its own frame sync signal that is generated by a DXR-to-XSR copy. This causes a frame sync to occur on every DXR-to-XSR copy. The data delays can be programmed as required. However, maximum packet frequency cannot be achieved in this method for data delays of 1 and 2.
- Both the receiver and transmitter can independently select an external frame synchronization on the FSR and FSX pins, respectively.

#### 26.2.5.4.1 Frame Period (FPER) and Frame Width (FWID)

The FPER bits in the sample rate generator register (SRGR) are a 12-bit down-counter that can count down the generated data clocks from 4095 to 0. FPER controls the period of active frame sync pulses. The FWID bits in SRGR are an 8-bit down-counter. FWID controls the active width of the frame sync pulse.

When the sample rate generator comes out of reset, FSG is in an inactive (low) state. After this, when  $FRST = 1$  in SPCR and  $FSGM = 1$  in SRGR, frame sync signals are generated. The frame width value ( $FWID + 1$ ) is counted down on every CLKG cycle until it reaches 0 when FSG goes low. Thus, the value of  $FWID + 1$  determines an active frame pulse width ranging from 1 to 256 data bit clocks. At the same time, the frame period value ( $FPER + 1$ ) is also counting down, and when this value reaches 0, FSG goes high again, indicating a new frame is beginning. Thus, the value of  $FPER + 1$  determines a frame length from 1 to 4096 data bits. When  $GSYNC = 1$  in SRGR, the value of  $FPER$  does not matter. [Figure 26-9](#) shows a frame of 16 CLKG periods ( $FPER = 15$  or 0000 1111b).

It is recommended that  $FWID$  be programmed to a value less than  $(R/X)WDLEN1/2$ .

**Figure 26-9. Programmable Frame Period and Width**

#### 26.2.5.4.2 Receive Frame Synchronization Selection: DLB and FSRM

[Table 26-5](#) shows how you can select various sources to provide the receive frame synchronization signal. Note that in digital loopback mode ( $DLB = 1$  in the serial port control register (SPCR)), the transmit frame sync signal is used as the receive frame sync signal and that DR is internally connected to DX.

**NOTE:** FSR\_int and FSX\_int are shown in [Figure 26-2](#).

**Table 26-5. Receive Frame Synchronization Selection**

| DLB Bit<br>in SPCR | FSRM Bit<br>in PCR | GSYNC Bit<br>in SRGR | Source of Receive Frame<br>Synchronization                                                                                             | FSR Pin Function                                                                                                               |
|--------------------|--------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0                  | 0                  | X                    | External frame sync signal drives the FSR input pin, whose signal is then inverted as determined by FSRP before being used as FSR_int. | Input.                                                                                                                         |
| 0                  | 1                  | 0                    | Sample rate generator frame sync signal (FSG) drives FSR_int, $FRST = 1$ .                                                             | Output. FSG is inverted as determined by FSRP before being driven out on the FSR pin.                                          |
| 0                  | 1                  | 1                    | Sample rate generator frame sync signal (FSG) drives FSR_int, $FRST = 1$ .                                                             | Input. The external frame sync input on FSR is used to synchronize CLKG and generate FSG.                                      |
| 1                  | 0                  | 0                    | FSX_int drives FSR_int. FSX is selected as shown in <a href="#">Table 26-6</a> .                                                       | High impedance.                                                                                                                |
| 1                  | X                  | 1                    | FSX_int drives FSR_int and is selected as shown in <a href="#">Table 26-6</a> .                                                        | Input. External FSR is not used for frame synchronization but is used to synchronize CLKG and generate FSG since $GSYNC = 1$ . |
| 1                  | 1                  | 0                    | FSX_int drives FSR_int and is selected as shown in <a href="#">Table 26-6</a> .                                                        | Output. Receive (same as transmit) frame synchronization is inverted as determined by FSRP before being driven out.            |

### 26.2.5.4.3 Transmit Frame Synchronization Selection: FSXM and FSGM

Table 26-6 shows how you can select the source of the transmit frame synchronization signal. The three choices are:

- External frame sync input
- The sample rate generator frame sync signal, FSG
- A signal that indicates a DXR-to-XSR copy has been made

**NOTE:** FSR\_int and FSX\_int are shown in Figure 26-2.

**Table 26-6. Transmit Frame Synchronization Selection**

| FSXM Bit in PCR | FSGM Bit in SRGR | Source of Transmit Frame Synchronization                                                         | FSX Pin Function                                                                               |
|-----------------|------------------|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| 0               | X                | External frame sync input on the FSX pin. This is inverted by FSXP before being used as FSX_int. | Input.                                                                                         |
| 1               | 1                | Sample rate generator frame sync signal (FSG) drives FSX_int. FRST = 1.                          | Output. FSG is inverted by FSXP before being driven out on FSX.                                |
| 1               | 0                | A DXR-to-XSR copy activates transmit frame sync signal.                                          | Output. 1-bit-clock-wide signal inverted as determined by FSXP before being driven out on FSX. |

### 26.2.5.4.4 Frame Detection

To facilitate detection of frame synchronization, the receive and transmit CPU interrupts (RINT and XINT) can be programmed to detect frame synchronization by setting the RINTM and XINTM bits in the serial port control register (SPCR) to 10b. The associated portion (receiver/transmitter) of the McBSP must be out of reset.

### 26.2.5.5 Data and Frames

#### 26.2.5.5.1 Frame Synchronization Phases

Frame synchronization indicates the beginning of a transfer on the McBSP. The data stream following frame synchronization can have up to two phases, phase 1 and phase 2. The number of phases can be selected by the phase bit, (R/X)PHASE, in RCR and XCR. The number of elements per frame and bits per element can be independently selected for each phase via (R/X)FRLN1/2 and (R/X)WDLEN1/2, respectively. Figure 26-10 shows a frame in which the first phase consists of two elements of 12 bits, each followed by a second phase of three elements of 8 bits each. The entire bit stream in the frame is contiguous; no gaps exist either between elements or phases. Table 26-7 shows the fields in the receive/transmit control registers (RCR/XCR) that control the frame length and element length for each phase for both the receiver and the transmitter. The maximum number of elements per frame is 128 for a single-phase frame and 256 elements in a dual-phase frame. The number of bits per element can be 8, 12, 16, 20, 24, or 32.

**NOTE:** For a dual-phase frame with internally generated frame synchronization, the maximum number of elements per phase depends on the word length. This is because the frame period, FPER, is only 12-bits wide and, therefore, provides 4096 bits per frame. Hence, the maximum number of 256 elements per dual-phase frame applies only when the WDLEN is 16 bits. However, any combination of element numbers and element size (defined by the FRLN and WDLEN bits, respectively) is valid as long as their product is less than or equal to 4096 bits. This limitation does not apply for dual-phase with external frame sync.

Figure 26-10. Dual-Phase Frame Example

Table 26-7. RCR/XCR Fields Controlling Elements per Frame and Bits per Element

| Serial Port | Frame Phase | RCR/XCR Field Control |                  |
|-------------|-------------|-----------------------|------------------|
|             |             | Elements per Frame    | Bits per Element |
| Receive     | 1           | RFLEN1                | RWDLEN1          |
| Receive     | 2           | RFLEN2                | RWDLEN2          |
| Transmit    | 1           | XFLEN1                | XWDLEN1          |
| Transmit    | 2           | XFLEN2                | XWDLEN2          |

#### 26.2.5.5.2 Frame Length: RFLEN1/2 and XFLEN1/2

Frame length specifies the maximum number of serial elements or logical time slots or channels that are available for transfer per frame synchronization signal. In multichannel selection mode, the frame length value is independent of, and perhaps different from, the actual number of channels that the device is programmed to receive or transmit per frame via the MCR, RCEREN, and XCEREN registers. See [Section 26.2.9](#) for details on multichannel selection mode operation. The 7-bit (R/X)FLEN1/2 bits in (R/X)CR support up to 128 elements per phase in a frame, as shown in [Table 26-8](#). (R/X)PHASE = 0 selects a single-phase data frame, and (R/X)PHASE = 1 selects a dual-phase frame for the data stream. For a single-phase frame, the value of (R/X)FLEN2 does not matter. Program the frame length fields with (w minus 1), where w represents the number of elements per frame. For [Figure 26-10](#), (R/X)FLEN1 = 1 or 000 0001b and (R/X)FLEN2 = 2 or 000 0010b.

Table 26-8. Receive/Transmit Frame Length Configuration

| (R/X)PHASE | (R/X)FLEN1          | (R/X)FLEN2          | Frame Length                                              |
|------------|---------------------|---------------------|-----------------------------------------------------------|
| 0          | $0 \leq n \leq 127$ | x                   | Single-phase frame; (n + 1) elements per frame            |
| 1          | $0 \leq n \leq 127$ | $0 \leq m \leq 127$ | Dual-phase frame; (n + 1) plus (m + 1) elements per frame |

#### 26.2.5.5.3 Element Length: RWDLEN1/2 and XWDLEN1/2

The (R/X)WDLEN1/2 fields in the receive/transmit control register (RCR and XCR) determine the element length in bits per element for the receiver and the transmitter for each phase of the frame, as indicated in [Table 26-7](#). [Table 26-9](#) shows how the value of these fields selects particular element lengths in bits. For the example in [Figure 26-10](#), (R/X)WDLEN1 = 001b and (R/X)WDLEN2 = 000b. If (R/X)PHASE = 0, indicating a single-phase frame, then (R/X)WDLEN2 is not used by the McBSP and its value does not matter.

**Table 26-9. Receive/Transmit Element Length Configuration**

| (R/X)WDLEN1/2 | Element Length (Bits) |
|---------------|-----------------------|
| 000           | 8                     |
| 001           | 12                    |
| 010           | 16                    |
| 011           | 20                    |
| 100           | 24                    |
| 101           | 32                    |
| 110           | Reserved              |
| 111           | Reserved              |

#### 26.2.5.5.4 Data Packing Using Frame Length and Element Length

The frame length and element length can be manipulated to effectively pack data. For example, consider a situation in which four 8-bit elements are transferred in a single-phase frame, as shown in [Figure 26-11](#). In this case:

- (R/X)PHASE = 0, indicating a single-phase frame
- (R/X)FRLLEN1 = 000 0011b, indicating a 4-element frame
- (R/X)WDLEN1 = 000b, indicating 8-bit elements

In this example, four 8-bit data elements are transferred to and from the McBSP by the CPU or the EDMA controller. Four reads of DRR and four writes of DXR are necessary for each frame.

**Figure 26-11. Single-Phase Frame of Four 8-Bit Elements**

The example in [Figure 26-11](#) can also be viewed as a data stream of a single-phase frame of one 32-bit data element, as shown in [Figure 26-12](#). In this case:

- (R/X)PHASE = 0, indicating a single phase frame
- (R/X)FRLLEN1 = 0, indicating a 1-element frame
- (R/X)WDLEN1 = 101b, indicating 32-bit elements

In this example, one 32-bit data element is transferred to and from the McBSP by the CPU or the EDMA controller. Thus, one read of DRR and one write of DXR is necessary for each frame. As a result, the number of transfers is one-fourth that of the previous example ([Figure 26-11](#)). This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 26-12. Single-Phase Frame of One 32-Bit Element

#### 26.2.5.5.5 Data Delay: RDATDLY and XDATDLY

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay. RDATDLY (in RCR) and XDATDLY (in XCR) specify the data delay for reception and transmission, respectively. The range of programmable data delay is zero to two bit clocks ((R/X)DATDLY = 00b to 10b), as shown in Figure 26-13. Typically, a 1-bit delay is selected because data often follows a 1-cycle active frame sync pulse.

Figure 26-13. Data Delay

Normally, a frame sync pulse is detected or sampled with respect to an edge of serial clock CLK(R/X). Thus, on a subsequent cycle (depending on data delay value), data can be received or transmitted. However, in the case of a 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle. For reception, this problem is solved by receive data being sampled on the first falling edge of CLKR when an active (high) FSR is detected. However, data transmission must begin on the rising edge of CLKX that generated the frame synchronization. Therefore, the first data bit is assumed to be in the XSR and DX. The transmitter then asynchronously detects the frame synchronization, FSX goes active, and it immediately starts driving the first bit to be transmitted on the DX pin.

Another common operation uses a data delay of 2. This configuration allows the serial port to interface to different types of T1 framing devices in which the data stream is preceded by a framing bit. During the reception of such a stream with a data delay of two bits, the framing bit appears after a 1-bit delay and data appears after a 2-bit delay). The serial port essentially discards the framing bit from the data stream, as shown in Figure 26-14. In transmission, by delaying the first transfer bit, the serial port essentially inserts a blank period (high-impedance period) in place of the framing bit. Here, it is expected that the framing device inserts its own framing bit or that the framing bit is generated by another device. Alternatively, you may pull up or pull down DX to achieve the desired value.

Figure 26-14. 2-Bit Data Delay Used to Discard Framing Bit

#### 26.2.5.5.6 Receive Data Justification and Sign Extension: RJUST

The RJUST bit in the serial port control register (SPCR) selects whether data in RBR is right- or left-justified (with respect to the MSB) in the DRR. If right justification is selected, RJUST further selects whether the data is sign-extended or zero-filled. Table 26-10 and Table 26-11 summarize the effect that various values of RJUST have on example receive data.

Table 26-10. Effect of RJUST Bit Values With 12-Bit Example Data ABCh

| RJUST Bit in SPCR | Justification | Extension        | Value in DRR |
|-------------------|---------------|------------------|--------------|
| 00                | Right         | Zero-fill MSBs   | 0000 0ABCh   |
| 01                | Right         | Sign-extend MSBs | FFFF FABCh   |
| 10                | Left          | Zero-fill LSBs   | ABCh 0000h   |
| 11                | Reserved      | Reserved         | Reserved     |

Table 26-11. Effect of RJUST Bit Values With 20-Bit Example Data ABCDEh

### 26.2.5.5.7 32-Bit Bit Reversal: RWDREVRS, XWDREVRS

Normally all transfers are sent and received with the MSB first; however, you can reverse the receive/transmit bit ordering of a 32-bit element (LSB first) using the 32-bit reversal feature of the McBSP by setting all of the following:

- (R/X)WDREVRS = 1 in the receive/transmit control register (RCR/XCR).
- (R/X)COMPAND = 01b in RCR/XCR.
- (R/X)WDLEN(1/2) = 101b in RCR/XCR to indicate 32-bit elements.

When you set the register fields as above, the bit ordering of the 32-bit element is reversed before being received by or sent from the serial port. If the (R/W)WDREVRS and (R/X)COMPAND fields are set as above, but the element size is not set to 32-bit, operation is undefined.

### 26.2.6 McBSP Buffer FIFO (BFIFO)

The McBSP Buffer FIFO (BFIFO) provides additional data buffering for the McBSP. The time it takes the host CPU or DMA controller to respond to DMA requests from the McBSP may vary; the additional buffering provided by the BFIFO allows greater tolerance to such variations. For convenience, the BFIFO is treated here as a block between the McBSP and the host/DMA controller (see [Figure 26-1](#)). Details on configuration of the BFIFO are provided in [Section 26.2.7.6](#).

### 26.2.7 McBSP Standard Operation

During a serial transfer, there are typically periods of serial port inactivity between packets or transfers. The receive and transmit frame synchronization pulse occurs for every serial transfer. When the McBSP is not in the reset state and has been configured for the desired operation, a serial transfer can be initiated by programming (R/X)PHASE = 0 for a single-phase frame with the required number of elements programmed in (R/X)FRLLEN1. The number of elements can range from 1 to 128 ((R/X)FRLLEN1 = 00h to 7Fh). The required serial element length is set in the (R/X)WDLEN1 field in the (R/X)CR. If a dual-phase frame is required for the transfer, RPHASE = 1 and each (R/X)FRLLEN1/2 can be set to any value between 0h and 7Fh.

[Figure 26-15](#) shows a single-phase data frame of one 8-bit element. Since the transfer is configured for a 1-bit data delay, the data on the DX and DR pins are available one bit clock after FS(R/X) goes active. This figure, as well as all others in this section, use the following assumptions:

- (R/X)PHASE = 0, specifying a single-phase frame
- (R/X)FRLLEN1 = 0b, specifying one element per frame
- (R/X)WDLEN1 = 000b, specifying eight bits per element
- (R/X)FRLLEN2 = (R/X)WDLEN2 = Value is ignored
- CLK(R/X)P = 0, specifying that the receive data is clocked on the falling edge and that transmit data is clocked on the rising edge
- FS(R/X)P = 0, specifying that active (high) frame sync signals are used
- (R/X)DATDLY = 01b, specifying a 1-bit data delay

**Figure 26-15. McBSP Standard Operation**

### 26.2.7.1 Receive Operation

Figure 26-16 shows serial reception. Once the receive frame synchronization signal (FSR) transitions to its active state, it is detected on the first falling edge of the receivers CLKR. The data on the DR pin is then shifted into the receive shift register (RSR) after the appropriate data delay as set by the RDATDLY bit in the receive control register (RCR). The contents of RSR is copied to RBR at the end of every element on the rising edge of the clock, provided RBR is not full with the previous data. Then, an RBR-to-DRR copy activates the RRDY status bit in the serial port control register (SPCR) to 1 on the following falling edge of CLKR. This indicates that the receive data register (DRR) is ready with the data to be read by the CPU or the EDMA controller. RRDY is deactivated when the DRR is read by the CPU or the EDMA controller. See also [Section 26.2.13.1.2](#) and [Section 26.2.14.1](#).

**Figure 26-16. Receive Operation**

### 26.2.7.2 Transmit Operation

Once transmit frame synchronization occurs, the value in the transmit shift register (XSR) is shifted out and driven on the DX pin after the appropriate data delay as set by the XDATDLY bit in the transmit control register (XCR). The XRDY bit in the serial port control register (SPCR) is activated after every DXR-to-XSR copy on the following falling edge of CLKX, indicating that the data transmit register (DXR) can be written with the next data to be transmitted. XRDY is deactivated when the DXR is written by the CPU or the EDMA controller. Figure 26-17 illustrates serial transmission. See [Section 26.2.7.5.4](#) for information on transmit operation when the transmitter is pulled out of reset (XRST = 1). See also [Section 26.2.13.1.3](#) and [Section 26.2.14.2](#).

**Figure 26-17. Transmit Operation**

### 26.2.7.3 Maximum Frame Frequency

The frame frequency is determined by the following equation, which calculates the period between frame synchronization signals:

$$\text{Frame frequency} = \frac{\text{Bit-clock frequency}}{\text{Number of bit clocks between frame sync signals}}$$

The frame frequency may be increased by decreasing the time between frame synchronization signals in bit clocks (which is limited only by the number of bits per frame). As the frame transmit frequency is increased, the inactivity period between the data frames for adjacent transfers decreases to 0. The minimum time between frame synchronization pulses is the number of bits transferred per frame. This time also defines the maximum frame frequency, which is calculated by the following equation:

$$\text{Maximum frame frequency} = \frac{\text{Bit-clock frequency}}{\text{Number of bits per frame}}$$

Figure 26-18 shows the McBSP operating at maximum frame frequency. The data bits in consecutive frames are transmitted continuously with no inactivity between bits. If there is a 1-bit data delay, as shown, the frame synchronization pulse overlaps the last bit transmitted in the previous frame.

**NOTE:** For (R/X)DATDLY = 0, the first bit of data transmitted is asynchronous to CLKX, as shown in Figure 26-13.

Maximum frame frequency may not be possible when the word length is 8-bits, depending on the clock divide value CLKGDV. The CPU or EDMA may not be able to service serial port requests that occur as frequently as every 8-bit clocks. This situation can be resolved by allowing additional space between words or choosing a slower bit clock (larger CLKGDV value).

## 26.2.7.4 Frame Synchronization Ignore

The McBSP can be configured to ignore transmit and receive frame synchronization pulses. The (R/X)FIG bit in (R/X)CR can be cleared to 0 to recognize frame sync pulses, or it can be set to 1 to ignore frame sync pulses. In this way, you can use (R/X)FIG either to pack data, if operating at maximum frame frequency, or to ignore unexpected frame sync pulses.

### 26.2.7.4.1 Frame Sync Ignore and Unexpected Frame Sync Pulses

RFIG and XFIG are used to ignore unexpected internal or external frame sync pulses. Any frame sync pulse is considered unexpected if it occurs one or more bit clocks earlier than the programmed data delay from the end of the previous frame specified by ((R/X)DATDLY). Setting the frame ignore bits to 1 causes the serial port to ignore these unexpected frame sync signals.

In reception, if not ignored (RFIG = 0), an unexpected FSR pulse discards the contents of RSR in favor of the incoming data. Therefore, if RFIG = 0, an unexpected frame synchronization pulse aborts the current data transfer, sets RSYNCERR in SPCR to 1, and begins the reception of a new data element. When RFIG = 1, the unexpected frame sync pulses are ignored.

In transmission, if not ignored (XFIG = 0), an unexpected FSX pulse aborts the ongoing transmission, sets the XSYNCERR bit in SPCR to 1, and reinitiates transmission of the current element that was aborted. When XFIG = 1, unexpected frame sync signals are ignored.

Figure 26-19 shows that element B is interrupted by an unexpected frame sync pulse when (R/X)FIG = 0. The reception of B is aborted (B is lost), and a new data element (C) is received after the appropriate data delay. This condition causes a receive synchronization error and thus sets the RSYNCERR bit. However, for transmission, the transmission of B is aborted and the same data (B) is retransmitted after the appropriate data delay. This condition is a transmit synchronization error and thus sets the XSYNCERR bit. Synchronization errors are discussed in [Section 26.2.7.5.2](#) and [Section 26.2.7.5.5](#).

**Figure 26-19. Unexpected Frame Synchronization With (R/X)FIG = 0**

Figure 26-20 shows McBSP operation when unexpected internal or external frame synchronization signals are ignored by setting (R/X)FIG = 1. Here, the transfer of element B is not affected by an unexpected frame synchronization.

**Figure 26-20. Unexpected Frame Synchronization With (R/X)FIG = 1**

#### 26.2.7.4.2 Data Packing using Frame Sync Ignore Bits

Section 26.2.5.5.4 describes one method of changing the element length and frame length to simulate 32-bit serial element transfers, thus requiring much less bus bandwidth than four 8-bit transfers require. This example works when there are multiple elements per frame.

Now consider the case of the McBSP operating at maximum packet frequency, as shown in Figure 26-21. Here, each frame has only a single 8-bit element. This stream takes one read transfer and one write transfer for each 8-bit element. Figure 26-22 shows the McBSP configured to treat this stream as a continuous stream of 32-bit elements. In this example, (R/X)FIG is set to 1 to ignore unexpected subsequent frames. Only one read transfer and one write transfer is needed every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth of the bandwidth needed to transfer four 8-bit blocks.

**Figure 26-21. Maximum Frame Frequency Operation With 8-Bit Data**

**Figure 26-22. Data Packing at Maximum Frame Frequency With (R/X)FIG = 1**

### 26.2.7.5 Serial Port Exception Conditions

There are five serial port events that can constitute a system error:

- Receive overrun (RFULL = 1 in SPCR)
- Unexpected receive frame synchronization (RSYNCERR = 1 in SPCR)
- Transmit data overwrite
- Transmit empty (XEMPTY = 0 in SPCR)
- Unexpected transmit frame synchronization (XSYNCERR = 1 in SPCR)

#### 26.2.7.5.1 Receive Overrun: RFULL

RFULL = 1 in the serial port control register (SPCR) indicates that the receiver has experienced overrun and is in an error condition. RFULL is set when the following conditions are met:

- DRR has not been read since the last RBR-to-DRR transfer.
- RBR is full and an RBR-to-DRR copy has not occurred.
- RSR is full and an RSR-to-RBR transfer has not occurred.

The data arriving on DR is continuously shifted into RSR (Figure 26-23). Once a complete element is shifted into RSR, an RSR-to-RBR transfer can occur only if an RBR-to-DRR copy is complete. Therefore, if DRR has not been read by the CPU or the EDMA controller since the last RBR-to-DRR transfer (RDY = 1), an RBR-to-DRR copy does not take place until RDY = 0. This prevents an RSR-to-RBR copy. New data arriving on the DR pin is shifted into RSR, and the previous contents of RSR are lost. After the receiver starts running from reset, a minimum of three elements must be received before RFULL can be set, because there was no last RBR-to-DRR transfer before the first element.

This data loss can be avoided if DRR is read no later than two and a half CLKR cycles before the end of the third element (data C) in RSR, as shown in Figure 26-24.

Either of the following events clears the RFULL bit to 0 and allows subsequent transfers to be read properly:

- Reading DRR
- Resetting the receiver (RRST = 0) or the device

Another frame synchronization is required to restart the receiver.

Figure 26-23 shows the receive overrun condition. Because element A is not read before the reception of element B is complete, B is not transferred to DRR yet. Another element, C, arrives and fills RSR. DRR is finally read, but not earlier than two and one half cycles before the end of element C. New data D overwrites the previous element C in RSR. If RFULL is still set after the DRR is read, the next element can overwrite D if DRR is not read in time.

Figure 26-24 shows the case in which RFULL is set but the overrun condition is averted by reading the contents of DRR at least two and a half cycles before the next element, C, is completely shifted into RSR. This ensures that a RBR-to-DRR copy of data B occurs before the next element is transferred from RSR to RBR.

**Figure 26-23. Serial Port Receive Overrun**

**Figure 26-24. Serial Port Receive Overrun Avoided**

### 26.2.7.5.2 Unexpected Receive Frame Synchronization: RSYNCERR

Figure 26-25 shows the decision tree that the receiver uses to handle all incoming frame synchronization pulses. The diagram assumes that the receiver has been activated (RRST = 1). Unexpected frame sync pulses can originate from an external source or from the internal sample rate generator. An unexpected frame sync pulse is defined as a sync pulse which occurs RDATDLY bit clocks earlier than the last transmitted bit of the previous frame. Any one of three cases can occur:

- Case 1: Unexpected FSR pulses with RFIG = 1. This case is discussed in Section 26.2.7.4.1 and shown in Figure 26-20. Here, receive frame sync pulses are ignored and the reception continues.
- Case 2: Normal serial port reception. There are three reasons for a receive not to be in progress:
  - This FSR is the first after RRST = 1.
  - This FSR is the first after DRR has been read clearing an RFULL condition.
  - The serial port is in the inter-packet intervals. The programmed data delay (RDATDLY) for reception may start during these inter-packet intervals for the first bit of the next element to be received. Thus, at maximum frame frequency, frame synchronization can still be received RDATDLY bit clocks before the first bit of the associated element.

For this case, reception continues normally, because these are not unexpected frame sync pulses.

- Case 3: Unexpected receive frame synchronization with RFIG = 0 (unexpected frame not ignored). This case was shown in Figure 26-19 for maximum packet frequency. Figure 26-26 shows this case during normal operation of the serial port with time intervals between packets. Unexpected frame sync pulses are detected when they occur the value in RDATDLY bit clocks before the last bit of the previous element is received on DR. In both cases, RSYNCERR in SPCR is set. RSYNCERR can be cleared only by receiver reset or by writing a 0 to this bit in SPCR. If RINTM = 11b in SPCR, RSYNCERR drives the receive interrupt (RINT) to the CPU.

---

**NOTE:** Note that the RSYNCERR bit in SPCR is a read/write bit, so writing a 1 to it sets the error condition. Typically, writing a 0 is expected.

---

**Figure 26-25. Decision Tree Response to Receive Frame Synchronization Pulse**

**Figure 26-26. Unexpected Receive Frame Synchronization Pulse**

### 26.2.7.5.3 Transmit With Data Overwrite

Figure 26-27 shows what happens if the data in DXR is overwritten before it is transmitted. Suppose you load the DXR with data C. A subsequent write to the DXR overwrites C with D before C is copied to the XSR. Thus, C is never transmitted on DX. The CPU can avoid overwriting data by polling XRDY before writing to DXR or by waiting for a programmed XINT to be triggered by XRDY (XINTM = 00b). The EDMA controller can avoid overwriting by synchronizing data writes with XEVT. See also [Section 26.2.13.1.3](#).

**Figure 26-27. Transmit With Data Overwrite**

#### 26.2.7.5.4 Transmit Empty: XEMPTY

XEMPTY indicates whether the transmitter has experienced underflow. Either of the following conditions causes XEMPTY to become active (XEMPTY = 0):

- During transmission, DXR has not been loaded since the last DXR-to-XSR copy, and all bits of the data element in XSR have been shifted out on DX.
- The transmitter is reset (XRST = 0 or the device is reset), and then restarted.

During an underflow condition, the transmitter continues to transmit the old data in DXR for every new frame sync signal FSX (generated by an external device, or by the internal sample rate generator) until a new element is loaded into DXR by the CPU or the EDMA controller. XEMPTY is deactivated (XEMPTY = 1) when this new element in DXR is transferred to XSR. In the case when the FSX is generated by a DXR-to-XSR copy (FSXM = 1 in PCR and FSGM = 0 in SRGR), the McBSP does not generate any new frame sync until new data is written to the DXR and a DXR-to-XSR copy occurs.

When the transmitter is taken out of reset (XRST = 1), it is in a transmit ready (XRDY = 1) and transmit empty (XEMPTY = 0) condition. If DXR is loaded by the CPU or the EDMA controller before FSX goes active, a valid DXR-to-XSR transfer occurs. This allows for the first element of the first frame to be valid even before the transmit frame sync pulse is generated or detected. Alternatively, if a transmit frame sync is detected before DXR is loaded, 0s are output on DX.

Figure 26-28 shows a transmit underflow condition. After B is transmitted, B is retransmitted on DX if you fail to reload the DXR before the subsequent frame synchronization. Figure 26-29 shows the case of writing to DXR just before a transmit underflow condition that would otherwise occur. After B is transmitted, C is written to DXR before the next transmit frame sync pulse occurs.

**Figure 26-28. Transmit Empty**

**Figure 26-29. Transmit Empty Avoided**

#### 26.2.7.5.5 Unexpected Transmit Frame Synchronization: XSYNCERR

A transmit frame sync error (XSYNCERR) may occur the first time the transmitter is enabled (XRST = 1) after a device reset. To avoid this, after enabling the transmitter for the first time, the following procedure must be followed:

1. Wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
2. Disable the transmitter (XRST = 0). This clears any XSYNCERR.
3. Re-enable the transmitter (XRST = 1).

See also [Section 26.2.12](#) for details on initialization procedure.

[Figure 26-30](#) shows the decision tree that the transmitter uses to handle all incoming frame synchronization signals. The diagram assumes that the transmitter has been started (XRST = 1). An unexpected transmit frame sync pulse is defined as a sync pulse that occurs XDATDLY bit clocks earlier than the last transmitted bit of the previous frame. Any one of three cases can occur:

- Case 1: Unexpected FSX pulses with XFIG = 1. This case is discussed in [Section 26.2.7.4.1](#) and shown in [Figure 26-20](#). In this case, unexpected FSX pulses are ignored, and the transmission continues.
- Case 2: FSX pulses with normal serial port transmission. This situation is discussed in [Section 26.2.7.2](#). There are two possible reasons for a transmit not to be in progress:
  - This FSX pulse is the first one to occur after XRST = 1.
  - The serial port is in the interpacket intervals. The programmed data delay (XDATDLY) may start during these interpacket intervals before the first bit of the next element is transmitted. Thus, if operating at maximum packet frequency, frame synchronization can still be received XDATDLY bit clocks before the first bit of the associated element.
- Case 3: Unexpected transmit frame synchronization with XFIG = 0. The case was shown in [Figure 26-19](#) for frame synchronization with XFIG = 0 at maximum packet frequency. [Figure 26-31](#) shows the case for normal operation of the serial port with interpacket intervals. In both cases, XSYNCERR in SPCR is set. XSYNCERR can be cleared only by transmitter reset or by writing a 0 to this bit in SPCR. If XINTM = 11b in SPCR, XSYNCERR drives the receive interrupt (XINT) to the CPU.

---

**NOTE:** The XSYNCERR bit in SPCR is a read/write bit, so writing a 1 to it sets the error condition. Typically, writing a 0 is expected.

---

**Figure 26-30. Decision Tree Response to Transmit Frame Synchronization Pulse**

**Figure 26-31. Unexpected Transmit Frame Synchronization Pulse**

### 26.2.7.6 McBSP Buffer FIFO (BFIFO)

The BFIFO contains two FIFOs: one Read FIFO (RFIFO) and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See [Figure 26-32](#) for a high-level block diagram of the BFIFO.

The BFIFO may be enabled/disabled and configured via the Write FIFO control register (WFIFOCTL) and the Read FIFO control register (RFIFOCTL). Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McBSP (see [Section 26.2.12](#) for details).

**Figure 26-32. McBSP Buffer FIFO (BFIFO) Block Diagram**

Note that the McBSP Buffer FIFO (BFIFO) has a different memory-map (see your device-specific data manual) than the McBSP memory-mapped registers (MMRs); hence, the BFIFO is accessible by way of a different Configuration Bus.

#### 26.2.7.6.1 BFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McBSP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McBSP generates transmit DMA requests as needed; the BFIFO is "invisible" to the McBSP.

When the Write FIFO is enabled, transmit DMA requests from the McBSP are sent to the BFIFO, which in turn generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled, upon a transmit DMA request from the McBSP, the WFIFO writes *WNUMDMA* 32-bit words to the McBSP, if and when there are at least *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied; at this point, it writes *WNUMDMA* words to the McBSP.

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded.

Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

#### 26.2.7.6.1.1 Transmit DMA Event Pacer

The BFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once *WNUMEVT* words have been written to the WFIFO, the WFIFO checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled.

Note that if transmit DMA event pacing is desired, the *WNUMEVT* bits in *WFIFOCTL* should be set to a non-zero integer multiple of the value in the *WNUMDMA* bits. If transmit DMA event pacing is not desired, then the value in the *WNUMEVT* bits should be set equal to the value in the *WNUMDMA* bits.

#### 26.2.7.6.2 BFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McBSP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McBSP generates receive DMA requests as needed; the BFIFO is "invisible" to the McBSP.

When the Read FIFO is enabled, receive DMA requests from the McBSP are sent to the BFIFO, which in turn generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McBSP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McBSP, if and when the RFIFO has space for *RNUMDMA* words. If the RFIFO does not have space, the RFIFO waits until this condition has been satisfied; at this point, it reads *RNUMDMA* words from the McBSP.

If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than *RNUMEVT* words, those words will be read correctly, emptying the RFIFO.

#### 26.2.7.6.2.1 Receive DMA Event Pacer

The BFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty.

Note that if receive DMA event pacing is desired, the *RNUMEVT* bits in *RFIFOCTL* should be set to a non-zero integer multiple of the value in *RNUMDMA* bits. If receive DMA event pacing is not desired, then the value in the *RNUMEVT* bits should be set equal to the value in the *RNUMDMA* bits.

#### 26.2.7.6.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

## 26.2.8 $\mu$ -Law/A-Law Companding Hardware Operation

Companding (compressing and expanding) hardware allows compression and expansion of data in either  $\mu$ -law or A-law format. The specification for  $\mu$ -law and A-law log PCM is part of the CCITT G.711 recommendation. The companding standard employed in the United States and Japan is  $\mu$ -law and allows 14 bits of dynamic range. The European companding standard is A-law and allows 13 bits of dynamic range. Any values outside these ranges are set to the most positive or most negative value. Thus, for companding to work best here, the data transferred to and from the McBSP via the CPU or the EDMA controller must be at least 16 bits wide.

The  $\mu$ -law and A-law formats encode data into 8-bit code elements. Companded data is always 8 bits wide, so the appropriate (R/X)WDLEN1/2 must be cleared to 0, indicating an 8-bit serial data stream. If companding is enabled and either phase of the frame does not have an 8-bit element length, companding continues as if the element length is eight bits.

When companding is used, transmit data is encoded according to the specified companding law, and receive data is decoded to 2s-complement format. Companding is enabled and the desired format is selected by appropriately setting (R/X)COMPAND in the (R/X)CR. Compression occurs during the process of copying data from DXR to XSR and expansion occurs from RBR to DRR, as shown in [Figure 26-33](#).

For transmit data to be compressed, it should be 16-bit, left-justified data, such as LAW16, as shown in [Figure 26-34](#). The value can be either 13 or 14 bits wide, depending on the companding law. This 16-bit data is aligned in DXR, as shown in [Figure 26-35](#).

For reception, the 8-bit compressed data in RBR is expanded to a left-justified 16-bit data, LAW16. This can be further justified to 32-bit data by programming the RJUST bits in the serial port control register (SPCR), as shown in [Table 26-12](#).

### 26.2.8.1 Companding Internal Data

If the McBSP is unused, the companding hardware can compand internal data. This hardware can be used to:

- Convert linear data to the appropriate  $\mu$ -law or A-law format.
- Convert  $\mu$ -law or A-law data to the linear format.
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 26-36 shows the method by which the McBSP can compand internal data. The data path is indicated by the (DLB) arrow. The McBSP is enabled in digital loopback (DLB) mode with companding appropriately enabled by the RCOMPAND and XCOMPAND bits. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or synchronization events (REVT and XEVT) allow synchronization of the CPU or the EDMA controller to these conversions, respectively. The time for this companding depends on the serial bit rate selected.

**Figure 26-36. Companding of Internal Data**

### 26.2.8.2 Bit Ordering

Normally, all transfers on the McBSP are sent and received with the MSB first. However, certain 8-bit data protocols (that do not use companded data) require the LSB to be transferred first. By setting the (R/X)COMPAND = 01b in (R/X)CR, the bit ordering of 8-bit elements is reversed (LSB first) before being sent to the serial port. Like the companding feature, this feature is enabled only if the appropriate (R/X)WDLEN1/2 bit is cleared to 0, indicating that 8-bit elements are to be serially transferred. A 32-bit bit reversal feature is also available, as shown in [Section 26.2.5.5.7](#)

## 26.2.9 Multichannel Selection Modes

This section defines and provides the functions and all related information concerning the multichannel selection modes.

### 26.2.9.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. Each McBSP supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that each contain 16 contiguous channels:

Block 0: Channels 0 through 15  
Block 1: Channels 16 through 31  
Block 2: Channels 32 through 47  
Block 3: Channels 48 through 63

Block 4: Channels 64 through 79  
Block 5: Channels 80 through 95  
Block 6: Channels 96 through 111  
Block 7: Channels 112 through 127

The blocks are assigned to partitions according to the selected partition mode. In the 2-partition mode, you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode, blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent. For example, it is possible to use 2 receive partitions (A and B) and 8 transmit partitions (A through H).

### 26.2.9.2 Multichannel Selection

When McBSP uses a time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels. The McBSP has one receive multichannel selection mode and three transmit multichannel selection modes.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

### 26.2.9.3 Configuring a Frame for Multichannel Selection

Before you enable a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (RPHASE/XPHASE = 0). Each frame represents a TDM data stream.
- Set a frame length (RFLEN1/XFLEN1) that includes the highest-numbered channel that is to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFLEN1 = 39). If XFLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

---

**NOTE:** The frame-sync pulse can be generated internally by the sample rate generator or it can be supplied externally by another source. In a multichannel mode configuration with external frame-sync generation, the McBSP transmitter will ignore the first frame-sync pulse after it is taken out of reset. The transmitter will transmit only on the second frame-sync pulse. The receiver will shift in data on the first frame-sync pulse, regardless of whether it is generated internally or externally.

---

#### 26.2.9.4 DX Enabler: DXENA

The DXENA bit in the serial port control register (SPCR) controls the high-impedance enable on the DX pin. When DXENA = 1, the McBSP enables extra delay for the DX pin turn-on time. This feature is useful for McBSP multichannel operations, such as in a time-division multiplexed (TDM) system. The McBSP supports up to 128 channels in a multichannel operation. These channels can be driven by different devices in a TDM data communication line, such as the T1/E1 line. In any multichannel operation where multiple devices transmit over the same DX line, you need to ensure that no two devices transmit data simultaneously, which results in bus contention. Enough dead time should exist between the transmission of the first data bit of the current device and the transmission of the last data bit of the previous device. In other words, the last data bit of the previous device needs to be disabled to a high-impedance state before the next device begins transmitting data to the same data line, as shown in [Figure 26-37](#).

When two McBSPs are used to transmit data over the same TDM line, bus contention occurs if DXENA = 0. The first McBSP turns off the transmission of the last data bit (changes DX from valid to a high-impedance state) after a disable time specified in the data manual. As shown in [Figure 26-37](#), this disable time is measured from the CLKX active clock edge. The next McBSP turns on its DX pin (changes from a high-impedance state to valid) after a delay time. Again, this delay time is measured from the CLKX active clock edge. Bus contention occurs because the dead time between the two devices is not enough. You need to apply alternative software or hardware methods to ensure proper multichannel operation in this case.

If you set DXENA = 1 in the second McBSP, the second McBSP turns on its DX pin after some extra delay time. This ensures that the previous McBSP on the same DX line is disabled before the second McBSP starts driving out data. The DX enabler controls only the high-impedance enable on the DX pin, not the data itself. Data is shifted out to the DX pin at the same time as in the case when DXENA = 0. The only difference is that with DXENA = 1, the DX pin is masked to a high-impedance state for some extra CPU cycles before the data is seen on the TDM data line. Therefore, only the first bit of data is delayed. Refer to the specific device datasheet for the exact amount of delay.

**Figure 26-37. DX Timing for Multichannel Operation**

#### 26.2.9.5 Using Two Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A.

### 26.2.9.5.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B (see [Table 26-13](#)), which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B (see [Table 26-14](#)). You can dynamically change which blocks of channels are assigned to the partitions, see [Section 26.2.9.5.2](#).

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bit in the multichannel control register (MCR). In the receive multichannel selection mode, the channels in this partition are controlled by the enhanced receive channel enable register partition A/B (RCERE0).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bit in MCR. In the receive multichannel selection mode, the channels in this partition are controlled by the enhanced receive channel enable register partition A/B (RCERE0).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bit in the multichannel control register (MCR). In one of the transmit multichannel selection modes, the channels in this partition are controlled by the enhanced transmit channel enable register partition A/B (XCERE0).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bit in MCR. In one of the transmit multichannel selection modes, the channels in this partition are controlled by the enhanced transmit channel enable register partition A/B (XCERE0).

**Table 26-13. Receive Channel Assignment and Control When Two Receive Partitions are Used**

| Receive Partition | Assigned Block of Receive Channels | RPABLK Bit in MCR | RPBBLK Bit in MCR | RCERE0 Bits |
|-------------------|------------------------------------|-------------------|-------------------|-------------|
| A                 | Block 0: channels 0 through 15     | 0                 | –                 | RCE0-RCE15  |
| A                 | Block 2: channels 32 through 47    | 1h                | –                 | RCE0-RCE15  |
| A                 | Block 4: channels 64 through 79    | 2h                | –                 | RCE0-RCE15  |
| A                 | Block 6: channels 96 through 111   | 3h                | –                 | RCE0-RCE15  |
| B                 | Block 1: channels 16 through 31    | –                 | 0                 | RCE16-RCE31 |
| B                 | Block 3: channels 48 through 63    | –                 | 1h                | RCE16-RCE31 |
| B                 | Block 5: channels 80 through 95    | –                 | 2h                | RCE16-RCE31 |
| B                 | Block 7: channels 112 through 127  | –                 | 3h                | RCE16-RCE31 |

**Table 26-14. Transmit Channel Assignment and Control When Two Transmit Partitions are Used**

| Transmit Partition | Assigned Block of Transmit Channels | XPABLK Bit in MCR | XPBBLK Bit in MCR | XCERE0 Bits |
|--------------------|-------------------------------------|-------------------|-------------------|-------------|
| A                  | Block 0: channels 0 through 15      | 0                 | –                 | XCE0-XCE15  |
| A                  | Block 2: channels 32 through 47     | 1h                | –                 | XCE0-XCE15  |
| A                  | Block 4: channels 64 through 79     | 2h                | –                 | XCE0-XCE15  |
| A                  | Block 6: channels 96 through 111    | 3h                | –                 | XCE0-XCE15  |
| B                  | Block 1: channels 16 through 31     | –                 | 0                 | XCE16-XCE31 |
| B                  | Block 3: channels 48 through 63     | –                 | 1h                | XCE16-XCE31 |
| B                  | Block 5: channels 80 through 95     | –                 | 2h                | XCE16-XCE31 |
| B                  | Block 7: channels 112 through 127   | –                 | 3h                | XCE16-XCE31 |

Figure 26-38 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0-15 have been assigned to partition A, and channels 16-31 have been assigned to partition B. In response to a frame-sync pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

**Figure 26-38. Alternating Between the Channels of Partition A and the Channels of Partition B**

#### 26.2.9.5.2 Reassigning Blocks During Reception/Transmission

If you want to use more than 32 channels, you can change which channel blocks are assigned to partitions A and B during the course of a data transfer. However, these changes must be carefully timed. While a partition is being transferred, its associated block assignment bits cannot be modified, and its associated channel enable register cannot be modified. For example, if block 3 is being transferred and block 3 is assigned to partition A, you cannot modify (R/X)PABLK to assign different channels to partition A, and you cannot modify (R/X)CERE0 to change the channel configuration for partition A. Several features of the McBSP helps to time the reassignment:

- The block of channels currently involved in reception/transmission (the current block) is reflected in the RCBLK/XCBLK bits. Your program can poll these bits to determine which partition is active. When a partition is not active, it is safe to change its block assignment and channel configuration.
- At the end of every block (at the boundary of two partitions), an interrupt can be sent to the CPU. In response to the interrupt, the CPU can then check the RCBLK/XCBLK bits and update the inactive partition.

Figure 26-39 shows an example of reassigning channels throughout a data transfer. In response to a frame-sync pulse, the McBSP alternates between partitions A and B. Whenever partition B is active, the CPU changes the block assignment for partition A. Whenever partition A is active, the CPU changes the block assignment for partition B.

**Figure 26-39. Reassigning Channel Blocks Throughout a McBSP Data Transfer**

## 26.2.9.6 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions. If you choose the 8-partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP partitions are activated in the following order: A, B, C, D, E, F, G, H. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A. In the 8-partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in [Table 26-15](#) and [Table 26-16](#). These assignments cannot be changed. [Table 26-15](#) and [Table 26-16](#) also show the registers used to control the channels in the partitions.

**Table 26-15. Receive Channel Assignment and Control When Eight Receive Partitions are Used**

| Receive Partition | Assigned Block of Receive Channels | Register Used For Channel Control |
|-------------------|------------------------------------|-----------------------------------|
| A                 | Block 0: channels 0 through 15     | RCERE0                            |
| B                 | Block 1: channels 16 through 31    | RCERE0                            |
| C                 | Block 2: channels 32 through 47    | RCERE1                            |
| D                 | Block 3: channels 48 through 63    | RCERE1                            |
| E                 | Block 4: channels 64 through 79    | RCERE2                            |
| F                 | Block 5: channels 80 through 95    | RCERE2                            |
| G                 | Block 6: channels 96 through 111   | RCERE3                            |
| H                 | Block 7: channels 112 through 127  | RCERE3                            |

**Table 26-16. Transmit Channel Assignment and Control When Eight Transmit Partitions are Used**

| Transmit Partition | Assigned Block of Transmit Channels | Register Used For Channel Control |
|--------------------|-------------------------------------|-----------------------------------|
| A                  | Block 0: channels 0 through 15      | XCERE0                            |
| B                  | Block 1: channels 16 through 31     | XCERE0                            |
| C                  | Block 2: channels 32 through 47     | XCERE1                            |
| D                  | Block 3: channels 48 through 63     | XCERE1                            |
| E                  | Block 4: channels 64 through 79     | XCERE2                            |
| F                  | Block 5: channels 80 through 95     | XCERE2                            |
| G                  | Block 6: channels 96 through 111    | XCERE3                            |
| H                  | Block 7: channels 112 through 127   | XCERE3                            |

[Figure 26-40](#) shows an example of the McBSP using the 8-partition mode. In response to a frame-sync pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

**Figure 26-40. McBSP Data Transfer in the 8-Partition Mode**

### 26.2.9.7 Receive Multichannel Selection Mode

The RCMC bit in the multichannel control register (MCR) determines whether all channels or only selected channels are enabled for reception. When RCMC = 0, all 128 receive channels are enabled and cannot be disabled. When RCMC = 1, the receive multichannel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate enhanced receive channel enable register (RCEREn). The way channels are assigned to the RCEREn depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit in MCR.
- If a receive channel is disabled, any bits received in that channel are passed only as far as the receive buffer register (RBR). The receiver does not copy the content of the RBR to the DRR, and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated, and if the receiver interrupt mode depends on RRDY (RINTM = 0), no interrupt is generated.

As an example of how the McBSP behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

1. Accepts bits shifted in from the DR pin in channel 0.
2. Ignores bits received in channels 1-14.
3. Accepts bits shifted in from the DR pin in channel 15.
4. Ignores bits received in channels 16-38.
5. Accepts bits shifted in from the DR pin in channel 39.

### 26.2.9.8 Transmit Multichannel Selection Mode

The XMCM bit in the multichannel control register (MCR) determines whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP has three transmit multichannel selection modes (XMCM = 1, XMCM = 2h, and XMCM = 3h), which are described in [Table 26-17](#).

**Table 26-17. Selecting a Transmit Multichannel Selection Mode With the XMCM Bits**

| XMCM Bit in MCR | Transmit Multichannel Selection Mode                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0               | No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.                                                                                                                                                                                                                                                                                                                                      |
| 1h              | All channels are disabled unless they are selected in the appropriate enhanced transmit channel enable register (XCEREn). If enabled, a channel in this mode is also unmasked.<br>The XMCME bit in MCR determines whether 32 channels or 128 channels are selectable in XCEREn.                                                                                                                                                                                   |
| 2h              | All channels are enabled, but they are masked unless they are selected in the appropriate enhanced transmit channel enable register (XCEREn).<br>The XMCME bit in MCR determines whether 32 channels or 128 channels are selectable in XCEREn.                                                                                                                                                                                                                    |
| 3h              | This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate enhanced receive channel enable register (RCEREn). Once enabled, they are masked unless they are also selected in the appropriate enhanced transmit channel enable register (XCEREn).<br>The XMCME bit in MCR determines whether 32 channels or 128 channels are selectable in RCEREn and XCEREn. |

As an example of how the McBSP behaves in a transmit multichannel selection mode, suppose that XMCM = 1 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP:

1. Shifts data to the DX pin in channel 0.
2. Places the DX pin in the high-impedance state in channels 1–14.
3. Shifts data to the DX pin in channel 15.
4. Places the DX pin in the high-impedance state in channels 16–38.
5. Shifts data to the DX pin in channel 39.

### 26.2.9.8.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The following definitions explain the channel control options:

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enabled channel</b>  | A channel that can begin transmission by passing data from the data transmit register (DXR) to the transmit shift register (XSR).                                                                                                                                                                                                                                                                                    |
| <b>Masked channel</b>   | A channel that cannot complete transmission. The DX pin is held in the high-impedance state; data cannot be shifted out on the DX pin.<br><br>In systems where symmetric transmit and receive provides software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention. |
| <b>Disabled channel</b> | A channel that is not enabled. A disabled channel is also masked.<br><br>Because no DXR-to-XSR copy occurs, the XRDY bit in SPCR is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 0 in SPCR), no interrupt is generated.<br><br>The XEMPTY bit in SPCR is not affected.                                                          |
| <b>Unmasked channel</b> | A channel that is not masked. Data in the XSR is shifted out on the DX pin.                                                                                                                                                                                                                                                                                                                                          |

### 26.2.9.8.2 Activity on McBSP Pins for Different Values of XMCM

Figure 26-41 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- In transmit control register (XCR):
  - XPHASE = 0: Single-phase frame (required for multichannel selection modes)
  - XFRLN1 = 3h: 4 words per frame
  - XWDLEN1 = 0: 8 bits per word
- In multichannel control register (MCR):
  - XMCM = 0: 2-partition mode (only partitions A and B used)

In the case where XMCM = 3h, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLN1, and XWDLEN1, respectively.

In Figure 26-41, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

### 26.2.9.9 Using Interrupts Between Block Transfers

When a multichannel selection mode is used, an interrupt request can be sent to the CPU at the end of every 16-channel block (at the boundary between partitions and at the end of the frame). In the receive multichannel selection mode, a receive interrupt (RINT) request is generated at the end of each block transfer if the RINTM bit in the serial port control register (SPCR) is set to 1. In any of the transmit multichannel selection modes, a transmit interrupt (XINT) request is generated at the end of each block transfer if the XINTM bit in SPCR is set to 1. When RINTM/XINTM = 1, no interrupt is generated unless a multichannel selection mode is on.

These interrupt pulses are active high and last for two McBSP internal input clock cycles.

This type of interrupt is especially helpful if you are using the two-partition mode and you want to know when you can assign a different block of channels to partition A or B.

**Figure 26-41. Activity on McBSP Pins for the Possible Values of XMCM**

(a)  $XMCM = 0$ : All channels enabled and unmasked

(b)  $XMCM = 1h$ ,  $XPABLK = 0$ ,  $XCERE0 = 0000\ 000Ah$ : Only channels 1 and 3 enabled and unmasked

(c)  $XMCM = 2h$ ,  $XPABLK = 0$ ,  $XCERE0 = 0000\ 000Ah$ : All channels enabled, only 1 and 3 unmasked

(d)  $XMCM = 3h$ ,  $RPABLK = 0$ ,  $XPABLK = x$ ,  $RCERE0 = 0000\ 0008h$ ,  $XCERE0 = 0000\ 000Ah$ : Receive channels: 1 and 3 enabled; transmit channels: 1 and 3 enabled, but only 3 unmasked

## 26.2.10 SPI Operation Using the Clock Stop Mode

The McBSP on this device does not support the SPI protocol.

## 26.2.11 Resetting the Serial Port: Rrst, Xrst, Grst, and Reset

Device reset or McBSP reset: When the McBSP is reset by device reset or McBSP reset, the state machine is reset to its initial state. All counters and status bits are reset. This includes the receive status bits RFULL, RRDY, and RSYNCERR, and the transmit status bits XEMPTY, XRDY, and XSYNCERR in the serial port control register (SPCR).

The serial port can be reset in the following two ways:

- Device reset (RESET pin is low) places the receiver, the transmitter, and the sample rate generator in reset. When the device reset is removed (RESET = 1), FRST = GRST = Rrst = Xrst = 0 in SPCR, keeping the entire serial port in the reset state.
- The serial port transmitter and receiver can be independently reset by the Xrst and Rrst bits in SPCR. The sample rate generator is reset by the GRST bit in SPCR.

Table 26-18 shows the state of the McBSP pins when the serial port is reset by these methods.

**Table 26-18. Reset State of McBSP Pins**

| Pin                                              | Direction | Device Reset ( RESET = 0) | McBSP Reset                                          |
|--------------------------------------------------|-----------|---------------------------|------------------------------------------------------|
| <b>Receiver Reset (Rrst = 0 and Grst = 1)</b>    |           |                           |                                                      |
| DR                                               | I         | Input                     | Input                                                |
| CLKR                                             | I/O/Z     | Input                     | Known state if input; CLKR if output                 |
| FSR                                              | I/O/Z     | Input                     | Known state if input; FSRP(inactive state) if output |
| CLKS                                             | I         | Input                     | Input                                                |
| <b>Transmitter Reset (Xrst = 0 and Grst = 1)</b> |           |                           |                                                      |
| DX                                               | O/Z       | High impedance            | High impedance                                       |
| CLKX                                             | I/O/Z     | Input                     | Known state if input; CLKX if output                 |
| FSX                                              | I/O/Z     | Input                     | Known state if input; FSXP(inactive state) if output |
| CLKS                                             | I         | Input                     | Input                                                |

### 26.2.11.1 Software Reset Considerations

**McBSP reset:** When the receiver and transmitter reset bits, Rrst and Xrst in SPCR, are written with 0, the respective portions of the McBSP are reset and activity in the corresponding section stops. All input-only pins, such as DR, and all other pins that are configured as inputs are in a known state. FS(R/X) is driven to its inactive state (same as its polarity bit, FS(R/X)P) if it is an output. If CLK(R/X) are programmed as outputs, they are driven by CLKG, provided that GRST = 1. The DX pin is in the high-impedance state when the transmitter is reset. During normal operation, the sample rate generator can be reset by writing a 0 to GRST. The sample rate generator should only be reset when not being used by the transmitter or the receiver. In this case, the internal sample rate generator clock CLKG, and its frame sync signal (FSG) is driven inactive (low). When the sample rate generator is not in the reset state (GRST = 1), FSR and FSX are in an inactive state when Rrst = 0 and Xrst = 0, respectively, even if they are outputs driven by FSG. This ensures that when only one portion of the McBSP is in reset, the other portion can continue operation when FRST = 1 and frame sync is driven by FSG.

**Sample-rate generator reset:** As mentioned previously, the sample rate generator is reset when the device is reset or when its reset bit, GRST in SPCR, is written with 0.

**Emulator software reset:** In the event of an emulator software reset initiated from the DSP, the McBSP register values are reset to their default values.

### 26.2.11.2 Hardware Reset Considerations

When the McBSP is reset due to device reset, the entire serial port (including the transmitter, receiver, and the sample rate generator) is reset. All input-only pins and 3-state pins should be in a known state. The output-only pin, DX, is in the high-impedance state. When the device is pulled out of reset, the serial port remains in the reset condition (RRST = XRST = FRST = GRST = 0 in SPCR).

### 26.2.12 McBSP Initialization Procedure

The McBSP initialization procedure varies depending on the specific system setup. [Section 26.2.12.1](#) provides a general initialization sequence.

The transmitter and the receiver of the McBSP can operate independently from each other. Therefore, they can be placed in or taken out of reset individually by modifying only the desired bit in the registers without disrupting the other portion. The steps in the following sections discuss the initialization procedure for taking both the transmitter and the receiver out of reset. To initialize only one portion, configure only the portion desired.

The McBSP internal sample rate generator and internal frame sync generator are shared between the transmitter and the receiver. [Table 26-19](#) and [Table 26-20](#) describe their usage base upon the clock and frame sync configurations of the receiver and transmitter, respectively.

**Table 26-19. Receiver Clock and Frame Configurations**

| CLKR Source | FSR Source | Comment on Configuration                                                                                            |
|-------------|------------|---------------------------------------------------------------------------------------------------------------------|
| Internal    | Internal   | The McBSP internal sample rate generator and internal frame sync generator are used by the receiver.                |
| External    | Internal   | The McBSP internal sample rate generator and internal frame sync generator are used by the receiver.                |
| Internal    | External   | The McBSP internal sample rate generator is used but the internal frame sync generator is not used by the receiver. |
| External    | External   | The McBSP internal sample rate generator and internal frame sync generator are not used by the receiver.            |

**Table 26-20. Transmitter Clock and Frame Configurations**

| CLKX Source | FSX Source | Comment on Configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Internal    | Internal   | The McBSP internal sample rate generator is used by the transmitter. The transmitter can generate frame sync FSX in one of two ways. First, it can generate FSX by using the internal frame sync generator (FSGM = 1). Alternatively, it can generate FSX upon each DXR-to-XSR copy (FSGM = 0). In this case, the internal frame sync generator can be kept in reset (FRST = 0) if it is not used by the receiver. You can follow the general initialization sequence in <a href="#">Section 26.2.12.1</a> . |
| External    | Internal   | The McBSP internal sample rate generator and internal frame sync generator are not used by the transmitter. This configuration is only valid with FSGM = 0 where the McBSP transmitter generates FSX upon each DXR-to-XSR copy. You can follow the general initialization sequence in <a href="#">Section 26.2.12.1</a> .                                                                                                                                                                                    |
| Internal    | External   | The McBSP internal sample rate generator is used by the transmitter but the internal frame sync generator is not.                                                                                                                                                                                                                                                                                                                                                                                            |
| External    | External   | The McBSP internal sample rate generator and internal frame sync generator are not used by the transmitter.                                                                                                                                                                                                                                                                                                                                                                                                  |

### 26.2.12.1 General Initialization Procedure

This section provides the general initialization procedure.

1. With the McBSP still in reset (Power and Sleep Controller (PSC) in the default state):
  - (a) Program the PSC registers in the System Module to put the McBSP in the enable state (see the *Power and Sleep Controller (PSC)* chapter).
  - (b) Perform the necessary device pin multiplexing setup (see your device-specific data manual).
2. Ensure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0 in SPCR). The respective portion of the McBSP needs to be in reset (XRST = 0 and/or RRST = 0 in SPCR).
3. Program the control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0). Also ensure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRST = 0).
4. Wait for proper internal synchronization. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR and the SCLKME bit in PCR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the McBSP is the bit clock master and the internal sample rate generator is used.
  - (a) Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
  - (b) On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to  $1/(\text{CLKGDV} + 1)$  of the sample rate generator source clock CLKSRG.
6. Skip this step if the transmitter is not used. If the transmitter is used, a transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
  - (a) Set the XRST bit to 1 to enable the transmitter.
  - (b) Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
  - (c) Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
7. Setup data acquisition as required:
  - (a) If the EDMA is used to service the McBSP, setup data acquisition as desired and start the EDMA in this step, before the McBSP is taken out of reset.
  - (b) If CPU interrupt is used to service the McBSP, enable the transmit and/or receive interrupt as required.
  - (c) If CPU polling is used to service the McBSP, no action is required in this step.
8. Set the XRST bit and/or the RRST bit to 1 to enable the corresponding section of the McBSP. The McBSP is now ready to transmit and/or receive.
  - (a) If the EDMA is used to service the McBSP, it services the McBSP automatically upon receiving the XEVT and/or REVT.
  - (b) If CPU interrupt is used to service the McBSP, the interrupt service routine is automatically entered upon receiving the XINT and/or RINT.
  - (c) If CPU polling is used to service the McBSP, it can do so now by polling the XRDY and/or RRDY bit.
9. If the internal frame sync generator is used (FSGM = 1), proceed to the additional steps to turn on the internal frame sync generator. Initialization is complete if any one of the following is true:
  - (a) The external device generates frame sync FSX and/or FSR. The McBSP is now ready to transmit and/or receive upon receiving external frame sync.
  - (b) The McBSP generates transmit frame sync FSX upon each DXR-to-XSR copy. The internal frame sync generator is not used (FSGM = 0).

The following additional steps to turn on the internal frame sync generator apply only if FSGM = 1:

10. Skip this step if the transmitter is not used. If the transmitter is used, ensure that DXR is serviced before you start the internal frame sync generator. You can do so by checking XEMPTY = 1 (XSR is not empty) in SPCR.
11. Set the FRST bit to 1 to start the internal frame sync generator. The internal frame sync signal FSG is generated on a CLKG active edge after 7 to 8 CLKG clocks have elapsed.

#### 26.2.12.2 Special Case: External Device is the Transmit Frame Master

Care must be taken if the transmitter expects a frame sync from an external device. After the transmitter comes out of reset (XRST = 1), it waits for a frame sync from the external device. If the first frame sync arrives very shortly after the transmitter is enabled, the CPU or EDMA controller may not have a chance to service the data transmit register (DXR). In this case, the transmitter shifts out the default data in the transmit shift register (XSR) instead of the desired value, which has not yet arrived in DXR. This causes problems in some applications, as the first data element in the frame is invalid. The data stream appears element-shifted (the first data word may appear in the second channel instead of the first).

To ensure proper operation when the external device is the frame master, you must assure that DXR is already serviced with the first word when a frame sync occurs. To do so, you can keep the transmitter in reset until the first frame sync is detected. Software is setup such that it will only take the transmitter out of reset (XRST = 1) promptly after detecting the first frame sync. This assures that the transmitter does not begin data transfers at the data pin during the first frame sync period. This also provides almost an entire frame period for the DSP to service DXR with the first word before the second frame sync occurs. The transmitter only begins data transfers upon receiving the second frame sync. At this point, DXR is already serviced with the first word.

##### 26.2.12.2.1 How to Detect First Frame Sync

Although the McBSP is capable of generating an interrupt to the CPU upon the detection of frame synchronization (XINTM = 2h and/or RINTM = 2h in the serial port control register (SPCR)), the McBSP requires the associated portion (receiver/transmitter) of the McBSP to be out of reset in order for the interrupt to be generated. Therefore, instead of directly using the McBSP interrupt to detect the first frame sync, you can use the GPIO peripheral. This can be achieved by connecting the frame sync signal to a GPIO pin. Software can either poll the GPIO pin to detect the first frame sync or program the GPIO peripheral to generate an interrupt to the CPU upon detecting the first frame sync edge. For more information on the GPIO peripheral, see the *General-Purpose Input/Output (GPIO)* chapter.

The following are some recommended GPIO pin(s) on the device that you can use to detect the first McBSP external frame sync:

- **GPIO pin located near the McBSP pins.** Connect the external frame sync to both the McBSP FSX/FSR pin(s) and the dedicated GPIO pin.
- **GPIO pin multiplexed with the McBSP FSX signal.** Note that on the device, the GPIO pins (of the GPIO peripheral) are multiplexed with the McBSP pins. Software can program the device's pin multiplexing register (PINMUX) to default these pins to the GPIO function, and only switch them to the McBSP function upon detecting the first frame sync. This method is only recommended if the external device is both the frame sync and clock master; that is, the external device drives both the FSX and CLKX signals. This method is not recommended if the McBSP is the clock master (driving CLKX and/or CLKR), as the "on-the-fly" pin multiplexed switching can cause a glitch on the CLKX/CLKR pin. For more details on pin multiplexing, see the device-specific data manual.

##### 26.2.12.2.2 Initialization Procedure When External Device is Frame Sync Master

The initialization procedure assumes the following:

- Using a GPIO pin multiplexed with the McBSP FSX signal. If a dedicated GPIO pin is used instead, skip step 1 and step 8b.
- Software polls the GPIO pin to detect the first frame sync. If the GPIO interrupt is used instead to detect the first frame sync, step 8 can be performed within an interrupt service routine (ISR).

1. The GPIO and McBSP signals are multiplexed together on the device. Start by programming the pin multiplexing register (PINMUX) to select the GPIO function on the GPIO/McBSP multiplexed pins. Program the GPIO peripheral so that these pins function as GPIO inputs.
2. Ensure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0 in SPCR). The respective portion of the McBSP needs to be in reset (XRST = 0 and/or RRSST = 0 in SPCR).
3. Program the sample rate generator register (SRGR) and other control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0 in SPCR). Also ensure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRSST = 0 in SPCR).
4. Wait for proper McBSP internal synchronization:
  - (a) If the external device provides the bit clock, wait for two CLKR or CLKX cycles. Skip step 5.
  - (b) If the McBSP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the McBSP is the bit clock master and the internal sample rate generator is used.
  - (a) Start the sample rate generator by setting the GRST bit in SPCR to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
  - (b) On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to  $1/(\text{CLKGDV} + 1)$  of the sample rate generator source clock CLKSRG.
6. A transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
  - (a) Set the XRST bit in SPCR to 1 to enable the transmitter.
  - (b) Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
  - (c) Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
7. Setup data acquisition as required:
  - (a) If the EDMA controller is used to service the McBSP, setup data acquisition as desired and start the EDMA controller in this step, before the McBSP is taken out of reset.
  - (b) If the CPU interrupt is used to service the McBSP, no action is required in this step.
  - (c) If CPU polling is used to service the McBSP, no action is required in this step.
8. Poll the GPIO pin (through reading the appropriate registers in the GPIO peripheral) to detect the first transmit frame sync from the external device. Upon detection of the first frame sync, perform the following in this order:
  - (a) Set the XRST bit and/or the RRSST bit to 1 to enable the respective portion of the McBSP. The McBSP is now ready to transmit and/or receive.
  - (b) Program PINMUX to switch the GPIO/McBSP multiplexed pins to the McBSP function.
9. Service the McBSP:
  - (a) If CPU polling is used to service the McBSP in normal operations, it can do so upon exit from the ISR.
  - (b) If the CPU interrupt is used to service the McBSP in normal operations, upon XRDY interrupt service routine is entered. The ISR should be setup to verify that XRDY = 1 and service the McBSP accordingly.
  - (c) If the EDMA controller is used to service the McBSP in normal operations, it services the McBSP automatically upon receiving the XEVT and/or REVT.
10. Upon detection of the second frame sync, DXR is already serviced and the transmitter is ready to transmit the valid data. The receiver is also serviced properly by the DSP.

## 26.2.13 Interrupt Support

The McBSP can send both receive and transmit interrupts to the DSP controller. For more details on the Interrupt Controller, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 26.2.13.1 Interrupt Events and Requests

The RRDY and XRDY bits in the serial port control register (SPCR) indicate the ready state of the McBSP receiver and transmitter, respectively. Writes and reads from the serial port can be synchronized by any of the following methods:

- Polling RRDY and XRDY bits in SPCR
- Using the events sent to the EDMA controller (REVT and XEVT)
- Using the interrupts to the CPU (RINT and XINT) that the events generate

Reading DRR and writing to DXR affects RRDY and XRDY, respectively.

#### 26.2.13.1.1 Interrupt Events: RINT and XINT

The receive interrupt (RINT) and transmit interrupt (XINT) signals inform the DSP of changes to the serial port status. Three options exist for configuring these interrupts. These options are set by the receive/transmit interrupt mode bits (RINTM and XINTM) in SPCR. The possible values of the mode, and the configurations they represent, are:

- (R/X)INTM = 00b: Interrupt on every serial element by tracking the (R/X)RDY bits in SPCR.
- (R/X)INTM = 01b: Interrupt at the end of a subframe (16 elements or less) within a frame. See [Section 26.2.9.9](#) for more details.
- (R/X)INTM = 10b: Interrupt on detection of frame synchronization pulses. The associated portion (receiver/transmitter) of the McBSP must be out of reset.
- (R/X)INTM = 11b: Interrupt on frame synchronization error. Note that if any of the other interrupt modes are selected, (R/X)SYNCERR may be read when servicing the interrupts to detect this condition. See [Section 26.2.7.5.2](#) and [Section 26.2.7.5.5](#) for more details on synchronization error.

#### 26.2.13.1.2 Receive Ready Status: RINT and RRDY

RRDY = 1 indicates that the RBR contents have been copied to DRR and that the data can now be read by either the CPU or the EDMA controller. Once that data has been read by either the CPU, RRDY is cleared to 0. Also, at device reset or serial port receiver reset (RRST = 0), the RRDY bit is cleared to 0 to indicate that no data has been received and loaded into DRR. RRDY directly drives the McBSP receive interrupt (RINT) to the CPU if RINTM = 00b (default value) in SPCR.

#### 26.2.13.1.3 Transmit Ready Status: XINT and XRDY

XRDY = 1 indicates that the DXR contents have been copied to XSR and that DXR is ready to be loaded with a new data word. When the transmitter transitions from reset to non-reset (XRST transitions from 0 to 1), XRDY also transitions from 0 to 1 indicating that DXR is ready for new data. Once new data is loaded by the CPU, the XRDY bit is cleared to 0. However, once this data is copied from DXR to XSR, the XRDY bit transitions again from 0 to 1. The CPU can write to DXR although XSR has not yet been shifted out on DX. XRDY directly drives the McBSP transmit interrupt (XINT) to the CPU if XINTM = 00b (default value) in SPCR.

---

**NOTE:** If the polling method is used to service the transmitter, the CPU should wait for one McBSP bit clock (CLKX) before polling again to write the next element in DXR. This is because XRDY transitions occur based on bit clock and not CPU clock. The CPU clock is much faster and can cause false XRDY status, leading to data errors due to overwrites.

---

### 26.2.13.2 Interrupt Multiplexing

The RINT and XINT interrupts generated by the McBSP peripheral to the CPU are multiplexed with other interrupt sources. Refer to the device-specific data manual to determine how pin multiplexing affects the McBSP.

## 26.2.14 EDMA Event Support

### 26.2.14.1 Receive Ready Status: REVT and RRDY

RRDY = 1 in the serial port control register (SPCR) indicates that the RBR contents have been copied to DRR and that the data can now be read by the EDMA controller. Once that data has been read by the EDMA controller, RRDY is cleared to 0. Also, at device reset or serial port receiver reset (RRST = 0 in SPCR), the RRDY bit is cleared to 0 to indicate that no data has been received and loaded into DRR. RRDY directly drives the McBSP receive event to the EDMA controller (via REVT).

For detailed information on using the EDMA to read or write to the McBSP, see the *Enhanced Direct Memory Access (EDMA3) Controller* chapter.

### 26.2.14.2 Transmit Ready Status: XEVT and XRDY

XRDY = 1 in the serial port control register (SPCR) indicates that the DXR contents have been copied to XSR and that DXR is ready to be loaded with a new data word. When the transmitter transitions from reset to non-reset (XRST transitions from 0 to 1 in SPCR), XRDY also transitions from 0 to 1 indicating that DXR is ready for new data. Once new data is loaded by the EDMA controller, the XRDY bit is cleared to 0. However, once this data is copied from DXR to XSR, the XRDY bit transitions again from 0 to 1. The EDMA controller can write to DXR although XSR has not yet been shifted out on DX. XRDY directly drives the transmit synchronization event to the EDMA controller (via XEVT).

For detailed information on using the EDMA to read or write to the McBSP, see the *Enhanced Direct Memory Access (EDMA3) Controller* chapter.

---

**NOTE:** If the polling method is used to service the transmitter, the CPU should wait for one McBSP bit clock (CLKX) before polling again to write the next element in DXR. This is because XRDY transitions occur based on bit clock and not CPU clock. The CPU clock is much faster and can cause false XRDY status, leading to data errors due to overwrites.

---

### 26.2.15 Power Management

The McBSP can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device.

In order for the McBSP to be placed in power-down mode by the PSC, ensure that the XRDY and RRDY flags in the serial port control register (SPCR) are cleared by performing the following steps:

1. Place the McBSP in reset by clearing the XRST, RREST, FRST, and GRST bits to 0 in SPCR.  
If EDMA is being used to service the transmitter and/or the receiver, disable the associated EDMA channels.  
For detailed information on using the EDMA to read or write to the McBSP, see the *Enhanced Direct Memory Access (EDMA3) Controller* chapter.
2. Switch the McBSP clocks and frames to internal clock source:
  - (a) Set the CLKSM and FSGM bits to 1 in the sample rate generator register (SRGR).
  - (b) Set the CLKXM, CLKRM, FSXM, and FSRM bits to 1 in the pin control register (PCR).
  - (c) Clear the SCLKME bit to 0 in PCR.
3. Bring the McBSP out of reset by setting the XRST, RREST, and GRST bits to 1 in SPCR.
4. Wait for two CLKSRG cycles for proper internal synchronization.
5. Write a dummy data value to the data transmit register (DXR) in order to clear the first XRDY flag.
6. Wait for at least one McBSP bit clock, since once the first dummy data value is internally copied from DXR to XSR, the XRDY flag transitions again from 0 to 1.
7. Write a second dummy data value to DXR in order to clear the second XRDY flag.
8. Check the RRDY flag in SPCR and if set to 1, read the data receive register (DRR) and discard the data to clear the RRDY flag.
9. Place the McBSP in power-down mode by issuing the proper PSC commands. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

**NOTE:** After waking up the McBSP from a power-down mode using the proper PSC commands, remember to reconfigure the SPCR, SRGR, and PCR registers to the clock and frame combination that they were in before entering the power-down sequence and discard the two dummy data values that were used to clear the XRDY flags. If EDMA is used, re-enable the corresponding EDMA channels.

### 26.2.16 Emulation Considerations

The FREE and SOFT bits are special emulation bits in the serial port control register (SPCR) that determine the state of the McBSP when an emulation suspend event occurs in the emulator. An emulation suspend event corresponds to any type of emulator access to the DSP, such as a hardware or software breakpoint, a probe point, or a printf instruction.

Table 26-21 shows the effects of the FREE and SOFT bits on the response of the McBSP to emulation suspend events.

**Table 26-21. McBSP Emulation Modes Selectable With the FREE and SOFT Bits of SPCR**

| FREE Bit in SPCR | SOFT Bit in SPCR | McBSP Emulation Mode                                                                                                                              |
|------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | 0                | Immediate stop mode (reset condition). The transmitter and receiver stop immediately in response to an emulation suspend event.                   |
| 0                | 1                | Soft stop mode. When an emulation suspend event occurs, the transmitter stops after completion of the current word. The receiver is not affected. |
| 1                | 0 or 1           | Free run mode. The transmitter and receiver continue to run when an emulation suspend event occurs.                                               |

## 26.3 Registers

[Table 26-22](#) lists the memory-mapped registers for the McBSP. See the device-specific data manual for the memory address of these registers. All other register offset addresses not listed in [Table 26-22](#) should be considered as reserved locations and the register contents should not be modified.

The McBSP control registers are accessible by the DSP CPU. You should halt the McBSP before making changes to the serial port control register (SPCR), receive control register (RCR), transmit control register (XCR), and pin control register (PCR). Changes made to these registers without halting the McBSP could result in an undefined state.

**Table 26-22. McBSP Registers**

| Offset | Acronym                 | Register Name                                           | Section                         |
|--------|-------------------------|---------------------------------------------------------|---------------------------------|
| -      | RBR <sup>(1)</sup>      | Receive buffer register                                 | —                               |
| -      | RSR <sup>(1)</sup>      | Receive shift register                                  | —                               |
| -      | XSR <sup>(1)</sup>      | Transmit shift register                                 | —                               |

| 18h    | RFIFOCTL <sup>(4)</sup> | Read FIFO Control Register                              | <a href="#">Section 26.3.14</a> |
| 1Ch    | RFIFOSTS <sup>(4)</sup> | Read FIFO Status Register                               | <a href="#">Section 26.3.15</a> |

<sup>(1)</sup> The RBR, RSR, and XSR are not directly accessible via the CPUs or the EDMA controller.

<sup>(2)</sup> The CPUs and EDMA controller can only read this register; they cannot write to it.

<sup>(3)</sup> The DRR and DXR are accessible via the CPUs or the EDMA controller.

<sup>(4)</sup> The McBSP Buffer FIFO (BFIFO) has a different memory-map (see your device-specific data manual) than the McBSP memory-mapped registers (MMRs); hence, the BFIFO is accessible by way of a different Configuration Bus.

### 26.3.1 Data Receive Register (DRR)

The data receive register (DRR) contains the value to be written to the data bus. The DRR is shown in [Figure 26-42](#) and described in [Table 26-23](#).

See the device-specific data manual for the memory address of these registers. Both the CPUs and the EDMA can access DRR in all the memory-mapped locations. An access to *any* EDMA bus location is equivalent to an access to DRR of the corresponding McBSP.

**Figure 26-42. Data Receive Register (DRR)**

LEGEND: R = Read only; -n = value after reset

**Table 26-23. Data Receive Register (DRR) Field Descriptions**

| Bit  | Field | Value        | Description                                                |
|------|-------|--------------|------------------------------------------------------------|
| 31-0 | DR    | 0-FFFF FFFFh | Data receive register value to be written to the data bus. |

### 26.3.2 Data Transmit Register (DXR)

The data transmit register (DXR) contains the value to be loaded into the data transmit shift register (XSR). The DXR is shown in [Figure 26-43](#) and described in [Table 26-24](#).

See the device-specific data manual for the memory address of these registers. DXR is accessible via the peripheral bus and via the EDMA bus. Both the CPUs and the EDMA can access DXR in all the memory-mapped locations.

**Figure 26-43. Data Transmit Register (DXR)**

LEGEND: R/W = Read/ Write; -n = value after reset

**Table 26-24. Data Transmit Register (DXR) Field Descriptions**

| Bit  | Field | Value        | Description                                                                            |
|------|-------|--------------|----------------------------------------------------------------------------------------|
| 31-0 | DX    | 0-FFFF FFFFh | Data transmit register value to be loaded into the data transmit shift register (XSR). |

### 26.3.3 Serial Port Control Register (SPCR)

The serial port is configured via the serial port control register (SPCR) and the pin control register (PCR). The SPCR contains McBSP status control bits. The SPCR is shown in [Figure 26-44](#) and described in [Table 26-25](#).

**Figure 26-44. Serial Port Control Register (SPCR)**

### 26.3.5 Transmit Control Register (XCR)

The transmit control register (XCR) configures parameters of the transmit operations. The XCR is shown in [Figure 26-46](#) and described in [Table 26-27](#).

**Figure 26-46. Transmit Control Register (XCR)**

### 26.3.6 Sample Rate Generator Register (SRGR)

The sample rate generator register (SRGR) controls the operation of various features of the sample rate generator. The SRGR is shown in [Figure 26-47](#) and described in [Table 26-28](#).

**Figure 26-47. Sample Rate Generator Register (SRGR)**

|       |       |       |       |    |       |        |

| Bit | Field  | Value | Description                                                                                                                                        |
|-----|--------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-0 | CLKGDV | 0-FFh | Sample-rate generator clock (CLKG) divider value is used as the divide-down number to generate the required sample-rate generator clock frequency. |

### 26.3.7 Multichannel Control Register (MCR)

The multichannel control register (MCR) has control and status bits for multichannel selection operation in the receiver (with an R prefix) and the same type of bits for the transmitter (with an X prefix). The MCR is shown in [Figure 26-48](#) and described in [Table 26-29](#). This I/O-mapped register enables you to:

- Enable all channels or only selected channels for reception (RMCM).
- Choose which channels are enabled/disabled and masked/unmasked for transmission (XMCM).
- Specify whether two partitions (32 channels at a time) or eight partitions (128 channels at a time) can be used (RMCME for reception, XMCME for transmission).
- Assign blocks of 16 channels to partitions A and B when the 2-partition mode is selected (RPABLK and RPBBLK for reception, XPABLK and XPBBLK for transmission).
- Determine which block of 16 channels is currently involved in a data transfer (RCBLK for reception, XCBLK for transmission).

| 25    | XMCME    | 0     | Transmit multichannel partition mode bit. XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). XMCME determines whether only 32 channels or all 128 channels are to be individually selectable.<br><br>2-partition mode. Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit.<br><br><b>If XMCM = 1 or 2h:</b> assign 16 channels to partition A with the XPABLK bit and assign 16 channels to partition B with the XPBBLK bit.<br><br><b>If XMCM = 3h:</b> (for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bit and assign 16 channels to receive partition B with the RPBBLK bit. |
|       |          | 1     | 8-partition mode. All partitions (A through H) are used. You can control up to 128 channels in the transmit multichannel selection mode selected with the XMCM bit.<br><br>You control the channels with the appropriate enhanced transmit channel enable register (XCEREn):<br>XCERE0: Channels 0 through 31<br>XCERE1: Channels 32 through 63<br>XCERE2: Channels 64 through 95<br>XCERE3: Channels 96 through 127                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 26-29. Multichannel Control Register (MCR) Field Descriptions (continued)**

| Bit   | Field  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|--------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24-23 | XPBBLK | 0-3h  | Transmit partition B block bit.<br><br>XPBBLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter.<br><br>The 128 transmit channels of the McBSP are divided equally among 8 blocks (0 through 7). When XPBBLK is applicable, use the XPBBLK bit to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B; use the XPABLK bit to assign one of the even-numbered blocks (0, 2, 4, or 6) to partition A.<br><br>If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the transmitter is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The XCBLK bit is regularly updated to indicate which block is active.<br><br>When XMCM = 3h (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK). |
|       |        | 0     | Block 1: channels 16 through 31                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|       |        | 1h    | Block 3: channels 48 through 63                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 22-21 | XPABLK | 0-3h  | Transmit partition A block bit.<br><br>XPABLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter. See the XPBBLK bit description for more information about assigning blocks to partitions A and B.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 9     | RMCME    | 0<br><br><br><br><br><br><br><br><br><br>1 | Receive multichannel partition mode bit. RMCME is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). RMCME determines whether only 32 channels or all 128 channels are to be individually selectable.<br><br>0 2-partition mode. Only partitions A and B are used. You can control up to 32 channels in the receive multichannel selection mode (RMCM = 1).<br>Assign 16 channels to partition A with the RPABLK bit and assign 16 channels to partition B with the RPBBLK bit.<br>You control the channels with the enhanced receive channel enable register partition A/B (RCERE0).<br><br>1 You can control up to 128 channels in the receive multichannel selection mode.<br>You control the channels with the appropriate enhanced receive channel enable register (RCEREn):<br>RCERE0: Channels 0 through 31<br>RCERE1: Channels 32 through 63<br>RCERE2: Channels 64 through 95<br>RCERE3: Channels 96 through 127                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 8-7   | RPBBLK   | 0-3h                                       | Receive partition B block bit.<br><br>RPBBLK is only applicable if channels can be individually disabled/enabled (RMCM = 1) and the 2-partition mode is selected (RMCME = 0). Under these conditions, the McBSP receiver can accept or ignore data in any of the 32 channels that are assigned to partitions A and B of the receiver.<br><br>The 128 receive channels of the McBSP are divided equally among 8 blocks (0 through 7). When RPBBLK is applicable, use the RPBBLK bit to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B; use the RPABLK bit to assign one of the even-numbered blocks (0, 2, 4, or 6) to partition A.<br><br>If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the receiver is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The RCBLK bit is regularly updated to indicate which block is active.<br><br>When XMCM = 3h (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK).<br><br>0 Block 1: channels 16 through 31<br>1h Block 3: channels 48 through 63<br>2h Block 5: channels 80 through 95<br>3h Block 7: channels 112 through 127 |

**Table 26-29. Multichannel Control Register (MCR) Field Descriptions (continued)**

| Bit | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6-5 | RPABLK   | 0-3h  | Receive partition A block bit.<br><br>RPABLK is only applicable if channels can be individually disabled/enabled (RMCM = 1) and the 2-partition mode is selected (RMCME = 0). Under these conditions, the McBSP receiver can accept or ignore data in any of the 32 channels that are assigned to partitions A and B of the receiver. See the RPBBLK bit description for more information about assigning blocks to partitions A and B. |
|     |          | 0     | Block 0: channels 0 through 15                                                                                                                                                                                                                                                                                                                                                                                                          |

|     |          | 0     | All 128 channels are enabled.                                                                                                                                                                                                                                                                                                                                                                                                           |
|     |          | 1     | Multichannel selection mode. Channels can be individually enabled or disabled.<br><br>The only channels enabled are those selected in the appropriate enhanced receive channel enable register (RCEREn). The way channels are assigned to RCEREn depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit.                                                                                             |

### 26.3.8 Enhanced Receive Channel Enable Registers (RCERE0-RCERE3)

The enhanced receive channel enable register (RCEREn) is shown in [Figure 26-49](#) and described in [Table 26-30](#). The RCEREn is used to enable any of 128 elements for receive. RCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCR). RCERE0-RCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCR).

The receive multichannel partition mode (RMCME) bit in the multichannel control register (MCR) is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). The RMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When RMCME = 0:** Only partitions A and B are used. RCERE0 is used to enable any of the 32 elements for a receive. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B. The 16 channels in partition A are assigned with the RPABLK bit in MCR and the 16 channels in partition B are assigned with the RPBBLK bit in MCR.
- **When RMCME = 1:** All partitions are used. RCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a receive. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B.

[Section 26.3.8.1](#) shows the 128 channels in a multichannel data stream and their corresponding enable bits in RCEREn.

### 26.3.8.1 RCEREn Used in the Receive Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the enhanced receive channel enable register (RCEREn) depends on whether 32 or 128 channels are individually selectable, as defined by the RMCME bit in the multichannel control register (MCR). For each of these two cases, [Table 26-31](#) shows which block of channels is assigned to each RCEREn used. For each RCEREn, [Table 26-31](#) shows which channel is assigned to each of the bits.

**Table 26-31. Use of the Receive Channel Enable Registers**

| Number of selectable channels | Block Assignments |                                                                                                                       | Channel Assignments |                                 |
|-------------------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------|---------------------|---------------------------------|
|                               | RCEREn            | Block assigned <sup>(1)</sup>                                                                                         | Bit in RCEREn       | Channel assigned <sup>(1)</sup> |
| 32<br>(RMCME = 0)             | RCERE0            | Channels <i>n</i> to ( <i>n</i> + 15)<br>The block of channels (0, 2, 4, or 6) is selected with the RPABLK bit in MCR | RCE0                | Channel <i>n</i>                |

<sup>(1)</sup> *n* is any even-numbered block 0, 2, 4, or 6. *m* is any odd-numbered block 1, 3, 5, or 7.

### 26.3.9 Enhanced Transmit Channel Enable Registers (XCERE0-XCERE3)

The enhanced transmit channel enable register (XCEREn) is shown in [Figure 26-50](#) and described in [Table 26-32](#). The XCEREn is used to enable any of 128 elements for transmit. XCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCR). XCERE0-XCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCR).

The transmit multichannel partition mode (XMCME) bit in the multichannel control register (MCR) is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). The XMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When XMCME = 0:** Only partitions A and B are used. XCERE0 is used to enable any of the 32 elements for a transmit. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit in MCR.
- **When XMCME = 1:** All partitions are used. XCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a transmit. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B.

[Section 26.3.9.1](#) shows the 128 channels in a multichannel data stream and their corresponding enable bits in XCEREn.

**Table 26-32. Enhanced Transmit Channel Enable Register *n* (XCEREn) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                          |
|------|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | XCERn |       | Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCR:                                                  |
|      |       |       | <b>When XMCM = 1h (all channels disabled unless selected):</b>                                                                                                                       |
|      |       | 0     | Disable and mask the channel that is mapped to XCERn.                                                                                                                                |
|      |       | 1     | Enable and unmask the channel that is mapped to XCERn.                                                                                                                               |
|      |       |       | <b>When XMCM = 2h (all channels enabled but masked unless selected):</b>                                                                                                             |
|      |       | 0     | Mask the channel that is mapped to XCERn.                                                                                                                                            |
|      |       | 1     | Unmask the channel that is mapped to XCERn.                                                                                                                                          |
|      |       |       | <b>When XMCM = 3h (all channels masked unless selected):</b>                                                                                                                         |
|      |       | 0     | Mask the channel that is mapped to XCERn. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. |
|      |       | 1     | Unmask the channel that is mapped to XCERn. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.              |

### 26.3.9.1 XCEREn Used in the Transmit Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the enhanced transmit channel enable register (XCEREn) depends on whether 32 or 128 channels are individually selectable, as defined by the XMCME bit in the multichannel control register (MCR). For each of these two cases, [Table 26-33](#) shows which block of channels is assigned to each XCEREn used. For each XCEREn, [Table 26-33](#) shows which channel is assigned to each of the bits.

When XMCM = 3h (symmetric transmission and reception), the transmitter uses the enhanced receive channel enable register (RCEREn) to enable channels and uses XCEREn to unmask channels for transmission.

**Table 26-33. Use of the Transmit Channel Enable Registers**

| Number of<br>selectable channels | Block Assignments |                                                                                                                                                                                                      | Channel Assignments |                                 |                    |           |

### 26.3.10 Pin Control Register (PCR)

The serial port is configured via the serial port control register (SPCR) and the pin control register (PCR). The PCR contains McBSP status control bits. The PCR is shown in [Figure 26-51](#) and described in [Table 26-34](#).

**Figure 26-51. Pin Control Register (PCR)**

### 26.3.11 BFIFO Revision Identification Register (BFIFOREV)

The Buffer FIFO (BFIFO) revision identification register (BFIFOREV) contains revision data for the Buffer FIFO (BFIFO). The BFIFOREV is shown in [Figure 26-52](#) and described in [Table 26-35](#).

**Figure 26-52. BFIFO Revision Identification Register (BFIFOREV)**

LEGEND: R = Read only; -n = value after reset

**Table 26-35. BFIFO Revision Identification Register (BFIFOREV) Field Descriptions**

| Bit  | Field | Value      | Description                         |
|------|-------|------------|-------------------------------------|
| 31-0 | REV   | 4431 1100h | Identifies revision of Buffer FIFO. |

### 26.3.12 Write FIFO Control Register (WFIFOCTL)

The Write FIFO control register (WFIFOCTL) is shown in [Figure 26-53](#) and described in [Table 26-36](#).

**NOTE:** The WNUM EVT and WNUM DMA values must be set prior to enabling the Write FIFO. If the Write FIFO is to be enabled, it must be enabled prior to taking the McBSP out of reset.

**Figure 26-53. Write FIFO Control Register (WFIFOCTL)**

## 27.1 Introduction

### 27.1.1 Purpose of the Peripheral

A number of applications use the multimedia card (MMC)/secure digital (SD) card to provide removable data storage. The MMC/SD card controller provides an interface to external MMC and SD cards. The communication between the MMC/SD card controller and MMC/SD card(s) is performed according to the MMC/SD protocol.

### 27.1.2 Features

The MMC/SD card controller has the following features:

- Supports interface to multimedia cards (MMC)
- Supports interface to secure digital (SD) memory cards
- Ability to use the MMC/SD protocol and Secure Digital Input Output (SDIO) protocol
- Programmable frequency of the clock that controls the timing of transfers between the MMC/SD controller and memory card
- 512-bit read/write FIFO to lower system overhead
- Signaling to support enhanced direct memory access (EDMA) transfers (slave)
- Maximum clock to MMC varies based on core voltage (see your device-specific data manual)
- Maximum clock to SD varies based on core voltage (see your device-specific data manual)

### 27.1.3 Functional Block Diagram

The MMC/SD card controller transfers data between the CPU and the EDMA controller on one side and the MMC/SD card on the other side, as shown in [Figure 27-1](#). This means you have a choice of performing data transfers using the CPU or EDMA as a mechanism to move data between the device memory and the FIFO. The CPU and the EDMA controller can read from or write to the data in the card by accessing the registers in the MMC/SD controller.

### 27.1.4 Supported Use Case Statement

The MMC/SD card controller supports the following user cases:

- MMC/SD card identification
- MMC/SD single-block read using CPU

### 27.1.5 Industry Standard(s) Compliance Statement

The MMC/SD card controller supports the following industry standards (with the exception noted below):

- MMC (Multimedia Card) Specification v4.0
- SD (Secure Digital) Physical Layer Specification v1.1
- SDIO (Secure Digital Input Output) Specification v2.0

The information in this chapter assumes that you are familiar with these standards.

The MMC/SD controller does not support the SPI mode of operation.

## 27.2 Architecture

The MMC/SD controller uses the MMC/SD protocol to communicate with the MMC/SD cards. You can configure the MMC/SD controller to work as an MMC or SD controller, based on the type of card the controller is communicating with. [Figure 27-2](#) summarizes the MMC/SD mode interface. [Figure 27-3](#) illustrates how the controller interfaces to the cards in MMC/SD mode.

In the MMC/SD mode, the MMC controller supports one or more MMC/SD cards. Regardless of the number of cards connected, the MMC/SD controller selects one by using identification broadcast on the data line. The following MMC/SD controller pins are used:

- **MMCSD\_CMD**: This pin is used for two-way communication between the connected card and the MMC/SD controller. The MMC/SD controller transmits commands to the card and the memory card drives responses to the commands on this pin.
- **MMCSD\_DAT0**, **MMCSD\_DAT0-3**, or **MMCSD\_DAT0-7**: MMC cards only use one data line (DAT0), four data lines (DAT0-3), or eight data lines (DAT0-7), and SD cards use one data line (DAT0) or four data lines (DAT0-3). The number of MMCSD\_DAT pins (the data bus width) is set by the WIDTH bit in the MMC control register (MMCCTL, see [Section 27.4.1](#)).
- **MMCSD\_CLK**: This pin provides the clock to the memory card from the MMC/SD controller.

**Figure 27-2. MMC/SD Controller Interface Diagram**

**Figure 27-3. MMC Configuration and SD Configuration Diagram**

### 27.2.1 Clock Control

There are two clocks, the function clock and the memory clock, in the MMC/SD controller ([Figure 27-4](#)).

The function clock determines the operational frequency of the MMC/SD controller and is the input clock to the MMC/SD card(s).

The memory clock appears on the MMCSD\_CLK pin of the MMC/SD controller interface. The memory clock controls the timing of communication between the MMC/SD controller and the connected memory card. The memory clock is generated by dividing the function clock in the MMC/SD controller. The divide-down value is set by CLKRT bits in the MMC memory clock control register (MMCCLK) and is determined by the following equation:

$$\text{memory clock frequency} = \text{function clock frequency} / (2 \times (\text{CLKRT} + 1))$$

**Figure 27-4. MMC/SD Controller Clocking Diagram**

## 27.2.2 Signal Descriptions

Table 27-1 shows the MMC/SD controller pins that each mode uses. The MMC/SD protocol uses the clock, command (two-way communication between the MMC controller and memory card), and data (MMCSD\_DAT0, MMCSD\_DAT0-3, or MMCSD\_DAT0-7 for MMC card; MMCSD\_DAT0 or MMCSD\_DAT0-3 for SD card) pins.

**Table 27-1. MMC/SD Controller Pins Used in Each Mode**

| Pin        | Type <sup>(1)</sup> | Function                               |                                        |                                |
|------------|---------------------|----------------------------------------|----------------------------------------|--------------------------------|
|            |                     | MMC and SD (1-bit mode) Communications | MMC and SD (4-bit mode) Communications | MMC (8-bit mode) Communication |
| MMCSD_CLK  | O                   | Clock line                             | Clock line                             | Clock line                     |
| MMCSD_CMD  | I/O                 | Command line                           | Command line                           | Command line                   |
| MMCSD_DAT0 | I/O                 | Data line 0                            | Data line 0                            | Data line 0                    |
| MMCSD_DAT1 | I/O                 | (Not used)                             | Data line 1                            | Data line 1                    |
| MMCSD_DAT2 | I/O                 | (Not used)                             | Data line 2                            | Data line 2                    |
| MMCSD_DAT3 | I/O                 | (Not used)                             | Data line 3                            | Data line 3                    |
| MMCSD_DAT4 | I/O                 |                                        | (Not used)                             | Data line 4                    |
| MMCSD_DAT5 | I/O                 |                                        | (Not used)                             | Data line 5                    |
| MMCSD_DAT6 | I/O                 |                                        | (Not used)                             | Data line 6                    |
| MMCSD_DAT7 | I/O                 |                                        | (Not used)                             | Data line 7                    |

<sup>(1)</sup> I = input to the MMC controller; O = output from the MMC controller.

## 27.2.3 Protocol Descriptions

The MMC/SD controller follows the MMC/SD protocol for completing any kind of transaction with the multimedia card and secure digital cards. For more detailed information, refer to the supported MMC and SD specifications in [Section 27.1.5](#).

### 27.2.3.1 MMC/SD Mode Write Sequence

[Figure 27-5](#) and [Table 27-2](#) show the signal activity when the MMC/SD controller is in the MMC/SD mode and is writing data to a memory card. The same block length must be defined in the MMC/SD controller and in the memory card before initiating a data write. In a successful write protocol sequence, the following steps occur:

- The MMC/SD controller requests the CSD content.
- The card receives the command and sends the content of the CSD register as its response.
- If the desired block length, WRITE\_BL\_LEN value, is different from the default value determined from the response, the MMC/SD controller sends the block length command.
- The card receives the command and sends responses to the command.
- The MMC/SD controller requests the card to change states from standby to transfer.
- The card receives the command and sends responses to the command.
- The MMC/SD controller sends a write command to the card.
- The card receives the command and sends responses to the command.
- The MMC/SD controller sends a block of data to the card.
- The card sends the CRC status to the MMC/SD controller.
- The card sends a low BUSY bit until all of the data has been programmed into the flash memory inside the card.

**Figure 27-5. MMC/SD Mode Write Sequence Timing Diagram**

**Table 27-2. MMC/SD Mode Write Sequence**

| Portion of the Sequence | Description                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WR CMD                  | Write command: A 6-byte WRITE_BLOCK command token is sent from the CPU to the card.                                                                                                                                                                             |
| CMD RSP                 | Command response: The card sends a 6-byte response of type R1 to acknowledge the WRITE_BLOCK to the CPU.                                                                                                                                                        |
| DAT BLK                 | Data block: The CPU writes a block of data to the card. The data content is preceded by one start bit and is followed by two CRC bytes and one end bit.                                                                                                         |
| CRC STAT                | CRC status: The card sends a one byte CRC status information, which indicates to the CPU whether the data has been accepted by the card or rejected due to a CRC error. The CRC status information is preceded by one start bit and is followed by one end bit. |
| BSY                     | BUSY bit: The CRC status information is followed by a continuous stream of low busy bits until all of the data has been programmed into the flash memory on the card.                                                                                           |

### 27.2.3.2 MMC/SD Mode Read Sequence

Figure 27-6 and Table 27-3 show the signal activity when the MMC controller is in the MMC/SD mode and is reading data from a memory card. The same block length must be defined in the MMC controller and in the memory card before initiating a data read. In a successful read protocol sequence, the following steps occur:

- The MMC/SD controller requests for the CSD content.
- The card receives the command and sends the content of the CSD register as its response.
- If the desired block length, READ\_BL\_LEN value, is different from the default value determined from the response, the MMC/SD controller sends the block length command.
- The card receives the command and sends responses to the command.
- The MMC/SD controller requests the card to change state from stand-by to transfer.
- The card receives the command and sends responses to the command.
- The MMC/SD controller sends a read command to the card.
- The card drives responses to the command.
- The card sends a block of data to the CPU.

**Table 27-3. MMC/SD Mode Read Sequence**

| Portion of the Sequence | Description                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| RD CMD                  | Read command: A 6-byte READ_SINGLE_BLOCK command token is sent from the CPU to the card.                                                           |
| CMD RSP                 | Command response: The card sends a response of type R1 to acknowledge the READ_SINGLE_BLOCK command to the CPU.                                    |
| DAT BLK                 | Data block: The card sends a block of data to the CPU. The data content is preceded by a start bit and is followed by two CRC byte and an end bit. |

### 27.2.4 Data Flow in the Input/Output FIFO

The MMC/SD controller contains a single 512-bit FIFO, organized as 8-bit × 64 entries, that is used for both reading data from the memory card and writing data to the memory card (see Figure 27-7). The conversion from the 32-bit bus to the byte format of the FIFO follows the little-endian convention (details are provided in later sections). The read and write FIFOs act as an interim location to store data transferred from/to the card momentarily via the CPU or EDMA. The FIFO includes logic to generate EDMA events and interrupts based on the amount of data in the FIFO and a programmable number of bytes received/transmitted. Flags are set when the FIFO is full or empty.

A high-level operational description is as follows:

- Data is written to the FIFO through the MMC data transmit register (MMCDXR). Data is read from the FIFO through the MMC data receive register (MMCDRR). This is true for both the CPU and EDMA driven transactions; however, for the EDMA transaction, the EDMA access to the FIFO is transparent.
- The ACCWD bits in the MMC FIFO control register (MMCFIFOCTL) determines the behavior of the FIFO full (FIFOFUL) and FIFO empty (FIFOEMP) status flags in the MMC status register 1 (MMCST1):
  - If ACCWD = 00b:
    - FIFO full is active when the write pointer + 4 > read pointer
    - FIFO empty is active when the write pointer - 4 < read pointer
  - If ACCWD = 01b:
    - FIFO full is active when the write pointer + 3 > read pointer
    - FIFO empty is active when the write pointer - 3 < read pointer
  - If ACCWD = 10b:
    - FIFO full is active when the write pointer + 2 > read pointer
    - FIFO empty is active when the write pointer - 2 < read pointer
  - If ACCWD = 11b:
    - FIFO full is active when the write pointer + 1 > read pointer
    - FIFO empty is active when the write pointer - 1 < read pointer

**Figure 27-7. FIFO Operation Diagram**

## 27.2.5 Data Flow in the Data Registers (MMCDRR and MMCDXR)

The CPU or EDMA controller can read 32 bits at a time from the FIFO by reading the MMC data receive register (MMCDRR) and write 32 bits at a time to the FIFO by writing to the MMC data transmit register (MMCDXR). However, since the memory card is an 8-bit device, it transmits or receives one byte at a time. [Figure 27-8](#) shows how the data size is handled by the data registers in little-endian mode.

**Figure 27-8. Little-Endian Access to MMCDXR/MMCDRR from the CPU or the EDMA**

## 27.2.6 FIFO Operation During Card Read Operation

### 27.2.6.1 EDMA Reads

The FIFO controller manages the activities of reading the data in from the card and issuing EDMA read events. Each time an EDMA read event is issued, an EDMA read request interrupt generates.

[Figure 27-9](#) provides details of the FIFO controllers operation. As data is received from the card, it is read into the FIFO. When the number of bytes of data received is equal to the level set by the FIFOLEV bits in MMCFIFOCTL, an EDMA read event is issued and new EDMA events are disabled until the EDMA is done with the transfer issued by the current event. Data is read from the FIFO by way of MMCDRR. The FIFO controller continues to read in data from the card while checking for the EDMA event to occur or for the FIFO to become full. Once the EDMA event finishes, new EDMA events are enabled. If the FIFO fills up, the FIFO controller stops the MMC/SD controller from reading any more data until the FIFO is no longer full.

An EDMA read event generates when the last data arrives, as determined by the MMC block length register (MMCBLEN) and the MMC number of blocks register (MMCNBLK) settings. This EDMA event flushes all of the data that was read from the card to the FIFO.

Each time an EDMA read event generates, an interrupt (DRRDYINT) generates and the DRRDY bit in the MMC status register 0 (MMCST0) is also set.

### 27.2.6.2 CPU Reads

The system CPU can also directly read the card data by reading the MMC data receive register (MMCDRR). The MMC/SD peripheral supports reads that are 1-, 2-, 3-, or 4-bytes wide as, shown in [Figure 27-8](#).

As data is received from the card, it is read into the FIFO. When the number of bytes of data received is equal to the level set by the FIFOLEV bits in MMCFIFOCTL, a DRRDYINT interrupt is issued and the DRRDY bit in the MMC status register 0 (MMCST0) is set. Upon receiving the interrupt, the CPU quickly reads out the bytes received (equal to the level set by the FIFOLEV bits). A DRRDYINT interrupt also generates when the last data arrives as determined by the MMC block length register (MMCBLEN) and the MMC numbers of blocks register (MMCNBLK) settings.

Figure 27-9. FIFO Operation During Card Read Diagram

## 27.2.7 FIFO Operation During Card Write Operation

### 27.2.7.1 EDMA Writes

The FIFO controller manages the activities of accepting data from the CPU or EDMA and passing the data to the MMC/SD controller. The FIFO controller issues EDMA write events as appropriate. Each time an EDMA write event is issued, an EDMA write request interrupt generates. Data is written into the FIFO through MMCDXR. Note that the EDMA access to MMCDXR is transparent.

Figure 27-10 provides details of the FIFO controller's operation. The CPU or EDMA controller writes data into the FIFO. The FIFO passes the data to the MMC/SD controller which manages writing the data to the card. When the number of bytes of data in the FIFO is less than the level set by the FIFOLEV bits in MMCFIFOCTL, an EDMA write event is issued and new EDMA events are disabled. The FIFO controller continues to transfer data to the MMC/SD controller while checking for the EDMA event to finish or for the FIFO to become empty. Once the EDMA event finishes, new EDMA events are enabled. If the FIFO becomes empty, the FIFO controller informs the MMC/SD controller.

Each time an EDMA write event generates, an interrupt (DXRDYINT) generates and the DXRDY bit in the MMC status register 0 (MMCST0) is also set.

### 27.2.7.2 CPU Writes

The system CPU can also directly write the card data by writing the MMC data transmit register (MMCDXR). The MMC/SD peripheral supports writes that are 1-, 2-, 3-, or 4-bytes wide, as shown in Figure 27-8.

The CPU makes use of the FIFO to transfer data to the card via the MMC/SD controller. The CPU writes the data to be transferred into MMCDXR. As is the case with the EDMA driven transaction, when the number of data in the FIFO is less than the level set by the FIFOLEV bits in MMCFIFOCTL, a DXRDYINT interrupt generates and the DXRDY bit in the MMC status register 0 (MMCST0) is set to signify to the CPU that space is available for new data.

---

**NOTE:** When starting the write transaction, the CPU is responsible for getting the FIFO ready to start transferring data by filling up the FIFO with data prior to invoking/posting the write command to the card. Filling up the FIFO is a requirement since no interrupt/event generates at the start of the write transfer.

---

## 27.2.8 Reset Considerations

The MMC/SD peripheral has two reset sources: hardware reset and software reset.

### 27.2.8.1 Software Reset Considerations

A software reset (such as a reset that the emulator generates) does not cause the MMC/SD controller registers to alter. After a software reset, the MMC/SD controller continues to operate as it was configured prior to the reset.

### 27.2.8.2 Hardware Reset Considerations

A hardware reset of the processor causes the MMC/SD controller registers to return to their default values after reset.

**Figure 27-10. FIFO Operation During Card Write Diagram**

## 27.2.9 Initialization

### 27.2.9.1 MMC/SD Controller Initialization

The general procedure for initializing the MMC/SD controller is given in the following steps. Details about the registers or register bit fields to be configured in the MMC/SD mode are in the subsequent subsections.

1. Place the MMC/SD controller in its reset state by setting the CMDRST bit and DATRST bit in the MMC control register (MMCCTL). You can set other bits in MMCCTL after reset.
2. Write the required values to other registers to complete the MMC/SD controller configuration.
3. Clear the CMDRST bit and the DATRST bit in MMCCTL to release the MMC/SD controller from its reset state. It is recommended not to rewrite the values that are written to the other bits of MMCCTL in .
4. Enable the MMCSD\_CLK pin so that the memory clock is sent to the memory card by setting the CLKEN bit in the MMC memory clock control register (MMCCLK).

---

**NOTE:** The MMC/SD cards require a clock frequency of 400 kHz or less for the card initialization procedure. Make sure that the memory clock confirms this requirement. Once card initialization completes, you can adjust the memory clock up to the lower of the card capabilities or the maximum frequency that is supported.

---

### 27.2.9.2 Initializing the MMC Control Register (MMCCTL)

The bits in the MMC control register (MMCCTL) affect the operation of the MMC/SD controller. The subsections that follow help you decide how to initialize each of control register bits.

In the MMC/SD mode, the MMC/SD controller must know how wide the data bus must be for the memory card that is connected. If an MMC card is connected, specify a 1-bit data bus (WIDTH = 0 in MMCCTL); if an SD card is connected, specify a 4-bit data bus (WIDTH = 1 in MMCCTL).

To place the MMC/SD controller in its reset state and disable it, set the CMDRST bit and DATRST bit in MMCCTL. The first step of the MMC/SD controller initialization process is to disable both sets of logic. When initialization is complete, but before you enable the MMCSD\_CLK pin, clear the CMDRST bit and DATRST bit in MMCCTL to enable the MMC/SD controller.

### 27.2.9.3 Initializing the Clock Controller Registers (MMCCLK)

A clock divider in the MMC/SD controller divides-down the function clock to produce the memory clock. Load the divide-down value into the CLKRT bits in the MMC memory clock control register (MMCCLK). The divide-down value is determined by the following equation:

*memory clock frequency = function clock frequency / (2 × (CLKRT + 1)), when DIV4 = 0 in MMCCLK*

*memory clock frequency = function clock frequency / (4 × (CLKRT + 1)), when DIV4 = 1 in MMCCLK*

The CLKEN bit in MMCCLK determines whether the memory clock appears on the MMCSD\_CLK pin. If you clear the CLKEN to 0, the memory clock is not provided except when required.

### 27.2.9.4 Initialize the Interrupt Mask Register (MMCIM)

The bits in the MMC interrupt mask register (MMCIM) individually enable or disable the interrupt requests. To enable the associated interrupt request, set the corresponding bit in MMCIM. To disable the associated interrupt request, clear the corresponding bit. Load zeros into the bits that are not used in the MMC/SD mode.

### 27.2.9.5 Initialize the Time-Out Registers (MMCTOR and MMCTOD)

Specify the time-out period for responses using the MMC response time-out register (MMCTOR) and the time-out period for reading data using the MMC data read time-out register (MMCTOD).

When the MMC/SD controller sends a command to a memory card, it must often wait for a response. The MMC/SD controller can wait indefinitely or up to 255 memory clock cycles. If you load 0 into MMCTOR, the MMC/SD controller waits indefinitely for a response. If you load a nonzero value into MMCTOR, the MMC/SD controller stops waiting after the specified number of memory clock cycles and then sets a response time-out flag (TOUTRS) in the MMC status register 0 (MMCST0). If you enable the associated interrupt request, the MMC/SD controller also sends an interrupt request to the CPU.

When the MMC/SD controller requests data from a memory card, it can wait indefinitely for that data or it can stop waiting after a programmable number of cycles. If you load 0 into MMCTOD, the MMC/SD controller waits indefinitely. If you load a nonzero value into MMCTOD, the MMC/SD controller waits the specified number of memory clock cycles and then sets a read data time-out flag (TOUTRD) in MMCST0. If you enable the associated interrupt request, the MMC/SD controller also sends an interrupt request to the CPU.

### 27.2.9.6 Initialize the Data Block Registers (MMCBLEN and MMCNBLK)

Specify the number of bytes in a data block in the MMC block length register (MMCBLEN) and the number of blocks in a multiple-block transfer in the MMC number of blocks register (MMCNBLK).

You must define the size for each block of data transferred between the MMC/SD controller and a memory card in MMCBLEN. The valid size depends on the type of read/write operations. A length of 0 bytes is prohibited.

For multiple-block transfers, you must specify how many blocks of data are to be transferred between the MMC/SD controller and a memory card. You can specify an infinite number of blocks by loading 0 into MMCNBLK. When MMCNBLK = 0, the MMC/SD controller continues to transfer data blocks until the transferring is stopped with a STOP\_TRANSMISSION command. To transfer a specific number of blocks, load MMCNBLK with a value from 1 to 65 535.

### 27.2.9.7 Monitoring Activity in the MMC/SD Mode

This section describes registers and specific register bits that you can use to obtain the status of the MMC/SD controller in the MMC/SD mode. You can determine the status of the MMC/SD controller by reading the bits in the MMC status register 0 (MMCST0) and MMC status register 1 (MMCST1).

#### 27.2.9.7.1 Determining Whether New Data is Available in MMCDRR

The MMC/SD controller sets the DRRDY bit in MMCST0 when the data in the FIFO is greater than the threshold set in the MMC FIFO control register (MMCFIFOCTL). If the interrupt request is enabled (EDRRDY = 1 in MMCIM), the processor is notified of the event by an interrupt. A read of the MMC data receive register (MMCDDR) clears the DRRDY flag.

#### 27.2.9.7.2 Verifying that MMCDXR is Ready to Accept New Data

The MMC/SD controller sets the DXRDY bit in MMCST0 when the amount of data in the FIFO is less than the threshold set in the MMC FIFO control register (MMCFIFOCTL). If the interrupt request is enabled (EDXRDY = 1 in MMCIM), the CPU is notified of the event by an interrupt.

#### 27.2.9.7.3 Checking for CRC Errors

The MMC/SD controller sets the CRCRS, CRCRD, and CRCWR bits in MMCST0 in response to the corresponding CRC errors of command response, data read, and data write. If the interrupt request is enabled (ECRCRS/ECRCRD/ECRCWR = 1 in MMCIM), the CPU is notified of the CRC error by an interrupt.

#### 27.2.9.7.4 Checking for Time-Out Events

The MMC/SD controller sets the TOUTRS and TOUTRD bits in MMCST0 in response to the corresponding command response or data read time-out event. If the interrupt request is enabled (ETOUTRS/ETOUTRD = 1 in MMCIM), the CPU is notified of the event by an interrupt.

#### 27.2.9.7.5 Determining When a Response/Command is Done

The MMC/SD controller sets the RSPDNE bit in MMCST0 when the response is done; or in the case of commands that do not require a response, when the command is done. If the interrupt request is enabled (ERSPDNE = 1 in MMCIM), the CPU is also notified.

#### 27.2.9.7.6 Determining Whether the Memory Card is Busy

The card sends a busy signal either when waiting for an R1b-type response or when programming the last write data into its flash memory. The MMC/SD controller has two flags to notify you whether the memory card is sending a busy signal. The two flags are complements of each other:

- The BSYDNE flag in MMCST0 is set if the card did not send or is not sending a busy signal when the MMC/SD controller is expecting a busy signal (BSYEXP = 1 in MMCCMD). The interrupt by this bit is enabled by a corresponding interrupt enable bit (EBSYDNE = 1 in MMCIM).
- The BUSY flag in MMCST1 is set when a busy signal is received from the card.

#### 27.2.9.7.7 Determining Whether a Data Transfer is Done

The MMC/SD controller sets the DATDNE bit in MMCST0 when all of the bytes of a data transfer have been transmitted/received. The DATDNE bit is polled to determine when to stop writing to the data transmit register (for a write operation) or when to stop reading from the data receive register (for a read operation). The CPU is also notified of the time-out event by an interrupt if the interrupt request is enabled (EDATDNE = 1 in MMCIM).

#### 27.2.9.7.8 Determining When Last Data has Been Written to Card (SanDisk SD cards)

Some SanDisk brand SD™ cards exhibit a behavior that requires a multiple-block write command to terminate with a STOP (CMD12) command before the data write sequence completes. To enable support of this function, the transfer done interrupt (TRNDNE) is provided. Set the ETRNDNE bit in MMCIM to enable the TRNDNE interrupt. This interrupt is issued when the last byte of data (as defined by MMCNBLK and MMCBLEN) is transferred from the FIFO to the output shift register. The CPU should respond to this interrupt by sending a STOP command to the card. This interrupt differs from DATDNE by timing. DATDNE does not occur until after the CRC and memory programming are complete.

#### 27.2.9.7.9 Checking For a Data Transmit Empty Condition

During transmission, a data value is passed from the MMC data transmit register (MMCDXR) to the data transmit shift register. The data is then passed from the shift register to the memory card one bit at a time. The DXEMP bit in MMCST1 indicates when the shift register is empty.

Typically, the DXEMP bit is not used to control data transfers; rather, it is checked during recovery from an error condition. There is no interrupt associated with the DXEMP bit.

#### 27.2.9.7.10 Checking for a Data Receive Full Condition

During reception, the data receive shift register accepts a data value one bit at a time. The entire value is then passed from the shift register to the MMC data receive register (MMCDRR). The DRFUL bit in MMCST1 indicates that when the shift register is full no new bits can be shifted in from the memory card.

The DRFUL bit is not typically used to control data transfers; rather, it is checked during recovery from an error condition. There is no interrupt associated with the DRFUL bit.

### 27.2.9.7.11 Checking the Status of the MMCSD\_CLK Pin

Read the CLKSTP bit in MMCST1 to determine whether the memory clock has been stopped on the MMCSD\_CLK pin.

### 27.2.9.7.12 Checking the Remaining Block Count During a Multiple-Block Transfer

During a transfer of multiple data blocks, the MMC number of blocks counter register (MMCNBLC) indicates how many blocks are remaining to be transferred. The MMCNBLC is a read-only register.

## 27.2.10 Interrupt Support

### 27.2.10.1 Interrupt Events and Requests

The MMC/SD controller generates the interrupt requests described in [Table 27-4](#). When an interrupt event occurs, its flag bit is set in the MMC status register 0 (MMCST0). If the enable bits corresponding to each flag are set in the MMC interrupt mask register (MMCIM), an interrupt request generates. All such requests are multiplexed to a single MMC/SD interrupt request from the MMC/SD peripheral to the CPU.

The MMC/SD interrupts are part of the maskable CPU interrupts. One CPU interrupt is associated with MMC functions and one CPU interrupt is associated with SD functions (see your device-specific data manual for details). The interrupt service routine (ISR) for the MMC/SD interrupt can determine the event that caused the interrupt by checking the bits in MMCST0. When MMCST0 is read, all register bits automatically clear. During a middle of data transfer, the DXRDY and DRRDY bits are set during every 256-bit or 512-bit transfer, depending on the MMC FIFO control register (MMCFIFOCTL) setting. Performing a write and a read in response to the interrupt generated by the FIFO automatically clears the corresponding interrupt bit/flag.

---

**NOTE:** You must be aware that an emulation read of the status register clears the interrupt status flags. To avoid inadvertently clearing the flag, be careful while monitoring MMCST0 via the debugger.

---

**Table 27-4. Description of MMC/SD Interrupt Requests**

| Interrupt Request | Interrupt Event                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRNDNEINT         | <b>For read operations:</b> The MMC/SD controller has received the last byte of data (before CRC check).<br><b>For write operations:</b> The MMC/SD controller has transferred the last word of data to the output shift register. |
| DATEDINT          | An edge was detected on the MMCSD_DAT3 pin.                                                                                                                                                                                        |
| DRRDYINT          | MMCDRR is ready to be read (data in FIFO is above threshold).                                                                                                                                                                      |
| DXRDYINT          | MMCDXR is ready to transmit new data (data in FIFO is less than threshold).                                                                                                                                                        |
| CRCRSINT          | A CRC error was detected in a response from the memory card.                                                                                                                                                                       |
| CRCRDINT          | A CRC error was detected in the data read from the memory card.                                                                                                                                                                    |
| CRCWRINT          | A CRC error was detected in the data written to the memory card.                                                                                                                                                                   |
| TOUTRSINT         | A time-out occurred while the MMC controller was waiting for a response to a command.                                                                                                                                              |
| TOUTRDINT         | A time-out occurred while the MMC controller was waiting for the data from the memory card.                                                                                                                                        |
| RSPDNEINT         | <b>For a command that requires a response:</b> The MMC controller has received the response without a CRC error.<br><b>For a command that does not require a response:</b> The MMC controller has finished sending the command.    |
| BSYDNEINT         | The memory card stops or is no longer sending a busy signal when the MMC controller is expecting a busy signal.                                                                                                                    |
| DATDNEINT         | <b>For read operations:</b> The MMC controller has received data without a CRC error.<br><b>For write operations:</b> The MMC controller has finished sending data.                                                                |

### 27.2.10.2 Interrupt Multiplexing

The interrupts from the MMC/SD peripheral to the CPU are not multiplexed with any other interrupt source.

### 27.2.11 DMA Event Support

The MMC/SD controller is capable of generating EDMA events for both read and write operations in order to request service from an EDMA controller. Based on the FIFO threshold setting, the EDMA event signals generate every time 256-bit or 512-bit data is transferred from the FIFO.

### 27.2.12 Power Management

You can put the MMC/SD peripheral in reduced-power modes to conserve power during periods of low activity. The processor power and sleep controller (PSC) controls the power management of the MMC/SD peripheral. The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 27.2.13 Emulation Considerations

The MMC/SD peripheral is not affected by emulation halt events (such as breakpoints).

## 27.3 Procedures for Common Operations

### 27.3.1 Card Identification Operation

Before the MMC/SD controller starts data transfers to or from memory cards in the MMC/SD native mode, it must first identify how many cards are present on the bus and configure them. For each card that responds to the ALL\_SEND\_CID broadcast command, the controller reads that card's unique card identification address (CID) and then assigns it a relative address (RCA). This address is much shorter than the CID and the MMC/SD controller uses this address to identify the card in all future commands that involve the card.

Only one card completes the response to ALL\_SEND\_CID at any one time. The absence of any response to ALL\_SEND\_CID indicates that all cards have been identified and configured.

---

**NOTE:** The following steps assume that the MMC/SD controller is configured to operate in MMC or SD mode, and the memory clock frequency on the MMCSD\_CLK pin is set for 400 kHz or less.

---

The procedure for a card identification operation is issued in open-drain bus mode for both MMC and SD cards.

#### 27.3.1.1 MMC Card Identification Procedure

The MMC card identification procedure is:

1. Use the MMC command register (MMCCMD) to issue the GO\_IDLE\_STATE (CMD0) command to the MMC cards. Using MMCCMD to issue the CMD0 command puts all cards (MMC and SD) in the idle state and no response from the cards is expected.
2. Use MMCCMD to issue the SEND\_OP\_CMD (CMD1) command with the voltage range supported (R3 response, if it is successful; R1b response, if the card is expected to be busy). Using MMCCMD to issue the CMD1 command allows the host to identify and reject cards that do not match the VDD range that the host supports.
3. If the response in [Step 2](#) is R1b (that is, the card is still busy due to power up), then return to [Step 2](#). If the card is not busy, go to [Step 4](#).
4. Use MMCCMD to send the ALL\_SEND\_CID (CMD2) command (R2 response is expected) to the MMC cards. Using MMCCMD to send the CMD2 command notifies all cards to send their unique card identification (CID) number. There should only be one card that successfully sends its full CID number to the host. The successful card goes into the identification state and does not respond to this command again.
5. Use MMCCMD to issue the SET\_RELATIVE\_ADDR (CMD3) command (R1 response is expected) in order to assign an address that is shorter than the CID number that will be used in the future to address the card in the future data transfer mode.

---

**NOTE:** This command is only addressed to the card that successfully sent its CID number in step 4. This card now goes into standby mode. This card also changes its output drivers from open-drain to push-pull. It stops replying to the CMD2 command, allowing for the identification of other cards.

---

6. Repeat [Step 4](#) and [Step 5](#) to identify and assign relative addresses to all remaining cards until no card responds to the CMD1 command. No card responding within 5 memory clock cycles indicates that all cards have been identified and the MMC card identification procedure terminates.

The sequence of events in this operation is shown in [Figure 27-11](#).

**Figure 27-11. MMC Card Identification Procedure**

### 27.3.1.2 SD Card Identification Procedure

The SD card identification procedure is:

1. Use the MMC command register (MMCCMD) to issue the GO\_IDLE\_STATE (CMD0) command to the MMC cards. Using MMCCMD to issue the CMD0 command puts all cards (MMC and SD) in the idle state and no response from the cards is expected.
2. Use MMCCMD to issue the APP\_CMD (CMD55) command (R1 response is expected) to indicate that the command that follows is an application command.
3. Use MMCCMD to send the SD\_SEND\_OP\_COND (ACMD41) command with the voltage range supported (R3 response is expected) to SD cards. Using MMCCMD to send the ACMD41 command allows the host to identify and reject cards that do not match the VDD range that the host supports.
4. Use MMCCMD to send the ALL\_SEND\_CID (CMD2) command (R2 response is expected) to the MMC cards. Using MMCCMD to send the CMD2 command notifies all cards to send their unique card identification (CID) number. There should only be one card that successfully sends its full CID number to the host. The successful card goes into identification state and does not respond to this command again.
5. Use MMCCMD to issue the SEND\_RELATIVE\_ADDR (CMD3) command (R1 response is expected) in order to ask the card to publish a new relative address for future use to address the card in data transfer mode.

**NOTE:** This command is only addressed to the card that successfully sent its CID number in step 4. This card now goes into standby mode. This card also changes its output drivers from open-drain to push-pull. It stops replying to the CMD2 command, allowing for the identification of other cards.

6. Repeat [Step 4](#) and [Step 5](#) to identify and retrieve relative addresses from all remaining SD cards until no card responds to the CMD2 command. No card responding within 5 memory clock cycles indicates that all cards have been identified and the MMC card and the identification procedure terminates.

The sequence of events in this operation is shown in [Figure 27-12](#).

**Figure 27-12. SD Card Identification Procedure**

### 27.3.2 MMC/SD Mode Single-Block Write Operation Using CPU

To perform a single-block write, the block length must be 512 bytes and the same length needs to be set in both the MMC/SD controller and the memory card. The procedure for this operation is:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the higher part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Use the MMC command register (MMCCMD) to send the SELECT/DESELECT\_CARD broadcast command. This selects the addressed card and deselects the others.
3. Write the destination start address to the MMC argument registers. Load the high part to the MMCARGH register and the low part to MMCARGL.
4. Read the card CSD to determine the card's maximum block length.
5. Use MMCCMD to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
6. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
7. Set the FIFO direction to transmit (FIFODIR bit in MMCFIFOCTL).
8. Set the access width (ACCWD bits in MMCFIFOCTL).
9. Enable the MMC interrupt.
10. Enable the DXRDYINT interrupt.
11. Write the first 32 bytes of the data block to the data transmit register (MMCDXR).
12. Use MMCCMD to send the WRITE\_BLOCK command to the card.
13. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
14. Wait for the MMC interrupt.
15. Use the MMC status register 0 (MMCST0) to check for errors and the status of the FIFO. If all of the data has not been written and if the FIFO is not full, go to [Step 16](#). If all of the data has been written, stop.
16. Write the next  $n$  bytes (this depends on the setting of the FIFOLEV bit in MMCFIFOCTL: 0 = 32 bytes, 1 = 64 bytes) of the data block to the MMC data transmit register (MMCDXR) and return to [Step 14](#).

The sequence of events in this operation is shown in [Figure 27-13](#).

**Figure 27-13. MMC/SD Mode Single-Block Write Operation**

### 27.3.3 MMC/SD Mode Single-Block Write Operation Using the EDMA

To perform a single-block write, the block length must be 512 bytes and the same length must be set in both the MMC/SD controller and the card.

The procedure for this operation is as follows:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Read the card CSD to determine the card's maximum block length.
3. Use the MMC command register (MMCCMD) to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
4. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
5. Set the FIFO direction to transmit (FIFODIR bit in MMCFIFOCTL).
6. Set the access width (ACCWD bits in MMCFIFOCTL).
7. Set the FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
8. Set up the DMA (DMA size must be greater than or equal to the FIFOLEV setting).
9. Use MMCCMD to send the WRITE\_BLOCK command to the card.
10. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
11. Wait for the DMA sequence to complete or for the DATADNE flag in the MMC status register 0 (MMCST0) to be set.
12. Use MMCST0 to check for errors.

### 27.3.4 MMC/SD Mode Single-Block Read Operation Using the CPU

To perform a single-block read, the same block length must be set in both the MMC/SD controller and the card.

The procedure for this operation is as follows:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MCARGH and the low part of the address to MMCARGL.
2. Use the MMC command register (MMCCMD) to send the SELECT/DESELECT\_CARD broadcast command. This selects the addressed card and deselects the others.
3. Write the source start address to the MMC argument registers. Load the high part to MMCARGH and the low part to MMCARGL.
4. Read card CSD to determine the card's maximum block length.
5. Use MMCCMD to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
6. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
7. Set the FIFO direction to receive (FIFODIR bit in MMCFIFOCTL).
8. Set the access width (ACCWD bits in MMCFIFOCTL).
9. Set the FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
10. Enable the MMC interrupt.
11. Enable the DRRDYINT interrupt.
12. Use MMCCMD to send the READ\_SINGLE\_BLOCK command.
13. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
14. Wait for the MMC interrupt.
15. Use the MMC status register 0 (MMCST0) to check for errors and the status of the FIFO. If the FIFO is not empty, go to [Step 16](#). If all of the data has been read, stop.
16. Read the next *n* bytes of data (this depends on the setting of the FIFOLEV bit in MMCFIFOCTL: 0 = 32 bytes, 1 = 64 bytes) from the MMC data receive register (MMCDRR) and return to [Step 14](#).

The sequence of events in this operation is shown in [Figure 27-14](#).

**Figure 27-14. MMC/SD Mode Single-Block Read Operation**

### 27.3.5 MMC/SD Mode Single-Block Read Operation Using EDMA

To perform a single-block read, the same block length needs to be set in both the MMC/SD controller and the card. The procedure for this operation is:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Read card CSD to determine the card's maximum block length.
3. Use the MMC command register (MMCCMD) to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
4. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
5. Set the FIFO direction to receive (FIFODIR bit in MMCFIFOCTL).
6. Set the access width (ACCWD bits in MMCFIFOCTL).
7. Set the FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
8. Set up DMA (DMA size needs to be greater than or equal to FIFOLEV setting).
9. Use MMCCMD to send the READ\_BLOCK command to the card.
10. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
11. Wait for DMA sequence to complete.
12. Use the MMC status register 0 (MMCST0) to check for errors.

### 27.3.6 MMC/SD Mode Multiple-Block Write Operation Using CPU

---

**NOTE:** This procedure uses a STOP\_TRANSMISSION command to end the block transfer. This assumes that the value in the MMC number of blocks counter register (MMCNBLK) is 0. A multiple-block operation terminates itself if you load MMCNBLK with the exact number of blocks you want transferred.

---

To perform a multiple-block write, the same block length needs to be set in both the MMC/SD controller and the card.

The procedure for this operation is:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Read card CSD to determine the card's maximum block length.
3. Use the MMC command register (MMCCMD) to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
4. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
5. Set the FIFO direction to transmit (FIFODIR bit in MMCFIFOCTL).
6. Set the access width (ACCWD bits in MMCFIFOCTL).
7. Set the FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
8. Enable the MMC interrupt.
9. Enable DXRDYINT interrupt.
10. Write the first 32 bytes of the data block to the MMC data transmit register (MMCDXR).
11. Use MMCCMD to send the WRITE\_MULTI\_BLOCK command to the card.
12. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
13. Wait for MMC interrupt.
14. Use the MMC status register 0 (MMCST0) to check for errors and to determine the status of the FIFO. If more bytes are to be written and the FIFO is not full, go to [Step 15](#). If all of the data has been written, go to [Step 16](#).

15. Write the next  $n$  bytes (depends on setting of FIFOLEV in MMCFIFOCTL: 0 = 32 bytes, 1 = 64 bytes) of the data block to MMCDXR, and return to [Step 13](#).
  16. Use MMCCMD to send the STOP\_TRANSMISSION command.
- The sequence of events in this operation is shown in [Figure 27-15](#).

**Figure 27-15. MMC/SD Multiple-Block Write Operation**

### 27.3.7 MMC/SD Mode Multiple-Block Write Operation Using EDMA

To perform a multiple-block write, the same block length needs to be set in both the MMC/SD controller and the card. The procedure for this operation is:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Read card CSD to determine the card's maximum block length.
3. Use the MMC command register (MMCCMD) to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
4. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
5. Set the FIFO direction to transmit (FIFODIR bit in MMCFIFOCTL).
6. Set the FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
7. Set the access width (ACCWD bits in MMCFIFOCTL).
8. Set up DMA (DMA size needs to be greater than or equal to FIFOLEV setting).
9. Use MMCCMD to send the WRITE\_MULTI\_BLOCK command to the card.
10. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
11. Wait for DMA sequence to complete or the DATADNE flag in the MMC status register 0 (MMCST0) is set.
12. Use MMCST0 to check for errors.
13. Use MMCCMD to send the STOP\_TRANSMISSION command.

### 27.3.8 MMC/SD Mode Multiple-Block Read Operation Using CPU

---

**NOTE:** This procedure uses a STOP\_TRANSMISSION command to end the block transfer. This assumes that the value in the MMC number of blocks counter register (MMCNBLK) is 0. A multiple-block operation terminates itself if you load MMCNBLK with the exact number of blocks you want transferred.

---

To perform a multiple-block read, the same block length needs to be set in both the MMC/SD controller and the card.

The procedure for this operation is:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Read card CSD to determine the card's maximum block length.
3. Use the MMC command register (MMCCMD) to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
4. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
5. Set the FIFO direction to receive (FIFODIR bit in MMCFIFOCTL).
6. Set FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
7. Set the access width (ACCWD bits in MMCFIFOCTL).
8. Enable the MMC interrupt.
9. Enable DRRDYINT interrupt.
10. Use MMCCMD to send the READ\_MULT\_BLOCKS command.
11. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
12. Wait for MMC interrupt.
13. Use the MMC status register 0 (MMCST0) to check for errors and to determine the status of the FIFO. If FIFO is not empty and more bytes are to be read, go to [Step 14](#). If all of the data has been read, go to [Step 15](#).

14. Read  $n$  bytes (depends on setting of FIFOLEV in MMCFIFOCTL: 0 = 32 bytes, 1 = 64 bytes) of data from the MMC data receive register (MMCDRR) and return to [Step 10](#).

15. Use MMCCMD to send the STOP\_TRANSMISSION command.

The sequence of events in this operation is shown in [Figure 27-16](#).

**Figure 27-16. MMC/SD Mode Multiple-Block Read Operation**

### 27.3.9 MMC/SD Mode Multiple-Block Read Operation Using EDMA

To perform a multiple-block read, the same block length must be set in both the MMC/SD controller and the card.

The procedure for this operation is as follows:

1. Write the card's relative address to the MMC argument registers (MMCARGH and MMCARGL). Load the high part of the address to MMCARGH and the low part of the address to MMCARGL.
2. Read card CSD to determine the card's maximum block length.
3. Use the MMC command register (MMCCMD) to send the SET\_BLOCKLEN command (if the block length is different than the length used in the previous operation). The block length must be a multiple of 512 bytes and less than the maximum block length specified in the CSD.
4. Reset the FIFO (FIFORST bit in MMCFIFOCTL).
5. Set the FIFO direction to receive (FIFODIR bit in MMCFIFOCTL).
6. Set the FIFO threshold (FIFOLEV bit in MMCFIFOCTL).
7. Set the access width (ACCWD bits in MMCFIFOCTL).
8. Set up DMA (DMA size needs to be greater than or equal to FIFOLEV setting).
9. Use MMCCMD to send the READ\_MULTI\_BLOCK command to the card.
10. Set the DMATRIG bit in MMCCMD to trigger the first data transfer.
11. Wait for DMA sequence to complete.
12. Use the MMC status register 0 (MMCST0) to check for errors.
13. Use MMCCMD to send the STOP\_TRANSMISSION command.

### 27.3.10 SDIO Card Function

To support the SDIO card, the following features are available in the MMC/SD controller:

- Read wait operation request
- Interrupt to CPU at the start of read wait operation
- Interrupt to CPU at the detection of SDIO interrupt

When in 1-bit mode and the transfer clock (memory clock) is off, this peripheral cannot recognize an SDIO interrupt from SD\_DATA1 line. Two options are available to deal with this situation:

1. Do not turn off the memory clock in 1-bit mode. The clock is enabled by the CLKEN bit in the MMC memory clock control register (MMCCLK).
2. If the memory clock needs to be turned off, physically connect a GPIO signal and SD\_DATA1, and use the GPIO as an external interrupt input. When the memory clock is enabled, disable the GPIO interrupt and enable the SDIO interrupt. When the memory clock is disabled, enable the GPIO interrupt and disable the SDIO interrupt by software.

#### 27.3.10.1 SDIO Control Register (SDIOCTL)

The SDIO card control register (SDIOCTL) is used to configure the read wait operation using the SD\_DATA2 line.

#### 27.3.10.2 SDIO Status Register 0 (SDIOST0)

The SDIO card status register 0 (SDIOST0) is used to check the status of the SD\_DATA1 signal, check the status of being in an interrupt period, or check the status of being in a read wait operation.

### 27.3.10.3 SDIO Interrupt Control Registers (SDIOIEN, SDIOIST)

The SDIO card controller issues an interrupt to the CPU when the read wait operation starts or when an SDIO interrupt is detected on the SD\_DATA1 line.

Interrupt flags of each case are checked with the SDIO interrupt status register (SDIOIST). To issue an actual interrupt to the CPU, enabling each interrupt in the SDIO interrupt enable register (SDIOIEN) is required.

When both interrupts are enabled, they are both reported to the CPU as an interrupt (whether one or both occurred). The interrupt(s) that occurred are determined by reading SDIOIST.

## 27.4 Registers

[Table 27-5](#) lists the memory-mapped registers for the multimedia card/secure digital (MMC/SD) card controller. See your device-specific data manual for the memory address of these registers.

**Table 27-5. Multimedia Card/Secure Digital (MMC/SD) Card Controller Registers**

### 27.4.1 MMC Control Register (MMCCTL)

The MMC control register (MMCCTL) is used to enable or configure various modes of the MMC controller. Set or clear the DATRST and CMDRST bits at the same time to reset or enable the MMC controller.

The MMC control register (MMCCTL) is shown in [Figure 27-17](#) and described in [Table 27-6](#).

**Figure 27-17. MMC Control Register (MMCCTL)**

|          |   |          |  |  |  |  |   |        |        |        |        |        |        |     |  |    |
|----------|---|----------|--|--|--|--|---|--------|--------|--------|--------|--------|--------|-----|--|----|

### 27.4.2 MMC Memory Clock Control Register (MMCCLK)

The MMC memory clock control register (MMCCLK) is used to:

- Select whether the MMCSD\_CLK pin is enabled or disabled (CLKEN bit).
- Select how much the function clock is divided-down to produce the memory clock (CLKRT bits). When the MMCSD\_CLK pin is enabled, the MMC controller drives the memory clock on this pin to control the timing of communications with attached memory cards. For more details about clock generation, see [Section 27.2.1](#).

The MMC memory clock control register (MMCCLK) is shown in [Figure 27-18](#) and described in [Table 27-7](#).

**Figure 27-18. MMC Memory Clock Control Register (MMCCLK)**

|       |          | 1     | The MMCSD_CLK pin is enabled; it shows the memory clock signal.                                                                                                                                                                  |
| 7-0   | CLKRT    | 0-FFh | Clock rate. Use this field to set the divide-down value for the memory clock. The function clock is divided down as follows to produce the memory clock:<br>memory clock frequency = function clock frequency/(2 × (CLKRT + 1) ) |

### 27.4.3 MMC Status Register 0 (MMCST0)

The MMC status register 0 (MMCST0) records specific events or errors. The transition from 0 to 1 on each bit in MMCST0 can cause an interrupt signal to be sent to the CPU. If an interrupt is desired, set the corresponding interrupt enable bit in the MMC interrupt mask register (MMCIM).

In most cases, when a status bit is read, it is cleared. The two exceptions are the DRRDY bit and the DXRDY bit; these bits are cleared only in response to the functional events described for them in [Table 27-8](#), or in response to a hardware reset.

The MMC status register 0 (MMCST0) is shown in [Figure 27-19](#) and described in [Table 27-8](#).

- NOTE:**
- 1) As the command portion and the data portion of the MMC/SD controller are independent, any command such as CMD0 (GO\_IDLE\_STATE) or CMD12 (STOP\_TRANSMISSION) can be sent to the card, even during block transfer. In this situation, the data portion detects this and waits, releasing the busy state only when the command sent was R1b (to be specific, command with BSYEXP bit), otherwise it continues transferring data.
  - 2) Bit 12 (TRNDNE) indicates that the last byte of a transfer has been completed. Bit 0 (DATDNE) occurs at end of a transfer, but not until the CRC check and programming has completed.

### 27.4.4 MMC Status Register 1 (MMCST1)

The MMC status register 1 (MMCST1) records specific events or errors. There are no interrupts associated with these events or errors.

The MMC status register 1 (MMCST1) is shown in [Figure 27-20](#) and described in [Table 27-9](#).

**Figure 27-20. MMC Status Register 1 (MMCST1)**

### 27.4.5 MMC Interrupt Mask Register (MMCIM)

The MMC interrupt mask register (MMCIM) is used to enable (bit = 1) or disable (bit = 0) status interrupts. If an interrupt is enabled, the transition from 0 to 1 of the corresponding interrupt bit in the MMC status register 0 (MMCST0) can cause an interrupt signal to be sent to the CPU.

The MMC interrupt mask register (MMCIM) is shown in [Figure 27-21](#) and described in [Table 27-10](#).

**Figure 27-21. MMC Interrupt Mask Register (MMCIM)**

### 27.4.6 MMC Response Time-Out Register (MMCTOR)

The MMC response time-out register (MMCTOR) defines how long the MMC controller waits for a response from a memory card before recording a time-out condition in the TOUTRS bit of the MMC status register 0 (MMCST0). If the corresponding ETOUTRS bit in the MMC interrupt mask register (MMCIM) is set, an interrupt is generated when the TOUTRS bit is set in MMCST0. If a memory card should require a longer time-out period than MMCTOR can provide, a software time-out mechanism can be implemented.

The MMC response time-out register (MMCTOR) is shown in [Figure 27-22](#) and described in [Table 27-11](#).

**Figure 27-22. MMC Response Time-Out Register (MMCTOR)**

### 27.4.7 MMC Data Read Time-Out Register (MMCTOD)

The MMC data read time-out register (MMCTOD) defines how long the MMC controller waits for the data from a memory card before recording a time-out condition in the TOUTRD bit of the MMC status register 0 (MMCST0). If the corresponding ETOUTRD bit in the MMC interrupt mask register (MMCIM) is set, an interrupt is generated when the TOUTRD bit is set in MMCST0. If a memory card should require a longer time-out period than MMCTOD can provide, a software time-out mechanism can be implemented.

The MMC data read time-out register (MMCTOD) is shown in [Figure 27-23](#) and described in [Table 27-12](#).

| 15-0  | TOD_15_0 | 0-FFFFh      | Data read time-out count. Used in conjunction with the TOD_25_16 bits in MMCTOR to form a 26-bit count (1 CLK clock cycle to 67 108 863 CLK clock cycles). See MMCTOR ( <a href="#">Section 27.4.6</a> ). |
|       |          | 0            | No time out                                                                                                                                                                                               |
|       |          | 1h-3FF FFFFh | 1 CLK clock cycle to 67 108 863 CLK clock cycles                                                                                                                                                          |

### 27.4.8 MMC Block Length Register (MMCBLEN)

The MMC block length register (MMCBLEN) specifies the data block length in bytes. This value must match the block length setting in the memory card.

The MMC block length register (MMCBLEN) is shown in [Figure 27-24](#) and described in [Table 27-13](#).

**NOTE:** The BLEN bits value must be the same as the CSD register settings in the MMC/SD card. To be precise, it should match the value of the READ\_BL\_LEN field for read, or WRITE\_BL\_LEN field for write.

**Figure 27-24. MMC Block Length Register (MMCBLEN)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-13. MMC Block Length Register (MMCBLEN) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                   |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------|
| 31-12 | Reserved | 0       | Reserved                                                                                                                      |
| 11-0  | BLEN     | 1h-FFFh | Block length. This field is used to set the block length, which is the byte count of a data block. The value 0 is prohibited. |

### 27.4.9 MMC Number of Blocks Register (MMCNBLK)

The MMC number of blocks register (MMCNBLK) specifies the number of blocks for a multiple-block transfer.

The MMC number of blocks register (MMCNBLK) is shown in [Figure 27-25](#) and described in [Table 27-14](#).

**Figure 27-25. MMC Number of Blocks Register (MMCNBLK)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-14. MMC Number of Blocks Register (MMCNBLK) Field Descriptions**

| Bit   | Field    | Value    | Description                                                                                                                                                        |
|-------|----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0        | Reserved                                                                                                                                                           |
| 15-0  | NBLK     | 0-FFFFh  | Number of blocks. This field is used to set the total number of blocks to be transferred.                                                                          |
|       |          | 0        | Infinite number of blocks. The MMC controller reads/writes blocks of data until a STOP_TRANSMISSION command is written to the MMC command register (MMC_CMD).      |
|       |          | 1h-FFFFh | n blocks. The MMC controller reads/writes only n blocks of data, even if the STOP_TRANSMISSION command has not been written to the MMC command register (MMC_CMD). |

### 27.4.10 MMC Number of Blocks Counter Register (MMCNBLC)

The MMC number of blocks counter register (MMCNBLC) is a down-counter for tracking the number of blocks remaining to be transferred during a multiple-block transfer.

The MMC number of blocks counter register (MMCNBLC) is shown in [Figure 27-26](#) and described in [Table 27-15](#).

**Figure 27-26. MMC Number of Blocks Counter Register (MMCNBLC)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-15. MMC Number of Blocks Counter Register (MMCNBLC) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                    |
|-------|----------|---------|--------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                       |
| 15-0  | NBLC     | 0-FFFFh | Read this field to determine the number of blocks remaining to be transferred. |

### 27.4.11 MMC Data Receive Register (MMCDRR)

The MMC data receive register (MMCDRR) is used for storing the received data from the MMC controller. The CPU or the DMA controller can read data from this register. MMCDRR expects the data in little-endian format.

The MMC data receive register (MMCDRR) is shown in [Figure 27-27](#) and described in [Table 27-16](#).

**Figure 27-27. MMC Data Receive Register (MMCDRR)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 27-16. MMC Data Receive Register (MMCDRR) Field Descriptions**

| Bit  | Field | Value        | Description   |
|------|-------|--------------|---------------|
| 31-0 | DRR   | 0-FFFF FFFFh | Data receive. |

### 27.4.12 MMC Data Transmit Register (MMCDXR)

The MMC data transmit register (MMCDXR) is used for storing the data to be transmitted from the MMC controller to the memory card. The CPU or the DMA controller can write data to this register to be transmitted. MMCDXR expects the data in little-endian format.

The MMC data transmit register (MMCDXR) is shown in [Figure 27-28](#) and described in [Table 27-17](#).

**Figure 27-28. MMC Data Transmit Register (MMCDXR)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 27-17. MMC Data Transmit Register (MMCDXR) Field Descriptions**

| Bit  | Field | Value        | Description    |
|------|-------|--------------|----------------|
| 31-0 | DXR   | 0-FFFF FFFFh | Data transmit. |

### 27.4.13 MMC Command Register (MMCCMD)

**NOTE:** Writing to the MMC command register (MMCCMD) causes the MMC controller to send the programmed command. Therefore, the MMC argument register (MMCARGHL) must be loaded properly before a write to MMCCMD.

The MMC command register (MMCCMD) specifies the type of command to be sent and defines the operation (command, response, additional activity) for the MMC controller. The content of MMCCMD is kept after the transfer to the transmit shift register. The MMC command register (MMCCMD) is shown in Figure 27-29 and described in Table 27-18.

When the CPU writes to MMCCMD, the MMC controller sends the programmed command, including any arguments in the MMC argument register (MMCARGHL). For the format of a command (index, arguments, and other bits), see Figure 27-30 and Table 27-19.

**Figure 27-29. MMC Command Register (MMCCMD)**

|          |  |          |  |       |  |        |  |       |  |        |  |         |  |       |  |   |  |

**Figure 27-30. Command Format**

**Table 27-19. Command Format**

| Bit Position of Command | Register    | Description                |
|-------------------------|-------------|----------------------------|
| 47                      | -           | Start bit                  |
| 46                      | -           | Transmission bit           |
| 45-40                   | MMCCMD(5-0) | Command index (CMD)        |
| 39-24                   | MMCARGHL    | Argument, high part (ARGH) |
| 23-8                    | MMCARGHL    | Argument, low part (ARGL)  |
| 7-1                     | -           | CRC7                       |
| 0                       | -           | End bit                    |

## 27.4.14 MMC Argument Register (MMCARGHL)

**NOTE:** Do not modify the MMC argument register (MMCARGHL) while it is being used for an operation.

The MMC argument register (MMCARGHL) specifies the arguments to be sent with the command specified in the MMC command register (MMCCMD). Writing to MMCCMD causes the MMC controller to send a command; therefore, MMCARGHL must be configured before writing to MMCCMD. The content of MMCARGHL is kept after the transfer to the shift register; however, modification to MMCARGHL is not allowed during a sending operation. For the format of a command, see [Figure 27-30](#) and [Table 27-19](#).

The MMC argument register (MMCARGHL) is shown in [Figure 27-31](#) and described in [Table 27-20](#).

**Figure 27-31. MMC Argument Register (MMCARGHL)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 27-20. MMC Argument Register (MMCARGHL) Field Descriptions**

| Bit   | Field | Value   | Description          |
|-------|-------|---------|----------------------|
| 31-16 | ARGH  | 0-FFFFh | Argument, high part. |
| 15-0  | ARGL  | 0-FFFFh | Argument, low part.  |

### 27.4.15 MMC Response Registers (MMCRSP0-MMCRSP7)

Each command has a preset response type. When the MMC controller receives a response, it is stored in some or all of the eight MMC response registers (MMCRSP7-MMCRSP0). The response registers are updated as the responses arrive, even if the CPU has not read the previous contents.

As shown in [Figure 27-32](#), [Figure 27-33](#), [Figure 27-34](#), and [Figure 27-35](#) each of the MMC response registers holds up to 16 bits. [Table 27-21](#) and [Table 27-22](#) show the format for each type of response and which MMC response registers are used for the bits of the response. The first byte of the response is a command index byte and is stored in the MMC command index register (MMCCIDX).

**Figure 27-32. MMC Response Register 0 and 1 (MMCRSP01)**

LEGEND: R/W = Read/Write; -n = value after reset

**Figure 27-33. MMC Response Register 2 and 3 (MMCRSP23)**

**Table 27-21. R1, R3, R4, R5, or R6 Response (48 Bits)**

| Bit Position of Response | Register               |
|--------------------------|------------------------|
| 47-40                    | MMCCIDX                |
| 39-24                    | MMCRSP7                |
| 23-8                     | MMCRSP6                |
| 7-0                      | MMCRSP5 <sup>(1)</sup> |
| -                        | MMCRSP4-0              |

<sup>(1)</sup> Bits 7-0 of the response are stored to bits 7-0 of MMCRSP5.

**Table 27-22. R2 Response (136 Bits)**

| Bit Position of Response | Register |
|--------------------------|----------|
| 135-128                  | MMCCIDX  |
| 127-112                  | MMCRSP7  |
| 111-96                   | MMCRSP6  |
| 95-80                    | MMCRSP5  |
| 79-64                    | MMCRSP4  |
| 63-48                    | MMCRSP3  |
| 47-32                    | MMCRSP2  |
| 31-16                    | MMCRSP1  |
| 15-0                     | MMCRSP0  |

### 27.4.16 MMC Data Response Register (MMCDRSP)

After the MMC controller sends a data block to a memory card, the return byte from the memory card is stored in the MMC data response register (MMCDRSP).

The MMC data response register (MMCDRSP) is shown in [Figure 27-36](#) and described in [Table 27-23](#).

**Figure 27-36. MMC Data Response Register (MMCDRSP)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-23. MMC Data Response Register (MMCDRSP) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                               |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                  |
| 7-0  | DRSP     | 0-FFh | During a write operation (see <a href="#">Section 27.2.3.1</a> ), the CRC status token is stored in DRSP. |

### 27.4.17 MMC Command Index Register (MMCCIDX)

The MMC command index register (MMCCIDX) stores the first byte of a response from a memory card. [Table 27-21](#) and [Table 27-22](#) show the format for each type of response.

The MMC command index register (MMCCIDX) is shown in [Figure 27-37](#) and described in [Table 27-24](#).

**Figure 27-37. MMC Command Index Register (MMCCIDX)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-24. MMC Command Index Register (MMCCIDX) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                            |
|------|----------|-------|--------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                               |
| 7    | STRT     | 0-1   | Start bit. When the MMC controller receives a response, the start bit is stored in STRT.               |
| 6    | XMIT     | 0-1   | Transmission bit. When the MMC controller receives a response, the transmission bit is stored in XMIT. |
| 5-0  | CIDX     | 0-3Fh | Command index. When the MMC controller receives a response, the command index is stored in CIDX.       |

### 27.4.18 SDIO Control Register (SDIOCTL)

The SDIO control register (SDIOCTL) is shown in [Figure 27-38](#) and described in [Table 27-25](#).

**Figure 27-38. SDIO Control Register (SDIOCTL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-25. SDIO Control Register (SDIOCTL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                            |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                                                                                               |
| 1    | RDWTCR   | 0     | Read wait enable for CRC error. To end the read wait operation, write 0 to RDWTRQ. (No need to clear RDWTCR).                                                          |
|      |          | 0     | Read wait is disabled.                                                                                                                                                 |
|      |          | 1     | Automatically start read wait on CRC error detection during multiple block read access and not the last block to be transferred. RDWTRQ is automatically set to 1.     |
| 0    | RDWTRQ   | 0     | Read wait request. To end the read wait operation, write 0 to RDWTRQ.                                                                                                  |
|      |          | 0     | End read wait operation and release MMCSD_DAT2.                                                                                                                        |
|      |          | 1     | Set a read wait request. Read wait operation starts 2 clocks after the end of the read data block. MMCIF asserts low level on MMCSD_DAT2 until RDWTRQ is cleared to 0. |

## 27.4.19 SDIO Status Register 0 (SDIOST0)

The SDIO status register 0 (SDIOST0) is shown in [Figure 27-39](#) and described in [Table 27-26](#).

**Figure 27-39. SDIO Status Register 0 (SDIOST0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-26. SDIO Status Register 0 (SDIOST0) Field Descriptions**

| Bit  | Field    | Value | Description                                               |
|------|----------|-------|-----------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                  |
| 2    | RDWTST   | 0     | Read wait status.                                         |
|      |          | 0     | Read wait operation not in progress.                      |
|      |          | 1     | Read wait operation in progress.                          |
| 1    | INTPRD   | 0     | Interrupt period.                                         |
|      |          | 0     | Interrupt not in progress.                                |
|      |          | 1     | Interrupt in progress.                                    |
| 0    | DAT1     | 0     | This bit reflects the external state of the SD_DATA1 pin. |
|      |          | 0     | Logic-low level on the SD_DATA1 pin.                      |
|      |          | 1     | Logic-high level on the SD_DATA1 pin.                     |

### 27.4.20 SDIO Interrupt Enable Register (SDIOIEN)

The SDIO interrupt enable register (SDIOIEN) is shown in [Figure 27-40](#) and described in [Table 27-27](#).

**Figure 27-40. SDIO Interrupt Enable Register (SDIOIEN)**

|          |  |  |  |  |  |  |       |         |       |  |    |
|----------|--|--|--|--|--|--|-------|---------|-------|--|----|
| 31       |  |  |  |  |  |  |       |         |       |  | 16 |

## ***Real-Time Clock (RTC)***

This chapter describes the real-time clock (RTC).

| Topic                          | Page        |
|--------------------------------|-------------|
| <b>28.1 Introduction .....</b> | <b>1337</b> |
| <b>28.2 Architecture .....</b> | <b>1338</b> |
| <b>28.3 Registers .....</b>    | <b>1344</b> |

## 28.1 Introduction

### 28.1.1 Purpose of the Peripheral

The real-time clock (RTC) provides a time reference to an application running on the device. The current date and time is tracked in a set of counter registers that update once per second. The time can be represented in 12-hour or 24-hour mode. The calendar and time registers are buffered during reads and writes so that updates do not interfere with the accuracy of the time and date.

Alarms are available to interrupt the CPU at a particular time, or at periodic time intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

### 28.1.2 Features

The real-time clock (RTC) provides the following features:

- 100-year calendar (xx00 to xx99)
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded-decimal (BCD) representation of time, calendar, and alarm
- 12-hour clock mode (with AM and PM) or 24-hour clock mode
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the CPU
- Supports external 32.768-kHz crystal or external clock source of the same frequency
- Isolated power supply

### 28.1.3 Block Diagram

Figure 28-1 shows a block diagram of the RTC.

**Figure 28-1. Real-Time Clock Block Diagram**

## 28.2 Architecture

### 28.2.1 Clock Source

The clock reference for the RTC is an external 32.768-kHz crystal or an external clock source of the same frequency. The RTC also has a separate power supply that is isolated from the rest of the system. When the CPU and other peripherals are without power, the RTC can remain powered to preserve the current time and calendar information.

The source for the RTC reference clock may be provided by a crystal or by an external clock source. The RTC has an internal oscillator buffer to support direct operation with a crystal. The crystal is connected between pins RTC\_XI and RTC\_XO. RTC\_XI is the input to the on-chip oscillator and RTC\_XO is the output from the oscillator back to the crystal. For more information about the RTC crystal connection, see your device-specific data manual.

An external 32.768-kHz clock source may be used instead of a crystal. In such a case, the clock source is connected to RTC\_XI, and RTC\_XO is left unconnected.

If the RTC is not used, the RTC\_XI pin should be held low and RTC\_XO should be left unconnected. The RTCDISABLE bit in the control register (CTRL) can be set to save power; however, the RTCDISABLE bit should not be cleared once it has been set. If the application requires the RTC module to stop and continue, the RUN bit in CTRL should be used instead.

### 28.2.2 Signal Descriptions

The RTC signals are listed in [Table 28-1](#).

**Table 28-1. Real-Time Clock Signals**

| Signal | I/O | Description                                                                                                                                                                                                       |
|--------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RTC_XI | I   | RTC time base input signal. RTC_XI can either be driven with a 32.768-kHz reference clock, or RTC_XI and RTC_XO can be connected to an external crystal. This signal is the input to the RTC internal oscillator. |
| RTC_XO | O   | RTC time base output signal. RTC_XO is the output from the RTC internal oscillator. If a crystal is not used as the time base for RTC_XI, RTC_XO should be left unconnected.                                      |

### 28.2.3 Isolated Power Supply

The RTC has a power supply that is isolated from the rest of the system. This allows the RTC to continue to run while the rest of the system is not powered. In this state, the RTC time and calendar counters continue to run, but the powered down CPU is not able to receive RTC interrupts. Separate power supply pins for the RTC are provided on the device package.

#### 28.2.3.1 Split-Power Circuitry

To decrease power consumption, RTC includes leakage-isolation circuitry that is activated by setting the SPLITPOWER bit in the control register (CTRL). Because of its isolated power supply, RTC does not have a power-on hardware reset signal. Therefore, upon initial device power-on, the RTC is in an unknown state until it has been properly configured. After the RTC module has been configured once, it functions as programmed as long as its power supply and clock source are provided.

#### 28.2.3.2 Power Considerations

The RTC leakage-isolation circuitry requires that the CPU supply be powered down to VSS when the RTC is powered on while the rest of the device is powered off. A floating CPU supply creates undesired RTC leakage current. Also, the RTC power consumption is higher when the CPU is powered on versus the RTC power consumption when the CPU is powered off. Therefore, if the RTC module is expected to run from a small-capacity power supply (ex. watch battery) while the rest of the device is powered off, a power system should be implemented such that the RTC is powered from a high-capacity power supply when the CPU is powered on.

## 28.2.4 Operation

### 28.2.4.1 Using the Real-Time Clock Time and Calendar Registers

The current time and date are maintained in the RTC time and calendar registers.

#### 28.2.4.1.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Although most of the time/calendar registers have 4 bits assigned to each BCD digit, some of the register fields are shorter since the range of valid numbers may be limited. For example, only 3 bits are required to represent the day since only BCD numbers 1 through 7 are required.

The following time and calendar registers are supported (BCD Format):

- SECOND - Second Count (00-59)
- MINUTE - Minute Count (00-59)
- HOUR - Hour Count (12HR: 01-12; 24HR: 00-23)
- DAY - Day of the Month Count (01-31)
- MONTH - Month Count (01-12; JAN = 1)
- YEAR - Year Count (00-99)
- DOTW - Day of the Week Count (0-6; SUN = 0)

Note that the ALARM registers which share the names above also share the same BCD formatting.

#### 28.2.4.1.2 12-Hour and 24-Hour Modes

The current time can be represented in 12-hour or 24-hour mode by configuring the HOURMODE bit in the control register (CTRL):

- When HOURMODE = 0, 24-hour mode is selected. The hours are represented as 00 through 23. The MERIDIEM bit in the HOURS register has no function and should be cleared.
- When HOURMODE = 1, 12-hour mode is selected. The hours are represented as 00 through 12. MERIDIEM = 0 indicates ante meridiem (AM), and MERIDIEM = 1 indicates post meridiem (PM).

#### 28.2.4.1.3 Reading from Time/Calendar Registers

The time/calendar registers are updated every second as the time changes. During a read of the SECOND register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values at the moment of the SECOND read request and not be subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUNDMIN bit in the control register (CTRL); the RTC automatically rounds the time values to the nearest minute upon the next read of the SECOND register.

#### 28.2.4.1.4 Writing to Time/Calendar Registers

When setting the RTC time and date, values are written directly to the time/calendar registers. Therefore, care must be taken to avoid writing to the time/calendar registers while the time is updating to the next second. This can be accomplished in one of two ways:

1. The RTC can be stopped by clearing the RUN bit in the control register (CTRL). When stopped, there is no danger of contention during writes because the registers do not auto-update.
2. The BUSY bit in the status register (STATUS) is low when a time update does not take place for at least 15  $\mu$ s. By checking for a low BUSY bit before writing to registers, the CPU is assured of a 15  $\mu$ s window of time during which multiple accesses to the time/calendar registers can be performed.

After writing to a time/calendar register, the RTC requires four peripheral clock cycles to update the register value. Any reads that take place within four peripheral clock cycles of a write returns old data.

Note that all registers in the RTC except for KICK $n$ R have write-protection. See [Section 28.2.6](#) for information on unlocking registers.

#### 28.2.4.2 Real-Time Clock Update Cycle

The RTC executes an update cycle once per second to update the current time in the time/calendar registers. The update cycle also compares each alarm register with the corresponding time register. These comparisons are done to determine when to trigger an alarm. The BUSY bit in the status register (STATUS) provides a mechanism to indicate when the time/calendar registers are updated. When the BUSY bit is high, an update takes place within 15  $\mu$ s. When BUSY returns low again, the update has been completed.

The BUSY bit should be checked when writing to any of the following registers while RTC is running:

- SECOND
- MINUTE
- HOUR
- DAY
- MONTH
- YEAR
- DOTW
- ALARMSECOND (when ALARM interrupt is enabled)
- ALARMMINUTE (when ALARM interrupt is enabled)
- ALARMHOUR (when ALARM interrupt is enabled)
- ALARMDAY (when ALARM interrupt is enabled)
- ALARMMONTH (when ALARM interrupt is enabled)
- ALARMYEAR (when ALARM interrupt is enabled)
- CTRL (SET32COUNTER field only -- the other fields in CTRL do not require BUSY to be low)
- INTERRUPT
- COMPLSB (when oscillator drift compensation is enabled)
- COMPMSB (when oscillator drift compensation is enabled)

#### 28.2.4.3 Oscillator Drift Compensation

If the RTC 32.768-kHz reference clock is susceptible to oscillator drift, the RTC provides the ability to compensate the update cycle by subtracting oscillator periods. The COMPMSB and COMPLSB registers hold the number of two's complement reference periods to subtract from the update cycle every hour. For example, [Figure 28-2](#) shows how programming the value of 2h into the compensation registers shortens the update cycle by two 32.786-kHz reference periods every hour. [Figure 28-2](#) also shows how programming the value of FFFEh (decimal negative 2) into the compensation register lengthens the update cycle by two reference periods every hour. To enable the oscillator compensation, the AUTOCOMP bit in the control register (CTRL) must be set.

**Figure 28-2. 32-kHz Oscillator Counter Compensation**

## 28.2.5 Interrupt Requests

The RTC provides the ability to interrupt the CPU based on two events: a periodic interrupt and an alarm interrupt. Although two interrupt sources are available, the RTC makes a single interrupt request to the CPU.

When the device is initially powered on, the RTC may issue spurious interrupt signals to the CPU. To avoid issues, a software reset should be performed on the RTC module before the CPU interrupt controller is initialized. See [Section 28.2.10](#) for more information on reset considerations.

### 28.2.5.1 Alarm Interrupt Enable and Status Bits

The ALARM bit in the interrupt register (INTERRUPT) enables the alarm interrupt. When the current time and date match the ALARMSECOND, ALARMMINUTE, ALARMHOUR, ALARMDAY, ALARMMONTH, and ALARMYEAR registers, the RTC issues an interrupt to the CPU and sets the ALARM bit in the status register (STATUS). Once set, the ALARM status bit stays high until cleared by a write of 1 to the ALARM bit.

As with writing to time and calendar registers ([Section 28.2.4.1.4](#)), writes to the INTERRUPT and STATUS registers should only be done when the RTC is stopped or when the BUSY bit is low.

Note that all registers in the RTC except for KICKnR have write-protection. See [Section 28.2.6](#) for information on unlocking registers.

### 28.2.5.2 Periodic Interrupt Enable and Status Bits

The **TIMER** bit and **EVERY** field in the interrupt register (**INTERRUPT**) work together to enable periodic interrupts. When the **TIMER** bit is enabled, interrupts are issued at a time period indicated by the **EVERY** field (0 = Second, 1h = Minute, 2h = Hour, 3h = Day). Regardless of the period selected in the **EVERY** field, the periodic timer status bits (**DAYEVT**, **HREVT**, **MINEVT**, **SECEVT**) are set in the status register (**STATUS**) whenever they are valid. Note that the appropriate status bits are set when the **TIME** bit is enabled, not when the desired interrupt is generated. Active periodic status bits remain high as long as the **TIMER** bit is enabled.

For example, if daily periodic interrupts are enabled and the time (in HH:MM:SS format) transitions from 23:59:59 to 00:00:00, the **STATUS** register sets all four periodic status bits (**DAYEVT**, **HREVT**, **MINEVT**, and **SECEVT**) because all four time periods were incremented. These bits all remain high until:

1. The **TIME** bit is cleared and all four status bits clear to zero until **TIME** is set again **OR**
2. The current time reaches 00:00:01. At that point, the **SECEVT** remains set while the **DAYEVT**, **HREVT**, and **MINEVT** bits are cleared. The next interrupt is not generated until the next day transition.

As with writing to time and calendar registers (Section 28.2.4.1.4), writes to the **INTERRUPT** and **STATUS** registers should only be done when the RTC is stopped or when the **BUSY** bit is low.

Note that all registers in the RTC except for **KICKnR** have write-protection. See Section 28.2.6 for information on unlocking registers.

### 28.2.6 Register Protection Against Spurious Writes

All registers in the RTC except for the **KICKnR** registers are protected from spurious writes. Out of reset, writes to protected registers are disabled until the registers are unlocked using the **KICKnR** registers. To unlock the registers, a key of 83E7 0B13h needs to be written to **KICK0R**, followed by a write of 95A4 F1E0h to **KICK1R**. Registers remain unlocked until write protection is enabled again by writing any value to **KICK0R** or **KICK1R**. The write protection state machine is shown in Figure 28-3.

**Figure 28-3. Kick State Machine**

### **28.2.7 General-Purpose Scratch Registers**

The RTC provides three general-purpose registers (SCRATCH $n$ ) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCH $n$  registers to be useful in indicating RTC states. For example, the SCRATCH $n$  registers may be used to indicate write-protection lock status or unintentional power downs.

To indicate write-protection, the software should write a unique value to one of the SCRATCH $n$  registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the SCRATCH register.

To indicate unintentional power downs, the software should write a unique value to one of the SCRATCH $n$  registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the SCRATCH register is cleared.

### **28.2.8 Real-Time Clock Response to Low Power Modes (Idle Configurations)**

The device is divided into idle domains that can be programmed to be idle or active. The state of all domains is called the idle configuration. The RTC runs on its own external clock source and is not affected by any of the other device idle domains.

### **28.2.9 Emulation Modes of the Real-Time Clock**

The RTC always continues to run regardless of the state (running/halted) of the emulation debugger software.

### **28.2.10 Reset Considerations**

When the device is initially powered on, the RTC may issue spurious interrupt signals to the CPU. To avoid issues, a software reset should be performed on the RTC module before the CPU interrupt controller is initialized.

As the RTC is configured, the SPLITPOWER bit in the control register (CTRL) should be set.

A software reset is performed on the RTC by setting the SWRESET bit in the oscillator register (OSC). The software reset applies to all registers except the oscillator (OSC) and kick (KICK $n$ R) registers. The RTC requires three 32.768-kHz reference clocks to pass before RTC registers can be accessed.

## 28.3 Registers

[Table 28-2](#) lists the memory-mapped registers for the RTC. See your device-specific data manual for the memory address of these registers.

**Table 28-2. Real-Time Clock (RTC) Registers**

| Address Offset | Acronym     | Register Description                 | Section                         |
|----------------|-------------|--------------------------------------|---------------------------------|
| 0h             | SECOND      | Seconds Register                     | <a href="#">Section 28.3.1</a>  |
| 4h             | MINUTE      | Minutes Register                     | <a href="#">Section 28.3.2</a>  |

### 28.3.1 Second Register (SECOND)

**NOTE:** Out of reset, the second register (SECOND) is write-protected. To disable write protection, correct keys must be written to the KICK<sub>n</sub>R registers (see [Section 28.2.6](#)).

The second register (SECOND) sets the second value of the current time. Seconds are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The SECOND register is shown in [Figure 28-4](#) and described in [Table 28-3](#).

**Figure 28-4. Second Register (SECOND)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-3. Second Register (SECOND) Field Descriptions**

| Bit  | Field    | Value | Description                                                            |
|------|----------|-------|------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved.                                                              |
| 6-4  | SEC1     | 0-5h  | Most significant digit of second value. Range for SEC1:SEC0 is 00-59.  |
| 3-0  | SEC0     | 0-9h  | Least significant digit of second value. Range for SEC1:SEC0 is 00-59. |

### 28.3.2 Minute Register (MINUTE)

**NOTE:** Out of reset, the minute register (MINUTE) is write-protected. To disable write protection, correct keys must be written to the KICK<sub>n</sub>R registers (see [Section 28.2.6](#)).

The minute register (MINUTE) sets the minute value of the current time. Minutes are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The MINUTE register is shown in [Figure 28-5](#) and described in [Table 28-4](#).

**Figure 28-5. Minute Register (MINUTE)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-4. Minute Register (MINUTE) Field Descriptions**

| Bit  | Field    | Value | Description                                                            |
|------|----------|-------|------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved.                                                              |
| 6-4  | MIN1     | 0-5h  | Most significant digit of minute value. Range for MIN1:MIN0 is 00-59.  |
| 3-0  | MIN0     | 0-9h  | Least significant digit of minute value. Range for MIN1:MIN0 is 00-59. |

### 28.3.3 Hour Register (HOUR)

**NOTE:** Out of reset, the hour register (HOUR) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The hour register (HOUR) sets the hour value of the current time. Hours are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The HOUR register is shown in [Figure 28-6](#) and described in [Table 28-5](#).

**Figure 28-6. Hour Register (HOUR)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-5. Hour Register (HOUR) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                       |
|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0      | Reserved.                                                                                                                         |
| 7    | MERIDIEM | 0<br>1 | Determines whether the hour is ante meridiem (AM) or post meridiem (PM) when 12-hour mode is enabled.<br>Hour is AM<br>Hour is PM |
| 6    | Reserved | 0      | Reserved.                                                                                                                         |
| 5-4  | HOUR1    | 0-2h   | Most significant digit of hours value. Range for HOUR1:HOUR0 is 00-24.                                                            |
| 3-0  | HOUR0    | 0-9h   | Least significant digit of hours value. Range for HOUR1:HOUR0 is 00-24.                                                           |

### 28.3.4 Day of the Month Register (DAY)

**NOTE:** Out of reset, the day of the month register (DAY) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The day of the month register (DAY) sets the day of the month value of the current date. Days are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The DAY register is shown in [Figure 28-7](#) and described in [Table 28-6](#).

**Figure 28-7. Days Register (DAY)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-6. Day Register (DAY) Field Descriptions**

| Bit  | Field    | Value | Description                                                                      |
|------|----------|-------|----------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved.                                                                        |
| 5-4  | DAY1     | 0-3h  | Most significant digit of day of the month value. Range for DAY1:DAY0 is 01-31.  |
| 3-0  | DAY0     | 0-9h  | Least significant digit of day of the month value. Range for DAY1:DAY0 is 01-31. |

### 28.3.5 Month Register (MONTH)

**NOTE:** Out of reset, the month register (MONTH) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The month register (MONTH) sets the month in the year value of the current date. The month is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The MONTH register is shown in [Figure 28-8](#) and described in [Table 28-7](#).

**Figure 28-8. Month Register (MONTH)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-7. Month Register (MONTH) Field Descriptions**

| Bit  | Field    | Value | Description                                                                        |
|------|----------|-------|------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved.                                                                          |
| 4    | MONTH1   | 0-1h  | Most significant digit of months value. For MONTH1:MONTH0, JAN = 01 and DEC = 12.  |
| 3-0  | MONTH0   | 0-9h  | Least significant digit of months value. For MONTH1:MONTH0, JAN = 01 and DEC = 12. |

### 28.3.6 Year Register (YEAR)

**NOTE:** Out of reset, the year register (YEAR) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The year register (YEAR) sets the year value of the current date. The year is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The YEAR register is shown in [Figure 28-9](#) and described in [Table 28-8](#).

**Figure 28-9. Year Register (YEAR)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-8. Year Register (YEAR) Field Descriptions**

| Bit  | Field    | Value | Description                                                             |
|------|----------|-------|-------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved.                                                               |
| 7-4  | YEAR1    | 0-9h  | Most significant digit of years value. Range for YEAR1:YEAR0 is 00-99.  |
| 3-0  | YEAR0    | 0-9h  | Least significant digit of years value. Range for YEAR1:YEAR0 is 00-99. |

### 28.3.7 Day of the Week Register (DOTW)

**NOTE:** Out of reset, the day of the week register (DOTW) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The day of the week register (DOTW) sets the day of the week value of the current date. The day of the week is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The DOTW register is shown in [Figure 28-10](#) and described in [Table 28-9](#).

**Figure 28-10. Day of the Week Register (DOTW)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-9. Day of the Week Register (DOTW) Field Descriptions**

| Bit  | Field    | Value | Description                                 |
|------|----------|-------|---------------------------------------------|
| 31-3 | Reserved | 0     | Reserved.                                   |
| 2-0  | DOTW     | 0-6h  | Day of the week. Sunday = 0, Saturday = 6h. |

### 28.3.8 Alarm Second Register (ALARMSECOND)

**NOTE:** Out of reset, the alarm second register (ALARMSECOND) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The alarm second register (ALARMSECOND) sets the second value for the alarm interrupt. Seconds are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The ALARMSECOND register is shown in [Figure 28-11](#) and described in [Table 28-10](#).

**Figure 28-11. Alarm Second Register (ALARMSECOND)**

|          |  |  |  |  |  |  |   |       |  |  |  |       |   |  |  |    |   |
|----------|--|--|--|--|--|--|---|-------|--|--|--|-------|---|--|--|----|---|
| 31       |  |  |  |  |  |  |   |       |  |  |  |       |   |  |  | 16 |   |

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-10. Alarm Second Register (ALARMSECOND) Field Descriptions**

| Bit  | Field    | Value | Description                                                                   |
|------|----------|-------|-------------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved.                                                                     |
| 6-4  | SEC1     | 0-5h  | Most significant digit of alarm seconds value. Range for SEC1:SEC0 is 00-59.  |
| 3-0  | SEC0     | 0-9h  | Least significant digit of alarm seconds value. Range for SEC1:SEC0 is 00-59. |

### 28.3.9 Alarm Minute Register (ALARMMINUTE)

**NOTE:** Out of reset, the alarm minute register (ALARMMINUTE) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The alarm minute register (ALARMMINUTE) sets the minute value for the alarm interrupt. Minutes are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The ALARMMINUTE register is shown in [Figure 28-12](#) and described in [Table 28-11](#).

**Figure 28-12. Alarm Minute Register (ALARMMINUTE)**

|          |  |  |  |  |  |  |   |       |  |  |  |       |   |  |  |    |   |
|----------|--|--|--|--|--|--|---|-------|--|--|--|-------|---|--|--|----|---|

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-11. Alarm Minute Register (ALARMMINUTE) Field Descriptions**

| Bit  | Field    | Value | Description                                                                   |
|------|----------|-------|-------------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved.                                                                     |
| 6-4  | MIN1     | 0-5h  | Most significant digit of alarm minutes value. Range for MIN1:MIN0 is 00-59.  |
| 3-0  | MIN0     | 0-9h  | Least significant digit of alarm minutes value. Range for MIN1:MIN0 is 00-59. |

### 28.3.10 Alarm Hour Register (ALARMHOUR)

**NOTE:** Out of reset, the alarm hour register (ALARMHOUR) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The alarm hour register (ALARMHOUR) sets the hour value for the alarm interrupt. Hours are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The ALARMHOUR register is shown in [Figure 28-13](#) and described in [Table 28-12](#).

**Figure 28-13. Alarm Hour Register (ALARMHOUR)**

| 5-4  | HOUR1    | 0-2h   | Most significant digit of hours value. Range for HOUR1:HOUR0 is 00-24.                                                            |
| 3-0  | HOUR0    | 0-9h   | Least significant digit of hours value. Range for HOUR1:HOUR0 is 00-24.                                                           |

### 28.3.11 Alarm Day of the Month Register (ALARMDAY)

**NOTE:** Out of reset, the alarm day of the month register (ALARMDAY) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The alarm day of the month register (ALARMDAY) sets the day of the month value for the alarm interrupt. Days are stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The ALARMDAYS register is shown in [Figure 28-14](#) and described in [Table 28-13](#).

**Figure 28-14. Alarm Day Register (ALARMDAY)**

**Table 28-13. Alarm Day Register (ALARMDAY) Field Descriptions**

| Bit  | Field    | Value | Description                                                                      |
|------|----------|-------|----------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved.                                                                        |
| 5-4  | DAY1     | 0-3h  | Most significant digit of day of the month value. Range for DAY1:DAY0 is 01-31.  |
| 3-0  | DAY0     | 0-9h  | Least significant digit of day of the month value. Range for DAY1:DAY0 is 01-31. |

### 28.3.12 Alarm Month Register (ALARMMONTH)

**NOTE:** Out of reset, the alarm month register (ALARMMONTH) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The alarm month register (ALARMMONTH) sets the month in the year value for the alarm interrupt. The month is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The ALARMMONTH register is shown in [Figure 28-15](#) and described in [Table 28-14](#).

**Figure 28-15. Alarm Month Register (ALARMMONTH)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-14. Alarm Month Register (ALARMMONTH) Field Descriptions**

| Bit  | Field    | Value | Description                                                                        |
|------|----------|-------|------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved.                                                                          |
| 4    | MONTH1   | 0-1h  | Most significant digit of months value. For MONTH1:MONTH0, JAN = 01 and DEC = 12.  |
| 3-0  | MONTH0   | 0-9h  | Least significant digit of months value. For MONTH1:MONTH0, JAN = 01 and DEC = 12. |

### 28.3.13 Alarm Year Register (ALARMYEAR)

**NOTE:** Out of reset, the alarm year register (ALARMYEAR) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The alarm year register (ALARMYEAR) sets the year for the alarm interrupt. The year is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The ALARMYEAR register is shown in [Figure 28-16](#) and described in [Table 28-15](#).

**Figure 28-16. Alarm Year Register (ALARMYEAR)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-15. Alarm Years Register (ALARMYEARS) Field Descriptions**

| Bit  | Field    | Value | Description                                                             |

| 31-8 | Reserved | 0     | Reserved.                                                               |
| 7-4  | YEAR1    | 0-9h  | Most significant digit of years value. Range for YEAR1:YEAR0 is 00-99.  |
| 3-0  | YEAR0    | 0-9h  | Least significant digit of years value. Range for YEAR1:YEAR0 is 00-99. |

## 28.3.14 Control Register (CTRL)

**NOTE:** Out of reset, the control register (CTRL) is write-protected. To disable write protection, correct keys must be written to the KICK<sub>n</sub>R registers (see [Section 28.2.6](#)).

The control register (CTRL) is shown in [Figure 28-17](#) and described in [Table 28-16](#).

**Figure 28-17. Control Register (CTRL)**

### 28.3.17 Compensation (LSB) Register (COMPLSB)

**NOTE:** Out of reset, the compensation (LSB) register (COMPLSB) is write-protected. To disable write protection, correct keys must be written to the KICKnR registers (see [Section 28.2.6](#)).

The compensation (LSB) register (COMPLSB) works together with the COMPMSB register to set the hourly oscillator compensation value. The AUTOCOMP bit in the control register (CTRL) must be enabled for compensation to take place. The COMPLSB register is shown in [Figure 28-20](#) and described in [Table 28-19](#).

**Figure 28-20. Compensation (LSB) Register (COMPLSB)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-19. Compensations Register (COMPLSB) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                         |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved.                                                                                                                                                                                                           |
| 7-0  | COMPLSB  | 0-FFh | Lower bits of the 16-bit compensation value. The COMPMSB:COMPLSB register value is subtracted from the 32-kHz period. Compensation values are two's complement. The COMPMSB:COMPLSB value of 7F:FFh is not allowed. |

### 28.3.18 Compensation (MSB) Register (COMPMSB)

**NOTE:** Out of reset, the compensation (MSB) register (COMPMSB) is write-protected. To disable write protection, correct keys must be written to the KICKnR registers (see [Section 28.2.6](#)).

The compensation (MSB) register (COMPMSB) works together with the COMPLSB register to set the hourly oscillator compensation value. The AUTOCOMP bit in the control register (CTRL) must be enabled for compensation to take place. The COMPMSB register is shown in [Figure 28-21](#) and described in [Table 28-20](#).

**Figure 28-21. Compensation (MSB) Register (COMPMSB)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-20. Compensations Register (COMPMSB) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                         |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved.                                                                                                                                                                                                           |
| 7-0  | COMPMSB  | 0-FFh | Lower bits of the 16-bit compensation value. The COMPMSB:COMPLSB register value is subtracted from the 32-kHz period. Compensation values are two's complement. The COMPMSB:COMPLSB value of 7F:FFh is not allowed. |

### 28.3.19 Oscillator Register (OSC)

**NOTE:** Out of reset, the oscillator register (OSC) is write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The oscillator register (OSC) is shown in [Figure 28-22](#) and described in [Table 28-21](#).

**Figure 28-22. Oscillator Register (OSC)**

LEGEND: R/W = Read/Write; R = Read only; W = Write only; - $n$  = value after reset

**Table 28-21. Oscillator Register (OSC) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                          |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved.                                                                                                                                                            |
| 5    | SWRESET  | 0     | Software reset. Always reads back 0.                                                                                                                                 |
|      |          | 0     | No action.                                                                                                                                                           |
|      |          | 1     | Reset RTC module and registers (except for OSC and KICK $n$ R registers). Registers must not be accessed for three 32-kHz reference periods after reset is asserted. |
| 4-0  | Reserved | 7h    | Reserved. This field is writeable, but should only be programmed to the value of 7h.                                                                                 |

## 28.3.20 Scratch Registers (SCRATCH0-SCRATCH2)

**NOTE:** Out of reset, the scratch registers (SCRATCH $n$ ) are write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)).

The scratch registers (SCRATCH $n$ ) are 32-bit general-purpose registers that have no effect on RTC functionality. They can be used by the user arbitrarily. The SCRATCH $n$  register is shown in [Figure 28-23](#) and described in [Table 28-22](#).

**Figure 28-23. Scratch Registers (SCRATCH $n$ )**

LEGEND: R/W = Read/Write; - $n$  = value after reset

**Table 28-22. Scratch Registers (SCRATCH $n$ ) Field Descriptions**

| Bit  | Field       | Value        | Description                                                                |
|------|-------------|--------------|----------------------------------------------------------------------------|
| 31-0 | SCRATCH $n$ | 0-FFFF FFFFh | General-purpose 32-bit registers that have no effect on RTC functionality. |

## 28.3.21 Kick Registers (KICK0R, KICK1R)

The kick registers (KICK $n$ R) are used to enable and disable write protection on the RTC registers. Out of reset, the RTC registers are write-protected. To disable write protection, correct keys must be written to the KICK $n$ R registers (see [Section 28.2.6](#)). The KICK $n$ R register is shown in [Figure 28-24](#) and described in [Table 28-23](#).

**Figure 28-24. Kick Registers (KICK $n$ R)**

LEGEND: R/W = Read/Write; - $n$  = value after reset

**Table 28-23. Kick Registers (KICK $n$ R) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                                                                       |
|------|----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | KICK $n$ | 0-FFFF FFFFh | To disable RTC register write protection, the value of 83E7 0B13h must be written to KICK0R, followed by the value of 95A4 F1E0h written to KICK1R. RTC register write protection is enabled when any value is written to KICK0R. |

## Serial ATA (SATA) Controller

This chapter describes the serial ATA (SATA) controller.

| Topic                          | Page        |
|--------------------------------|-------------|
| <b>29.1 Introduction .....</b> | <b>1361</b> |
| <b>29.2 Architecture .....</b> | <b>1365</b> |
| <b>29.3 Use Cases.....</b>     | <b>1370</b> |
| <b>29.4 Registers .....</b>    | <b>1390</b> |

## 29.1 Introduction

During these times, the parallel ATA (PATA) interface has gone through changes to sustain the demands of the newly emerging applications needs. However, the PATA controller reached a point where it required major changes to satisfy the upcoming applications requirements and this led to its successor, the birth of the SATA controller. This device has a built-in SATA controller with a single HBA port operating in Advanced Host Controller Interface (AHCI) mode and is used to interface to data storage devices at both 1.5 Gbits/second and 3.0 Gbits/second line speeds. AHCI describes a system memory structure that contains a generic area for control and status, and a table of entries describing a command list where each command list entry contains information necessary to program an SATA device, and a pointer to a descriptor table for transferring data between system memory and the device.

### 29.1.1 Purpose of the Peripheral

The SATA controller addresses the drawback of the PATA interface architecture, throughput, and protocol perspectives. PATA required 40/80 wire parallel cable with a length requirement not exceeding 18 inches. With the current hardware design, PATA's maximum transfer rate saturated to a 133 Mbytes/second of transfer. In addition to newly added features, like Hot swapping and native command queuing, the SATA controller abandoned the parallel physical interface and transitioned to a serial format using two differential pairs supporting up to 3 Gbits/second transfer rate, translating to a 300 Mbytes/second raw throughput.

With the intent on handling the previous and current role of the PATA controller and addressing the future needs, the SATA controller is architected with the option of operating in a Legacy mode, a mode that behaves similar to the PATA controller from the protocol/driver perspective, and a new AHCI mode that is different from the Legacy mode allowing it to overcome the drawbacks of PATA as well as extending PATA's capabilities. The SATA controller that is supported by this device supports AHCI mode of operation only. AHCI is a PCI class device that acts as a data movement engine between system memory and serial ATA devices. However, the AHCI controller on this device is integrated within the core chipset, a common attribute for embedded devices. The AHCI controller supported has no support for Legacy mode of operation.

Communication between a device and software moves from the task file via byte-wide accesses to a command FIS located in system memory that is fetched by the HBA. This reduces command setup time significantly, allowing for many more devices to be added to a single host controller. Software no longer communicates directly to a device via the task file. In other words, all data transfers between the device and system memory occur through the HBA acting as a bus master to system memory. Whether the transaction is of a DMA type or a PIO type (the use of the PIO command type is strongly discouraged and all transfers should be performed using DMA unless otherwise that a transaction is only performed via PIO command), the HBA fetches and stores data to memory, offloading the CPU. There is no accessible data port. Software written for AHCI is not allowed to utilize any of the legacy mechanisms to program devices.

The SATA controller uses a less massive thinner flexible cable that can be up to 3 feet (1 meter) in length allowing for easier routing and better air ventilation inside a case. Its power budget is significantly reduced to 250 mV compared to the required 5V power of PATA.

Like its predecessor, the SATA controller is most commonly used by PCs and portable devices to interface a host processor with data storage or CD/audio devices. It also has the support for hot swapping capability. It also supports the use of a Port Multiplier to increase the number of devices that can be attached to the single HBA port.

### 29.1.2 Features Supported

The main features of the SATA controller are:

- Synopsis DWH Serial ATA 1.5 Gbps and 3 Gbps speeds core
- Support for the AHCI controller spec 1.1
- Integrated TI SERDES PHY
- Integrated Rx and Tx data buffers
- Supports all SATA power management features
- Internal DMA engine per port
- Hardware-assisted native command queuing (NCQ) for up to 32 entries

- 32-bit addressing
- Supports port multiplier with command-based switching
- Activity LED support
- Mechanical presence switch
- Cold presence detect

### 29.1.3 Features Not Supported

Features not supported in this SATA controller are:

- Legacy mode of operation
- Master/slave type of configuration
- Far-end analog loopback
- Message signaled interrupts
- 64-bit addressing

### 29.1.4 Functional Block Diagram

The SATA subsystem (SATASS) is a fully contained serial ATA host with built-in DMA. It uses the AHCI standard for communication with a SATA device. It has no support for the Legacy mode of operation. [SATA Subsystem Functional Block Diagram](#) shows a high-level block diagram of the SATA subsystem (core and the integrated TI PHY). [SATA Core Block Diagram](#) shows a high-level block diagram of the SATA core.

## SATA Subsystem Functional Block Diagram (continued)

### SATA Core Block Diagram

### 29.1.5 Terminology Used in this Document

The following is a brief explanation of some terms used in this document:

| Term         | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AHCI         | Advanced host controller Interface (necessary for implementing newly supported features like native command queuing). Freon device supports only this mode of operation, i.e., has no support for Legacy mode. It also reduces CPU/Software overhead when moving data in and out of the system memory. Note that system software is responsible to ensure that queued and non-queued commands are not mixed in the command list. |
| ATA/ATAPI    | AT attachment/ATA packet interface                                                                                                                                                                                                                                                                                                                                                                                               |
| CF           | Compact Flash                                                                                                                                                                                                                                                                                                                                                                                                                    |
| device       | External SATA or ATAPI device attached to the SATA controller                                                                                                                                                                                                                                                                                                                                                                    |
| DMA          | DMA within the ATA controller, not the processor EDMA system                                                                                                                                                                                                                                                                                                                                                                     |
| DWORD        | DWORD is 32 bits of data.                                                                                                                                                                                                                                                                                                                                                                                                        |
| command list | A memory buffer for as much as 32 commands. Each command is entered in a command slot. This is a required feature when supporting command queuing.                                                                                                                                                                                                                                                                               |
| command slot | A subset of the command list. It is the memory buffer for a single command. A total of 32 command slots exist.                                                                                                                                                                                                                                                                                                                   |
| D2H          | Device to HBA. Mostly used to indicate the direction of the transmission of FIS that is from device to the HBA (host).                                                                                                                                                                                                                                                                                                           |
| FIS          | Frame Information Structure. A frame is made of a data payload with computed CRC and a start and end primitives.                                                                                                                                                                                                                                                                                                                 |
| H2D          | HBA to device. Mostly used to indicate the direction of the transmission of FIS that is from HBA (host) to device.                                                                                                                                                                                                                                                                                                               |
| HBA          | Host bus adapter. It is the SATA controller that implements the AHCI specification to communicate between system memory and Serial ATA devices.                                                                                                                                                                                                                                                                                  |
| Legacy mode  | This mode of operation makes the user access (application software or driver) to view the SATA controller in a similar fashion as a PATA controller. This device does not support this mode of operation but AHCI mode of operation.                                                                                                                                                                                             |

| Term            | Meaning                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OOB             | Out of band. OOB signaling is used for during device detection and when recovering from power states.                                                                                                                                                                                                    |
| PORT            | Refers to HBA port mainly, within this document. However, the PORT is also be used to refer to a port of a PORT Multiplier.                                                                                                                                                                              |
| PRD             | Physical region descriptor. A PRD table is a data structure used by DMA engines that comply with the ATA/ATAPI Host Adapters standard. The PRD describes memory regions to be used as the source or destination of data during DMA transfers. A PRD table is often referred to as a scatter/gather list. |
| PM              | Port Multiplier. A Port Multiplier allows extending an HBA port connection capability to connect to multiple SATA devices, a maximum of 15 devices. Note that the operating bandwidth is shared amongst all the Devices when using this type of configuration                                            |
| SATA controller | Serial ATA controller, also HBA.                                                                                                                                                                                                                                                                         |
| System memory   | The memory that is external from the SATA controller but is a memory that is accessible by the built in SATA controller DMA or the CPU.                                                                                                                                                                  |

### 29.1.6 Industry Standard(s) Compliance

This module is compliant with the SATA revision 2.6 Gold standard and the AHCI revision 1.1 specifications.

## 29.2 Architecture

This section discusses the architecture of the Serial ATA Controller. The Serial ATA Controller supports Advanced Host Controller Interface (AHCI) operation only. It does not support the Legacy mode of operation. Since the controller complies with the AHCI standard (version 1.1) the details of its operation is detailed within the AHCI version 1.1 specification. See the specification for the general behavior of the SATA Core operation. The SATA Controller supported within the Freon device has a single HBA port.

### 29.2.1 Clock Control

The SATA controller uses two internal clocks (SYSCLK2 and SYSCLK4) and one external differential clock (REFCLKP/N) for its operation. SATA controller access to CPU and its resources is implemented through, SYSCLK2 (PLL0 output frequency divided by 2). SYCLK2 to the SATA controller is gated by the PSC and is required to be enabled prior to accessing the SATA controller. SYCLK4 (PLL0 output frequency divided by 4), is the keep alive clock and is always ON.

A high quality low jitter external differential clock is required as a source clock input for the PHY and the frequency of the input clock should be between 75MHz and 375 MHz (depending upon the supported multiplier used). Maximum Jitter should not exceed 50ps pk-pk. Duty cycle must be between 40 and 60%. Nominal Rise/fall time should be 700 ps.

This input frequency requirement is dependent upon the supported PHY PLL multiplier value. The MPY field of the port PHY control register (P0PHYCR) is programmed with the PLL multiplier value based on the input frequency clock. Note that the PHY PLL output frequency should be exactly 1.5GHz (for both 3 and 1.5 Gbits/Sec line rate) and its accuracy is very important to the operation of the SATA controller.

[Table 29-1](#) shows the MPY bit field of P0PHYCR for supported PHY PLL multiplier values.

**Table 29-1. MPY Bit Field of P0PHYCR**

| MPY Bit Field Value | Effect   |
|---------------------|----------|
| 0                   | Reserved |
| 1h                  | 5×       |
| 2h                  | 6×       |
| 3h                  | Reserved |
| 4h                  | 8×       |
| 5h                  | 10×      |
| 6h                  | 12×      |
| 7h                  | 12.5×    |
| 8h                  | 15×      |
| 9h                  | 20×      |
| Ah                  | 25×      |
| Bh-Fh               | Reserved |

## 29.2.2 Signal Description

This device has bonded the Data lines (two sets of differential data lines) along the pins necessary for detecting device insertion, power supply needs and powering a device. The power pins necessary to power up a cold SATA device should be handled external to the device, on the board along the signal path connector.

**Table 29-2. Signal Descriptions**

| Terminal Name  | Type   | Description                                                                       |
|----------------|--------|-----------------------------------------------------------------------------------|
| SATA_RXP       | Input  | SATA receive data (positive)                                                      |
| SATA_RXN       | Input  | SATA receive data (negative)                                                      |
| SATA_TXP       | Output | SATA transmit data (positive)                                                     |
| SATA_TXN       | Output | SATA transmit data (negative)                                                     |
| SATA_REFCLKP   | Input  | SATA PHY reference clock (positive)                                               |
| SATA_REFCLKN   | Input  | SATA PHY reference clock (negative)                                               |
| SATA_MP_SWITCH | Input  | SATA mechanical presence switch input                                             |
| SATA_CP_DET    | Input  | SATA cold presence detect input                                                   |
| SATA_CP_POD    | Output | SATA cold presence power-on output                                                |
| SATA_LED       | Output | SATA LED control output                                                           |
| SATA_REG       | Output | SATA PHY PLL regulator output. Requires an external 0.1 $\mu$ F filter capacitor. |
| SATA_VDDR      | Power  | SATA PHY 1.8V internal regulator supply                                           |
| SATA_VDD       | Power  | SATA PHY 1.2V logic supply                                                        |
| SATA_VSS       | Ground | SATA PHY ground reference                                                         |

## 29.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. Refer to the device-specific data manual to determine how pin multiplexing affects the SATA.

## 29.2.4 Interfacing to Single and Multiple Devices

The SATA Controller supports a single HBA port. This HBA port can be used to interface directly to a single SATA device or to multiple SATA devices via a Port Multiplier. Note that on a multiple target setup, the available bandwidth will be shared amongst all the attached devices.

Note that Port Multipliers and Power Supplies for external SATA devices, when needed, should be furnished external to the device. However, the appropriate signals for controlling power and device detection are bonded and can be controlled via software.

### 29.2.4.1 Interfacing to a Single Device

If you need to interface directly to a single device, there is no need of populating a Port Multiplier. The software needs to ensure that the PMP field within the Command Header and the PM\_PORT field of the FIS be cleared at all times.

If the external SATA device is not Self Powered, it is the responsibility of the System Designer to populate and furnish the right power supply needed. Consult the SATA specification for details.

### 29.2.4.2 Interfacing to Multiple Devices

Interfacing to multiple devices is similar to interfacing with a single device, except the existence of a Port Multiplier on the setup. The couple of additional tasks from the software perspective is that the requirement for the software to detect and configure the Port Multiplier prior and then after when accessing individual SATA devices, the software is required to populate the PMP field of the Command Headers and PM\_PORT field of the FISes with the Port Multiplier Port value.

### 29.2.5 DMA

The HBA port contains two DMA engines: one to fetch commands from the command list and one to move FISes in and out of system memory.

The DMA used to move FISes in and out of system memory has a port DMA control register (PODMACR) to control the burst transfer. This DMA is used to transfer all information between system memory and the attached SATA device, as well as configuration and status FISes.

You can program the maximum burst size that is issued on the system bus independently for both reads and writes. The DMA issues transactions this size or smaller (in DWORD increments). This is used to optimize burst size for overall system throughput efficiency. See [Section 29.4.33](#) for details on valid values. Note that programming a burst size of greater than a transaction size, while not invalid, is meaningless because the DMA maximizes out at transaction size.

You can also program the transaction size for both receive and transmit (see [Section 29.4.33](#)). The transaction size is the minimum amount of data that the DMA works on. For example, if there is a FIS coming from the device to the host, the DMA does not begin transferring data into system memory until there is at least rx\_transaction\_size (RXTS) data in the receive FIFO. During transmit, the DMA reads data from system memory in tx\_transaction\_size (TXTS) increments to put into the transmit FIFO. Note that transactions may be broken up into multiple bursts based on burst size, crossing of a 1K boundary, or end-of-frame.

### 29.2.6 Transport Layer

The transport layer handles all of the transport layer functions of the SATA protocol. During reception, it receives a FIS from the Link layer via the Rx FIFO, decodes the type, and routes it to the proper location via the port DMA. During transmission, it transfers a FIS constructed by the port DMA to the link layer via the Tx FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system.

The transport layer also contains the Tx and Rx FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystems ability to buffer data before flow control must be asserted. It also affects the maximum programmable transaction and burst sizes that can be programmed into the port DMA. The Tx FIFO size is 32 DWORDS (124 bytes) deep and the Rx FIFO size is 64 DWORDS (256 bytes) deep.

### 29.2.7 Link Layer

The link layer maintains the link and supports all SATA link layer functionality including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/de-framing
- CRC calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

### 29.2.8 Phy

The SATASS includes an integrated TI SERDES macro as a phy. The phy handles all of the serialization/de-serialization, symbol alignment, and Rx OOB signal detection. There is some logic between the Synopsis core and the SERDES for control and configuration.

### 29.2.9 Reset

SATA peripheral reset is handled using the power and sleep controller (PSC). For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter. Other types of resets supported by the SATA controller are part of the AHCI specification is discussed within the AHCI specification 1.1. See the standard specification for the details on HBA reset, port rest and software reset.

### 29.2.10 Initialization

Proper initialization of the HBA is required after power-up to ensure proper operation of the SATA controller peripheral. The initialization process starts by performing a write to one-time write-only registers, this is documented as firmware initialization within the AHCI specification, where the values written depends on the features that the applications supports followed by software initialization. This part of the initialization is similar to what a PC BIOS does and allows you to enable/disable some features by software.

The software can then continue with a normal initialization that is required by the software and the details and sequence of initialization done here is also documented within the AHCI specification. In general, all resources that are required by the AHCI controller, PHY initialization, structures and memories for Command Slots, FIS, and Data Memories are configured and the FIS DMAs is enabled. The software will then spin-up the device and ensure that a proper Device Detection and Speed Negotiation has completed prior to enabling the Command DMA.

Note that DMA Configuration/Initialization should take place after Device Detection and Speed Negotiation. If done earlier, the default value is used (this is the recommended setting) since RESET removes the initialized value. The only time it is advisable to change the DMA Configuration is if you need to prioritize System Resource access. It also requires that the Command DMA is not running (P0CMD.ST = 0) when modifying the value of the DMA Configuration fields.

#### 29.2.10.1 Initialization (Firmware and Software)

Software reads the HBA capabilities register (CAP), ports implemented register (PI), AHCI version register (VS), global parameter 1 register (GPARAM1R), global parameter 2 register (GPARAM2R), and the port parameter register (PPARAMR) to obtain information about the subsystems capabilities. The software should then take the following steps to configure each port for operation:

1. Do all firmware capability writes.
2. Setup all appropriate structures in memory as per the AHCI specification.
3. Configure the PHY using the port PHY control register (P0PHYCR):
  - (a) Set the MPY bit field for the PLL multiply factor.
  - (b) Set LOS = 1 (enable loss of signal detection)
  - (c) Set ENPLL = 1 (enable the PLL)
4. Set the port command list base address register (P0CLB).
5. Set the port FIS base address register (P0FB).
6. Set appropriate bits in the port command register (P0CMD).
7. Program the port serial ATA control register (P0SCTL).
8. Wait for Device Detection and Speed Negotiation to end.
9. Program the port DMA control register (P0DMACR).
10. Enable the appropriate interrupts.
11. Enable FIS reception in P0CMD.
12. Spin-up the device(s), if necessary.

### 29.2.10.2 Issuing a Command

Once the host and device are configured, perform the following steps to issue a command:

1. Create the appropriate FIS in system memory.
2. Create the PRD.
3. Queue the command to the command queue list (location specified by the port command list base address register (POCLB)).

For detailed information, see the AHCI Specification Version 1.1.

### 29.2.11 Interrupt Support

The AHCI controller supports both standard interrupt sourcing, where interrupts are generated when enabled events occur, or a different type method of generating interrupts that minimize interrupt loading by either generating interrupts in a batch or periodically.

The interrupt handling method where interrupt loading issue is a factor is handled using Command Completion Coalescing method.

#### 29.2.11.1 Command Completion Coalescing

Command Completion Coalescing (CCC) is a feature designed to reduce the interrupt and command completion overhead in a heavily loaded system. The feature enables the number of interrupts taken per completion to be reduced significantly, while ensuring a minimum quality of service for command completions. When software specified number of commands have completed or a software specified timeout has expired, an interrupt is generated by hardware to allow software to process completed commands. the command completion coalescing ports register (CCC\_PORTS) should be programmed with 1 to indicate that the single available port, Port0, is selected.

For a detailed explanation of the CCC initialization and usage, see the AHCI Specification 1.1 Section 11.6.

##### 29.2.11.1.1 CCC Interrupt Based on Timer Expiration

When CCC is enabled and the desired method to receive an interrupt is based on a timer elapse condition, then you need to communicate a resolution for a 1ms time by programming the BIST DWORD error count register (TIMER1MS) with the VBUS cycle count derived from the VBUS clock frequency sourced to the SATA controller. For a DSP clock frequency of 300 MHz, the VBUS Clock is 150 MHz and the 1ms cycle count is  $150 \text{ MHz}/1000 = 150000$ . This means that when the TV bit in the command completion coalescing control register (CCC\_CTL) is a non-zero value and the EN bit in CCC\_CTL is set to 1 (CCC is enabled), it will take 15 ms or  $15 \times 150000 = 2,250,000$  VBUS cycles for the timer to elapse and when it does, the CCC generates an interrupt. This happens periodically until disabled.

---

**NOTE:** Make sure the CC bit in the command completion coalescing control register (CCC\_CTL) is cleared to 0.

---

##### 29.2.11.1.2 CCC Interrupt Based on Completion Count

When CCC is enabled and the desired method to receive an interrupt is based on a completion count, that is, the CC bit in the command completion coalescing control register (CCC\_CTL) is programmed with a non-zero value and the CCC interrupt is enabled (EN bit in CCC\_CTL is set to 1), an interrupt is sourced from the SATA controller when the programmed desired number of interrupt is received.

---

**NOTE:** Make sure the TV bit in the command completion coalescing control register (CCC\_CTL) is cleared to 0.

---

### 29.2.11.2 Non CCC Interrupt Configuration

For a standard interrupt handling method where every event that is enabled generates an interrupt, is handled as follows. For more information, see the AHCI Specification.

After insuring that CCC is disabled, the EN bit in the command completion coalescing control register (CCC\_CTL) is 0, in order for the SATA Core to source interrupts, the interrupt should be enabled at both the global level (the IE bit in the global HBA control register (GHC) is 1) and at the port level by enabling the bit fields for the desired interrupt. An enable bit at a Port level that control interrupts dispatch to the processor interrupt handling resource. So long as the CPU interrupt handler is configured properly, the CPU receives the interrupt when the enabled event occurs.

### 29.2.12 EDMA Event Support

The SATA controller makes use of its own built-in DMA and has no need nor utilizes the processor EDMA.

### 29.2.13 Power Management

The SATA controller can be placed in reduced power modes to conserve power during periods of no use. The main power management of the peripheral is controlled by the processor power and sleep controller (PSC). The PSC acts as a master controller for power management of all of the peripherals on the processor. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

During times of the SATA peripheral use, the SATASS supports the industry standard power-down modes (both Partial and Slumber low-power modes) as provided within the SATA specification. These modes allow for power savings through powering down part of the SERDES PHY and the ability to gate off the clocks to the link layer. The Port Power Control Module is used to enter and exit these modes that may have the normal functional clocks gated off.

---

**NOTE:** When SATA communication is in the idle state, that is, when no disk activity takes place, the communication remains active with both the host and the device sending a logical sync primitive and scrambled data at the speed negotiated continuously. For power sensitive applications, the power consumed during the disk inactivity stage might be undesirable and it might be a desired task to place the communication interface into an electrical idle (Partial or Slumber) state until data transfer activity is needed in order to conserve power.

---

## 29.3 Use Cases

The following sections include some sample program snippets that can be used as a guide for software development. The example demonstrates one of the ways of creating the necessary structures; properly aligned system memory resources, initialization, as well as performing basic DMA Read/Write transfer using Couple of Command Slots.

[Section 29.3.1](#) contains examples in relations to System Memory resource allocations, Structures, and Subroutines used by the Initialization and Read/Write Transfer functions. The remaining sections include examples of basic Initialization, DMA Write transfer, and DMA Read transfer examples.

### 29.3.1 General Utilities: Structures and Subroutines Sample Program Uses

```

/* Allocating memory for Command List. The structure pointed to by this
   address range is 1K-bytes in length and must be 1K-byte aligned.
   Note that each command header occupies 32 bytes of memory and 32
   command headers require 1024 bytes of memory.
*/

```

### 29.3.3 Example of DMA Write Transfer

```
void performDmaWrite(void) {
// WRITE DMA
/*
    When performing the Non-Queued Command "Write DMA" the following captures the FISes that are
    communicated between Host (HBA) and Device (SpeedBridge or SATA Drive).

    HBA ==> Device    H2D FIS (Command FIS that has the "Write DMA" Command within H2D.Command
    field).
    Device ==> HBA    DMA Activate FIS (Device notifies HBA that it's ready to receive data).
    HBA ==> Device    Data FIS (Actual Data Requested and pointed by the DMA/PRD Contents within
    Command Table).
    Device ==> HBA    D2H FIS (Completion Status from Device)

    If need to capture Interrupt (just have only the Flag set) at:
    Global Level (IS Register), need to enable P0IE.Interrupt field.
    Port Level (No Enable bit needs to be set. P0IS will be set if D2H FIS DW0.Byte1.bit6 is set).

    If need to generate Interrupt at:
    Global Level (enable interrupt by setting GHC.IE bit field and P0IE.xxx should be set to
    enable particular interrupt). Port Level interrupt handling is a subset of Global Level.
    Port Level (So long as Global Level interrupt is not enabled, GHC.IE is set, Interrupt will
    not be sent to CPU just from Port Level only).
*/
// Write to Disk

    cmdSlot2Use=0;
    associateSysMem2Hba(cmdSlot2Use);    // Associate Sys Memory to CmdList and PRDs to Cmd Table

    //Initialize PRD Data Buffer Memory
    //  initMemory((Uint32 *)&prdTableDataBuff[cmdSlot2Use],
    (sata_input_prdLength*DATABUFFERLEN/4), 0x12345678, 0x01010101);

    // Configure Device 28 bit LBA Address (Start Address for Rd/Wr Transfer);
    Dev28bitLbaAddress    = sata_input_startAddress; // 28-Bit LBA Address

    // If problem exist when setuping CmdList, stay here. If not continue
    setupCfisEntriesForDataRdWr(&CmdLists[cmdSlot2Use], DATA_DIR_WR, DMA_PROTOCOL); // Usage:
    setupCfisEntriesForDataRdWr(CmdListHeader *, DataDir, xferProtocol)
    // DataDir = DATA_DIR_RD or
DATA_DIR_WR, xferProtocol = PIO/DMA_PROTOCOL
    // Write cfis Data
    buildCmdFis(&CmdTable[cmdSlot2Use]);

    //getCmdFis(&CmdTable[0]);

    startCmdListProcessing(); // Stay here if unable to start processing command list.

    submitCmd (NON_QUEUED_CMD, cmdSlot2Use);    // Usage: CommandType (QUEUED(NON_QUEUED)_CMD,
    Command Slot);

    if(intHandlingMethod == USE_INT_HANDLER) { //    USE_POLLING or USE_INT_HANDLER
        while(intIsrFlag==0);
        intIsrFlag=0;
    }
    else
        while(sataRegs->IS == 0);    // Stay here until an interrupt is received.

    // If P0IS.DPS is set, A PRD with the 'I' bit set has transferred all of its data.
    // This bitfield might not bit set for Non-Queued DMA. Applicable for Queued DMA
    //while(getRegStatus((Uint32*)&sataRegs->P0IS, AHCI_P0IS_DPS) == 0); // getRegStatus(ptr2int,field Mask)
```

```

>P0CI, (1<<cmdSlot2Use)) == (1<<cmdSlot2Use));    // Wait Until P0CI[ChHeader] to be cleared by
HBA

    // Clears both P0IS and IS register. Only Clears RWC bit fields. So, it is OK for this task.
    clearIntOrErrorDiag(INTFIELDS, sataRegs->P0IS);    // Clear P0IS Register
}

```

### 29.3.4 Example of DMA Read Transfer

```

void performDmaRead() {
// READ DMA
/*
When performing the Non-Queued Command "Read DMA" the following captures the FISes that are
communicated between Host (HBA) and Device (SpeedBridge or SATA Drive).

HBA ==> Device    H2D FIS (Command FIS that has the "Read DMA" Command within H2D.Command
field).
Device ==> HBA    Data FIS (Actual Data Requested and pointed by the DMA/PRD Contents within
Command Table).
Device ==> HBA    D2H FIS (Completion Status from Device)

If need to capture Interrupt (just have only the Flag set) at:
Global Level (IS Register), need to enable P0IE.Interrupt field.
Port Level (No Enable bit needs to be set. P0IS will be set if D2H FIS DW0.Byte1.bit6 is set).

If need to generate Interrupt at:
Global Level (enable interrupt by setting GHC.IE bit field and P0IE.xxx should be set to
enable particular interrupt). Port Level interrupt handling is a subset of Global Level.
Port Level (So long as Global Level interrupt is not enabled, GHC.IE is set, Interrupt will
not be sent to CPU just from Port Level only).
*/
// Read from Disk
cmdSlot2Use=1;
associateSysMem2Hba(cmdSlot2Use);    // Associate Sys Memory to CmdList and PRDs to Cmd Table

//Initialize PRD Data Buffer Memory
//  initMemory((Uint32 *)&prdTableDataBuff[cmdSlot2Use],
(sata_input_prdLength*DATABUFFERLEN/4), 0xDEADBEEF, 0x00000000);

// Configure Device 28 bit LBA Address (Start Address for Rd/Wr Transfer);
Dev28bitLbaAddress    = sata_input_startAddress; // 28-Bit LBA Address

    setupCfisEntriesForDataRdWr(&CmdLists[cmdSlot2Use], DATA_DIR_RD, DMA_PROTOCOL);    // Usage:
setupCfisEntriesForDataRdWr(CmdListHeader *, DataDir, xferProtocol)
// DataDir = DATA_DIR_RD or
DATA_DIR_WR, xferProtocol = PIO/DMA_PROTOCOL
// Write cfis Data
buildCmdFis(&CmdTable[cmdSlot2Use]);

//getCmdFis(&CmdTable[cmdSlot2Use]);

startCmdListProcessing(); // Stay here if unable to start processing command list.

submitCmd (NON_QUEUED_CMD, cmdSlot2Use); // Usage: CommandType (QUEUED(NON_QUEUED)_CMD,
Command Slot);

if(intHandlingMethod == USE_INT_HANDLER) { //    USE_POLLING or USE_INT_HANDLER
    while(intIsrFlag==0);
    intIsrFlag=0;
}

```

```

    }
    else
        while(sataRegs->IS == 0); // Stay here until an interrupt is received.

    // If P0IS.DPS is set, A PRD with the 'I' bit set has transferred all of its data.
    // This bitfield might not bit set for Non-Queued DMA. Applicable for Queued DMA
    //while(getRegStatus((Uint32*)&sataRegs->P0IS, AHCI_P0IS_DPS) == 0); // getRegStatus(ptr2int,field Mask)

    // Clears both P0IS and IS register. Only Clears RWC bit fields. So, it is OK for this task.
    clearIntOrErrorDiag(INTFIELDS, sataRegs->P0IS); // Clear P0IS Register
}

```

## 29.4 Registers

Due to the support of a standard controller, that is compliant with the AHCI 1.1 specifications, the memory-map of the controller and the register descriptions matches the memory-map documented within the standard. For features that are not part of the standard, for example, DMA burst control or built-in self test, the reserved locations are used to document the necessary registers required by the non-standard features.

The subsystem core contains register space for global host programming and space for port programming (this device supports a single Host Port, but the AHCI specification calls for the support of multiple Host ports and the register space partitioning comes from this perspective). All registers that start below offset address 100h are global and meant to apply to the entire HBA. The port control registers are the same for all ports and there are as many register banks as there are ports for hosts with multiple ports. This device supports only one HBA port and has a single register bank for Port 0. [Table 29-3](#) shows the single bank of registers that are available for use.

**Table 29-3. SATASS Memory Summary**

| Module Name        | Base Address | Size      |
|--------------------|--------------|-----------|
| SATA Core (Global) | 01E1 8000h   | 256 Bytes |
| SATA Port 0        | 01E1 8100h   | 128 Bytes |

[Table 29-4](#) lists the registers in the subsystem. Note that a special class of registers whose reset state is listed as W/RO (write/read only) requires a one time initialization after power-up. These registers are written once after a hard reset by firmware, and then remain as read-only thereafter; these registers are not affected by software reset.

**Table 29-4. SATA Controller Registers**

| Address Offset | Acronym   | Register Description                           | Section                         |

### 29.4.1 HBA Capabilities Register (CAP)

The HBA capabilities register (CAP) indicates basic capabilities of the DWC SATA AHCI to the driver software. The CAP is shown in [Figure 29-1](#) and described in [Table 29-5](#).

**Figure 29-1. HBA Capabilities Register (CAP)**

|      |      |       |        |        |      |     |       |      |      |     |     |      |     |
|------|------|-------|--------|--------|------|-----|-------|------|------|-----|-----|------|-----|
| 31   | 30   | 29    | 28     | 27     | 26   | 25  | 24    | 23   | 20   | 19  | 18  | 17   | 16  |
| S64A | SNCQ | SSNTF | SMPS   | SSS    | SALP | SAL | SCLO  | ISS  | SNZO | SAM | SPM | Rsvd |     |
| R-0  | R-1  | R-1   | W/RO-0 | W/RO-0 | R-1  | R-1 | R-1   | R-2h |      | R-0 | R-1 | R-1  | R-0 |

LEGEND: R/W = Read/Write; R = Read only; W/RO: written once after hard reset by firmware, then remain as read-only;  
-n = value after reset

**Table 29-5. HBA Capabilities Register (CAP) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                              |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | S64A     | 0     | Indicates Support for 64-Bit Addressing. The SATASS only supports 32-bit addressing so this bit is always 0.                                                                                             |
| 30    | SNCQ     | 1     | Supports Native Command Queuing. SATASS supports SATA native command queuing by handling DMA Setup FIS natively.                                                                                         |
| 29    | SSNTF    | 1     | Supports SNotification Register. SATASS supports P0SNTF (SNotification) register and its associated functionality.                                                                                       |
| 28    | SMPS     | 0     | Supports Mechanical Presence Switch. This bit is set by firmware when the platform supports a mechanical presence switch for hot plug operation.                                                         |
| 27    | SSS      | 0     | Supports Staggered Spin-Up. Only writable once after power up.                                                                                                                                           |
| 26    | SALP     | 1     | Supports Aggressive Link Power Management. SATASS supports auto-generating (Port-initiated) Link Layer requests to the PARTIAL or SLUMBER power management states when there are no commands to process. |
| 25    | SAL      | 1     | Supports Activity LED.                                                                                                                                                                                   |
| 24    | SCLO     | 1     | Supports Command List Override. Supports the P0CMD.CLO bit functionality for Port Multiplier devices enumeration.                                                                                        |
| 23-20 | ISS      | 2h    | Interface Speed Support. SATASS Supports 1.5 and 3 Gbps.                                                                                                                                                 |
| 19    | SNZO     | 0     | Supports Non-Zero DMA Offsets. Not supported.                                                                                                                                                            |
| 18    | SAM      | 1     | Supports AHCI Mode Only. SATASS supports AHCI mode only and does not support legacy, task-file based register interface.                                                                                 |
| 17    | SPM      | 1     | Supports Port Multiplier. SATASS supports command-based switching Port Multiplier on any of its Ports.                                                                                                   |
| 16    | Reserved | 0     | Reserved.                                                                                                                                                                                                |
| 15    | PMD      | 1     | PIO Multiple DRQ Block. SATASS supports multiple DRQ block data transfers for the PIO command protocol.                                                                                                  |
| 14    | SSC      | 1     | Slumber State Capable. SATASS supports transitions to the interface SLUMBER power management state.                                                                                                      |
| 13    | PSC      | 1     | Partial State Capable. SATASS supports transitions to the interface PARTIAL power management state.                                                                                                      |
| 12-8  | NCS      | 1Fh   | Number of Command Slots. SATASS supports 32 command slots per Port.                                                                                                                                      |
| 7     | CCCS     | 1     | Command Completion Coalescing Supported. SATASS supports command completion coalescing.                                                                                                                  |
| 6     | EMS      | 0     | Enclosure Management Supported. Enclosure Management is not supported.                                                                                                                                   |
| 5     | SXS      | 0     | Supports External SATA.                                                                                                                                                                                  |
| 4-0   | NP       | 0     | Number of Ports. Indicates the number of Ports supported by the SATSS.<br>1 Port                                                                                                                         |

### 29.4.2 Global HBA Control Register (GHC)

The global HBA control register (GHC) provides various global functions for the SATASS. The GHC is shown in [Figure 29-2](#) and described in [Table 29-6](#).

### Figure 29-2. Global HBA Control Register (GHC)

### Table 29-6. Global HBA Control Register (GHC) Field Descriptions

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | AE       | 1     | AHCI Enable. This bit is always set since SATASS supports only AHCI mode as indicated by the SAM bit in the HBA capabilities register (CAP) = 1.                                                                                                                                                                                                                                                                                                                                                                       |
| 30-2 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 1    | IE       |       | Interrupt Enable. This global bit enables interrupts from the SATASS. This field is reset on Global reset (GHC.HR = 1).                                                                                                                                                                                                                                                                                                                                                                                                |
|      |          | 0     | All interrupt sources from all the Ports are disabled (masked).                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|      |          | 1     | Interrupts are enabled and any SATASS interrupt event causes interrupt output assertion.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0    | HR       | 0     | HBA Reset. When set by the software, this bit causes an internal Global reset of the SATASS. All state machines that relate to data transfers and queuing return to an idle state, and all the Ports are reinitialized by sending COMRESET if staggered spin-up is not supported. If staggered spin-up is supported, then it is the responsibility of the software to spin-up each Port after this reset has completed. The SATASS clears this bit when the reset action is done. A software write of 0 has no effect. |

### 29.4.3 Interrupt Status Register (IS)

The interrupt status register (IS) indicates which port inside of the subsystem has a pending interrupt. The IS is shown in [Figure 29-3](#) and described in [Table 29-7](#).

**Figure 29-3. Interrupt Status Register (IS)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -n = value after reset

**Table 29-7. Interrupt Status Register (IS) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1-0  | IPS[n]   | 0-1   | Interrupt Pending Status. If a bit <i>n</i> is set to 1 If set, the corresponding Port has an interrupt pending. Software can use this information to determine which Ports require service after an interrupt. The bits of this field are set by the Ports that have interrupt events pending in the port interrupt status register (POIS) bits and enabled by the port interrupt enable register (POIE) bits. Set bits are cleared by the software writing 1 to all bits to clear. |

#### 29.4.4 Ports Implemented Register (PI)

The ports implemented register (PI) indicates which ports are exposed by the SATASS and are available for software to use. It is loaded by the BIOS. For example, if the SATASS supports 8 Ports as indicated in the CAP.NP, only Ports 1, 3, 5, and 7 could be available, while Ports 0, 2, 4, and 6 being unavailable. Note that this sub-system only has a single port so software should write a 0x1 to this bit at power-up. The PI is shown in [Figure 29-4](#) and described in [Table 29-8](#).

### Figure 29-4. Ports Implemented Register (PI)

LEGEND: R/W = Read/Write; R = Read only; W/RO: written once after hard reset by firmware, then remain as read-only; -n = value after reset

### Table 29-8. Ports Implemented Register (PI) Field Descriptions

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 1-0  | PI[n]    | 0-1   | Ports Implemented. This register is bit significant. If a bit <i>n</i> is set to 1, the corresponding Port is available for software to use. If a bit <i>n</i> is cleared to 0, the Port is not available for software to use. The maximum number of bits that can be set to 1 is CAP.NP + 1. At least one bit must be set to 1. The contents of this register are relevant to the command completion coalescing ports register (CCC_PORTS). |

#### 29.4.5 AHCI Version Register (VS)

The AHCI version register (VS) indicates the version of the Synopsis AHCI core embedded in the SATASS. The VS is shown in [Figure 29-5](#) and described in [Table 29-9](#).

### Figure 29-5. AHCI Version Register (VS)

LEGEND: R = Read only; -n = value after reset

| 15-0  | MNR   | 100h  | Minor Revision Number. |

### 29.4.6 Command Completion Coalescing Control Register (CCC\_CTL)

The command completion coalescing control register (CCC\_CTL) is used to configure the command completion coalescing (CCC) feature for the SATASS core. It is reset on Global reset. The CCC\_CTL is shown in [Figure 29-6](#) and described in [Table 29-10](#).

**Figure 29-6. Command Completion Coalescing Control Register (CCC\_CTL)**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | TV       | 0-FFFFh | Time-out value. This bit field specifies the CCC time-out value in 1 ms intervals. Software loads this value prior to enabling CCC. This bit field is: <ul style="list-style-type: none"> <li>Read/Write (R/W) when EN = 0</li> <li>Read only (R) when EN = 1</li> </ul> A time-out value of 0 is reserved and should not be used.                                                                                                                                                             |
| 15-8  | CC       | 0-FFh   | Command Completions. This bit field specifies the number of command completions that are necessary to cause a CCC interrupt. Software loads this value prior to enabling CCC. This bit field is: <ul style="list-style-type: none"> <li>Read/Write (R/W) when EN = 0</li> <li>Read only (R) when EN = 1</li> </ul> A value of 0 disables CCC interrupts being generated based on the number of commands completed, that is, CCC interrupts are only generated based on the timer in this case. |
| 7-3   | INT      | 0-1Fh   | Interrupt. This bit field specifies the interrupt used by the CCC feature, using the number of ports configured for the core. For a single Port instantiation, INT should be programmed to 1. When a CCC interrupt occurs, the IS.IPS[INT] bit is set to 1.                                                                                                                                                                                                                                    |
| 2-1   | Reserved | 0       | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0     | EN       | 0<br>1  | CCC feature enable. When EN = 1, software can not change the bit fields: TV and CC.<br>CCC feature is disabled and no CCC interrupts are generated.<br>CCC feature is enabled and CCC interrupts may be generated based on the time-out or command completion conditions.                                                                                                                                                                                                                      |

### 29.4.7 Command Completion Coalescing Ports Register (CCC\_PORTS)

The command completion coalescing ports register (CCC\_PORTS) specifies the Ports that are coalesced as part of the command completion coalescing (CCC) feature when CCC\_CTL.EN = 1. It is reset on Global reset. The CCC\_PORTS is shown in [Figure 29-7](#) and described in [Table 29-11](#).

**Figure 29-7. Command Completion Coalescing Ports Register (CCC\_PORTS)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 29-11. Command Completion Coalescing Ports Register (CCC\_PORTS) Field Description**

| Bit  | Field  | Value | Description                                                                                                                                                                                                                     |
|------|--------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | PRT[n] |       | Ports. This field is bit significant. Each bit <i>n</i> corresponds to a particular Port, where bit 0 corresponds to Port0. Bits set to 1 must also have the corresponding bit set to 1 in the ports implemented register (PI). |
|      |        | 0     | The corresponding Port is not part of the CCC feature.                                                                                                                                                                          |
|      |        | 1     | The corresponding Port is part of the CCC feature.                                                                                                                                                                              |

### 29.4.8 BIST Active FIS Register (BISTAFR)

The BIST active FIS register (BISTAFR) is shown in [Figure 29-8](#) and described in [Table 29-12](#).

**Figure 29-8. BIST Active FIS Register (BISTAFR)**

LEGEND: R = Read only; -n = value after reset

**Table 29-12. BIST Active FIS Register (BISTAFR) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                |
| 15-8  | NCP      | 0-FFh   | Non-Compliant Pattern. Least significant byte of the received BIST Activate FIS second DWORD (bits [7:0]). This value defines the required pattern for the far-end transmit only modes (PD=80h or A0h). If the following reserved values are decoded, the simultaneous switching pattern is transmitted by default.                                                                                      |
|       |          | 0-49h   | Reserved                                                                                                                                                                                                                                                                                                                                                                                                 |

| 7-0   | PD       | 0-FFh   | Pattern Definition. Indicates the pattern definition field of the received BIST Activate FIS (bits [23:16]) of the first DWORD. It is used to put the SATASS in one of the following BIST modes. All reserved values should not be used by the device; otherwise, the FIS is negatively acknowledged with R_ERRp. For far-end transmit only modes, the NCP bit field contains the required data pattern. |

**Table 29-13. BIST Control Register (BISTCR) Field Descriptions**

| Bit   | Field    | Value          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|----------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-19 | Reserved | 0              | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 18    | TXO      | 0              | Transmit Only. This bit is used to initiate transmission of one of the non-compliant patterns defined by the BISTCR.PATTERN value when the device is disconnected.                                                                                                                                                                                                                                                                                                                                                        |
| 17    | CNTCLR   | 0              | Counter Clear. This bit clears BIST error count registers. Writing a 1 clears BISTFCTR, BISTSR, and BISTDECR registers.                                                                                                                                                                                                                                                                                                                                                                                                   |
| 16    | NEALB    | 0<br>1         | Near-end Analog Loopback. Places the Port PHY into near-end analog loopback mode.<br>Near-end analog loopback is not requested.<br>Initiates a near-end analog loopback request. BISTCR.CP field contains the appropriate pattern. This mode should be initiated either in the PARTIAL or SLUMBER power mode, or with the device disconnected from the Port PHY (Link NOCOMM state). BIST Activate FIS is not sent to the device in this mode.                                                                            |
| 15-11 | Reserved | 0              | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 10-8  | LLC      | 0-7h<br>0<br>1 | Link Layer Control. This bit field controls the Port Link Layer functions: scrambler, descrambler, and repeat primitive drop (RPD). In normal mode, the functions scrambler, descrambler, or RPD are changed only during Port reset (P0SCTL.DET = 1). Note the different meanings for normal and BIST modes of operation:<br><b>Bit 10 (RPD):</b><br>Repeat primitive drop function is disabled in normal mode, enabled in BIST mode.<br>Repeat primitive drop function is enabled in normal mode, disabled in BIST mode. |
|       |          | 0<br>1         | <b>Bit 9 (DESCRAM):</b><br>Descrambler is disabled in normal mode, enabled in BIST mode.<br>Descrambler is enabled in normal mode, disabled in BIST mode.                                                                                                                                                                                                                                                                                                                                                                 |
|       |          | 0<br>1         | <b>Bit 8 (SCRAM):</b><br>Scrambler is disabled in normal mode, enabled in BIST mode.<br>Scrambler is enabled in normal mode, disabled in BIST mode.<br>The SCRAM bit is cleared (enabled) by the Port when the Port enters a responder far-end transmit BIST mode with scrambling enabled (BISTAFR.PD = 80h).                                                                                                                                                                                                             |
| 7     | Reserved | 0              | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6     | ERREN    | 0<br>1         | Error Enable. Used to allow or filter (disable) PHY internal errors outside the FIS boundary to set corresponding port serial ATA error register (P0SERR) bits.<br>Filter errors outside the FIS, allow errors inside the FIS.<br>Allow errors outside or inside the FIS.                                                                                                                                                                                                                                                 |
| 5     | FLIP     | 0-1            | Flip Disparity. Enables changing disparity of the current test pattern to the opposite every time its state is changed by software.                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 29-13. BIST Control Register (BISTCR) Field Descriptions (continued)**

| Bit | Field   | Value | Description                                                                                                                                                                                                                                    |
|-----|---------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | PV      |       | Pattern Version. Selects either short or long version of the SSOP, HTDP, LTDP, LFSCP, and COMP patterns.                                                                                                                                       |
|     |         | 0     | Short pattern version                                                                                                                                                                                                                          |
|     |         | 1     | Long pattern version                                                                                                                                                                                                                           |
| 3-0 | PATTERN | 0-Fh  | Defines one of the following SATA compliant patterns for far-end retimed/ far-end analog/near-end analog initiator modes, or non-compliant patterns for transmit-only responder mode when initiated by software writing to the BISTCR.TXO bit. |
|     |         | 0     | Simultaneous switching outputs pattern (SSOP)                                                                                                                                                                                                  |
|     |         | 1h    | High-transition density pattern                                                                                                                                                                                                                |
|     |         | 2h    | Low-transition density pattern                                                                                                                                                                                                                 |
|     |         | 3h    | Low-frequency spectral component pattern (LFSCP)                                                                                                                                                                                               |
|     |         | 4h    | Composite pattern (COMP)                                                                                                                                                                                                                       |
|     |         | 5h    | Lone bit pattern (LBP)                                                                                                                                                                                                                         |

|     |         | 7h    | High-frequency test pattern (HFTP)                                                                                                                                                                                                             |
|     |         | 8h    | Low-frequency test pattern (LFTP)                                                                                                                                                                                                              |
|     |         | 9h-Fh | Reserved.                                                                                                                                                                                                                                      |

#### 29.4.10 BIST FIS Count Register (BISTFCTR)

The BIST FIS count register (BISTFCTR) contains the received BIST FIS count in the loopback initiator far-end retimed, far-end analog and near-end analog modes. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit. This register does not roll over and freezes when the FFFF FFFFh value is reached. It takes approximately 65 hours of continuous BIST operation to reach this value. The BISTFCTR is shown in [Figure 29-10](#) and described in [Table 29-14](#).

**Figure 29-10. BIST FIS Count Register (BISTFCTR)**

| Bit  | Field    | Value        | Description              |
|------|----------|--------------|--------------------------|
| 31-0 | BISTFCTR | 0-FFFF FFFFh | Received BIST FIS Count. |

#### 29.4.11 BIST Status Register (BISTSR)

The BIST status register (BISTSR) contains errors detected in the received BIST FIS in the loopback initiator far-end retimed, far-end analog and near-end analog modes. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit. The BISTSR is shown in [Figure 29-11](#) and described in [Table 29-15](#).

### Table 29-15. BIST Status Register (BISTSR) Field Description

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved | 0       | Reserved.                                                                                                                                                                                                                                                                                                                                                               |
| 23-16 | BRSTERR  | 0-FFh   | Burst Error. This bit field contains the burst error count. It is accumulated each time a burst error condition is detected: DWORD error is detected in the received frame and 1.5 seconds (27,000 frames) passed since the previous burst error was detected. The BRSTERR value does not roll over and freezes at FFh. This bit field is updated if BIST_MODE = DWORD. |
| 15-0  | FRAMERR  | 0-FFFFh | Frame Error. This bit field contains the frame error count. It is accumulated (new value is added to the old value) each time a new BIST frame with a CRC error is received. The FRAMERR value does not roll over and freezes at FFFFh.                                                                                                                                 |

### 29.4.14 Global Parameter 1 Register (GPARAM1R)

The global parameter 1 register (GPARAM1R) is a read-only register that contains encoded information about the configuration of the embedded Synopsis AHCI SATA Core. The GPARAM1R is shown in [Figure 29-14](#) and described in [Table 29-18](#).

**Figure 29-14. Global Parameter 1 Register (GPARAM1R)**

|          |           |     |          |     |          |         |            |          |       |            |   |    |  |
|----------|-----------|-----|----------|-----|----------|---------|------------|----------|-------|------------|---|----|--|

| 14       |           | 13  |          | 12  |          | 11      |            | 10       |       | 9          |   | 8  |  |
| LATCH_M  | BIST_M    |     | PHY_TYPE |     | Reserved |         | RETURN_ERR |          |       | AHB_ENDIAN |   |    |  |
| R-0      |           | R-0 |          | R-0 |          | R-0     |            | R-1      |       | R-2h       |   |    |  |
| 7        |           | 6   |          | 5   |          | 3       |            |          | 2     |            | 0 |    |  |
| S_HADDR  | M_HADDR   |     | S_HDATA  |     |          |         |            | M_HDATA  |       |            |   |    |  |
| R-0      |           | R-0 |          | R-0 |          |         |            |          | R-0   |            |   |    |  |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-18. Global Parameter 1 Register (GPARAM1R) Field Descriptions**

| Bit   | Field      | Value | Description                                                               |
|-------|------------|-------|---------------------------------------------------------------------------|
| 31    | ALIGN_M    | 1     | Rx Data Alignment. Data is always aligned.                                |
| 30    | RX_BUFFER  | 1     | Rx Data Buffer. Core includes an Rx Data Buffer.                          |
| 29-28 | PHY_DATA   | 0     | PHY Data Width. Indicates width = 0 (8-bits).                             |
| 27    | PHY_RST    | 0     | PHY Reset Mode. Indicates that the phy reset output is active-low.        |
| 26-21 | PHY_CTRL   | 20h   | PHY Control Width. Indicates that there are 32-bits of phy control.       |
| 20-15 | PHY_STAT   | 2h    | PHY Status Width. Indicates that there are 32-bits of phy status.         |
| 14    | LATCH_M    | 0     | Latch Mode. Indicates that the subsystem does not include latches.        |
| 13    | BIST_M     | 0     | BIST Loopback Checking Depth. Checks errors per FIS.                      |
| 12    | PHY_TYPE   | 0     | PHY Interface Type. Indicates a non-Synopsis phy.                         |
| 11    | Reserved   | 0     | Reserved.                                                                 |
| 10    | RETURN_ERR | 1     | AHB Error Response. Indicates AHB Errors are returned.                    |
| 9-8   | AHB_ENDIAN | 2h    | Bus Endianness. Indicates that endianness may be configured by input pin. |
| 7     | S_HADDR    | 0     | Slave address bus width. Indicates 32-bit wide address bus.               |
| 6     | M_HADDR    | 0     | Master address bus width. Indicates 32-bit wide address bus.              |
| 5-3   | S_HDATA    | 0     | Slave Data Bus Width. Indicates 32-bit data bus.                          |
| 2-0   | M_HDATA    | 0     | Master Data Bus Width. Indicates 32-bit data bus.                         |

### 29.4.15 Global Parameter 2 Register (GPARAM2R)

The global parameter 2 register (GPARAM2R) is a read-only register that contains encoded information about the configuration of the embedded Synopsis AHCI SATA Core. The GPARAM2R is shown in [Figure 29-15](#) and described in [Table 29-19](#).

**Figure 29-15. Global Parameter 2 Register (GPARAM2R)**

LEGEND: R = Read only; -n = value after reset

**Table 29-19. Global Parameter 2 Register (GPARAM2R) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                           |
|-------|-------------|-------|-------------------------------------------------------------------------------------------------------|
| 31-15 | Reserved    | 0     | Reserved.                                                                                             |
| 14    | DEV_CP      | 1     | Cold Presence Detect. CPD is supported in SATASS.                                                     |
| 13    | DEV_MP      | 1     | Mechanical Presence Switch. MP is supported in SATASS.                                                |
| 12    | ENCODE_M    | 1     | 8b/10b Encoding/Decoding. Indicates 8-bit/10-bit encoding and decoding are done in the Synopsis core. |
| 11    | RXOOB_CLK_M | 0     | Rx OOB Clock Mode. Indicates that the Rx OOB Functions are on the Rx Clock.                           |
| 10    | RX_OOB_M    | 0     | Rx OOB Mode. Indicates that Rx Out-of-Band signals are detected in the phy.                           |
| 9     | TX_OOB_M    | 1     | Tx OOB Mode. Indicates that Tx Out-of-Band signaling is done by the Synopsis Core.                    |
| 8-0   | RXOOB_CLK   | 96h   | Rx OOB Clock Frequency. Reflects the hexadecimal value of the RXOOB_CLK_FREQ parameter.               |

### 29.4.16 Port Parameter Register (PPARAMR)

The port parameter register (PPARAMR) is a read-only register that contains encoded information about the selected Port configuration parameters settings. The Port is selected by the TESTR.PSEL field. Note, there is only one port on this sub-system. The PPARAMR is shown in [Figure 29-16](#) and described in [Table 29-20](#).

**Figure 29-16. Port Parameter Register (PPARAMR)**

**Table 29-20. Port Parameter Register (PPARAMR) Field Descriptions**

| Bit   | Field         | Value | Description                                                                                                             |
|-------|---------------|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31-10 | Reserved      | 0     | Reserved.                                                                                                               |
| 9     | TX_MEM_M      | 0     | Tx FIFO Memory Read Port Type. Indicates that the Tx FIFO memory is asynchronous read.                                  |
| 8     | TX_MEM_S      | 0     | Tx FIFO Memory Type. Indicates that the Tx FIFO memory is outside of the core (but still inside the subsystem wrapper). |
| 7     | RX_MEM_M      | 0     | Rx FIFO Memory Read Port Type. Indicates that the Rx FIFO memory is asynchronous read.                                  |
| 6     | RX_MEM_S      | 0     | Rx FIFO Memory Type. Indicates that the Rx FIFO memory is outside of the core (but still inside the subsystem wrapper). |
| 5-3   | TX_FIFO_DEPTH | 0     | Tx FIFO Depth. Indicates that the depth of the Tx FIFO is 32 DWORDS.                                                    |
| 2-0   | RX_FIFO_DEPTH | 1     | Rx FIFO Depth. Indicates that the depth of the Rx FIFO is 64 DWORDS.                                                    |

### 29.4.17 Test Register (TESTR)

The test register (TESTR) is used to put the SATASS slave interface into a test mode and to select a Port for BIST operation. The TESTR is shown in [Figure 29-17](#) and described in [Table 29-21](#).

**Figure 29-17. Test Register (TESTR)**

| 0     | TEST_IF  | 0<br>1 | <p>Test Interface. Places the DWC SATA AHCI slave interface into the test mode.</p> <p>0 Normal mode: the read back value of some registers is a function of the DWC SATA AHCI state and does not match the value written.</p> <p>1 Test mode: the read back value of the registers matches the value written. Normal operation is disabled. The following registers are accessed in this mode:</p> <ul style="list-style-type: none"> <li>GHC register: IE bit</li> <li>BISTAFR register: NCP and PD bits become read/write</li> <li>BISTCR register: LLC, ERREN, FLIP, PV, PATTERN</li> <li>BISTFCTR, BISTSR, BISTDECR registers become read/write</li> <li>P0CLB/CLBU, P0FB/FBU registers</li> <li>P0IS register: RW1C and UFS bits become read/write</li> <li>P0IE register</li> <li>P0CMD register: ASP, ALPE, DLAE, ATAPI, PMA bits</li> <li>P0TFD, P0SIG registers become read/write</li> <li>P0SCTL register</li> <li>P0SERR register: R/W1C bits become read/write bits</li> <li>P0SACT, P0CI, P0SNTF registers become read/write</li> <li>P0DMACR register</li> <li>P0PHYCR register</li> <li>P0PHYSR register becomes read/write</li> </ul> <p>Notes:</p> <p>Interrupt is asserted if any of the IS register bits is set after setting the corresponding P0IS and P0IE registers and GHC.IE = 1.</p> <p>CAP.SMPS/SSS, PI, P0CMD.ESP/CPD/MPSP/ HPCP register bits are W/RO (written once after power-on reset, then remain as read-only) type and can not be used in test mode.</p> <p>Global DWC SATA AHCI reset must be issued (GHC.HR = 1) after TEST_IF bit is cleared following the test mode operation.</p> |

### 29.4.18 Version Register (VERSIONR)

The version register (VERSIONR) contains the 32-bit SATASS version. The VERSIONR is shown in [Figure 29-18](#) and described in [Table 29-22](#).

**Figure 29-18. Version Register (VERSIONR)**

LEGEND: R = Read only; -n = value after reset

**Table 29-22. Version Register (VERSIONR) Field Description**

| Bit  | Field   | Value      | Description        |
|------|---------|------------|--------------------|
| 31-0 | VERSION | 3133 302Ah | Version of SATASS. |

### 29.4.19 ID Register (IDR)

The ID register (IDR) contains the 32-bit SATASS ID. The IDR is shown in [Figure 29-19](#) and described in [Table 29-23](#).

**Figure 29-19. ID Register (IDR)**

LEGEND: R = Read only; -n = value after reset

**Table 29-23. ID Register (IDR) Field Description**

| Bit  | Field | Value      | Description   |
|------|-------|------------|---------------|
| 31-0 | ID    | 4E40 4903h | ID of SATASS. |

### 29.4.20 Port Command List Base Address Register (P0CLB)

The port command list base address register (P0CLB) contains the 32-bit base address of the command list. The P0CLB is shown in [Figure 29-20](#) and described in [Table 29-24](#).

**Figure 29-20. Port Command List Base Address Register (P0CLB)**

|       |    |   |          |

| CLB   |    |   | Reserved |
| R/W-0 |    |   | R-0      |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-24. Port Command List Base Address Register (P0CLB) Field Description**

| Bit   | Field    | Value      | Description                                                                                                                                                                                                                                                                                                        |
|-------|----------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-10 | CLB      | 0-3F FFFFh | Command List Base Address. Indicates the 32-bit base physical address for the command list for this port. This base is used when fetching commands to execute. The structure pointed to by this address range is 1Kbyte in length. This address must be 1Kbyte-aligned as indicated by bits [9:0] being read-only. |

### 29.4.21 Port FIS Base Address Register (P0FB)

The port FIS base address register (P0FB) contains the 32-bit base address of the destination for incoming received FISes. The P0FB is shown in [Figure 29-21](#) and described in [Table 29-25](#).

**Figure 29-21. Port FIS Base Address Register (P0FB)**

## 29.4.22 Port Interrupt Status Register (P0IS)

The port interrupt status register (P0IS) is used to generate SATASS interrupts when any of the bits are set. Bits in this register are set by some internal conditions, and cleared by software writing ones in the positions it wants to clear. This register is reset on Global reset. The P0IS is shown in [Figure 29-22](#) and described in [Table 29-26](#).

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | CPDS     | 0-1   | Cold Port Detect Status. This bit is set when the external input changes its state due to the insertion or removal of a device. This bit is only valid if the port supports cold presence detection as indicated by the POCMD.CPD bit being set to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 30   | TFES     | 0-1   | Task File Error Status. This bit is set whenever the P0TFD register is updated by the device and the error bit (P0TFD.STS[0]) is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 29   | HBFS     | 0-1   | Host Bus Fatal Error Status. This bit is set when SATASS bus master detects an ERROR response from the slave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 28   | HBDS     | 0-1   | Host Bus Data Error Status. This bit is always cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 27   | IFS      | 0-1   | Interface Fatal Error Status. This bit is set if any of the following conditions is detected: <ul style="list-style-type: none"> <li>• SYNC escape is received from the device during H2D Register or Data FIS transmission.</li> <li>• One or more of the following errors are detected during Data FIS transfer: Protocol (P0SERR.ERR_P), CRC (P0SERR.DIAG_C), Handshake (P0SERR.DIAG_H), PHY Not Ready (P0SERR.ERR_C).</li> <li>• Unknown FIS is received with good CRC, but the length exceeds 64 bytes.</li> <li>• PRD table byte count is zero.</li> </ul> Port DMA transitions to a fatal state until software clears P0CMD.ST bit or resets the interface by way of Port or Global reset.                                       |
| 26   | INFS     | 0-1   | Interface Non-fatal Error Status. This bit is set if any of the following conditions is detected: <ul style="list-style-type: none"> <li>• One or more of the following errors are detected during non-data FIS transfer: Protocol (P0SERR.ERR_P), CRC (P0SERR.DIAG_C), Handshake (P0SERR.DIAG_H), PHY Not Ready (P0SERR.ERR_C).</li> <li>• Command list underflow during read operation (DMA read) when software builds command table that has more total bytes than the transaction given to the device.</li> </ul> In both cases, Port operation continues normally. If error is detected during non-data FIS transmission, this FIS is retransmitted continuously until it succeeds or software times out and resets the interface. |
| 25   | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 24   | OFS      | 0-1   | Overflow Status. This bit is set if command list overflow is detected during read or write operation when software builds a command table that has fewer total bytes than the transaction given to the device. Port DMA transitions to a fatal state until software clears P0CMD.ST bit or resets the interface by way of Port or Global reset.                                                                                                                                                                                                                                                                                                                                                                                         |
| 23   | IPMS     | 0-1   | Incorrect Port Multiplier Status. Indicates that the HBA received a FIS from a device whose Port Multiplier field did not match what was expected. <p>This bit may be set during enumeration of devices on a Port Multiplier due to the normal Port Multiplier enumeration process. The software should only use the IPMS bit after enumeration is complete on the Port Multiplier.</p>                                                                                                                                                                                                                                                                                                                                                 |
| 22   | PRCS     | 0-1   | PHYReady Change Status. When set to 1, indicates the internal PHY Ready signal changed state. This bit reflects the state of the P0SERR.DIAG_N bit. To clear this bit, the software must clear the P0SERR.DIAG_N bit to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 21-8 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 29-26. Port Interrupt Status Register (P0IS) Field Descriptions (continued)**

| Bit | Field | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | DMPS  | 0-1    | Device Mechanical Presence Status. This bit is set when the state of SATA_MP_SWITCH input pin changes as a result of a mechanical switch attached to this port being opened or closed. This bit is only valid if both CAP.SMPS and POCMD.MPSP are set to 1.                                                                                                                                                                                                                                                                          |
| 6   | PCS   | 0<br>1 | Port Connect Change Status. This bit reflects the state of the P0SERR.DIAG_X bit. This bit is only cleared when P0SERR.DIAG_X is cleared.<br>0 No change in Current Connect Status<br>1 Change in Current Connect Status                                                                                                                                                                                                                                                                                                             |
| 5   | DPS   | 0-1    | Descriptor Processed. A PRD with the I bit set has transferred all of its data.<br><br>Note: This is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts could happen close in time together such that the second interrupt is missed when the first PRD interrupt is being cleared.                                                                                                                                                                                  |
| 4   | UFS   | 0-1    | Unknown FIS Interrupt. When set to 1, indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the P0SERR.DIAG_F bit to 0.<br><br>Note: The UFS bit does not directly reflect the P0SERR.DIAG_F bit. P0SERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. Software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync. |
| 3   | SDBS  | 0-1    | Set Device Bits Interrupt. A Set Device Bits FIS has been received with the I bit set and has been copied into system memory.                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2   | DSS   | 0-1    | DMA Setup FIS Interrupt. A DMA Setup FIS has been received with the I bit set and has been copied into system memory.                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1   | PSS   | 0-1    | PIO Setup FIS Interrupt. A PIO Setup FIS has been received with the I bit set, it has been copied into system memory, and the data related to that FIS has been transferred.                                                                                                                                                                                                                                                                                                                                                         |
| 0   | DHRS  | 0-1    | Device to Host Register FIS Interrupt. A D2H Register FIS has been received with the I bit set, and has been copied into system memory.                                                                                                                                                                                                                                                                                                                                                                                              |

### 29.4.23 Port Interrupt Enable Register (P0IE)

The port interrupt enable register (P0IE) enables and disables the reporting of the corresponding interrupt to system software. When a bit is set (1), and the corresponding interrupt condition is active, then the SATASS intrq output is asserted. Interrupt sources that are disabled (0) are still reflected in the status registers. This register is symmetrical with the P0IS register. This register is reset on Global reset. The P0IE is shown in Figure 29-23 and described in Table 29-27.

**Figure 29-23. Port Interrupt Enable Register (P0IE)**

**Table 29-27. Port Interrupt Enable Register (P0IE) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                            |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------|
| 31   | CPDE     | 0-1   | Cold Port Detect Enable. When set to 1, GHC.IE = 1, and P0IS.CPDS = 1, the intrq output is asserted.                   |
| 30   | TFEE     | 0-1   | Task File Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBFS = 1, the intrq output is asserted.                    |
| 29   | HBFE     | 0-1   | Host Bus Fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBFS = 1, the interq output is asserted.              |
| 28   | HBDE     | 0-1   | Host Bus Data Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBDS = 1, the intrq output is asserted.                |
| 27   | IFE      | 0-1   | Interface Fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.IFS = 1, the intrq output is asserted.               |
| 26   | INFE     | 0-1   | Interface Non-fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.INFS = 1, the intrq output is asserted.          |
| 25   | Reserved | 0     | Reserved.                                                                                                              |
| 24   | OFE      | 0-1   | Overflow Enable. When set to 1, GHC.IE = 1, and P0IS.OFS = 1, the intrq output is asserted.                            |
| 23   | IPME     | 0-1   | Incorrect Port Multiplier Enable. When set to 1, GHC.IE = 1, and P0IS.IPMS = 1, the intrq output is asserted.          |
| 22   | PRCE     | 0-1   | PHYReady Change Enable. When set to 1, GHC.IE = 1, and P0IS.PRCS = 1, the intrq output is asserted.                    |
| 21-8 | Reserved | 0     | Reserved.                                                                                                              |
| 7    | DMPE     | 0-1   | Device Mechanical Presence Enable. When set to 1, GHC.IE = 1, and P0IS.DMPS = 1, the intrq output is asserted.         |
| 6    | PCE      | 0-1   | Port Change Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PCS = 1, the intrq output is asserted.               |
| 5    | DPE      | 0-1   | Descriptor Processed Interrupt Enable. When set to 1, GHC.IE = 1 and P0IS.DPS = 1, the intrq output is asserted.       |
| 4    | UFE      | 0-1   | Unknown FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.UFS = 1, the intrq output is asserted.               |
| 3    | SDBE     | 0-1   | Set Device Bits FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.SDBS = 1, the intrq output is asserted.      |
| 2    | DSE      | 0-1   | DMA Setup FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PSS = 1, the intrq output is asserted.             |
| 1    | PSE      | 0-1   | PIO Setup FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PSS = 1, the intrq output is asserted.             |
| 0    | DHRE     | 0-1   | Device Host Register FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.DHRS = 1, the intrq output is asserted. |

### 29.4.24 Port Command Register (P0CMD)

The port command register (P0CMD) contains bits controlling various Port functions. All read/write bits are reset on Global reset. The P0CMD is shown in [Figure 29-24](#) and described in [Table 29-28](#).

**Figure 29-24. Port Command Register (P0CMD)**

| 31-28 | ICC      | 0-Fh   | Interface Communication Control. Controls power management states of the interface. If the Link layer is currently in the L_IDLE state, writes to this bit field causes the Port to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this bit field have no effect.<br><br>When system software writes a nonreserved value other than No-Op (0), the Port performs the action and updates this bit field back to Idle (0). If software writes to this bit field to change the state to a state the link is already in (that is, interface is in the active state and a request is made to go to the active state), the Port takes no action and returns this bit field to Idle. If the interface is in a low power state and software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state.<br><br>0 No-Op/ Idle: When software reads this value, it indicates the Port is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred.<br><br>1h Active: Causes the Port to request a transition of the interface into the active state.<br><br>2h Partial: Causes the Port to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface remains in its current state.<br><br>3h-5h Reserved<br><br>6h Slumber: Causes the Port to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface remains in its current state.<br><br>7h-Fh Reserved |
| 27    | ASP      | 0<br>1 | Aggressive Slumber/Partial.<br><br>0 When cleared to 0 and P0CMD.ALPE = 1, the Port aggressively enters the PARTIAL state when it clears the P0CI register, and the P0SACT register is cleared when it clears the P0SACT register and P0CI is cleared.<br><br>1 When set to 1 and P0CMD.ALPE = 1, the Port aggressively enters the SLUBMER state when it clears the P0CI register and the P0SACT register is cleared, or when it clears the P0SACT register and P0CI is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

When this bit is set to 1, POCMD.HPCP should also be set to 1.                                                                                                                                                                                                                                                                                                                                                                                  |
| 18   | HPCP     | 0<br>1 | Hot Plug.<br>Ports signal and power connectors are not externally accessible.<br>Ports signal and power connectors are externally accessible via a joint signal-power connector for blindmate device hot plug.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 17   | PMA      | 0<br>1 | Port Multiplier Attached.<br>Note: Software is responsible for detecting whether a Port Multiplier is present. There is no auto detection.<br>When cleared to 0 by software, indicates that a Port Multiplier is not attached to this Port.<br>When set to 1 by software, indicates that a Port Multiplier is attached to this Port.                                                                                                                                                                                                                                                                                                          |
| 16   | CPS      | 0<br>1 | Cold Presence State. Reports whether a device is currently detected on this port as indicated by the P0_cp_det input state (assuming POCMD.CPD = 1).<br>Note: The reset value of this port may be 1 if P0_cp_det is a 1 at reset.<br>No device is attached.<br>Device is attached.                                                                                                                                                                                                                                                                                                                                                            |
| 15   | CR       | 0-1    | Command List Running. When this bit is set to 1, the command list DMA engine for this Port is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 14   | FR       | 0-1    | FIS Receive Running. When set to 1, the FIS Receive DMA engine for this port is running. Refer to the AHCI specification for details on when this bit is set and cleared by the Port.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 13   | MPSS     | 0<br>1 | Mechanical Presence Switch State. Reports the state of a mechanical presence switch attached to this port as indicated by the P0_mp_switch input state (assuming CAP.SMPS = 1 and POCMD.MPSP = 1). If CAP.SMPS = 0, then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and POCMD.MPSP are set to 1.<br>Note: The reset of this bit may change based on the SATA_MP_SWITCH state at reset.<br>Switch is closed.<br>Switch is open.                                                                                                                                                                              |
| 12-8 | CCS      | 0-1Fh  | Current Command Slot. This bit field is valid when POCMD.ST is set to 1 and is set to the command slot value of the command that is currently being issued by the Port. When POCMD.ST transitions from 1 to 0, this bit field is reset to 0. After POCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is POCMD.CCS + 1. For example, after the Port has issued its first command, if CCS = 0 and POCI is set to 3h, the next command that will be issued is from command slot 1.                         |
| 7-5  | Reserved | 0      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 4    | FRE      | 0-1    | FIS Receive Enable. When set to 1, the Port may post received FISes into the FIS receive area pointed to by P0FB. When cleared, received FISes are not accepted by the Port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area.<br>System software must not set this bit until P0FB has been programmed with a valid pointer to the FIS receive area, and if software wishes to move the base, this bit must first be cleared, and software must wait for the POCMD.FR bit to be cleared. Refer to the Synopsis spec for important restrictions on changing POCMD.FRE. |
| 3    | CLO      | 1      | Command List Override. Setting this bit to 1 causes P0TFD.STS.BSY and P0TFD.STS.DRQ to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the P0TFD.STS register. This bit is cleared to 0 when P0TFD.STS.BSY and P0TFD.STS.DRQ have been cleared to 0. A write to this register with a value of 0 has no effect.<br>This bit should only be set to 1 immediately prior to setting POCMD.ST bit to 1 from a previous value of 0. Setting this bit to 1 at any other time is not supported and results in indeterminate behavior.                       |
| 2    | POD      | 0-1    | Power On Device. This bit is read/write if cold presence detection is supported on this port as indicated by POCMD.CPD = 1. This bit is read-only 1 if cold presence detection is not supported and POCMD.CPD = 0. When set, the Port asserts the P0_cp_pod output pin so that it may be used to provide power to a cold-presence detectable port.                                                                                                                                                                                                                                                                                            |

**Table 29-28. Port Command Register (P0CMD) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | SUD   | 0-1   | Spin-Up Device. This bit is read/write if staggered spin-up is supported as indicated by the CAP.SSS = 1. This bit is read-only 1 if staggered spin-up is not supported and CAP.SSS = 0. On an edge detect from 0 to 1, the Port starts a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface.<br><br>Note: the SUD bit is read-only 0 on power-up until CAP.SSS bit is written with the required value. |
| 0   | ST    | 0-1   | Start. When set to 1, the Port processes the command list. When cleared, the Port does not process the command list. Whenever this bit is changed from a 0 to a 1, the Port starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, the P0CI register is cleared by the Port upon transition into an idle state. Refer to the AHCI specification for important restrictions on when this bit can be set to 1.       |

### 29.4.25 Port Task File Data Register (P0TFD)

The port task file data register (P0TFD) contains Error and Status registers updated every time a new Register FIS. The P0TFD is shown in [Figure 29-25](#) and described in [Table 29-29](#).

**Figure 29-25. Port Task File Data Register (P0TFD)**

LEGEND: R = Read only; -n = value after reset

**Table 29-29. Port Task File Data Register (P0TFD) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                             |
|-------|----------|--------|-------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0      | Reserved.                                                                                                               |
| 15-8  | ERR      | 0-FFh  | Error. Contains the latest copy of the task file error register.                                                        |
| 7-0   | STS      | 0-FFh  | Status. Contains the latest copy of the task file status register.<br><br>Note: the HBA updates the entire 8-bit field. |
|       |          | 0      | ERR – Indicates an error during the transfer                                                                            |
|       |          | 1h-2h  | Reserved                                                                                                                |
|       |          | 3h     | DRQ – Indicates a data transfer is requested                                                                            |
|       |          | 4h-6h  | Reserved                                                                                                                |
|       |          | 7h     | BSY – Indicates the interface is busy                                                                                   |
|       |          | 8h-FFh | Reserved                                                                                                                |

### 29.4.26 Port Signature Register (P0SIG)

The port signature register (P0SIG) contains the Device Signature information. The P0SIG is shown in [Figure 29-26](#) and described in [Table 29-30](#).

**Figure 29-26. Port Signature Register (P0SIG)**

LEGEND: R = Read only; -n = value after reset

**Table 29-30. Port Signature Register (P0SIG) Field Description**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                             |
|------|-------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | SIG   | 0-FFFF FFFFh | Signature. Contains the signature received from a device on the first D2H Register FIS. This register is updated once after a reset sequence. Reset on Global or Port reset. The bit order as is:<br><br>Bits 31-24: LBA High (Cylinder High) Register<br>Bits 23-16: LBA Mid (Cylinder Low) Register<br>Bits 15-8: LBA Low (Sector Number) Register<br>Bits 7-0: Sector Count Register |

### 29.4.27 Port Serial ATA Status (SStatus) Register (P0SSTS)

The port serial ATA status register (P0SSTS) conveys the current state of the interface and host. The Port updates it continuously and asynchronously. When the Port transmits a COMRESET to the device, this register is updated to its reset values (Global reset, Port reset, or COMINIT from the device). The P0SSTS is shown in [Figure 29-27](#) and described in [Table 29-31](#).

**Figure 29-27. Port Serial ATA Status Register (P0SSTS)**

LEGEND: R = Read only; -n = value after reset

**Table 29-31. Port Serial ATA Status Register (P0SSTS) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                       |
|-------|----------|-------|---------------------------------------------------------------------------------------------------|
| 31-12 | Reserved | 0     | Reserved.                                                                                         |
| 11-8  | IPM      | 0-Fh  | Interface Power Management. Indicates the current interface state.                                |
|       |          | 0     | Device is not present or communication is not established.                                        |

## 29.4.28 Port Serial ATA Control (SControl) Register (P0SCTL)

The port serial ATA control register (P0SCTL) is used by software to control SATA interface capabilities. Writes to this register result in an action being taken by the Port PHY interface. Reads from the register return the last value written to it. Reset on Global reset. These bits are static and should not be changed frequently due to the clock crossing between the Transport and Link Layers. Software must wait for at least seven periods of the slower clock (clk\_asic or vbus clock) before changing this register. The P0SCTL is shown in [Figure 29-28](#) and described in [Table 29-32](#).

### 29.4.29 Port Serial ATA Error (SError) Register (P0SERR)

The port serial ATA error register (P0SERR) represents all the detected interface errors accumulated since the last time it was cleared. The set bits in the SError register indicate that the corresponding error condition became true one or more times since the last time the bit was cleared. The set bits in this register are explicitly cleared by a write operation to the register, Global reset, or Port reset (COMRESET). The value written to clear the set error bits should have ones encoded in the bit positions corresponding to the bits that are to be cleared. All bits in the following table have a reset value of 0. The P0SERR is shown in Figure 29-29 and described in Table 29-33.

**Figure 29-29. Port Serial ATA Error Register (P0SERR)**

|          |         |         |        |         |         |         |         |         |

**Table 29-33. Port Serial ATA Error Register (P0SERR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                    |
|-------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                      |
| 26    | DIAG_X   | 0-1   | Exchanged. This bit is set to 1 when PHY COMINIT signal is detected. This bit is reflected in the POIS.PCS bit.                                                                                                                                                                                                                |
| 25    | DIAG_F   | 0-1   | Unknown FIS Type. Indicates that one or more FISes were received by the Transport layer with good CRC, but had a type field that was not recognized/known and the length was less than or equal to 64 bytes.<br>Note: If the Unknown FIS length exceeds 64 bytes, the DIAG_F bit is not set and the DIAG_T bit is set instead. |
| 24    | DIAG_T   | 0-1   | Transport State Transition Error. Indicates that a Transport Layer protocol violation was detected.                                                                                                                                                                                                                            |
| 23    | DIAG_S   | 0-1   | Link Sequence Error. Indicates that one or more Link state machine error conditions was encountered. One of the conditions that cause this bit to be set is the device doing SYNC escape during FIS transmission.                                                                                                              |
| 22    | DIAG_H   | 0-1   | Handshake Error. Indicates that one or more R-ERRp was received in response to frame transmission. Such errors may be the result of a CRC error detected by the device, a disparity or 8-bit/10-bit decoding error, or other error condition leading to a negative handshake on a transmitted frame.                           |
| 21    | DIAG_C   | 0-1   | CRC Error. Indicates that one ore more CRC errors were detected by the Link layer during FIS reception.                                                                                                                                                                                                                        |
| 20    | DIAG_D   | 0     | Disparity Error. This bit is always 0 since it is not used by the AHCI specification.                                                                                                                                                                                                                                          |
| 19    | DIAG_B   | 0-1   | 10B to 8B Decode Error. Indicates errors were detected by 10b8b decoder.<br>Note: This bit is set only when an error is detected on the received FIS data word. This bit is not set when an error is detected on the primitive, regardless of whether it is inside or outside the FIS.                                         |
| 18    | DIAG_W   | 0-1   | Comm Wake. This bit is set when the PHY COMWAKE signal is detected.                                                                                                                                                                                                                                                            |
| 17    | DIAG_I   | 0-1   | PHY Internal Error. This bit is set when the PHY detects some internal error.<br>Note: The TI phy does not support any errors so this bit will never be set.                                                                                                                                                                   |
| 16    | DIAG_N   | 0-1   | PHYReady Change. Indicates that the PHY Ready signal changed state. This bit is reflected in the POIS.PRCs bit.                                                                                                                                                                                                                |
| 15-12 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                      |

**Table 29-33. Port Serial ATA Error Register (P0SERR) Field Descriptions (continued)**

| Bit | Field    | Value | Description                                                                                                                                                                                                                                                                                                              |
|-----|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11  | ERR_E    | 0-1   | Internal Error. This bit is set to 1 when one or more AHB bus ERROR responses are detected on the master or the slave interfaces.                                                                                                                                                                                        |
| 10  | ERR_P    | 0-1   | Protocol Error. This bit is set to 1 when any of the following conditions are detected: <ul style="list-style-type: none"> <li>• Transport state transition error (DIAG_T)</li> <li>• Link sequence error (DIAG_S)</li> <li>• RxFIFO overflow</li> <li>• Link bad end error (WTRM instead of EOF is received)</li> </ul> |
| 9   | ERR_C    | 0-1   | Non-recovered Persistent Communication Error. This bit is set to 1 when the PHY Ready signal is negated due to the loss of communication with the device or problems with the interface, but not after transition from active to Partial or Slumber power management state.                                              |
| 8   | ERR_T    | 0-1   | Non-recovered Transient Data Integrity Error. This bit is set if any of the following P0SERR register bits is set during Data FIS transfer: <ul style="list-style-type: none"> <li>• ERR_P (Protocol)</li> <li>• DIAG_C (CRC)</li> <li>• DIAG_H (Handshake)</li> <li>• ERR_C (PHY Ready negation)</li> </ul>             |
| 7-2 | Reserved | 0     | Reserved.                                                                                                                                                                                                                                                                                                                |
| 1   | ERR_M    | 0-1   | Recovered Communication Error. This bit is set to 1 when the PHY Ready condition is detected after interface initialization, but not after transition from partial or Slumber power management state to active state.                                                                                                    |
| 0   | ERR_I    | 0-1   | Recovered Data Integrity. This bit is set if any of the following P0SERR register bits is set during non-Data FIS transfer: <ul style="list-style-type: none"> <li>• ERR_P (Protocol)</li> <li>• DIAG_C (CRC)</li> <li>• DIAG_H (Handshake)</li> <li>• ERR_C (PHY Ready negation)</li> </ul>                             |

### 29.4.30 Port Serial ATA Active (SActive) Register (P0SACT)

The port serial ATA active (SActive) register (P0SACT) is used to indicate what command slots have commands in them. The P0SACT is shown in [Figure 29-30](#) and described in [Table 29-34](#).

**Figure 29-30. Port Serial ATA Active Register (P0SACT)**

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -n = value after reset

**Table 29-34. Port Serial ATA Active Register (P0SACT) Field Description**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | DS[n] | 0-1   | <p>This field is bit significant. Each bit <i>n</i> corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. This bit field is set by software prior to issuing a native queued command for a particular command slot. Prior to writing P0CI[TAG] to 1, software sets DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits in this bit field by sending a Set Device Bits FIS to the Port. The Port clears bits in this bit field that are set to 1 in the SActive field of the Set Device Bits FIS. The Port only clears bits that correspond to native queued commands that have completed successfully.</p> <p>Software should only write to this bit field when P0CMD.ST bit is set to 1. This bit field is cleared when P0CMD.ST is written from a 1 to a 0 by software. This bit field is not cleared by a Port reset (COMRESET) or a software reset.</p> |

### 29.4.31 Port Command Issue Register (P0CI)

The port command issue register (P0CI) is used to indicate what that a command has been constructed and may be carried out. The P0CI is shown in [Figure 29-31](#) and described in [Table 29-35](#).

**Figure 29-31. Port Serial ATA Active (SActive) Register (P0SACT)**

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -n = value after reset

**Table 29-35. Port Serial ATA Active (SActive) Register (P0SACT) Field Description**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CI[n] | 0-1   | <p>Command Issued. This field is bit significant. Each bit <i>n</i> corresponds to a command slot, where bit 0 corresponds to command slot 0. This bit field is set by software to indicate to the Port that a command has been built in system memory for a command slot and may be sent to the device. When the Port receives a FIS that clears the BSY, DRQ, and ERR bits for the command, it clears the corresponding bit <i>n</i> in this register for that command slot. Bits in this field can only be set to 1 by software when P0CMD.ST is set to 1.</p> |

### 29.4.32 Port Serial ATA Notification Register (POSNTF)

The port serial ATA notification register (POSNTF) is used to determine if asynchronous notification events have occurred for directly connected devices and devices connected to a Port Multiplier. The POSNTF is shown in [Figure 29-32](#) and described in [Table 29-36](#).

**Figure 29-32. Port Serial ATA Notification Register (POSNTF)**

| 15-0  | PMN[n]   | 0-1   | PM Notify. Indicates whether a particular device with the corresponding PM Port number issued a Set Device Bits FIS to the SATASS Port with the Notification bit set. Individual bits are cleared by software writing 1s to the corresponding bit <i>n</i> positions. This bit field is reset on Global reset, but it is not reset by Port reset (COMRESET) or software reset. <ul style="list-style-type: none"> <li>PM Port 0 sets bit 0</li> <li>PM Port 0 sets bit 1</li> </ul> |

### 29.4.33 Port DMA Control Register (P0DMACR)

The port DMA control register (P0DMACR) contains bits for controlling the Port DMA engine. The software can change the fields of this register only when P0CMD.ST=0. Power-up (system reset), Global reset, or Port reset (COMRESET) reset this register to the default value. The P0DMACR is shown in [Figure 29-33](#) and described in [Table 29-37](#).

**Figure 29-33. Port DMA Control Register (P0DMACR)**

**Table 29-37. Port DMA Control Register (P0DMACR) Field Description (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-4 | RXTS  | 0-Fh  | Receive Transaction Size (RX_TRANSACTION_SIZE). This field defines the Port DMA transaction size in DWORDs for receive (system bus write, device read) operation. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1. The maximum value of this bit field is determined by the Rx FIFO Depth (P0_RXFIFO_DEPTH). If software attempts to write a value exceeding this maximum value, the maximum value would be set instead. |

| 3-0 | TXTS  | 0-Fh  | Transmit Transaction Size (TX_TRANSACTION_SIZE). This field defines the DMA transaction size in DWORDs for transmit (system bus read, device write) operation. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1. The maximum value of this bit field is determined by the Tx FIFO Depth (P0_TXFIFO_DEPTH). If software attempts to write a value exceeding this maximum value, the maximum value would be set instead.    |

### 29.4.34 Port PHY Control Register (P0PHYCR)

The port PHY control register (P0PHYCR) is used to control the PHY. These ports are configured for the WIZ6C2B2N5W0M (Maverick B2) macro. Refer to that spec for further details.

Note: This description is only valid for configuration GS60. See the corresponding P0PHYSR Register description for each configuration. The P0PHYCR is shown in [Figure 29-34](#) and described in [Table 29-38](#).

| 31  | ENPLL |       | <p>Enable Phy PLL. This must be enabled by software before initialization is started on the device. This bit should not be enabled unless the MPY field has been previously set or is being set in the same write. Changing the MPY field while the PLL is enabled disrupts the link clocks and may disrupt the link, requiring a port reset to fix. The PLL may be turned off while the link is in a low-power state (Partial or Slumber). If it is, then it must be re-enabled ~1us + 200 refclock cycles before software attempts to remove the low power state.</p> <div style="border: 1px solid black; padding: 10px; margin: 10px 0;"> <p style="text-align: center;"><b>CAUTION</b></p> <p>If the PLL is disabled in a low-power state, the SATASS cannot wake up from low power based on a device request. If the device requests wakeup and the SATASS does not respond, a port reset may be required after software re-enables the PLL and removes the low-power state. Caution should be taken to never disable the PLL if it is possible that the device will request a wake up from low power.</p> </div> |
|     |       | 0     | Phy PLL is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|     |       | 1     | Phy PLL is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 30    | OVERRIDE |        | Override for Clock Stopping. Normally the functional clock can only be stopped if the link is put into Partial or Slumber power mode. However, if there is no device attached (such as in a removable media situation) you may wish to stop the functional clocks but not be able to enter a low-power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low-power state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |   |    |   |   |   |   |      |       |    |      |       |    |       |       |    |       |       |    |      |       |    |       |       |    |       |       |    |       |       |    |       |       |    |       |       |    |       |       |    |       |       |    |      |       |    |       |       |    |       |        |
|       |          |        | <div><div>CAUTION</div><div>When there is a device attached and the OVERRIDE bit is used, if the functional clock is stopped when the link is not in a low-power state may ruin the link and cause undetermined behavior. Configures the clock/data recovery algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 0                  | First order, threshold of 1. Phase offset tracking up to $\pm 312$ ppm. Suitable for use in asynchronous systems with low frequency offset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 1h                 | First order, threshold of 16. Phase offset tracking up to $\pm 260$ ppm in the presence of ..10101010.. training pattern, or $\pm 195$ ppm in the presence of $2^7$ PRBS. Suitable for use in synchronous systems. Offers superior rejection of random jitter, but is less responsive to systematic variation such as sinusoidal jitter.                                                                                                                                                                                                                                                                                                                          |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 2h                 | Second order, high precision, threshold of 1. Highest precision frequency offset matching but relatively poor response to changes in frequency offset, and long lock time. Suitable for use in systems with fixed frequency offset.                                                                                                                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 3h                 | Second order, high precision, threshold of 16. Highest precision frequency offset matching but poorest response to changes in frequency offset, and longest lock time. Suitable for use in systems with fixed frequency offset and low systematic variation.                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 4h                 | Second order, low precision, threshold of 1. Best response to changes in frequency offset and fastest lock time, but lowest precision frequency offset matching. Suitable for use in systems with spread spectrum clocking.                                                                                                                                                                                                                                                                                                                                                                                                                                       |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 5h                 | Second order, low precision, threshold of 16. Good response to changes in frequency offset and fast lock time, but low precision frequency offset matching. Suitable for use in systems with spread spectrum clocking.                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 6h                 | First order, threshold of 1 with fast lock. Phase offset tracking up to $\pm 1560$ ppm in the presence of ..10101010.. training pattern; and $\pm 312$ ppm, otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
|       |                                                                                                                                                                                                                                                                                                                                     | 7h                 | Second order, low precision with fast lock. As per setting 100, but with improved response to changes in frequency offset when not close to lock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |

Selects input termination options suitable for a variety of AC or DC coupled scenarios. |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
| 0     | Common point set to $V_{\text{SSA}}$ . This configuration is for applications that are AC coupled at the receive end that require a 0V common mode. Common mode termination is direct to $V_{\text{SSA}}$ .                                                                                                                         |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
| 1h    | Common point set to $0.8 V_{\text{DDA}}$ . This configuration is for AC coupled systems. The transmitter has no effect on the receiver common mode, which is set to optimize the input sensitivity of the receiver. Common mode termination is via a 50 pF capacitor to $V_{\text{SSA}}$ . This mode is probably not used for SATA. |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
| 2h    | Common point set to $0.2 V_{\text{DDA}}$ . This configuration is for applications (DC coupled or AC coupled at the transmit end) that require a low common mode. Common mode termination is via a 50 pF capacitor to $V_{\text{SSA}}$ .                                                                                             |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |
| 3h    | Common point floating, wide common mode range. This configuration utilizes the internal AC coupled level shifters to support a wide common mode range, and it therefore requires DC balanced coding. It can also be used to achieve high single ended impedance. This mode is probably not used for SATA.                           |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                                                                               |   |         |   |    |          |  |       |          |  |    |          |         |    |          |         |    |          |         |    |          |         |    |          |         |    |          |        |    |          |        |    |          |        |

### 29.4.35 Port PHY Status Register (P0PHYSR)

The port PHY status register (P0PHYSR) is used to reflect the PHY status. Note: In multi-port configurations, each of these registers will read identically. This description is only valid for the configuration GS60. See the corresponding P0PHYSR Register description for each configuration. The P0PHYSR is shown in [Figure 29-35](#) and described in [Table 29-39](#).

**Figure 29-35. Port PHY Status Register (P0PHYSR)**

LEGEND: R = Read only; -n = value after reset

**Table 29-39. Port PHY Status Register (P0PHYSR) Field Description**

| Bit  | Field    | Value | Description                                                |
|------|----------|-------|------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved.                                                  |
| 1    | SIGDET   | 0-1   | Signal Detect. Indicates that Port # has a signal present. |
| 0    | LOCK     | 0-1   | PLL Lock. Indicates that the PLL has locked.               |

## ***Serial Peripheral Interface (SPI)***

This chapter describes the serial peripheral interface (SPI) module. See your device-specific data manual to determine how many SPIs are available on your device.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>30.1 Introduction .....</b> | <b>1430</b> |
| <b>30.2 Architecture .....</b> | <b>1432</b> |
| <b>30.3 Registers .....</b>    | <b>1458</b> |

## 30.1 Introduction

### 30.1.1 Purpose of the Peripheral

The SPI is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (2 to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communication between the device and external peripherals. Typical applications include interface to external I/O or peripheral expansion via devices such as shift registers, display drivers, SPI EPROMS and analog-to-digital converters.

### 30.1.2 Features

The SPI has the following features:

- 16-bit shift register
- 16-bit Receive buffer register (SPIBUF) and 16-bit Receive buffer emulation 'alias' register (SPIEMU)
- 16-bit Transmit data register (SPIDAT0) and 16-bit Transmit data and format selection register (SPIDAT1)
- 8-bit baud clock generator
- Serial clock (SPIx\_CLK) I/O pin
- Slave in, master out (SPIx\_SIMO) I/O pin
- Slave out, master in (SPIx\_SOMI) I/O pin
- SPI enable ( $\overline{\text{SPIx\_ENA}}$ ) I/O pin (4-pin or 5-pin mode only)
- Multiple slave chip select ( $\overline{\text{SPIx\_SCS}}[\bar{n}]$ ) I/O pins (4-pin or 5-pin mode only)
- Programmable SPI clock frequency range
- Programmable character length (2 to 16 bits)
- Programmable clock phase (delay or no delay)
- Programmable clock polarity (high or low)
- Interrupt capability
- DMA support (read/write synchronization events)

The SPI allows software to program the following options:

- SPI pins as functional or digital I/O pins
- SPI Master or Slave mode
- SPIx\_CLK frequency (SPI module clock/3 through SPI module clock/256)
- 3-pin, 4-pin, and 5-pin options
- Character length (2 to 16 bits) and shift direction (MSB/LSB first)
- Clock phase (delay or no delay) and polarity (high or low)
- Delay between transmissions in master mode.
- Chip select setup and hold times in master mode
- Chip select hold in master mode

### 30.1.3 Functional Block Diagram

The [Figure 30-1](#) shows the SPI block diagram.

**Figure 30-1. SPI Block Diagram**

NOTE: The value *x* indicates the applicable SPI; that is, SPI0, SPI1, etc. See your device-specific data manual to determine how many SPIs are available on your device. The value *n* indicates the SPI pins available. See your device-specific data manual to determine how many SPI pins are available on your device.

A Indicates the log controlled by SPI register bits.

B Solid line represents data flow for SPI master mode. Dashed line represents data flow for SPI slave mode.

### 30.1.4 Industry Standard(s) Compliance Statement

The programmable configuration capability of the SPI allows it to gluelessly interface to a variety of SPI format devices. The SPI does not conform to a specific industry standard.

## 30.2 Architecture

This section describes the SPI operation modes. It gives an overview of SPI operation and then provides details on the 3-pin, 4-pin, and 5-pin options, as well as more specific details on the supported data formats.

### 30.2.1 Clock

The SPI clock (SPIx\_CLK) is derived from the SPI module clock. The maximum clock bit rate supported is SPI module clock/3, as determined by the PRESCALE field in the SPI data format register  $n$  (SPIFMT $n$ ). The SPIx\_CLK frequency is calculated as:

$$\text{SPIx\_CLK frequency} = [\text{SPI module clock}] / [\text{SPIFMT}n.\text{PRESCALE} + 1]$$

### 30.2.2 Signal Descriptions

Table 30-1 shows the SPI pins used to interface to external devices.

**Table 30-1. SPI Pins**

| Pin <sup>(1)</sup>         | Type         | Function                                                             |
|----------------------------|--------------|----------------------------------------------------------------------|
| SPIx_SIMO                  | Input/Output | Serial data input in slave mode, serial data output in master mode   |
| SPIx_SOMI                  | Input/Output | Serial data output in slave mode, serial data input in master mode   |
| SPIx_CLK                   | Input/Output | Serial clock input in slave mode, serial clock output in master mode |
| SPIx_SCS[n] <sup>(2)</sup> | Input/Output | Slave chip select output in master mode, input in slave mode         |
| SPIx_ENA                   | Input/Output | Input in master mode, output in slave mode indicates slave is ready  |

<sup>(1)</sup> The value  $x$  indicates the applicable SPI; that is, SPI0, SPI1, etc. See your device-specific data manual to determine how many SPIs are available on your device.

<sup>(2)</sup> The value  $n$  indicates the SPI pins available; that is, SPIx\_SCS[0], SPIx\_SCS[1], etc. See your device-specific data manual to determine how many SPI pins are available on your device.

### 30.2.3 Operation Modes

The SPI operates in master or slave mode. The SPI bus master is the device that drives the SPIx\_CLK, SPIx\_SIMO, and optionally the SPIx\_SCS[n] signals, and therefore initiates SPI bus transfers. The CLKMOD and MASTER bits in the SPI global control register 1 (SPIGCR1) select between master and slave mode. In both master and slave mode, the SPI supports four options:

- 3-pin option
- 4-pin with chip select option
- 4-pin with enable option
- 5-pin with enable and chip select option

The 3-pin option is the basic clock, data in, and data out SPI interface and uses the SPIx\_CLK, SPIx\_SIMO, and SPIx\_SOMI pins. The 4-pin with chip select option adds the SPIx\_SCS[n] pin that is used to support multiple SPI slave devices on a single SPI bus. The 4-pin with enable option adds the SPIx\_ENA pin that is used to increase the overall throughput by adding hardware handshaking. The 5-pin option uses all the SPI pins and is a superset of the different options.

### 30.2.4 Programmable Registers

A general representation of the SPI programmable registers is shown in [Table 30-2](#). For details on registers, see [Section 30.3](#).

**Table 30-2. SPI Registers**

| Offset Address <sup>(1)</sup> | Acronym  | Name                              | Description                                                                                                                                           | Section                         |
|-------------------------------|----------|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| 0h                            | SPIGCR0  | Global control register 0         | Contains the software reset bit for the module                                                                                                        | <a href="#">Section 30.3.1</a>  |
| 4h                            | SPIGCR1  | Global control register 1         | Controls basic configurations of the module                                                                                                           | <a href="#">Section 30.3.2</a>  |
| 8h                            | SPIINT0  | Interrupt register                | Enable bits for interrupts, error, DMA and other functionality.                                                                                       | <a href="#">Section 30.3.3</a>  |
| Ch                            | SPIVLV   | Level register                    | SPI interrupt levels are set in this register.                                                                                                        | <a href="#">Section 30.3.4</a>  |
| 10h                           | SPIFLG   | Flag register                     | Shows the status of several events during the operation.                                                                                              | <a href="#">Section 30.3.5</a>  |
| 14h                           | SPIPC0   | Pin control register 0            | Determines if pins operate as general I/O or SPI functional pin                                                                                       | <a href="#">Section 30.3.6</a>  |
| 18h                           | SPIPC1   | Pin control register 1            | Controls the direction of data on the I/O pins                                                                                                        | <a href="#">Section 30.3.7</a>  |
| 1Ch                           | SPIPC2   | Pin control register 2            | Reflects the values on the I/O pins                                                                                                                   | <a href="#">Section 30.3.8</a>  |
| 20h                           | SPIPC3   | Pin control register 3            | Controls the values sent to the I/O pins                                                                                                              | <a href="#">Section 30.3.9</a>  |
| 24h                           | SPIPC4   | Pin control register 4            | Sets data values in the SPIPC3 register                                                                                                               | <a href="#">Section 30.3.10</a> |
| 28h                           | SPIPC5   | Pin control register 5            | Clears values in the SPIPC3 register                                                                                                                  | <a href="#">Section 30.3.11</a> |

<sup>(1)</sup> The actual address of these registers is device specific and CPU specific. See your device-specific data manual to verify the SPI register addresses.

### 30.2.5 Master Mode Settings

The four master mode options are defined by the configuration bit settings listed in [Table 30-3](#). Other configuration bits may take any value in the range listed in [Table 30-4](#). The values listed in [Table 30-3](#) and [Table 30-4](#) should not be changed while the ENABLE bit in the SPI global control register 1 (SPIGCR1) is set to 1. Note that in certain cases the allowed values may still be ignored. For example, [Table 30-4](#) indicates that SPIDELAY may take a range of values in Master 3-pin mode; however, SPIDELAY has no effect in Master 3-pin mode. For complete details on each mode, see the following sections that explain the SPI operation for each of the master modes.

**Table 30-3. SPI Register Settings Defining Master Modes**

| Register | Bit(s)   | Master 3-pin | Master 4-pin<br>Chip Select | Master 4-pin Enable | Master 5-pin |
|----------|----------|--------------|-----------------------------|---------------------|--------------|
| SPIGCR0  | RESET    | 1            | 1                           | 1                   | 1            |
| SPIGCR1  | ENABLE   | 1            | 1                           | 1                   | 1            |
| SPIGCR1  | LOOPBACK | 0            | 0                           | 0                   | 0            |
| SPIGCR1  | CLKMOD   | 1            | 1                           | 1                   | 1            |
| SPIGCR1  | MASTER   | 1            | 1                           | 1                   | 1            |
| SPIPC0   | SOMIFUN  | 1            | 1                           | 1                   | 1            |
| SPIPC0   | SIMOFUN  | 1            | 1                           | 1                   | 1            |
| SPIPC0   | CLKFUN   | 1            | 1                           | 1                   | 1            |
| SPIPC0   | ENAFUN   | 0            | 0                           | 1                   | 1            |
| SPIPC0   | SCS0FUN  | 0            | 1                           | 0                   | 1            |

**Table 30-4. Allowed SPI Register Settings in Master Modes**

| Register            | Bit(s)      | Master 3-pin | Master 4-pin<br>Chip Select | Master 4-pin Enable | Master 5-pin |

| SPIDELAY            | C2EDELAY    | 0 to FFh     | 0 to FFh                    | 0 to FFh            | 0 to FFh     |

#### 30.2.5.1 Master Mode Timing Options

The SPI in master mode supports several options to modify the timing of its generation of the chip select signal ( $\overline{\text{SPiX\_SCS}}[n]$ ). This allows the SPI to support the timing requirements of various slave devices without adding additional overhead to the CPU by generating the appropriate delays automatically.

### 30.2.5.1.1 Chip Select Setup Time

The master can be configured to provide a (slow) slave device a certain chip select setup time to the first edge on SPIx\_CLK. This delay is controlled by the C2TDELAY field in the SPI delay register (SPIDELAY) and can be configured between 3 and 257 SPI module clock cycles. The C2TDELAY is applicable only in 4-pin with chip select and 5-pin SPI master modes. The C2TDELAY begins when the SPI master asserts SPIx\_SCS[n]. The C2T delay period is specified by:

*Maximum duration of C2TDELAY period = SPIDELAY.C2TDELAY + 2 (SPI module clock cycles)*

Note that if SPIDELAY.C2TDELAY = 0, then the C2TDELAY period = 0.

The previous value of the CSHOLD bit in the SPI transmit data register (SPIDAT1) must be cleared to 0 for the C2T delay to be enabled.

---

**NOTE:** If the SPIDAT1.CSHOLD bit is set within the control field, the current hold time and the following setup time will not be applied in between transaction.

---

### 30.2.5.1.2 Chip Select Hold Time

The master can be configured to provide a (slow) slave device a certain chip select hold time after the last edge on SPIx\_CLK. This delay is controlled by the T2CDELAY bit in the SPI delay register (SPIDELAY) and can be configured between 2 and 256 SPI module clock cycles. The T2CDELAY is applicable only in 4-pin with chip select and 5-pin SPI master modes. The T2CDELAY begins after the data shifting period ends. The T2C delay period is specified by:

*Maximum duration of T2CDELAY period = SPIDELAY.T2CDELAY + 1 (SPI module clock cycle)*

Note that if SPIDELAY.T2CDELAY = 0, then the T2CDELAY period = 0. If the PHASE bit in the SPI data format register *n* (SPIFMTn) is 0, then the T2CDELAY period lasts for an additional 1/2 SPIx\_CLK time over that specified by the above equation.

The current value of the CSHOLD bit in the SPI transmit data register (SPIDAT1) must be cleared to 0 for T2C delay to be enabled.

---

**NOTE:** If the SPIDAT1.CSHOLD bit is set within the control field, the current hold time and the following setup time will not be applied in between transaction.

---

### 30.2.5.1.3 Automatic Delay Between Transfers

The SPI master can automatically insert a delay of between 2 and 65 SPI module clock cycles between transmissions. This delay is controlled by the WDELAY field in the SPI data format register *n* (SPIFMTn) and is enabled by setting the WDEL bit in the SPI transmit data register (SPIDAT1) to 1. The WDELAY period begins when the T2EDELAY period terminates (if T2E delay period is enabled) or when the T2CDELAY period terminates (if T2E delay period was disabled and T2C delay period was enabled) or when the master deasserts SPIx\_SCS[n] (if T2E and T2C delay periods are disabled). If a transfer is initiated by writing a 32-bit value to SPIDAT1, then the new values of SPIDAT1.WDEL and SPIFMTn.WDELAY are used; otherwise, the old values of SPIDAT1.WDEL and SPIFMTn.WDELAY are used. The WDELAY delay period is specified by:

*Maximum duration of WDELAY period = SPIFMTn.WDELAY + 2 (SPI module clock cycles)*

### 30.2.5.1.4 Chip Select Hold Option

There are slave devices available that require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers. The SPI can support both types of slave devices. The CSHOLD bit in the SPI transmit data register (SPIDAT1) selects between the two options.

If the chip select hold option is enabled, the chip select will not toggle between two consecutive accesses; therefore, the SPIDELAY.T2CDELAY of the first transfer and the SPIDELAY.C2TDELAY of the second transfer will not be applied. However, the wait delay could still be applied between the two transactions, if the WDEL bit in SPIDAT1 is set to 1.

The current and previous values of the CSHOLD bit are retained. Though the current value of the CSHOLD bit is initialized to 0 when the RESET bit in the SPI global control register 0 (SPIGCR0) is cleared to 0, the previous value of the CSHOLD bit is not initialized. The previous value of the CSHOLD bit must be explicitly initialized by writing twice to the CSHOLD bit.

### 30.2.6 Slave Mode Settings

The four slave mode options are defined by the configuration bit settings listed in [Table 30-5](#). Other configuration bits may take any value in the range listed in [Table 30-6](#). The values listed in [Table 30-5](#) and [Table 30-6](#) should not be changed while the ENABLE bit in the SPI global control register 1 (SPIGCR1) is set to 1. Note that in certain cases the allowed values may still be ignored. For complete details on each mode, see the following sections that explain the SPI operation for each of the slave modes.

**Table 30-5. SPI Register Settings Defining Slave Modes**

| Register | Bit(s)   | Slave 3-pin | Slave 4-pin Chip Select | Slave 4-pin Enable | Slave 5-pin |
|----------|----------|-------------|-------------------------|--------------------|-------------|
| SPIGCR0  | RESET    | 1           | 1                       | 1                  | 1           |
| SPIGCR1  | ENABLE   | 1           | 1                       | 1                  | 1           |
| SPIGCR1  | LOOPBACK | 0           | 0                       | 0                  | 0           |
| SPIGCR1  | CLKMOD   | 0           | 0                       | 0                  | 0           |
| SPIGCR1  | MASTER   | 0           | 0                       | 0                  | 0           |
| SPIPC0   | SOMIFUN  | 1           | 1                       | 1                  | 1           |
| SPIPC0   | SIMOFUN  | 1           | 1                       | 1                  | 1           |
| SPIPC0   | CLKFUN   | 1           | 1                       | 1                  | 1           |
| SPIPC0   | ENAFUN   | 0           | 0                       | 1                  | 1           |
| SPIPC0   | SCS0FUN  | 0           | 1                       | 0                  | 1           |

**Table 30-6. Allowed SPI Register Settings in Slave Modes**

| Register                           | Bit(s)      | Slave 3-pin | Slave 4-pin Chip Select | Slave 4-pin Enable | Slave 5-pin |
|------------------------------------|-------------|-------------|-------------------------|--------------------|-------------|
| SPIINT0                            | ENABLEHIGHZ | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | WDELAY      | 0 to 3Fh    | 0 to 3Fh                | 0 to 3Fh           | 0 to 3Fh    |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | PARPOL      | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | PARENA      | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | WAITENA     | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | SHIFTDIR    | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | DISCSTIMERS | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | POLARITY    | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | PHASE       | 0,1         | 0,1                     | 0,1                | 0,1         |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | PRESCALE    | 2 to FFh    | 2 to FFh                | 2 to FFh           | 2 to FFh    |
| SPIFMT <sub>n</sub> <sup>(1)</sup> | CHARLEN     | 2 to 10h    | 2 to 10h                | 2 to 10h           | 2 to 10h    |
| SPIDELAY                           | C2TDELAY    | 0 to FFh    | 0 to FFh                | 0 to FFh           | 0 to FFh    |
| SPIDELAY                           | T2CDELAY    | 0 to FFh    | 0 to FFh                | 0 to FFh           | 0 to FFh    |
| SPIDELAY                           | T2EDELAY    | 0 to FFh    | 0 to FFh                | 0 to FFh           | 0 to FFh    |
| SPIDELAY                           | C2EDELAY    | 0 to FFh    | 0 to FFh                | 0 to FFh           | 0 to FFh    |

<sup>(1)</sup> In slave mode, only SPIFMT0 is used. When SPIDAT1 is written, the DFSEL field in SPIDAT1 is cleared to 0 to select SPIFMT0.

### 30.2.7 SPI Operation: 3-Pin Mode

**NOTE:** If only unidirectional communication is required, the SPIx\_CLK pin and the two data pins (SPIx\_SOMI and SPIx\_SIMO) must all be configured as functional pins. A 2-pin unidirectional mode is not supported.

The SPI 3-pin mode uses only the clock (SPIx\_CLK) and data (SPIx\_SOMI and SPIx\_SIMO) pins for bidirectional communication between master and slave devices. Figure 30-2 shows the basic 3-pin SPI option.

To select the 3-pin SPI option, the SPIx\_CLK, SPIx\_SOMI, and SPIx\_SIMO pins should be configured as functional pins by configuring the SPI pin control register 0 (SPIPC0). The SPIx\_SCS[n] and SPIx\_ENA pins can be used as general-purpose I/O pins by configuring the SPIPC1 through SPIPC5 registers.

The SPI operates in either master or slave mode. The CLKMOD and MASTER bits in the SPI global control register 1 (SPIGCR1) select between master and slave mode; both must be programmed to 1 to configure the SPI for master mode or to 0 to configure the SPI for slave mode. The SPI bus master is the device that drives the SPIx\_CLK signal and initiates SPI bus transfers. In SPI master mode, the SPIx\_SOMI pin output buffer is in a high-impedance state and the SPIx\_CLK and the SPIx\_SIMO pin output buffer is enabled. In SPI slave mode, the SPIx\_SIMO and SPIx\_CLK pin output buffer is in a high-impedance state and the SPIx\_SOMI pin output buffer is enabled.

In master mode with the 3-pin option, the DSP writes transmit data to the SPI transmit data registers (SPIDAT0[15:0] or SPIDAT1[15:0]). This initiates a transfer. A series of clocks pulses will be driven out on the SPIx\_CLK pin to complete the transfer. Each clock pulse on the SPIx\_CLK pin causes the simultaneous transfer (in both directions) of one bit by both the master and slave SPI devices. CPU writes to the configuration bits in SPIDAT1 (not writing to SPIDAT1[15:0]) do not result in a new transfer. When the selected number of bits has been transmitted, the received data is transferred to the SPI receive buffer register (SPIBUF) for the CPU to read. Data is stored right-justified in SPIBUF.

In slave mode with 3-pin option, CPU writes to SPIDAT0[15:0] or SPIDAT1[15:0] makes the slave ready to transmit. CPU writes to the configuration bits in SPIDAT1 (not writing to SPIDAT1[15:0]) do not make the slave ready to transmit.

**NOTE:** Either SPIDAT0 or SPIDAT1 can be used on both master and slaves sides.

**Figure 30-2. SPI 3-Pin Option**

### 30.2.8 SPI Operation: 4-Pin with Chip Select Mode

The 4-pin with chip select option is a superset of the 3-pin option and uses the chip select ( $\overline{\text{SPIx\_SCS}}[n]$ ) pin in addition to the clock ( $\text{SPIx\_CLK}$ ) and data ( $\text{SPIx\_SOMI}$  and  $\text{SPIx\_SIMO}$ ) pins. [Figure 30-3](#) shows the SPI 4-pin chip select option.

To select the 4-pin with chip select option, the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SOMI}$ ,  $\text{SPIx\_SIMO}$ , and  $\overline{\text{SPIx\_SCS}}[n]$  pins should be configured as functional pins by configuring the SPI pin control register 0 ( $\text{SPIPC0}$ ). The  $\overline{\text{SPIx\_ENA}}$  pin can be used as a general-purpose I/O pin by configuring the  $\text{SPIPC1}$  through  $\text{SPIPC5}$  registers.

In SPI master mode, the  $\text{SPIx\_SOMI}$  pin output buffer is in a high-impedance state and the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SIMO}$ , and  $\overline{\text{SPIx\_SCS}}[n]$  pin output buffer is enabled. In SPI slave mode, the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SIMO}$ , and  $\overline{\text{SPIx\_SCS}}[n]$  pin output buffer is in a high-impedance state, and the  $\text{SPIx\_SOMI}$  pin output buffer is enabled when  $\overline{\text{SPIx\_SCS}}[n]$  is asserted and in a high-impedance state when  $\overline{\text{SPIx\_SCS}}[n]$  is deasserted.

In slave mode with the chip select option enabled, the SPI ignores all transactions on the bus unless  $\overline{\text{SPIx\_SCS}}[n]$  is asserted by the bus master. It also 3-states its output pin when  $\overline{\text{SPIx\_SCS}}[n]$  is deasserted by the master to avoid conflicting with the active slave device on the bus.

In master mode, the  $\overline{\text{SPIx\_SCS}}[n]$  pin functions as an output, and toggles when a specific slave device is selected. However, this is most useful on devices that support multiple  $\overline{\text{SPIx\_SCS}}[n]$  pins.

However, one reason to use the  $\overline{\text{SPIx\_SCS}}[n]$  pin as a functional pin for the SPI master is to take advantage of the timing parameters that can be set using the SPI delay register ( $\text{SPIDELAY}$ ). The  $\text{SPIDELAY}$  allows delays to be added automatically so that the slave timing requirements between clock and chip select may be more easily met. Another reason would be to make use of the error detection built into the SPI.

---

**NOTE:** Either  $\text{SPIDAT0}$  or  $\text{SPIDAT1}$  can be used on both master and slaves sides.

---

**Figure 30-3. SPI 4-Pin Option with  $\overline{\text{SPIx\_SCS[n]}}$**

**NOTE:** During an SPI transfer, if the slave mode SPI detects a deassertion of its chip select even before its internal character length counter overflows, then it 3-states its SPIx\_SOMI pin. Once this condition has occurred, if a SPIx\_CLK edge is detected while the chip select is deasserted, the SPI stops the transfer and sets an error flag DLENERR (data length) and generates an interrupt if enabled.

### 30.2.9 SPI Operation: 4-Pin with Enable Mode

The 4-pin with enable option is a superset of the 3-pin option and uses the enable ( $\overline{\text{SPIx\_ENA}}$ ) pin in addition to the clock ( $\text{SPIx\_CLK}$ ) and data ( $\text{SPIx\_SOMI}$  and  $\text{SPIx\_SIMO}$ ) pins. Figure 30-4 shows the SPI 4-pin enable option.

To select the 4-pin with enable option, the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SOMI}$ ,  $\text{SPIx\_SIMO}$ , and  $\overline{\text{SPIx\_ENA}}$  pins should be configured as functional pins by configuring the SPI pin control register 0 ( $\text{SPIPC0}$ ). The  $\overline{\text{SPIx\_SCS}}[n]$  pins can be used as general-purpose I/O pins by configuring the  $\text{SPIPC1}$  through  $\text{SPIPC5}$  registers.

In SPI master mode, the  $\text{SPIx\_SOMI}$  and  $\overline{\text{SPIx\_ENA}}$  pin output buffer is in a high-impedance state and the  $\text{SPIx\_CLK}$  and  $\text{SPIx\_SIMO}$  pin output buffer is enabled. In SPI slave mode, the  $\text{SPIx\_CLK}$  and  $\text{SPIx\_SIMO}$  pin output buffer is in a high-impedance state, and the  $\text{SPIx\_SOMI}$  pin output buffer is enabled. In SPI slave mode, the  $\overline{\text{SPIx\_ENA}}$  pin output buffer enable depends upon the status of the transmit buffer and the configuration of the  $\text{ENABLEHIGHZ}$  bit in the SPI interrupt register ( $\text{SPIINT0}$ ).

The handshake operation works this way:

- After a transfer completes, both the master and slave SPI modules need to be serviced.
- The slave SPI deasserts  $\overline{\text{SPIx\_ENA}}$  after the transfer, indicating it requires servicing and is not ready.
- The slave should begin servicing its SPI by first reading receive data from the SPI receive buffer register ( $\text{SPIBUF}$ ).
- Next, the slave device should write transmit data to the SPI transmit data registers ( $\text{SPIDAT0}$  or  $\text{SPIDAT1}$ ). This causes the slave SPI to assert  $\overline{\text{SPIx\_ENA}}$  indicating it is ready for the next transmission.
- In parallel, the master device can service its SPI at any time. It does not need to insert a delay before writing to its  $\text{SPIDAT0}$  or  $\text{SPIDAT1}$  in order to avoid overrunning the slave device. Instead, the master SPI module will automatically delay the next transfer until the slave has asserted  $\overline{\text{SPIx\_ENA}}$  again to indicate it is ready for the transmission.

This handshake allows the two SPIs to communicate at the maximum rate possible. Without the handshake pin, the master must insert a delay between each transfer long enough to support the worst case response time of the slave servicing its SPI or risk an overrun condition. With the handshake, the throughput is determined by the average response time of the two devices servicing their SPI ports.

The  $\overline{\text{SPIx\_ENA}}$  pin can be driven in a push-pull or open-drain mode, depending upon the setting of the  $\text{ENABLEHIGHZ}$  bit.

---

**NOTE:** Either  $\text{SPIDAT0}$  or  $\text{SPIDAT1}$  can be used on both master and slaves sides.

---

**Figure 30-4. SPI 4-Pin Option with  $\overline{\text{SPIx\_ENA}}$**

### 30.2.10 SPI Operation: 5-Pin Mode

The 5-pin mode is a superset of both 4-pin modes. To use the 5-pin mode, both the  $\overline{\text{SPIx\_ENA}}$  and the  $\text{SPIx\_SCS}[n]$  pins must be configured as functional pins, in addition to the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SIMO}$ , and  $\text{SPIx\_SOMI}$  pins by configuring the SPI pin control register 0 (SPIPC0). [Figure 30-5](#) shows the SPI 5-pin option.

In SPI master mode, the  $\text{SPIx\_SOMI}$  and  $\overline{\text{SPIx\_ENA}}$  pin output buffer is in a high-impedance state and the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SIMO}$ , and  $\text{SPIx\_SCS}[n]$  pin output buffer is enabled. In SPI slave mode, the  $\text{SPIx\_CLK}$ ,  $\text{SPIx\_SIMO}$ , and  $\text{SPIx\_SCS}[n]$  pin output buffer is in a high-impedance state, and the  $\text{SPIx\_SOMI}$  pin output buffer is enabled and disabled asynchronously by the  $\text{SPIx\_SCS}[n]$  input and the  $\overline{\text{SPIx\_ENA}}$  pin output buffer enable depends upon the status of the transmit buffer and the state of the  $\text{SPIx\_SCS}[n]$  input. In SPI slave mode, the assertion of the  $\overline{\text{SPIx\_ENA}}$  pin by the slave is delayed until the master asserts  $\text{SPIx\_SCS}[n]$ , thereby, allowing multiple SPI slaves on a single SPI bus, each slave with its own enable pin.

If the  $\overline{\text{SPIx\_ENA}}$  pin is in high-impedance mode ( $\text{ENABLEHIGHZ} = 1$  in the SPI interrupt register (SPIINT0)), the slave SPI will put this signal into the high-impedance state by default. The slave SPI will drive the  $\overline{\text{SPIx\_ENA}}$  signal low when new data is written to the slave transmit shift register and the slave has been selected by the master ( $\text{SPIx\_SCS}[n]$  is low).

If the  $\overline{\text{SPIx\_ENA}}$  pin is in push-pull mode ( $\text{ENABLEHIGHZ} = 0$ ), the slave SPI will drive this pin high by default when it is in functional mode. The slave SPI will drive the  $\overline{\text{SPIx\_ENA}}$  signal low when new data is written to the slave transmit shift register and the slave is selected by the master ( $\text{SPIx\_SCS}[n]$  is low). If the slave is deselected by the master ( $\text{SPIx\_SCS}[n]$  goes high), the slave  $\overline{\text{SPIx\_ENA}}$  signal is driven high automatically.

---

**NOTE:** Either SPIDAT0 or SPIDAT1 can be used on both master and slaves sides.

---

**Figure 30-5. SPI 5-Pin Option with  $\overline{\text{SPIx\_ENA}}$  and  $\overline{\text{SPIx\_SCS[n]}}$** 

**NOTE:** Push-Pull mode of the  $\overline{\text{SPIx\_ENA}}$  pin can be used only when there is a single slave in the system. When there are multiple SPI slave devices connected to the common  $\overline{\text{SPIx\_ENA}}$  pin, all the slaves should configure their  $\overline{\text{SPIx\_ENA}}$  pins in high-impedance mode.

During an SPI transfer, if slave mode SPI detects a deassertion of its chip select even before its internal character length counter overflows, then it 3-states its SPIx\_SOMI and  $\overline{\text{SPIx\_ENA}}$  (if SPIINT0.ENABLEHIGHZ bit is set to 1) pins. Once this condition has occurred, if a SPIx\_CLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets an error flag DLENERR (data length) and generates an interrupt if enabled.

### 30.2.11 Data Formats

The SPI provides the capability to configure four independent data formats. These formats are configured by programming the corresponding SPI data format registers (SPIFMT $n$ ). In each data format, the following characteristics of the SPI operation are selected:

- Character length from 2 to 16 bits: The character length is configured by the SPIFMT $n$ .CHARLEN field.
- Shift direction (MSB first or LSB first): The shift out direction is configured by the SPIFMT $n$ .SHIFTDIR bit.
- Clock polarity: The clock polarity is configured by the SPIFMT $n$ .POLARITY bit.
- Clock phase: The clock phase is configured by the SPIFMT $n$ .PHASE bit.

The data format is chosen on each transaction. Transmit data is written to the SPI transmit data register 1 (SPIDAT1) and in the same write the data word format select (DFSEL) bit in SPIDAT1 indicates which data format is to be used for the next transaction. Alternatively, the data format can be configured once and applies to all transactions that follow until the data format is changed.

#### 30.2.11.1 Character Length

The character length is configured by the SPIFMT $n$ .CHARLEN bit. Legal values are 2 bits (2h) to 16 bits (10h). The character length is independently configured for each of the four data formats; and it must be programmed in both master mode and slave mode.

Transmit data is written to SPIDAT1. The transmit data must be written right-justified irrespective of the character length. The SPI automatically sends out the data correctly based on the chosen data format.

Figure 30-6 shows how a 12-bit word (EC9h) needs to be written to the transmit buffer in order to be transmitted correctly.

**Figure 30-6. Format for Transmitting 12-Bit Word**

| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| x   | x   | x   | x   | 1   | 1   | 1  | 0  | 1  | 1  | 0  | 0  | 1  | 0  | 0  | 1  |

The data received in SPIBUF is right-justified irrespective of the character length and is padded with 0s when character length is less than 16.

Figure 30-7 shows how a 10-bit word (3A2h) is stored in the buffer once it is received.

**Figure 30-7. Format for 10-Bit Received Word**

|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| 0   | 0   | 0   | 0   | 0   | 0   | 1  | 1  | 1  | 0  | 1  | 0  | 0  | 0  | 1  | 0  |

#### 30.2.11.2 Shift Direction

The shift out direction is configured as most-significant bit (MSB) first or least significant bit (LSB) first. The shift out direction is selected by the SPIFMT $n$ .SHIFTDIR bit. The shift out direction is independently configured for each of the four data formats.

- When SPIFMT $n$ .SHIFTDIR is 0, the transmit data is shifted out MSB first.
- When SPIFMT $n$ .SHIFTDIR is 1, the transmit data is shifted out LSB first.

### 30.2.11.3 Clock Phase and Polarity

The SPI provides the flexibility to program four different clock mode combinations that SPIx\_CLK may operate, enabling a choice of the clock phase (delay or no delay) and the clock polarity (rising edge or falling edge). When operating with PHASE active, the SPI makes the first bit of data available after SPIDAT1 is written and before the first edge of SPIx\_CLK. The data input and output edges depend on the values of both the POLARITY and PHASE bits as shown in Table 30-7.

**Table 30-7. Clocking Modes**

| POLARITY | PHASE | Action                                                                                                                                                         |
|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0        | 0     | Data is output on the rising edge of SPIx_CLK. Input data is latched on the falling edge.                                                                      |
| 0        | 1     | Data is output one half-cycle before the first rising edge of SPIx_CLK and on subsequent falling edges. Input data is latched on the rising edge of SPIx_CLK.  |
| 1        | 0     | Data is output on the falling edge of SPIx_CLK. Input data is latched on the rising edge.                                                                      |
| 1        | 1     | Data is output one half-cycle before the first falling edge of SPIx_CLK and on subsequent rising edges. Input data is latched on the falling edge of SPIx_CLK. |

Figure 30-8 to Figure 30-11 illustrate the four possible signals of SPIx\_CLK corresponding to each mode. Having four signal options allows the SPI to interface with different types of serial devices. Also shown are the SPIx\_CLK control bit polarity and phase values corresponding to each signal.

**Figure 30-8. Clock Mode with POLARITY = 0 and PHASE = 0**

**Figure 30-9. Clock Mode with POLARITY = 0 and PHASE = 1**

**Figure 30-10. Clock Mode with POLARITY = 1 and PHASE = 0**

**Figure 30-11. Clock Mode with POLARITY = 1 and PHASE = 1**

### 30.2.11.4 SPI Data Transfer Example

Figure 30-12 illustrates an SPI data transfer between two devices using a character length of five bits.

**Figure 30-12. Five Bits per Character (5-Pin Option)**

### 30.2.12 Interrupt Support

The SPI interrupt system is controlled by three registers:

- The SPI interrupt level register (SPILVL) controls the interrupt level. The interrupt level must be set to select the level one interrupt (INT1).
- The SPI interrupt register (SPIINT) contains bits to selectively enable/disable each interrupt event.
- The SPI flag register (SPIFLG) contains flags indicating the interrupt conditions that have occurred.

To identify the interrupt source in the SPI peripheral, the CPU reads the SPI flag status register (SPIFLG) or the INTVECT1 code in the SPI interrupt vector register 1 (INTVEC1).

Check your device-specific data manual for details on the exact CPU interrupt numbers assigned to the SPI interrupts.

### 30.2.13 DMA Events Support

If handling the SPI message traffic on a character-by-character basis requires too much CPU overhead, then the CPU can configure the system DMA to handle the SPI data transfer.

The SPI module has two DMA synchronization event outputs for receive (REVT) and transmit (XEVT), allowing DMA transfers to be triggered by SPI read receive and write transmit events. The SPI module enables DMA requests by enabling the DMA request enable (DMAREQEN) bit in the SPI interrupt register (SPIINT0).

When a character is to be transmitted the SPI module signals the DMA via the XEVT signal. The DMA controller then transfers the data from the source buffer into the SPI transmit data register (SPIDAT1). When a character is received, the SPI module signals the DMA via the REVT signal. The DMA controller then reads the data from the SPI receive buffer register (SPIBUF) and transfers it to a destination buffer for ready access.

In most cases, if the DMA is being used to service received data from the SPI, the receive interrupt enable (RXINTEN) bit in SPIINT0 should be cleared to 0. This prevents the CPU from responding to the received data in addition to the DMA. For specific SPI synchronization event number assignments and detailed DMA features, see your device-specific data manual.

### 30.2.14 Robustness Features

The SPI module includes many features to make the SPI communication link robust. A internal loopback test mode can be used to facilitate a power on self test routine. Additionally, the SPI master continually monitors the bus for faults on its data line. The handshaking between master and slave can be monitored as well, and appropriate actions can be taken (interrupt, timeout) when the handshake breaks down. The following sections describe these robustness features in more detail.

#### 30.2.14.1 SPI Internal Loopback Test Mode (Master Only)

##### CAUTION

The internal loop-back self-test mode should not be entered during a normal data transaction or unpredictable operation may occur.

To select the loopback mode, the SPIx\_CLK, SPIx\_SOMI, SPIx\_SIMO pins should be configured as functional pins by configuring the SPI pin control register 0 (SPIPC0) and by setting the LOOPBACK bit in the SPI global control register 1 (SPIGCR1). The SPIx\_ENA and SPIx\_SCS[n] pins can be used as general-purpose I/O pins by configuring the SPIPC1 through SPIPC5 registers. The internal loop-back self-test mode can be utilized to test the SPI transmit path and receive path including the transmit and receive buffers. In this mode, the transmit signal is internally fed back to the receiver and the SPIx\_SIMO, SPIx\_SOMI, and SPIx\_CLK pins are in a high-impedance state. This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

#### 30.2.14.2 SPI Transmission Continuous Self-Test

During a data transfer, the SPI inputs the value from its data output pin on the appropriate SPIx\_CLK edge. This value is compared against the expected value and any difference indicates a fault on the SPI bus. If a fault is detected, then the BITERR bit in the SPI receive buffer register (SPIBUF) and the BITERRFLG bit in the SPI flag register (SPIFLG) are set and an error interrupt is generated if enabled. The SPI continuous self-test mode is not available in SPI loopback mode.

### 30.2.14.3 SPI Detection of Slave Desynchronization

In the 4-pin with enable and 5-pin modes, the SPI master can monitor the slave  $\overline{\text{SPIx\_ENA}}$  activity to detect a desynchronization event.

Some conditions that may cause a desynchronization event are:

- Master or slave device being reset during a transmission.
- Asserting a software reset of the SPI module during transmission.
- Having an incorrect SPI pin configuration, causing the  $\overline{\text{SPIx\_ENA}}$  pin to behave incorrectly.
- Signal integrity problem causing additional clocks to be recognized by the slave.

The master can detect two desynchronization error conditions on the  $\overline{\text{SPIx\_ENA}}$  pin:

1. Slave deasserts  $\overline{\text{SPIx\_ENA}}$  after a transmission has begun, but before it completes.
2. Slave fails to deassert  $\overline{\text{SPIx\_ENA}}$  within a certain time period after the completion of the last bit of the transmission.

The first error condition is straightforward to detect. To detect the second error condition, the SPI module includes an eight-bit counter with a timeout count that can be configured through the T2EDELAY field in the SPI delay register (SPIDELAY).

When a desynchronization event is detected, the DESYNC bit in the SPI receive buffer register (SPIBUF) and the DESYNCFLG bit in the SPI flag register (SPIFLG) are set and a desynchronization error interrupt is asserted if enabled.

---

**NOTE:** Remember that even though the desynchronization is detected by the master device, the problem causing the desynchronization event can be on either the master or the slave device.

---

The T2EDELAY period begins once the T2CDELAY period terminates or after the data shifting period in case the T2CDELAY is disabled. It defines the maximum time for the slave to deassert the  $\overline{\text{SPIx\_ENA}}$  signal. If the slave device does not deassert the  $\overline{\text{SPIx\_ENA}}$  signal before the T2EDELAY timeout value expires, the SPIFLG.DESYNC flag is set and a desynchronization interrupt is asserted if enabled. The T2E delay period does not always complete, sometimes it is skipped or terminated early. The T2E delay period terminates immediately after the  $\overline{\text{SPIx\_ENA}}$  input is sampled (using the SPI module clock at intervals of  $\text{SPIFMTn.PRESCALE} + 2$ ) as deasserted. However, assuming the T2E period completes its duration is specified by:

*Maximum duration of T2EDELAY period =  $\text{SPIDELAY.T2EDELAY} + \text{SPIFMTn.PRESCALE} + 2$  (SPI module clock cycles)*

The T2EDELAY period is enabled only when the  $\overline{\text{SPIx\_ENA}}$  is asserted at the beginning of the T2E delay period, the SPIDELAY.T2EDELAY field has a non-zero value, and SPIFMTn.WAITENA bit is set to 1.

### 30.2.14.4 $\overline{\text{SPIx\_ENA}}$ Signal Time-Out

In 5-pin mode, in addition to the slave desynchronization detection, the master can also detect whether the slave fails to respond to the  $\overline{\text{SPIx\_SCS[n]}}$  signal by asserting  $\overline{\text{SPIx\_ENA}}$  in a timely manner.

This condition could be the result of a serious error, or it could simply be the result of the slave device taking too long to service its SPI.

To detect this condition, the C2EDELAY field in the SPI delay register (SPIDELAY) is used. The C2EDELAY period begins once the C2TDELAY period terminates or when the master asserts  $\overline{\text{SPIx\_SCS[n]}}$  (if C2TDELAY is disabled). It defines the maximum time for the addressed slave to respond by activating the  $\overline{\text{SPIx\_ENA}}$  signal. If the slave does not respond with the  $\overline{\text{SPIx\_ENA}}$  signal before the timeout value expires, then the TIMEOUT bit in the SPI receive buffer register (SPIBUF) and the TIMEOUTFLG bit in the SPI flag register (SPIFLG) are set, an interrupt is asserted if enabled, and the current transfer is terminated. The C2E delay period does not always complete, sometimes it is skipped or terminated early. The C2E delay period terminates immediately after the  $\overline{\text{SPIx\_ENA}}$  input is sampled (using the SPI module clock at intervals of  $\text{SPIFMTn.PRESCALE} + 2$ ) as asserted. However, assuming the C2E period completes its duration is specified by:

Maximum duration of C2EDELAY period = SPIDELAY.C2EDELAY + SPIFMTn.PRESCALE + 2 (SPI module clock cycles)

The C2EDELAY period is enabled only when the  $\overline{\text{SPiX\_ENA}}$  is deasserted at the beginning of the C2E delay period and SPIFMTn.WAITENA bit is set to 1. If SPIFMTn.WAITENA bit is set to 1 and C2EDELAY is cleared to 0, then the master waits indefinitely for the slave to assert SPiX\_ENA.

#### 30.2.14.5 SPI Data Length Error

An SPI can generate an error flag by detecting any mismatch in length of received/transmitted data with the programmed character length under certain conditions.

**Master Mode:** During a data transfer, if the SPI detects a deassertion of the  $\overline{\text{SPiX\_ENA}}$  pin (by the slave) while the character counter is not overflowed, then an error flag is set indicating the data length error. This can be caused by a slave receiving extra clocks (because of noise on the SPiX\_CLK line).

---

**NOTE:** In SPI master mode, the data length error will be generated only if the  $\overline{\text{SPiX\_ENA}}$  pin is used as a functional pin.

---

**Slave Mode:** During a transfer, if the SPI detects a deassertion of the  $\overline{\text{SPiX\_SCS[n]}}$  pin before its character length counter overflows, then an error flag is set indicating the data length error. If the slave SPI misses one or more SPiX\_CLK pulses from the master, this situation can occur. This error in slave mode would mean that both the transmitted and received data were not complete.

---

**NOTE:** In SPI slave mode, the data length error flag will be generated only if the  $\overline{\text{SPiX\_SCS[n]}}$  pin is configured as a functional pin.

---

### 30.2.15 Reset Considerations

This section describes the software and hardware reset considerations.

#### 30.2.15.1 Software Reset Considerations

The SPI module contains a software reset (RESET) bit in the SPI global control register 0 (SPIGCR0) that is used to reset the SPI module. As a result of a reset, the SPI module register values go to their reset state. The RESET bit must be set before any operation on the SPI is done.

#### 30.2.15.2 Hardware Reset Considerations

In the event of a hardware reset, the SPI module register values go to their reset state and the application software needs to reprogram the registers to the desired values.

### 30.2.16 Power Management

The SPI module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off so the module is completely inactive.

The SPI local low-power mode is asserted by setting the POWERDOWN bit in the SPI global control register 1 (SPIGCR1). Setting this bit stops the clocks to the SPI internal logic and the SPI registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SPI for that particular access alone.

Since entering a low-power mode has the effect of suspending all state machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. As a result, application software must ensure that a low-power mode is not entered during a transmission or reception of data.

### 30.2.17 General-Purpose I/O Pin

Each of the SPI pins may be programmed via the SPI pin control registers (SPIPC0 to SPIPC5) to be a general-purpose I/O (GPIO) pin.

When the SPI pins are not used as functional pins, they may be programmed to be either general input or general output pins by configuring SPIPC0. For example, in 3-pin mode, SPIx\_SOMI, SPIx\_SIMO, and SPIx\_CLK must be configured as SPI pins, while the SPIx\_SCS[n] and SPIx\_ENA pins should be configured as GPIO pins. The direction is controlled by configuring SPIPC1.

If configured as a general-purpose output, then SPIPC3 controls the output value. There is also a write 1 to set (SPIPC4) and a write 1 to clear (SPIPC5) for the data out value. These registers allow different tasks running on the CPU to manipulate the SPI I/O pins without read-modify-write hazards.

SPIPC2 reflects the current value on the pin when the particular pin is configured as a functional or general-purpose input pin. When the pin is configured as a functional or general-purpose output pin, SPIPC2 indicates the value that is attempted to be driven on the pin.

### 30.2.18 Emulation Considerations

#### CAUTION

Viewing or otherwise reading the following SPI registers: SPIBUF, SPIFLG, and INTVEC1 through the JTAG debugger causes their contents to change, possibly invalidating the results of the debug session. Be sure to set up the debugger to avoid reading these registers.

The SPI module does not support soft or hard stop during emulation breakpoints. The SPI module will continue to run if an emulation breakpoint is encountered.

In addition, any status registers that are cleared after reading will be affected if viewed in a memory or watch window of the debugger; since the emulator will read these registers to update the value displayed in the window.

### 30.2.19 Initialization

Perform the following procedure for initializing the SPI:

1. Reset the SPI by clearing the RESET bit in the SPI global control register 0 (SPIGCR0) to 0.
2. Take the SPI out of reset by setting SPIGCR0.RESET to 1.
3. Configure the SPI for master or slave mode by configuring the CLKMOD and MASTER bits in the SPI global control register 1 (SPIGCR1).
4. Configure the SPI for 3-pin, 4-pin with chip select, 4-pin with enable, or 5-pin mode by configuring the SPI pin control register 0 (SPIPC0).
5. Choose the SPI data format register *n* (SPIFMT*n*) to be used by configuring the DFSEL bit in the SPI transmit data register (SPIDAT1). In slave mode, only SPIFMT0 is supported.
6. Configure the SPI data rate, character length, shift direction, phase, polarity and other format options using SPIFMT*n* selected in step 5.
7. If SPI master, then configure the master delay options using the SPI delay register (SPIDELAY). In slave mode, SPIDELAY is not relevant.
8. Select the error interrupt notifications by configuring the SPI interrupt register (SPIINT0) and the SPI interrupt level register (SPILVL).
9. Enable the SPI communication by setting the SPIGCR1.ENABLE to 1.
10. Setup and enable the DMA for SPI data handling and then enable the DMA servicing for the SPI data requests by setting the SPIINT0.DMAREQEN to 1.
11. Handle SPI data transfer requests using DMA and service any SPI error conditions using the interrupt service routine.

## 30.2.20 Timing Diagrams

This section contains timing diagrams illustrating the C2TDELAY, C2EDELAY, T2CDELAY, T2EDELAY, and WDELAY delays and their interaction with the  $\overline{\text{SPIx\_SCS}}[n]$  and  $\overline{\text{SPIx\_ENA}}$  pins for all SPI modes.

### 30.2.20.1 SPI 3-Pin Mode

Figure 30-13 illustrates the WDELAY option in SPI 3-pin master mode. This is the only delay available in this mode. In CASE1, a new transfer is initiated during the WDELAY period and the transfer begins immediately after the WDELAY period ends. In CASE2, while WDELAY has completed, a new transfer will not begin until SPIDAT0/SPIDAT1 have been written with new data.

**Figure 30-13. SPI 3-Pin Master Mode with WDELAY**

### 30.2.20.2 SPI 4-Pin with $\overline{\text{SPIx\_SCS}}[n]$ Mode

Figure 30-14 illustrates the T2CDELAY, WDELAY and C2TDELAY delays in SPI 4-pin with  $\overline{\text{SPIx\_SCS}}[n]$  master mode. C2EDELAY and T2EDELAY are not available in this mode. All the three delay periods T2CDELAY, WDELAY, and C2TDELAY proceed to completion when enabled.

**Figure 30-14. SPI 4-Pin with  $\overline{\text{SPIx\_SCS}}[n]$  Mode with T2CDELAY, WDELAY, and C2TDELAY**

### 30.2.20.3 SPI 4-Pin with $\overline{\text{SPIx\_ENA}}$ Mode

Figure 30-15 shows the T2EDELAY and WDELAY delays in SPI 4-pin with  $\overline{\text{SPIx\_ENA}}$  master mode. T2CDELAY, C2TDELAY, and C2EDELAY are not available in this mode.

- In CASE1, the  $\overline{\text{SPIx\_ENA}}$  is deasserted during the T2EDELAY period. Consequently the T2EDELAY period is terminated early (a) and the WDELAY period begins immediately (b) if enabled. The next transfer is initiated as soon as the slave asserts  $\overline{\text{SPIx\_ENA}}$  again.
- In CASE2, the T2EDELAY period (c) completes before the  $\overline{\text{SPIx\_ENA}}$  is deasserted. As a result the DESYNC error is set. However since the  $\overline{\text{SPIx\_ENA}}$  is deasserted during the WDELAY period (d), the master delays the next transfer until the  $\overline{\text{SPIx\_ENA}}$  is asserted again.
- In CASE3, the T2EDELAY (e) and WDELAY (f) period (if enabled) both expire before the  $\overline{\text{SPIx\_ENA}}$  input is deasserted. The DESYNC error is set at the end of the T2EDELAY period (e). However in this case the master begins the next transfer immediately after it is initiated and ignores the  $\overline{\text{SPIx\_ENA}}$  during the transfer even if it is subsequently deasserted.

If the T2EDELAY delay period is disabled then the DESYNC error is not set. The SPI master behavior in this case depends on whether the  $\overline{\text{SPIx\_ENA}}$  gets deasserted during the WDELAY period (CASE2) or  $\overline{\text{SPIx\_ENA}}$  gets deasserted after the WDELAY period completes (CASE3).

**Figure 30-15. SPI 4-Pin with  $\overline{\text{SPIx\_ENA}}$  Mode Demonstrating T2EDELAY and WDELAY**

### 30.2.20.4 SPI 5-Pin Mode

Figure 30-16 shows the T2CDELAY, T2EDELAY, and WDELAY delays in SPI 5-pin master mode.

- In CASE1, the  $\overline{\text{SPIx\_EN}}_A$  is deasserted during the T2CDELAY period. However the T2CDELAY period proceeds to completion(a), the T2EDELAY period is skipped (if enabled) and the WDELAY period begins immediately (b) (if enabled). The next transfer is initiated as soon as the slave asserts  $\overline{\text{SPIx\_EN}}_A$  again.
- In CASE2, the  $\overline{\text{SPIx\_EN}}_A$  signal is deasserted by the slave during the T2EDELAY period (d) which begins upon the completion of the T2CDELAY period (c). The deassertion of the  $\overline{\text{SPIx\_EN}}_A$  causes the T2EDELAY period to terminate early and the WDELAY period (e) begins immediately (if enabled) after the T2EDELAY period terminates. The next transfer is initiated as soon as the slave asserts  $\overline{\text{SPIx\_EN}}_A$  again.
- In CASE3, the  $\overline{\text{SPIx\_EN}}_A$  signal is deasserted by the slave during the WDELAY period (h) which begins upon the completion of the T2CDELAY period (f) and T2EDELAY period (g). As a result the DESYNC error is set at the end of the T2EDELAY period (g). However since the  $\overline{\text{SPIx\_EN}}_A$  is deasserted during the WDELAY period (h), the master delays the next transfer until the  $\overline{\text{SPIx\_EN}}_A$  is asserted again.
- In CASE4, the  $\overline{\text{SPIx\_EN}}_A$  signal is not deasserted until after the completion of the T2CDELAY (j), T2EDELAY (k) and WDELAY (m) (if enabled) periods. The DESYNC error is set at the end of the T2EDELAY period (k). However in this case the master begins the next transfer immediately after it is initiated and ignores the  $\overline{\text{SPIx\_EN}}_A$  during the transfer even if it is subsequently deasserted.

If the T2EDELAY delay period is disabled then the DESYNC error is not set. The SPI master behavior in this case depends on whether the  $\overline{\text{SPIx\_EN}}_A$  gets deasserted during the T2CDELAY period (CASE1), WDELAY period (CASE3) or after the WDELAY period completes (CASE4).

If the slave deasserts the  $\overline{\text{SPIx\_EN}}_A$  signal before the completion of the configured master delays (T2CDELAY, T2EDELAY, WDELAY) then the master delays the next transfer until the slave asserts the  $\overline{\text{SPIx\_EN}}_A$  again. However if the slave delays the  $\overline{\text{SPIx\_EN}}_A$  deassertion until after the completion of the configured master delays then the master begins the next transfer immediately after it is initiated and ignores the  $\overline{\text{SPIx\_EN}}_A$  during the transfer even if it is subsequently deasserted.

Figure 30-17 shows the C2TDELAY and C2EDELAY in SPI 5-pin master mode.

- In CASE1, the  $\overline{\text{SPIx\_EN}}_A$  signal is asserted during the C2TDELAY period (a). However the C2TDELAY period proceeds to completion(a), the C2EDELAY period is skipped (if enabled) and the master begins generating the SPI clock for transmission.
- In CASE2, the  $\overline{\text{SPIx\_EN}}_A$  signal is asserted during the C2EDELAY period (d) which begins upon the completion of C2TDELAY period (c). The assertion of the  $\overline{\text{SPIx\_EN}}_A$  causes the C2EDELAY period to terminate early and the master begins generating the SPI clock for transmission.
- In CASE3, the  $\overline{\text{SPIx\_EN}}_A$  signal is not asserted until after the completion of the C2TDELAY (f) and C2EDELAY (g) periods. The TIMEOUT error is set at the end of the C2EDELAY period (g). The master deasserts the  $\overline{\text{SPIx\_SCS}}[n]$  signal immediately and clears the current transmit request.

If the C2EDELAY delay period is disabled then the SPI master behavior depends on whether the  $\overline{\text{SPIx\_EN}}_A$  gets asserted during the C2TDELAY period (CASE1) or after the C2TDELAY period completes (CASE2). In latter case there is no limit on how long the master will wait for the slave to respond with  $\overline{\text{SPIx\_EN}}_A$  asserted and hence there is no limit on period 'd' shown in CASE2. Thus when C2EDELAY period is disabled the TIMEOUT error is not set.

**Figure 30-16. SPI 5-Pin Mode Demonstrating T2CDELAY, T2EDELAY, and WDELAY**

**Figure 30-17. SPI 5-Pin Mode Demonstrating C2TDELAY and C2EDELAY**

### 30.3 Registers

This section describes the SPI control, data, and pin registers. The offset is relative to the associated base address of the module. See your device-specific data manual for the memory address of these registers.

**Table 30-8. SPI Registers**

| Offset Address | Acronym  | Register Description                                              | Section                         |
|----------------|----------|-------------------------------------------------------------------|---------------------------------|
| 0h             | SPIGCR0  | SPI Global Control Register 0                                     | <a href="#">Section 30.3.1</a>  |

| Bit   | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|-----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved  | 0     | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 24    | ENABLE    | 0     | SPI enable. This bit enables the SPI transfers. The other SPI configuration registers except SPIINT0.DMAREQEN should be configured before writing a 1 to this bit. This will prevent the SPI from responding to bus operations erroneously while it is in the process of being configured. The SPIINT0.DMAREQEN should be enabled after setting ENABLE. If SPIINT0.DMAREQEN is enabled before setting ENABLE then the first DMA request that occurs before the SPI is ready for data transfer may get dropped. |
|       |           | 1     | When ENABLE bit is cleared to 0, the following SPI registers get forced to their default states (to 0s except for RXEMPTY bit in SPIBUF):                                                                                                                                                                                                                                                                                                                                                                      |
|       |           |       | <ul style="list-style-type: none"> <li>Both TX and RX shift registers</li> <li>The TXDATA fields of SPIDAT0 and SPIDAT1 registers</li> <li>All the fields of the SPIFLG register</li> <li>Contents of SPIBUF and the internal RXBUF registers</li> </ul>                                                                                                                                                                                                                                                       |
|       |           | 0     | SPI is not activated for transfers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|       |           | 1     | Activates SPI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 23-17 | Reserved  | 0     | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 16    | LOOPBACK  | 0     | Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPIx_SIMO and SPIx_SOMI pins are configured with SPI functionality, then the SPIx_SIMO pin is internally connected to the SPIx_SOMI pin. The transmit data is looped back as receive data and is stored in the receive field of the concerned buffer.                                                                                                                                                   |
|       |           | 1     | Externally, during loop-back operation, the SPIx_CLK pin outputs an inactive value, SPIx_SIMO and SPIx_SOMI pins remain in high-impedance state. The SPI has to be initialized in master mode before the loop-back can be selected. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result.                                                                                                                                                                                  |
|       |           | 0     | Internal loop-back test mode disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|       |           | 1     | Internal loop-back test mode enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 30-11. SPI Interrupt Register (SPIINT0) Field Descriptions (continued)**

| Bit | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | BITERRENA  | 0<br>1 | Enables interrupt on bit error. An interrupt is to be generated when the SPIFLG.BITERRFLG is set.<br>No interrupt asserted upon bit error.<br>Enables an interrupt on a bit error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3   | DESYNCENA  | 0<br>1 | Enables interrupt on desynchronized slave. DESYNCENA is used in master mode only. The desynchronization monitor is active in master mode for the 4-pin with enable and 5-pin options. An interrupt is to be generated when the SPIFLG.DESYNCF LG is set.<br>No interrupt asserted upon desynchronization error.<br>Enables an interrupt on desynchronization of the slave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2   | PARERRENA  | 0<br>1 | Enables interrupt on parity error. An interrupt is to be generated when the SPIFLG.PARERRFLG is set.<br>No interrupt asserted upon parity error.<br>Enables an interrupt on a parity error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1   | TIMEOUTENA | 0<br>1 | Enables interrupt on $\overline{\text{SPiX\_ENA}}$ signal time-out. An interrupt is to be generated when SPIFLG.TIMEOUTFLG is set.<br>No interrupt asserted upon $\overline{\text{SPiX\_ENA}}$ signal time-out.<br>Enables an interrupt on a time-out of the $\overline{\text{SPiX\_ENA}}$ signal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 0   | DLENERRENA | 0<br>1 | Data length error interrupt enable. A data length error occurs under the following conditions.<br>Master: In a 4-pin with $\overline{\text{SPiX\_ENA}}$ mode or 5-pin mode, if the $\overline{\text{SPiX\_ENA}}$ pin from the slave is deasserted before the master has completed its transfer, the data length error is set. That is, if the character length counter has not overflowed while $\overline{\text{SPiX\_ENA}}$ deassertion is detected, then it means that the slave has neither received full data from the master nor has it transmitted complete data.<br>Slave: In a 4-pin with chip select mode or 5-pin mode, if the incoming valid $\overline{\text{SPiX\_SCS[n]}}$ pin is deactivated before the character length counter overflows, then data length error is set.<br>No interrupt is generated upon data length error.<br>Enables an interrupt when data length error occurs. |

### 30.3.4 SPI Interrupt Level Register (SPILVL)

The SPI interrupt level register (SPILVL) is shown in [Figure 30-21](#) and described in [Table 30-12](#).

**Figure 30-21. SPI Interrupt Level Register (SPILVL)**

| 31-10 | Reserved   | 4000h  | Reads return default value and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9     | TXINTFLG   | 0<br>1 | Transmitter empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new data can be written to it. This flag is set when a data is copied to the shift register either directly or from the TXBUF register. This bit is cleared by one of following ways: <ul style="list-style-type: none"> <li>Writing a new data to either SPIDAT0 or SPIDAT1</li> <li>Writing a 0 to SPIGCR1.ENABLE</li> </ul> 0 Transmit buffer is now full. No interrupt pending for transmitter empty.<br>1 Transmit buffer is empty. An interrupt is pending to fill the transmitter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8     | RXINTFLG   | 0<br>1 | Receiver full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). This bit is cleared under the following ways: <ul style="list-style-type: none"> <li>Reading the SPIBUF register. During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit.</li> <li>Reading INTVEC1 register when there is a receive buffer full interrupt</li> <li>Writing a 1 to this bit</li> <li>Writing a 0 to SPIGCR1.ENABLE</li> <li>System reset</li> </ul> 0 No new received data pending. Receive buffer is empty.<br>1 A newly received data is ready to be read. Receive buffer is full.<br><b>Note:</b> Clearing RXINTFLG bit by writing a 1 before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. This way, one can ignore a received data. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and the RXEMPTY bit will be cleared again. The SPIBUF contents should be read first if this situation needs to be avoided.                                                                                                                                                                                                                                     |
| 7     | Reserved   | 0      | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 6     | OVRNINTFLG | 0<br>1 | Receiver overrun flag. The bit is set when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. This bit is cleared under the following conditions: <ul style="list-style-type: none"> <li>Reading INTVEC1 register when there is a receive buffer overrun interrupt</li> <li>Writing a 1 to this bit</li> </ul> 0 Overrun condition did not occur.<br>1 Overrun condition has occurred.<br><b>Note:</b> Reading SPIBUF register does not clear the OVRNINTFLG bit. If an overrun interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.<br><b>Note:</b> A special condition under which OVRNINTFLG flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR and DLENERR occur, then OVRNINTFLG will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receiver overrun. |

**Table 30-13. SPI Flag Register (SPIFLG) Field Descriptions (continued)**

| Bit | Field      | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | Reserved   | 0     | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4   | BITERRFLG  | 0     | This bit is set when a mismatch of internal transmit data and transmitted data is detected. The SPI samples the signal of the transmit pin (master: SPIx_SIMO, slave: SPIx_SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag is set. A possible reason for a bit error can be a too high bit rate/capacitive load or another master/slave trying to transmit at the same time. This flag can be cleared by one of the following ways: <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIGCR1.ENABLE bit to 0.</li> </ul> |
|     |            | 0     | No bit error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|     |            | 1     | A bit error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3   | DESYNCFLG  | 0     | Desynchronization of slave device. Desynchronization monitor is active in master mode only. The master monitors the $\overline{\text{SPIx\_EN\!A}}$ signal coming from the slave device and sets the DESYNCFLG bit if the $\overline{\text{SPIx\_EN\!A}}$ signal is not deasserted after the last bit is transmitted plus $t_{\text{TZDELAY}}$ . Desynchronization can occur if a slave device misses a clock edge coming from the master. This flag can be cleared by one of the following ways: <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIGCR1.ENABLE bit to 0.</li> </ul>                                                    |
|     |            | 0     | No slave desynchronization detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|     |            | 1     | Slave is desynchronized<br><b>Note:</b> Inconsistency of DESYNCFLG in SPI. Due to the nature of this error, under some circumstances it is possible for a desynchronized error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But deince will be detected after the buffer transfer is completed. So, if CPU/DMA reads the received data quickly when an receive interrupt is detected, then the status flag may not reflect the correct deince condition.                                                               |
| 2   | PARERRFLG  | 0     | Calculated parity differs from received parity bit. If the parity generator is enabled an even or odd parity bit is added at the end of a data word . During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARERRFLG flag is set. This flag can be cleared by one of the following ways: <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIGCR1.ENABLE bit to 0.</li> </ul>                                                                                                                                                |
|     |            | 0     | No parity error detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|     |            | 1     | A parity error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1   | TIMEOUTFLG | 0     | Time-out due to non-activation of $\overline{\text{SPIx\_EN\!A}}$ signal. This flag is applicable only for the master mode. The SPI generates a time-out because the slave hasn't responded in time by activating the $\overline{\text{SPIx\_EN\!A}}$ signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUTFLG flag is set. This flag can be cleared by one of the following ways: <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIGCR1.ENABLE bit to 0.</li> </ul>                                                    |
|     |            | 0     | No $\overline{\text{SPIx\_EN\!A}}$ signal time-out occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|     |            | 1     | An $\overline{\text{SPIx\_EN\!A}}$ signal time-out occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0   | DLENERRFLG | 0     | Data length error flag. ### 30.3.8 SPI Pin Control Register 2 (SPIPC2)

The SPI pin control register 2 (SPIPC2) is shown in [Figure 30-25](#) and described in [Table 30-16](#).

**Figure 30-25. SPI Pin Control Register 2 (SPIPC2)**

LEGEND: R = Read only; U = Undefined; -n = value after reset

- <sup>(1)</sup> Not all devices support multiple slave chip select ( $\overline{\text{SPIx\_SCS}}[n]$ ) pins, see your device-specific data manual for supported pins. If the pins are not available, the corresponding bit is reserved and should be cleared to 0.

**Table 30-16. SPI Pin Control Register 2 (SPIPC2) Field Descriptions**

| Bit   | Field      | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-12 | Reserved   | 0     | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                   |

|       |            | 1     | Current value of $\overline{\text{SPIx\_SCS}}[n]$ pin is logic 1.                                                                                                                                                                                                                                                                                                                                                                              |

### 30.3.9 SPI Pin Control Register 3 (SPIPC3)

The SPI pin control register 3 (SPIPC3) is shown in [Figure 30-26](#) and described in [Table 30-17](#).

**Figure 30-26. SPI Pin Control Register 3 (SPIPC3)**

|          |                            |  |  |  |  |  |  |  |  |  |  |          |          |         |         |       |  |
|----------|----------------------------|--|--|--|--|--|--|--|--|--|--|----------|----------|---------|---------|-------|--|
| 31       | Reserved                   |  |  |  |  |  |  |  |  |  |  |          |          |         |         | 16    |  |
| R-0      |                            |  |  |  |  |  |  |  |  |  |  |          |          |         |         |       |  |
| 15       | 12                         |  |  |  |  |  |  |  |  |  |  | 11       | 10       | 9       | 8       |       |  |
| Reserved |                            |  |  |  |  |  |  |  |  |  |  | SOMIDOUT | SIMODOUT | CLKDOUT | ENADOUT |       |  |
| R-0      |                            |  |  |  |  |  |  |  |  |  |  | R/W-0    |          | R/W-0   | R/W-0   | R/W-0 |  |
| 7        | SCS0DOUT[n] <sup>(1)</sup> |  |  |  |  |  |  |  |  |  |  |          |          |         |         | 0     |  |
| R/W-0    |                            |  |  |  |  |  |  |  |  |  |  |          |          |         |         |       |  |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

<sup>(1)</sup> Not all devices support multiple slave chip select ( $\overline{\text{SPIx\_SCS}}[n]$ ) pins, see your device-specific data manual for supported pins. If the pins are not available, the corresponding bit is reserved and should be cleared to 0.

**Table 30-17. SPI Pin Control Register 3 (SPIPC3) Field Descriptions**

| Bit   | Field       | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|-------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-12 | Reserved    | 0      | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 11    | SOMIDOUT    | 0<br>1 | SPIx_SOMI data out write. This bit is only active when the SPIx_SOMI pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin.<br>Current value of SPIx_SOMI pin is logic 0.<br>Current value of SPIx_SOMI pin is logic 1.                                                                                                                                                                                                                                                                                                                                                  |
| 10    | SIMODOUT    | 0<br>1 | SPIx_SIMO data out write. This bit is only active when the SPIx_SIMO pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin.<br>Current value of SPIx_SIMO pin is logic 0.<br>Current value of SPIx_SIMO pin is logic 1.                                                                                                                                                                                                                                                                                                                                                  |
| 9     | CLKDOUT     | 0<br>1 | SPIx_CLK data out write. This bit is only active when the SPIx_CLK pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin.<br>Current value of SPIx_CLK pin is logic 0.<br>Current value of SPIx_CLK pin is logic 1.                                                                                                                                                                                                                                                                                                                                                      |
| 8     | ENADOUT     | 0<br>1 | $\overline{\text{SPIx\_ENA}}$ data out write. Only active when the $\overline{\text{SPIx\_ENA}}$ pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin.<br>Current value of $\overline{\text{SPIx\_ENA}}$ pin is logic 0.<br>Current value of $\overline{\text{SPIx\_ENA}}$ pin is logic 1.                                                                                                                                                                                                                                                                              |
| 7-0   | SCS0DOUT[n] | 0<br>1 | $\overline{\text{SPIx\_SCS}}[n]$ data out write. Only active when the $\overline{\text{SPIx\_SCS}}[n]$ pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin <i>n</i> .<br>Not all devices support multiple slave chip select ( $\overline{\text{SPIx\_SCS}}[n]$ ) pins, see your device-specific data manual for supported pins. If the pins are not available, the corresponding bit is reserved and should be cleared to 0.<br>Current value of $\overline{\text{SPIx\_SCS}}[n]$ pin is logic 0.<br>Current value of $\overline{\text{SPIx\_SCS}}[n]$ pin is logic 1. |

### 30.3.10 SPI Pin Control Register 4 (SPIPC4)

The SPI pin control register 4 (SPIPC4) is shown in [Figure 30-27](#) and described in [Table 30-18](#).

**Figure 30-27. SPI Pin Control Register 4 (SPIPC4)**

|       |                           |  |  |  |  |  |  |  |  |  |  |         |    |         |   |        |        |
|-------|---------------------------|--|--|--|--|--|--|--|--|--|--|---------|----|---------|---|--------|--------|

<sup>(1)</sup> Not all devices support multiple slave chip select ( $\overline{\text{SPIx\_SCS}}[n]$ ) pins, see your device-specific data manual for supported pins.

**Table 30-21. SPI Data Register 1 (SPIDAT1) Field Descriptions**

| Bit   | Field    | Value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|----------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-29 | Reserved | 0                           | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 28    | CSHOLD   | 0<br>1                      | Chip select hold mode. The CSHOLD bit is supported in master mode only. In slave mode, this bit is ignored. CSHOLD defines the behavior of the chip select line at the end of a data transfer.<br>The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed.<br>The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select hold information equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared.                                                                                                                                                                                                                                                                                                                             |
| 27    | Reserved | 0                           | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 26    | WDEL     | 0<br>1                      | Enable the delay counter at the end of the current transaction. The WDEL bit is supported in master mode only. In slave mode, this bit is ignored.<br>No delay will be inserted. However, $\overline{\text{SPIx\_SCS}}[n]$ pin will still be deactivated for at least 2 SPI module clock cycles if CSHOLD = 0.<br>After a transaction, SPIFMTn.WDELAY of the selected data format will be loaded into the delay counter. No transaction will be performed until the SPIFMTn.WDELAY counter overflows. The $\overline{\text{SPIx\_SCS}}[n]$ pin will be deactivated for at least (WDELAY + 2) × SPI module clock period.                                                                                                                                                                                                                                                                                                                          |
| 25-24 | DFSEL    | 0-3h<br>0<br>1h<br>2h<br>3h | Data word format select<br>Data word format 0 is selected<br>Data word format 1 is selected<br>Data word format 2 is selected<br>Data word format 3 is selected<br><br><b>Note: Preselecting a Format Register.</b> Writing to just the control field (using byte writes) does not initiate any SPI transfer in master mode. This feature can be used to set up SPIx_CLK phase or polarity before actually starting the transfer by just updating the DFSEL fields in the control field to select the required phase/polarity combination.                                                                                                                                                                                                                                                                                                                                                                                                       |
| 23-16 | CSNR[n]  | 0<br>1                      | Chip select number. The CSNR field defines the state of the $\overline{\text{SPIx\_SCS}}[n]$ pins during a master data transfer. The value of the CSNR field is driven directly on the $\overline{\text{SPIx\_SCS}}[n]$ pins. Each bit in the CSNR field corresponds to an $\overline{\text{SPIx\_SCS}}[n]$ pin, for example, CSNR[0] corresponds to $\overline{\text{SPIx\_SCS}}[0]$ (see your device-specific data manual to determine how many SPI pins are available on your device).<br><br>The state of the chip select pins when no transmissions are active is specified through the CSDEF field in the SPI default chip select register (SPIDEF). The chip select pins can remain in their active state by setting the CSHOLD bit to 1. When the SPI is configured in slave mode, this field must be written as 00h.<br><br>$\overline{\text{SPIx\_SCS}}[n]$ pin is driven low.<br>$\overline{\text{SPIx\_SCS}}[n]$ pin is driven high. |

**Table 30-21. SPI Data Register 1 (SPIDAT1) Field Descriptions (continued)**

| Bit  | Field  | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|--------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TXDATA | 0-FFFFh | Transfer data. When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, the TXBUF will hold the written values.<br><br>SPIGCR1.ENABLE must be set to 1 before this register can be written to. Writing a 0 to the SPIGCR1.ENABLE forces the lower 16 bits of the SPIDAT1 to 0.<br><br><b>Note:</b> Irrespective of the character length, the transmit data should be right-justified before writing to SPIDAT1. |

### 30.3.14 SPI Receive Buffer Register (SPIBUF)

The SPI receive buffer register (SPIBUF) is shown in [Figure 30-31](#) and described in [Table 30-22](#).

**Figure 30-31. SPI Buffer Register (SPIBUF)**

|          |       |        |        |        |        |         |         |

**Table 30-22. SPI Buffer Register (SPIBUF) Field Descriptions**

| Bit | Field   | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|---------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | RXEMPTY | 0<br>1 | Receive data buffer empty. When host reads the RXDATA field or the entire SPIBUF register this automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into SPIBUF, the RXEMPTY flag is cleared. This flag gets set to 1 under following conditions: <ul style="list-style-type: none"> <li>Reading the RXDATA field of the SPIBUF register.</li> <li>Writing 1 to clear the RXINTFLG bit in the SPIFLG register.</li> </ul> New data has been received and copied into the SPIBUF register.<br>No data received since last reading of the SPIBUF register.<br>Write-Clearing the SPIFLG.RXINTFLG bit before reading the SPIBUF register indicates the received data is being ignored. Conversely, SPIFLG.RXINTFLG can be cleared by reading the RXDATA field of the SPIBUF register or the entire SPIBUF register.                                                                                                                                                                                                                                                                                                                                          |
| 30  | RXOVR   | 0<br>1 | Receive data buffer overrun. When a data transfer is completed and the received data is copied into the RXBUF while it is already full, RXOVR is set. An overrun always occurs to the RXBUF, and SPIBUF contents never get overwritten until after it is read by the CPU/DMA.<br>Reading SPIBUF register does not clear the RXOVR bit. If an overrun interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.<br><b>Note:</b> A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR and DLENERR occur, then RXOVR will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receiver overrun.<br>No receive data overrun condition occurred since last time reading the data field.<br>A receive data overrun condition occurred since last time reading the data field. |

**Table 30-22. SPI Buffer Register (SPIBUF) Field Descriptions (continued)**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 29    | TXFULL   | 0<br>1  | <p>Transmit data buffer full. This flag is a read-only flag. Writing into SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the data is copied to the shift register, the TXFULL flag will be cleared. Writing to the SPIDAT0/SPIDAT1 register when both TXBUF and the TX shift register are empty does not set the TXFULL flag.</p> <p>The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.</p> <p>The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 28    | BITERR   | 0<br>1  | <p>Bit error. There was a mismatch of internal transmit data and transmitted data. The SPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the flag BITERR is set. A possible reason for a bit error can be noise, a too-high bit rate/capacitive load, or another master/slave trying to transmit at the same time.</p> <p><b>Note:</b> This flag is cleared to 0 when RXDATA portion of the SPIBUF register is read.</p> <p>No bit error occurred.</p> <p>A bit error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 27    | DESYNC   | 0<br>1  | <p>Desynchronization of slave device. This bit is active in master mode only. The master monitors the <math>\overline{\text{SPiX\_ENA}}</math> signal coming from the slave device and sets the DESYNC flag if <math>\overline{\text{SPiX\_ENA}}</math> is deactivated before the last reception point or after the last bit is transmitted plus <math>t_{\text{TZDELAY}}</math>. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.</p> <p><b>Note:</b> Possible inconsistency of DESYNC flag in SPI. Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if CPU/DMA reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition.</p> <p><b>Note:</b> This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</p> <p>No slave de-synchronization detected.</p> <p>A slave device is desynchronized.</p> |
| 26    | PARERR   | 0<br>1  | <p>Parity error. The calculated parity differs from received parity bit. If the parity generator is enabled an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARERR flag is set.</p> <p><b>Note:</b> This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</p> <p>No parity error detected.</p> <p>A parity error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25    | TIMEOUT  | 0<br>1  | <p>Time-out because of non-activation of <math>\overline{\text{SPiX\_ENA}}</math> pin. This bit is valid in master mode only. The SPI generates a time-out because the slave hasn't responded in time by activating the <math>\overline{\text{SPiX\_ENA}}</math> signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set.</p> <p><b>Note:</b> This flag is cleared to 0 when RXDATA portion of the SPIBUF register is read.</p> <p>No <math>\overline{\text{SPiX\_ENA}}</math> pin time-out occurred.</p> <p>An <math>\overline{\text{SPiX\_ENA}}</math> signal time-out occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 24    | DLENERR  | 0<br>1  | <p>Data length error flag.</p> <p><b>Note:</b> This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</p> <p>No data length error has occurred.</p> <p>A data length error has occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 23-16 | Reserved | 0       | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 15-0  | RXDATA   | 0-FFFFh | SPI receive data. This is the received data, transferred from the receive shift-register at the end of a transfer completion. Irrespective of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 30.3.15 SPI Emulation Register (SPIEMU)

The SPI emulation register (SPIEMU) is shown in [Figure 30-32](#) and described in [Table 30-23](#).

**Figure 30-32. SPI Emulation Register (SPIEMU)**

LEGEND: R = Read only; -n = value after reset

**Table 30-23. SPI Emulation Register (SPIEMU) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                          |
|-------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reads return zero and writes have no effect.                                                                                                                                         |
| 15-0  | RXDATA   | 0-FFFFh | SPI receive data. SPI emulation is a mirror of the SPIBUF register. The only difference between SPIEMU and SPIBUF is that a read from SPIEMU does not clear any of the status flags. |

### 30.3.16 SPI Delay Register (SPIDELAY)

The SPI delay register (SPIDELAY) is shown in [Figure 30-33](#) and described in [Table 30-24](#).

**Figure 30-33. SPI Delay Register (SPIDELAY)**

|          |    |          |    |

**Table 30-24. SPI Delay Register (SPIDELAY) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | C2TDELAY | 0-FFh | <p>Chip-select-active-to-transmit-start-delay. C2TDELAY is used in master mode only. It defines a setup time for the slave device that delays the data transmission from the chip select active edge by a multiple of SPI module clock cycles. C2TDELAY can be configured between 3 and 257 SPI module clock cycles. See <a href="#">Figure 30-34</a>.</p> <p>The setup time value is calculated as follows:<br/> <math>t_{C2TDELAY} = (C2TDELAY + 2) \times \text{SPI module clock period}</math></p> <p><b>Note:</b> If C2TDELAY = 0, then <math>t_{C2TDELAY} = 0</math>.</p> <p>Example: SPI module clock = 25 MHz -&gt; SPI module clock period = 40 ns; C2TDELAY = 06h;<br/> <math>t_{C2TDELAY} = 320 \text{ ns}</math>;</p> <p>When the chip select signal becomes active, the slave has to prepare for data transfer within 320 ns.</p> <p><b>Note:</b> If phase = 1, the delay between <math>\overline{\text{SPiX\_SCS}}[n]</math> falling edge to the first edge of <math>\text{SPiX\_CLK}</math> will have an additional 0.5 <math>\text{SPiX\_CLK}</math> period delay. This delay is as per the SPI protocol.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 23-16 | T2CDELAY | 0-FFh | <p>Transmit-end-to-chip-select-inactive-delay. T2CDELAY is used in master mode only. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of SPI module clock cycles after the last bit is transferred. T2CDELAY can be configured between 2 and 256 SPI module clock cycles. See <a href="#">Figure 30-35</a>.</p> <p>The hold time value is calculated as follows:<br/> <math>t_{T2CDELAY} = (T2CDELAY + 1) \times \text{SPI module clock period}</math></p> <p><b>Note:</b> If T2CDELAY = 0, then <math>t_{T2CDELAY} = 0</math></p> <p>Example: <math>\text{VBUSPCLK} = 25 \text{ MHz}</math> -&gt; <math>\text{VBUSPCLK}</math> period = 40 ns; T2CDELAY = 03h;<br/> <math>t_{T2CDELAY} = 160 \text{ ns}</math>;</p> <p>After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns.</p> <p><b>Note:</b> If phase = 0, then between the last edge of <math>\text{SPiX\_CLK}</math> and rise-edge of <math>\overline{\text{SPiX\_SCS}}[n]</math> there will be an additional delay of 0.5 <math>\text{SPiX\_CLK}</math> period. This is as per the SPI protocol.</p> <p>Both C2TDELAY and T2CDELAY counters will not have any dependancy on the <math>\overline{\text{SPiX\_ENA}}</math> pin value. Even if the <math>\overline{\text{SPiX\_ENA}}</math> pin is asserted by the slave, the master will continue to delay the start of <math>\text{SPiX\_CLK}</math> until the C2TDELAY counter overflows.</p> <p>Similarly, even if the <math>\overline{\text{SPiX\_ENA}}</math> pin is deasserted by the slave, the master will continue to hold the <math>\overline{\text{SPiX\_SCS}}[n]</math> pins active until the T2CDELAY counter overflows. This way, it is assured that the setup/hold times of the <math>\overline{\text{SPiX\_SCS}}[n]</math> pins are determined by the delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.</p> |

**Table 30-24. SPI Delay Register (SPIDELAY) Field Descriptions (continued)**

| Bit  | Field   | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|---------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-8 | T2DELAY | 0-FFh | <p>Transmit-data-finished-to-<math>\overline{\text{SPIx\_ENA}}</math>-pin-inactive-time-out. T2DELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before the <math>\overline{\text{SPIx\_ENA}}</math> signal has to become inactive and after the CS becomes inactive. The SPI clock depends on which data format is selected. If the slave device is missing one or more clock edges, it is becoming desynchronized. Although the master has finished the data transfer the slave is still waiting for the missed clock pulses and the <math>\overline{\text{SPIx\_ENA}}</math> signal is not disabled. The T2DELAY defines a time-out value that triggers the DESYNC flag, if the <math>\overline{\text{SPIx\_ENA}}</math> signal is not deactivated in time. The DESYNC flag is set to indicate that the slave device did not deassert its <math>\overline{\text{SPIx\_ENA}}</math> pin in time to acknowledge that it has received all the bits of the sent character. The DESYNC flag is also set if the SPI detects a deassertion of the <math>\overline{\text{SPIx\_ENA}}</math> pin even before the end of the transmission. See <a href="#">Figure 30-36</a>.</p> <p>The time-out value is calculated as follows:<br/> <math>t_{\text{T2DELAY}} = \text{T2DELAY}/\text{SPIClock}</math></p> <p>Example: SPIClock = 8 Mbit/s; T2DELAY = 10h;<br/> <math>&gt; t_{\text{T2DELAY}} = 2 \mu\text{s}</math>;</p> <p>The slave device has to disable the <math>\overline{\text{SPIx\_ENA}}</math> signal within 2 <math>\mu\text{s}</math>; otherwise, the DESYNC flag in SPIFLG is set and an interrupt is asserted if enabled.</p> |
| 7-0  | C2DELAY | 0-FFh | <p>Chip-select-active-to-<math>\overline{\text{SPIx\_ENA}}</math>-signal-active-time-out. C2DELAY is used only in master mode and it applies only if the addressed slave generates an <math>\overline{\text{SPIx\_ENA}}</math> signal as a hardware handshake response. C2DELAY defines the maximum time between the SPI activates the chip select signal and the addressed slave has to respond by activating the <math>\overline{\text{SPIx\_ENA}}</math> signal. C2DELAY defines a time-out value as a multiple of SPI clocks. See <a href="#">Figure 30-37</a>.</p> <p><b>Note:</b> If the slave device is not responding with the <math>\overline{\text{SPIx\_ENA}}</math> signal before the time-out value is reached, the TIMEOUT flag in SPIFLG is set and an interrupt is asserted if enabled.</p> <p>The timeout value is calculated as follows:<br/> <math>t_{\text{C2DELAY}} = \text{C2DELAY}/\text{SPIClock}</math></p> <p>Example: SPIClock = 8 Mbit/s; C2DELAY = 30h;<br/> <math>&gt; t_{\text{C2DELAY}} = 6 \mu\text{s}</math>;</p> <p>The slave device has to activate the <math>\overline{\text{SPIx\_ENA}}</math> signal within 6 <math>\mu\text{s}</math> after the SPI has activated the chip select signal (<math>\text{SPIx\_SCS}[n]</math>); otherwise, the TIMEOUT flag in SPIFLG is set and an interrupt is asserted if enabled.</p>                                                                                                                                                                                                                                                                                                                |

### 30.3.17 SPI Default Chip Select Register (SPIDEF)

The SPI default chip select register (SPIDEF) is shown in [Figure 30-38](#) and described in [Table 30-25](#).

**Figure 30-38. SPI Default Chip Select Register (SPIDEF)**

|          |  |  |  |  |   |                         |  |  |  |  |    |   |
|----------|--|--|--|--|---|-------------------------|--|--|--|--|----|---|
| 31       |  |  |  |  |   |                         |  |  |  |  | 16 |   |
| Reserved |  |  |  |  |   |                         |  |  |  |  |    |   |
| R-0      |  |  |  |  |   |                         |  |  |  |  |    |   |
| 15       |  |  |  |  | 8 | 7                       |  |  |  |  |    | 0 |
| Reserved |  |  |  |  |   | CSDEF[n] <sup>(1)</sup> |  |  |  |  |    |   |
| R-0      |  |  |  |  |   | R/W-FFh                 |  |  |  |  |    |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

<sup>(1)</sup> Not all devices support multiple slave chip select ( $\overline{\text{SPIx\_SCS}}[n]$ ) pins, see your device-specific data manual for supported pins. If the pins are not available, the corresponding bit is reserved and should be cleared to 0.

**Table 30-25. SPI Default Chip Select Register (SPIDEF) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 7-0  | CSDEF[n] | 0     | Chip select default pattern. The CSDEF field defines the state of the the $\overline{\text{SPIx\_SCS}}[n]$ pins when no transmissions are performed. The value of the CSDEF field is driven directly on the $\overline{\text{SPIx\_SCS}}[n]$ pins. Each bit in the CSDEF field corresponds to an $\overline{\text{SPIx\_SCS}}[n]$ pin, for example, CSDEF[0] corresponds to $\overline{\text{SPIx\_SCS}}[0]$ (see your device-specific data manual to determine how many SPI pins are available on your device). |
|      |          | 1     | The state of the chip select pins during a transmission is specified through the CSNR field in the SPI transmit data register (SPIDAT1). The chip select pins can remain in their active state by setting the CSHOLD bit in SPIDAT1 to 1. In slave mode, the CSDEF field should be set to FFh.                                                                                                                                                                                                                   |
|      |          | 0     | $\overline{\text{SPIx\_SCS}}[n]$ pin is driven low.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|      |          | 1     | $\overline{\text{SPIx\_SCS}}[n]$ pin is driven high.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 30.3.18 SPI Data Format Registers (SPIFMT<sub>n</sub>)

The SPI data format registers (SPIFMT0, SPIFMT1, SPIFMT2, and SPIFMT3) are shown in [Figure 30-39](#) and described in [Table 30-26](#).

**Figure 30-39. SPI Data Format Register (SPIFMT<sub>n</sub>)**

| Bit   | Field       | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-30 | Reserved    | 0      | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 29-24 | WDELAY      | 0-3Fh  | Delay in between transmissions. Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to:<br><br>$WDELAY \times P_{SPI \text{ module clock}} + 2 \times P_{SPI \text{ module clock}}$ $P_{SPI \text{ module clock}} \rightarrow \text{Period of SPI module clock}$                                                                                                                                                                                                                                                                                                                                                                                 |
| 23    | PARPOL      | 0<br>1 | Parity polarity: even or odd. PARPOL can be modified in privilege mode only.<br>0 An even parity flag is added at the end of the transmit data stream.<br>1 An odd parity flag is added at the end of the transmit data stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 22    | PARENA      | 0<br>1 | Parity enable.<br>0 No parity generation/ verification is performed.<br>1 A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the PARERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit.                                                                                                                                                                                                                                                                                                                   |
| 21    | WAITENA     | 0<br>1 | The master waits for $\overline{SPIx\_ENA}$ signal from slave. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with $\overline{SPIx\_ENA}$ signal and slaves without $\overline{SPIx\_ENA}$ signal can be mixed.<br>0 The SPI does not wait for the $\overline{SPIx\_ENA}$ signal from the slave and directly starts the transfer.<br>1 Before the SPI starts the data transfer it waits for the $\overline{SPIx\_ENA}$ signal to become low. If the $\overline{SPIx\_ENA}$ signal is not pulled down by the addressed slave before the internal time-out counter (C2DELAY) overflows, then the master aborts the transfer and sets the TIMEOUT error flag. |
| 20    | SHIFTDIR    | 0<br>1 | Shift direction.<br>0 Most significant bit is shifted out first.<br>1 Least significant bit is shifted out first.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 19    | Reserved    | 0      | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 18    | DISCSTIMERS | 0<br>1 | Disable chip select timers for this format register. The C2DELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format if not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip select delay timers for any slaves.<br>0 Both C2DELAY and T2CDELAY counts are inserted for the chip selects.<br>1 No C2DELAY or T2CDELAY is inserted in the chip select timings.                                                                                                                                                              |

**Table 30-26. SPI Data Format Register (SPIFMT<sub>n</sub>) Field Descriptions (continued)**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17   | POLARITY | 0      | SPI clock polarity.                                                                                                                                                                                                                                                                                                                                                                                                       |
|      |          | 1      | SPI clock signal is low-inactive (before and after data transfer the clock signal is low).                                                                                                                                                                                                                                                                                                                                |
| 16   | PHASE    | 0      | SPI clock signal is high-inactive (before and after data transfer the clock signal is high).                                                                                                                                                                                                                                                                                                                              |
|      |          | 1      | SPI clock delay.                                                                                                                                                                                                                                                                                                                                                                                                          |
| 15-8 | PRESCALE | 0      | SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge.                                                                                                                                                                                                                  |
|      |          | 1      | SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.                                                                                                                                                                                        |
| 15-8 | PRESCALE | 2h-FFh | SPI prescaler. It determines the bit transfer rate if the SPI is the network master and is directly derived from the SPI module clock. If the SPI is configured as slave, PRESCALE needs to be configured to a valid value, but PRESCALE is ignored.<br><br>The clock rate can be calculated as:<br>SPI clock frequency = SPI module clock/(PRESCALE + 1)<br><b>Note:</b> PRESCALE values less than 2h are not supported. |
| 7-5  | Reserved | 0      | Reads return zero and writes have no effect.                                                                                                                                                                                                                                                                                                                                                                              |
| 4-0  | CHARLEN  | 0-1Fh  | SPI data word length. Legal values are 2h (data word length = 2 bit) to 10h (data word length = 16). Illegal values, such as 0 or 1Fh are not detected and their effect is indeterminate.                                                                                                                                                                                                                                 |

### 30.3.19 SPI Interrupt Vector Register 1 (INTVEC1)

The SPI interrupt vector register 1 (INTVEC1) is shown in [Figure 30-40](#) and described in [Table 30-27](#).

**Figure 30-40. SPI Interrupt Vector Register 1 (INTVEC1)**

| 5-1     | INTVECT1                                                                                                       | 0-1Fh | <p>Interrupt vector for interrupt line INT1. INTVECT1 returns the vector of the pending interrupt at interrupt line INT1. If more than one interrupt is pending, INTVECT1 always references the highest priority interrupt source first. The interrupts available for SPI in the descending order of their priorities are as given below.</p> <ul style="list-style-type: none"><li>• Transmission error Interrupt</li><li>• Receive buffer overrun interrupt</li><li>• Receive buffer full interrupt</li><li>• Transmit buffer empty interrupt</li></ul> <p>The INTVECT1 field just reflects the status of SPIFLG in a vectorized format. So, any updates to SPIFLG will automatically reflect in the vector value in this register.</p> <p>Vectors for each of these interrupts will be reflected on the INTVECT1 bits, when they occur. Reading the vectors for the receive buffer overrun and receive buffer full interrupts will automatically clear the respective flags in the SPIFLG. Reading the vector register when transmitter empty is indicated does not clear the TXINTFLG in SPIFLG. Writing a new data to SPIDAT0/SPIDAT1 clears the transmitter empty interrupt. On reading the INTVECT1 bits, the vector of the next highest priority interrupt (if any) will be then reflected on the INTVECT1 bits. If two or more interrupts occur simultaneously, the vector for the highest priority interrupt will be reflected on the INTVECT1 bits.</p> <p>The following are the SPI interrupt vectors for line INT1:</p> <table><tr><td>0</td><td>No interrupt pending</td></tr><tr><td>1h-10h</td><td>Reserved</td></tr><tr><td>11h</td><td>Error interrupt pending. Refer to lower halfword of SPIINT0 to determine more details about the type of error.</td></tr><tr><td>12h</td><td>The pending interrupt is receive buffer full interrupt.</td></tr><tr><td>13h</td><td>The pending interrupt is receive buffer overrun interrupt.</td></tr><tr><td>14h</td><td>The pending interrupt is transmit buffer empty interrupt.</td></tr><tr><td>15h-1Fh</td><td>Reserved</td></tr></table> | 0 | No interrupt pending | 1h-10h | Reserved | 11h | Error interrupt pending. ## 64-Bit Timer Plus

This chapter describes the operation of the software-programmable 64-bit Timer Plus. See your device-specific data manual to determine how many Timer modules are available on your device.

| Topic                          | Page        |

## 31.1 Introduction

The 64-bit Timer Plus can be programmed in 64-bit mode, dual 32-bit unchained mode, or dual 32-bit chained mode. Some Timer Plus implementations have signal connections to internal device reset that can be used in watchdog timer mode. New features over previous timers include: external clock/event input, period reload, external event capture, and timer counter register read reset.

### 31.1.1 Purpose of the Peripheral

The timer can support four basic modes of operation: a 64-bit general-purpose (GP) timer, dual unchained 32-bit GP timers, dual chained 32-bit timers, or a watchdog timer. The GP timer modes can be used to generate periodic interrupts and DMA synchronization events. The watchdog timer mode is used to provide a recovery mechanism for the device in the event of a fault condition (such as a non-exiting code loop).

### 31.1.2 Features

The 64-bit timer consists of the following features -- some features may not be supported on all timer instantiations (see your device-specific data manual for supported features):

- 64-bit count-up counter
- Timer modes:
  - 64-bit general-purpose timer mode
  - Dual 32-bit unchained general-purpose timer mode
  - Dual 32-bit chained timer mode
  - Watchdog timer mode
- 2 possible clock sources:
  - Internal clock
  - External clock/event input via timer input pins
- 3 possible operation modes:
  - One-time operation (timer runs for one period then stops)
  - Continuous operation (timer automatically resets to zero after each period and continues to operate)
  - Continuous operation with period reload (timer automatically assumes the value of the reload registers after each period and continues to operate)
- Generates interrupts to CPU
- Generates sync events to DMA
- Generates output event to device reset (watchdog only)
- Generates output event to timer output pins (if pins are available)
- External event capture via timer input pins (if pins are available)

### 31.1.3 Block Diagram

A block diagram of the timer is shown in Figure 31-1. Detailed information about the architecture and operation of the timers is in Section 31.1.5 and Section 31.1.6.

**Figure 31-1. Timer Block Diagram**

### 31.1.4 Industry Standard Compatibility Statement

This peripheral is not intended to conform to any specific industry standard.

### Architecture

### 31.1.5 Architecture – General-Purpose Timer Mode

This section describes the timer in the general-purpose (GP) timer mode.

#### 31.1.5.1 Backward Compatible Mode

The Timer Plus supports the following additional features over the other timers:

- External clock/event input
- Period reload
- External event capture mode
- Timer counter register read reset mode
- Timer counter capture registers
- Register for interrupt/DMA generation control and status

By default, period reload, external event capture mode, timer counter register read reset mode, timer counter capture registers, and interrupt/DMA/TM64P\_OUT generation control and status are not available. To enable these features, you must set the PLUSEN bit in the timer global control register (TGCR). These features are described throughout the following sections. External clock/event input is always available, regardless of the state of the backward compatible bit.

### 31.1.5.2 Clock Control

The timer can use an internal or external clock source for the counter period. The following sections explain how to select the clock source.

As shown in [Table 31-1](#) and [Figure 31-2](#), the timer clock source is selected using the clock source (CLKSRC12) bit in the timer control register (TCR). Two clock sources are available to drive the timer clock:

- internal clock by setting CLKSRC12 = 0.
- external clock on input pin TM64P\_IN12 by setting CLKSRC12 = 1.

At reset, the clock source is the internal clock. Details on each of the clock source configuration options are included in the following sections.

**Table 31-1. Timer Clock Source Selection**

| CLKSRC12 | Input Clock                   |
|----------|-------------------------------|
| 0        | Internal clock (default)      |
| 1        | External clock on timer input |

**Figure 31-2. Timer Clock Source Block Diagram**

#### 31.1.5.2.1 Using the Internal Clock Source to the Timer

The internal clock source to the timer is generated by the PLL controller. This clock source determines the speed of the timer since the timer counts up in units of source clock cycles. When determining the period and prescaler settings for the timer, choose the desired period in units of source clock cycles. For details on the generation of the on-chip clocks, see the *Phase-Locked Loop Controller (PLL)* chapter.

The CLKSRC12 parameter in the timer control register (TCR) determines whether an internal or external clock is used as the clock source for the timer. If the timer is configured in 64-bit mode or 32-bit chained mode, CLKSRC12 controls the clock source for the entire timer. If the timer is configured in dual 32-bit unchained mode (TIMMODE = 01 in TGCR), CLKSRC12 controls the timer 1:2 side of the timer only.

To select the internal clock as the clock source for the timer, CLKSRC12 in TCR must be cleared to 0.

#### 31.1.5.2.2 Using the External Clock Source to the Timer

An external clock source can be provided to clock the timer through the timer input pin TM64P\_IN12. The CLKSRC12 parameter in the timer control register (TCR) determines whether an internal or external clock is used as the clock source for the timer. If the timer is configured in 64-bit mode or 32-bit chained mode, CLKSRC12 controls the clock source for the entire timer. If the timer is configured in dual 32-bit unchained mode (TIMMODE = 01 in TGCR), CLKSRC12 controls the timer 1:2 side of the timer only.

At reset, the clock source defaults to the internal clock. Details on each of the clock source configuration options are included in the following sections. To select the external clock as the clock source for the timer, CLKSRC12 in TCR must be set to 1. The external clock source frequency must be no greater than the timer peripheral reference clock (see your device-specific data manual).

### 31.1.5.3 Signal Descriptions

As shown in [Figure 31-2](#), the TM64P\_IN12 pin may be used as input to the timer. This signal can be used to drive the clock/event count or be used as an external event input for event capture mode. Pin TM64P\_OUT12 may be used as an output from the timer to generate a clock or pulse signal.

### 31.1.5.4 Timer Modes

The following section describes the general-purpose (GP) timer modes.

#### 31.1.5.4.1 64-Bit Timer Mode

The timer can be configured as a 64-bit timer by clearing the TIMMODE bit in the timer global control register (TGCR) to 0. At reset, 0 is the default setting for the TIMMODE bit.

In this mode, the timer operates as a single 64-bit up-counter ([Figure 31-3](#)). The counter registers (TIM12 and TIM34) form a 64-bit timer counter register and the period registers (PRD12 and PRD34) form a 64-bit timer period register. When the timer is enabled, the timer counter starts incrementing by 1 at every timer input clock cycle. When the timer counter matches the timer period, a maskable timer interrupt (TINT12) and a timer EDMA (TEVT12) are generated. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. The timer can be stopped, restarted, reset, or disabled using control bits in TGCR.

**Figure 31-3. 64-Bit Timer Mode Block Diagram**

### 31.1.5.4.1.1 Enabling the 64-Bit Timer

The TIM12RS and TIM34RS bits in TGCR control whether the timer is in reset or capable of operating. For the timer to operate in 64-bit timer mode, the TIM12RS and TIM34RS bits must be set to 1.

The ENAMODE12 bit in the timer control register (TCR) controls whether the timer is disabled, enabled to run once, enabled to run continuously, or enabled to run continuously with period reload; the ENAMODE34 bit has no effect in 64-bit timer mode. When the timer is disabled (ENAMODE12 = 0), the timer does not run and maintains its current count value. When the timer is enabled for one time operation (ENAMODE12 = 1), it counts up until the counter value equals the period value and then stops. When the timer is enabled for continuous operation (ENAMODE12 = 2h), the counter counts up until it reaches the period value, then resets itself to zero and begins counting again. When the timer is enabled for continuous operation with period reload (ENAMODE12 = 3h), the counter counts up until it reaches the period value, then resets itself to zero, reloads the period registers (PRD12 and PRD34) with the value in the period reload registers (REL12 and REL34), and begins counting again.

Table 31-2 shows the bit values in TGCR to configure the 64-bit timer.

**Table 31-2. 64-Bit Timer Configurations**

| 64-Bit Timer Configuration                                             | TGCR Bit |         | TCR Bit   |
|------------------------------------------------------------------------|----------|---------|-----------|
|                                                                        | TIM12RS  | TIM34RS | ENAMODE12 |
| To place the 64-bit timer in reset                                     | 0        | 0       | 0         |
| To disable the 64-bit timer (out of reset)                             | 1h       | 1h      | 0         |
| To enable the 64-bit timer for one-time operation                      | 1h       | 1h      | 1h        |
| To enable the 64-bit timer for continuous operation                    | 1h       | 1h      | 2h        |
| To enable the 64-bit timer for continuous operation with period reload | 1h       | 1h      | 3h        |

Once the timer stops, if an external clock is used as the timer clock, the timer must remain disabled for at least one external clock period or the timer will not start counting again. When using the external clock, the count value is synchronized to the internal clock.

Note that when both the timer counter and timer period are cleared to 0, the timer can be enabled but the timer counter does not increment because the timer period is 0.

### 31.1.5.4.1.2 Reading the Counter Registers

When reading the timer count in 64-bit timer mode, the CPU must first read TIM12 followed by TIM34. When TIM12 is read, the timer copies TIM34 into a shadow register. When reading TIM34, the hardware logic returns the shadow register value. This ensures that the values read from the registers are not affected by the fact that the timer may continue to run as the registers are read. When reading the timers in 32-bit mode, TIM12 and TIM34 may be read in any order.

### 31.1.5.4.1.3 64-Bit Timer Configuration Procedure

To configure the GP timer to operate as a 64-bit timer, follow the steps below:

1. Select 64-bit mode (TIMMODE in TGCR).
2. Remove the timer from reset (TIM12RS and TIM34RS in TGCR).
3. Select the desired timer period (PRD12 and PRD34). Program with the desired timer period value - 1.
4. Enable the timer (ENAMODE12 in TCR).
5. If ENAMODE12 = 3h, write the desired timer period for the next timer cycle in the period reload registers (REL12 and REL34). Program with the desired timer period value - 1. This step can be done at any time before the current timer cycle ends.

#### 31.1.5.4.2 Dual 32-Bit Timer Modes

Each of the general-purpose timers can be configured as dual 32-bit timers by configuring the TIMMODE bit in the timer global control register (TGCR). In dual 32-bit timer mode, the two 32-bit timers can be operated independently (unchained mode) or in conjunction with each other (chained mode).

##### 31.1.5.4.2.1 Chained Mode

The general-purpose timers can each be configured as a dual 32-bit chained timer by setting the TIMMODE bit to 3h in TGCR.

In the chained mode ([Figure 31-4](#)), one 32-bit timer (timer 3:4) is used as a 32-bit prescaler and the other 32-bit timer (timer 1:2) is used as a 32-bit timer. The 32-bit prescaler is used to clock the 32-bit timer. The 32-bit prescaler uses one counter register (TIM34) to form a 32-bit prescale counter register and one period register (PRD34) to form a 32-bit prescale period register.

When the timer is enabled, the prescale counter starts incrementing by 1 at every timer input clock cycle. One cycle after the prescale counter matches the prescale period, a clock signal is generated and the prescale counter register is reset to 0 (see the example in [Figure 31-5](#)).

The other 32-bit timer (timer 1:2) uses one counter register (TIM12) to form a 32-bit timer counter register and one period register (PRD12) to form a 32-bit timer period register. This timer is clocked by the output clock from the prescaler. The timer counter increments by 1 at every prescaler output clock cycle. When the timer counter matches the timer period, a maskable timer interrupt (TINT12) and a timer EDMA event (TEVT12) are generated. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. The timer can be stopped, restarted, reset, or disabled using the TIM12RS and TIM34RS bits in TGCR. In the chained mode, the upper 16-bits of the timer control register (TCR) are not used.

**Figure 31-4. Dual 32-Bit Timers Chained Mode Block Diagram**

**Figure 31-5. Dual 32-Bit Timers Chained Mode Example**

32-bit prescaler settings: count = TIM34 = 200; period = PRD34 = 202  
 32-bit timer settings: count = TIM12 = 3; period = PRD12 = 4

### 31.1.5.4.2.1.1 Enabling the 32-Bit Timer Chained Mode

The TIM12RS and TIM34RS bits in TGCR determine whether the timer is in reset, or if it is capable of operating. The TIM12RS bit controls the reset of the timer 1:2 side of the timer and the TIM34RS bits control the reset of the timer 3:4 side of the timer. For the timer to operate, the TIM12RS and TIM34RS bits must be set to 1.

The ENAMODE12 bit in the timer control register (TCR) controls whether the timer is disabled, enabled to run once, enabled to run continuously, or enabled to run continuously with period reload; the ENAMODE34 bit has no effect in 32-bit timer chained mode. When the timer is disabled (ENAMODE12 = 0), the timer does not run and maintains its current count value. When the timer is enabled for one time operation (ENAMODE12 = 1), it counts up until the counter value equals the period value and then stops. When the timer is enabled for continuous operation (ENAMODE12 = 2h), the counter counts up until it reaches the period value, then resets itself to zero and begins counting again. When the timer is enabled for continuous operation with period reload (ENAMODE12 = 3h), the counter counts up until it reaches the period value, then resets itself to zero, reloads the period registers (PRD12 and PRD34) with the value in the period reload registers (REL12 and REL34), and begins counting again.

Table 31-3 shows the bit values in TGCR to configure the 32-bit timer in chained mode.

**Table 31-3. 32-Bit Timer Chained Mode Configurations**

| 32-Bit Timer Configuration                                                                         | TGCR Bit |         | TCR Bit   |
|----------------------------------------------------------------------------------------------------|----------|---------|-----------|
|                                                                                                    | TIM12RS  | TIM34RS | ENAMODE12 |
| To place the 32-bit timer chained mode in reset                                                    | 0        | 0       | 0         |
| To disable the 32-bit timer chained mode (out of reset)                                            | 1h       | 1h      | 0         |
| To enable the 32-bit timer chained mode for one-time operation                                     | 1h       | 1h      | 1h        |
| To enable the 32-bit timer chained mode for continuous operation                                   | 1h       | 1h      | 2h        |
| To enable the 32-bit timer chained mode for continuous operation with period reload (Timer 3 only) | 1h       | 1h      | 3h        |

Once the timer stops, if an external clock is used as the timer clock, the timer must remain disabled for at least one external clock period or the timer will not start counting again. When using the external clock, the count value is synchronized to the internal clock.

Note that when both the timer counter and timer period are cleared to 0, the timer can be enabled but the timer counter does not increment because the timer period is 0.

### 31.1.5.4.2.1.2 32-Bit Timer Chained Mode Configuration Procedure

To configure the GP timer to operate as a dual 32-bit chained mode timer, follow the steps below:

1. Select 32-bit chained mode (TIMMODE in TGCR).
2. Remove the timer from reset (TIM12RS and TIM34RS in TGCR).
3. Select the desired timer period (PRD12). Program with the desired timer period value - 1.
4. Select the desired timer prescaler value (PRD34).
5. Enable the timer (ENAMODE12 in TCR).
6. If ENAMODE12 = 3h, write the desired timer period for the next timer cycle in the period reload registers (REL12 and REL34). Program with the desired timer period value - 1. This step can be done at any time before the current timer cycle ends.

### 31.1.5.4.2.2 Unchained Mode

The general-purpose timers can be configured as a dual 32-bit unchained timers by setting the TIMMODE bit to 1 in TGCR.

In the unchained mode (Figure 31-6), the timer operates as two independent 32-bit timers. One 32-bit timer (timer 3:4) operates as a 32-bit timer being clocked by a 4-bit prescaler. The other 32-bit timer (timer 1:2) operates as a 32-bit timer with no prescaler.

Independent of the normal timer behavior, eight compare registers (CMPn) are compared against the value of the TIM12 register when the PLUSEN bit in TGCR is set. Upon a successful non-zero match, an interrupt and a DMA event are generated without affecting the TIM12 value, behavior, or associated counter registers. Note that some timer instantiations may not map the CMP interrupt and DMA events to the CPU and DMA engines (see your device-specific data manual for information).

**Figure 31-6. Dual 32-Bit Timers Unchained Mode Block Diagram**

### 31.1.5.4.2.2.1 32-Bit Timer With a 4-Bit Prescaler

In the unchained mode, the 4-bit prescale is clocked by the internal clock. The 4-bit prescaler uses the timer divide-down ratio (TDDR34) bit in TGCR to form a 4-bit prescale counter register and the prescale counter bits (PSC34) to form a 4-bit prescale period register (see [Figure 31-6](#)). When the timer is enabled, the prescale counter starts incrementing by 1 at every timer input clock cycle. One cycle after the prescale counter matches the prescale period, a clock signal is generated for the 32-bit timer.

The 32-bit timer uses TIM34 as a 32-bit timer counter register and PRD34 as a 32-bit timer period register. The 32-bit timer is clocked by the output clock from the 4-bit prescaler (see the example in [Figure 31-7](#)). The timer counter increments by 1 at every prescaler output clock cycle. When the timer counter matches the period, a maskable timer interrupt (TINT34) and a timer DMA event (TEVT34) are generated. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. The timer can be stopped, restarted, reset, or disabled using the TIM34RS bit in TGCR. For timer 3:4, the lower 16 bits of the timer control register (TCR) have no control.

**Figure 31-7. Dual 32-Bit Timers Unchained Mode Example**

4-bit prescaler settings: count = TDDR34 = 1; period = PSC34 = 2

32-bit timer settings: count = TIM34 = 15; period = PRD34 = 16

### 31.1.5.4.2.2.2 32-Bit Timer with No Prescaler

The other 32-bit timer (timer 1:2) uses TIM12 as the 32-bit counter register and PRD12 as a 32-bit timer period register (see [Figure 31-6](#)). When the timer is enabled, the timer counter increments by 1 at every timer input clock cycle. When the timer counter matches the timer period, a maskable timer interrupt (TINT12), a timer DMA event (TEVT12), and a timer output event on TM64P\_OUT12 are generated. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. The timer can be stopped, restarted, reset, or disabled using the TIM12RS bit in TGCR. For timer 1:2, the upper 16 bit of the timer control register (TCR) have no control.

### 31.1.5.4.2.2.3 Enabling the 32-Bit Unchained Mode Timer

The TIM12RS and TIM34RS bits in TGCR determine whether the timer is in reset, or if it is capable of operating. The TIM12RS bit controls the reset of the timer 1:2 side of the timer and the TIM34RS bit controls the reset of the timer 3:4 side of the timer. For the timer to operate, the TIM12RS and/or TIM34RS bits must be set to 1.

The ENAMODEn bit in the timer control register (TCR) controls whether the timer is disabled, enabled to run once, or enabled to run continuously.

- When the timer is disabled (ENAMODEn = 0), the timer does not run and maintains its current count value.
- When the timer is enabled for one time operation (ENAMODEn = 1), it counts up until the counter value equals the period value and then stops.
- When the timer is enabled for continuous operation (ENAMODEn = 2h), the counter counts up until it reaches the period value, then resets itself to zero and begins counting again.
- When the timer is enabled for continuous operation with period reload (ENAMODEn = 3h), the counter counts up until it reaches the period value, then resets itself to zero, reloads the period registers (PRD12 and/or PRD34) with the value in the period reload registers (REL12 and/or REL34), and begins counting again.

Table 31-4 shows the bit values in TGCR to configure the 32-bit timer in unchained mode.

Once the timer stops, if an external clock is used as the timer clock, the timer must remain disabled for at least one external clock period or the timer will not start counting again. When using the external clock, the count value is synchronized to the internal clock.

Note that when both the timer counter and timer period are cleared to 0, the timer can be enabled but the timer counter does not increment because the timer period is 0.

**Table 31-4. 32-Bit Timer Unchained Mode Configurations**

| 32-Bit Timer Configuration                                                                                 | TGCR Bit |         | TCR Bit   |           |
|------------------------------------------------------------------------------------------------------------|----------|---------|-----------|-----------|
|                                                                                                            | TIM12RS  | TIM34RS | ENAMODE12 | ENAMODE34 |
| To place the 32-bit timer unchained mode with 4-bit prescaler in reset                                     | x        | 0       | x         | 0         |
| To disable the 32-bit timer unchained mode with 4-bit prescaler (out of reset)                             | x        | 1h      | x         | 0         |
| To enable the 32-bit timer unchained mode with 4-bit prescaler for one-time operation                      | x        | 1h      | x         | 1h        |
| To enable the 32-bit timer unchained mode with 4-bit prescaler for continuous operation                    | x        | 1h      | x         | 2h        |
| To enable the 32-bit timer unchained mode with 4-bit prescaler for continuous operation with period reload | x        | 1h      | x         | 3h        |
| To place the 32-bit timer unchained mode with no prescaler in reset                                        | 0        | x       | 0         | x         |
| To disable the 32-bit timer unchained mode with no prescaler (out of reset)                                | 1h       | x       | 0         | x         |
| To enable the 32-bit timer unchained mode with no prescaler for one-time operation                         | 1h       | x       | 1h        | x         |
| To enable the 32-bit timer unchained mode with no prescaler for continuous operation                       | 1h       | x       | 2h        | x         |
| To enable the 32-bit timer unchained mode with no prescaler for continuous operation with period reload    | 1h       | x       | 3h        | x         |

#### 31.1.5.4.2.2.4 32-Bit Timer Unchained Mode Configuration Procedure

To configure timer 1:2, follow the steps below:

1. Select 32-bit unchained mode (TIMMODE in TGCR).
2. Remove the timer 1:2 from reset (TIM12RS in TGCR).
3. Select the desired timer period for timer 1:2 (PRD12). Program with the desired timer period value - 1.
4. Select the desired clock source for timer 1:2 (CLKSRC12 in TCR).
5. Enable timer 1:2 (ENAMODE12 in TCR).
6. If ENAMODE12 = 3h, write the desired timer period for the next timer cycle in the period reload register (REL12). Program with the desired timer period value - 1. This step can be done at any time before the current timer cycle ends.

To configure timer 3:4, follow the steps below:

1. Select 32-bit unchained mode (TIMMODE in TGCR).
2. Remove the timer 3:4 from reset (TIM34RS in TGCR).
3. Select the desired timer period for timer 3:4 (PRD34). Program with the desired timer period value - 1.
4. Select the desired prescaler value for timer 3:4 (PSC34 in TGCR).
5. Enable timer 3:4 (ENAMODE34 in TCR).
6. If ENAMODE34 = 3h, write the desired timer period for the next timer cycle in the period reload register (REL34). Program with the desired timer period value - 1. This step can be done at any time before the current timer cycle ends.

#### 31.1.5.4.2.2.5 Event Capture Mode

When the PLUSEN bit in the timer global control register (TGCR) is set, Event Capture Mode is available for TIM12 when the timer is configured in 32-bit unchained mode. When Event Capture Mode is enabled, the timer cycle is restarted when an external input event occurs on pin TM64P\_IN12. In particular, when an external input event occurs, the timer stops counting, generates output events (TINT12, TEVT12, and TM64P\_OUT12), copies values from the timer counter register TIM12 to the timer capture register CAP12, reloads the timer period register PRD12 if in continuous mode with period reload (ENAMODE = 3h), and then restarts counting in continuous mode. Event Capture Mode is available only when the timer clock source is the internal timer (CLKSRC = 0) and the timer is in continuous mode (ENAMODE = 2h or 3h).

Capture mode is enabled using the Capture mode enable bit CAPMODE12 in the timer control register (TCR). The type of input event is selected by the capture event mode bit CAPEVTMODE12 in the timer control register (TCR). All of the following input event types are available:

- Rising edge of input signal
- Falling edge of input signal
- Rising or falling edge of input signal

#### 31.1.5.4.2.2.6 Timer Counter Register Read Reset Mode

Read Reset Mode is available when the PLUSEN bit in the timer global control register (TGCR) is set and the timer is configured in 32-bit unchained mode. When Read Reset Mode is enabled, the timer cycle will restart when the timer counter registers are read (TIM12 and/or TIM34). In particular, when the timer registers are read, the timer stops counting, copies values from the timer counter registers (TIM12 and/or TIM34) to the timer capture registers (CAP12 and/or CAP34), reloads the timer period registers (PRD12 and/or PRD34) if in continuous mode with period reload (ENAMODE = 3h), and then restarts counting in continuous mode. Timer output events (TINTn, TEVTn, and TM64P\_OUTn) are not generated during this process. Read Reset Mode is enabled using the read reset mode enable bit (READRSTMODE) in the timer control register (TCR).

### 31.1.5.4.3 Timer Capture Registers

When the timer has a timeout due to a normal expiration of timer, external input event in Event Capture Mode, or read of timer counter registers in Read Reset Mode, the values of the timer counter registers (TIM12 and TIM34) are copied onto the timer counter capture registers (CAP12 and CAP34). Note that the value in TDDR is not captured when a read of TIM34 happens.

### 31.1.5.4.4 Counter and Period Registers Used in GP Timer Modes

Table 31-5 summarizes how the counter registers (TIMn) and period registers (PRDn) are used in each GP timer mode.

**Table 31-5. Counter and Period Registers Used in GP Timer Modes**

| Timer Mode                       | Counter Registers     | Period Registers     |
|----------------------------------|-----------------------|----------------------|
| 64-bit general-purpose           | TIM34:TIM12           | PRD34:PRD12          |
| Dual 32-bit chained:             |                       |                      |
| Prescaler (Timer 3:4)            | TIM34                 | PRD34                |
| Timer (Timer 1:2)                | TIM12                 | PRD12                |
| Dual 32-bit unchained:           |                       |                      |
| Timer (Timer 1:2)                | TIM12                 | PRD12                |
| Timer with prescaler (Timer 3:4) | TDDR34 bits and TIM34 | PSC34 bits and PRD34 |

### 31.1.5.5 Timer Operation Boundary Conditions

The following boundary conditions affect the timer operation.

#### 31.1.5.5.1 Timer Counter Overflow

Timer counter overflow can happen when the timer counter register is set to a value greater than the value in the timer period register. The counter reaches its maximum value (FFFF FFFFh or FFFF FFFF FFFF FFFFh), rolls over to 0, and continues counting until it reaches the timer period. An example is in Figure 31-8.

**Figure 31-8. 32-Bit Timer Counter Overflow Example**

#### 31.1.5.5.2 Writing to Registers of an Active Timer

Writes to most timer registers are not allowed when the timer is active, except for setting the timer period reload registers (REL12 and REL34) and stopping and resetting the timers. In the 64-bit and dual 32-bit timer modes, registers that are protected by hardware are:

- TIM12
- TIM34
- PRD12
- PRD34
- TCR (except the ENAMODE bit)
- TGCR (except the TIM12RS and TIM34RS bits)

### 31.1.5.6 General-Purpose Timer Power Management

The timer can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter. The timer can be placed in an idle mode to conserve power when it is not being used.

### 31.1.6 Architecture – Watchdog Timer Mode

This section describes the use of the timer as a watchdog timer. In order to fully function in watchdog timer mode, the timer must be internally connected to the device hardware reset signal. For information on which timer instantiation can function as a watchdog timer, see your device-specific data manual.

#### 31.1.6.1 Watchdog Timer

As a 64-bit watchdog timer, the peripheral can be used to prevent system lockup when the software becomes trapped in loops with no controlled exit.

After a hardware reset, the watchdog timer is disabled. The timer then can be configured as a watchdog timer using the timer mode (TIMMODE) bit in the timer global control register (TGCR) and the watchdog timer enable (WDEN) bit in the watchdog timer control register (WDTCR). In the watchdog timer mode, the timer requires a special service sequence to be executed periodically. Without this periodic servicing, the timer counter increments until it matches the timer period and causes a watchdog timeout event.

When the timeout event occurs, the watchdog timer resets the entire processor.

#### 31.1.6.2 Watchdog Timer Mode Restrictions

The watchdog timer mode has the following restrictions:

- No external clock source
- No one-time enabling

#### 31.1.6.3 Watchdog Timer Mode Operation

The watchdog timer mode is selected and enabled when:

- TIMMODE = 2h in TGCR
- WDEN = 1 in WDTCR

Figure 31-9 shows the timer when it is used in the watchdog timer mode. The counter registers (TIM12 and TIM34) form a 64-bit timer counter register and the period registers (PRD12 and PRD34) form a 64-bit period register. When the timer counter matches the timer period, the timer generates a watchdog timeout event which resets the entire processor.

To activate the watchdog timer, a certain sequence of events must be followed, as shown in the state diagram of Figure 31-10.

Once the watchdog timer is activated, it can be disabled only by a watchdog timeout event or by a hardware reset. A special key sequence is required to prevent the watchdog timer from being accidentally serviced while the software is trapped in a loop or by some other software failure.

To prevent a watchdog timeout event, the timer has to be serviced periodically by writing A5C6h followed by DA7Eh to the watchdog timer service key (WDKEY) bits in WDTCR before the timer finishes counting up. Both A5C6h and DA7Eh are allowed to be written to the WDKEY bits, but only the correct sequence of A5C6h followed by DA7Eh to the WDKEY bits services the watchdog timer. Any other writes to the WDKEY bits triggers the watchdog timeout event immediately.

When the watchdog timer is in the Timeout state, the watchdog timer is disabled, the WDEN bit is cleared to 0, and the timer is reset.

**Figure 31-9. Watchdog Timer Mode Block Diagram**

**Figure 31-10. Watchdog Timer Operation State Diagram**

After a hardware reset, the watchdog timer is disabled; however, reads or writes to the watchdog timer registers are allowed. Once the WDEN bit is set (enabling the watchdog timer) and A5C6h is written to the WDKEY bits, the watchdog timer enters the Pre-active state. In the Pre-active state:

- A write to WDTCSR is allowed only when the write comes with the correct key (A5C6h or DA7Eh) to the WDKEY bits.
- A write of DA7Eh to the WDKEY bits when the WDEN bit is set to 1 resets the counters and activates the watchdog timer.

The watchdog timer must be configured before the watchdog timer enters the Active state. The WDEN bit must be set to 1 before writing DA7Eh to the WDKEY bits in the Pre-active state. Every time the watchdog timer is serviced by the correct WDKEY sequence, the watchdog timer counter is automatically reset.

#### 31.1.6.4 Watchdog Timer Register Write Protection

Once the watchdog timer enters the Pre-active state (see [Figure 31-10](#)), writes to TIM12, TIM34, PRD12, PRD34, and WDTCSR are write protected (except for the WDKEY field). While the watchdog timer is in the Timeout state, writing to the WDEN bit has no effect.

Once the watchdog timer enters its Initial state (see [Figure 31-10](#)), do not write to TGCR.

#### 31.1.6.5 Watchdog Timer Power Management

The watchdog timer cannot be placed in power-down mode.

#### 31.1.7 Reset Considerations

The timer has two reset sources: hardware reset and the timer reset (TIM12RS and TIM34RS) bits in the timer global control register (TGCR).

##### 31.1.7.1 Software Reset Considerations

When the TIM12RS bit in TGCR is cleared to 0, the TIM12 register is held with the current value.

When the TIM34RS bit in TGCR is cleared to 0, the TIM34 register is held with the current value.

##### 31.1.7.2 Hardware Reset Considerations

When a hardware reset is asserted, all timer registers are set to their default values.

#### 31.1.8 Interrupt Support

Each of the timers can send either one of two separate interrupt events (TINT<sub>n</sub>) to the CPU, depending on the operating mode of the timer. The timer interrupts are generated when the count value in the counter register reaches the value specified in the period register.

When the PLUSEN bit in the timer global control register (TGCR) is set, matches between TIM12 and CMP<sub>n</sub> in dual 32-bit unchained mode will also generate interrupts. Setting the PLUSEN bit also enables additional features for control, status, and generation of interrupts. See [Section 31.1.11](#) for more information.

#### 31.1.9 DMA Event Support

Each of the timers can send either one of two separate timer events (TEVT<sub>n</sub>) to the DMA engine, depending on the operating mode of the timer. The timer events are generated when the count value in the counters register reaches the value specified in the period register.

When the PLUSEN bit in the timer global control register (TGCR) is set, matches between TIM12 and CMP<sub>n</sub> in dual 32-bit unchained mode will also generate DMA events. Setting the PLUSEN bit also enables additional features for control, status, and generation of dma events are enabled. See [Section 31.1.11](#) for more information.

### 31.1.10 TM64P\_OUT Event Support

The timer can generate an output pulse (Figure 31-11) or clock (Figure 31-12) signals on the TM64P\_OUT12 pin. The output signal is generated when the count value in the counter registers reaches the value specified in the period registers (TSTAT12 drives the TM64P\_OUT12 pin). Table 31-6 gives equations for various TSTAT12 timing parameters in pulse and clock modes.

The output mode is selected with the clock/pulse bit (CP<sub>n</sub>) in the timer control register (TCR). In pulse mode, the PWID12 bit in TCR sets the pulse width between 1 to 4 timer clock periods. The TM64P\_OUT12 pin may be inverted using the INVOUTP12 bit in TCR.

**Figure 31-11. Timer Operation in Pulse Mode (CP<sub>n</sub> = 0)**

**Figure 31-12. Timer Operation in Clock Mode (CP<sub>n</sub> = 1)**

**Table 31-6. TSTAT Parameters in Pulse and Clock Modes**

| Mode  | Frequency                                                              | Period                                                                 | Width High                                                    | Width Low                                                                         |
|-------|------------------------------------------------------------------------|------------------------------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Pulse | $\frac{f(\text{clock source})}{\text{timer period register}}$          | $\frac{\text{timer period register}}{f(\text{clock source})}$          | $\frac{(\text{PWID} + 1)}{f(\text{clock source})}$            | $\frac{\text{timer period register} - (\text{PWID} + 1)}{f(\text{clock source})}$ |
| Clock | $\frac{f(\text{clock source})}{2 \times \text{timer period register}}$ | $\frac{2 \times \text{timer period register}}{f(\text{clock source})}$ | $\frac{\text{timer period register}}{f(\text{clock source})}$ | $\frac{\text{timer period register}}{f(\text{clock source})}$                     |

## External Timer Pin GPIO Mode

The external timer pins (TM64P\_IN12 and TM64P\_OUT12) can be individually configured to function as general-purpose input/output (GPIO) pins. In GPIO mode, the pins are able to detect and drive arbitrary data. The pins are also able to source external interrupt events. Some timer instantiations may not have external pins, see your device-specific data manual for pin information.

The GPIO interrupt and GPIO enable register (GPINTGPEN) enables the GPIO mode and associated interrupts. The GPIO data and GPIO direction register (GPDATGPDIR) determines if GPIO-enabled pins are used as input or output pins; and it is the means by which data is read-from or written-to the GPIO pins.

Normal timer counting modes cannot be used when the GPIO mode is enabled -- TIM12RS in the timer global control register (TGCR) cannot be brought out of reset when either GPEN012 or GPEN112 in GPINTGPEN is asserted.

### 31.1.11 Interrupt/DMA Event Generation Control and Status

When the PLUSEN bit in the timer global control register (TGCR) is set, the timer supports additional features for control and status of interrupt and DMA event generation. Interrupt/DMA events are generated when the count value in the timer counter registers reaches the value specified in the timer period registers and interrupt/DMA events are also generated when the Event Capture Mode is enabled and an external event occurs.

To generate events in the case when the value in the timer counter registers equals the value specified in the timer period registers, set the period compare interrupt enable bit (PRDINTEN $n$ ) in the interrupt control and status register (INTCTLSTAT). The event status for this case is reflected in the period compare interrupt status bit (PRDINTSTAT $n$ ), which is also in INTCTLSTAT. The PRDINTSTAT $n$  bit is cleared by writing a 1 to the bit.

Similarly, to generate events in Event Capture Mode, set the event interrupt enable bit (EVTINTEN $n$ ) in INTCTLSTAT. The event status for this case is reflected in the external interrupt status bit (EVTINTSTAT $n$ ) in INTCTLSTAT. The EVTINTSTAT $n$  bit is cleared by writing a 1 to the bit.

### 31.1.12 Power Management

The general-purpose timers can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 31.1.13 Emulation Considerations

Each timer has an emulation management register (EMUMGT). As shown in [Table 31-7](#), the FREE and SOFT bits of EMUMGT determine how the timer responds to an emulation suspend event. An emulation suspend event corresponds to any type of emulator access to the CPU, such as a hardware or software breakpoint or a probe point.

Note that during emulation, the timer count values will increment once every timer peripheral clock (not CPU clock). So when single-stepping through code, the timer values will not update on every CPU clock cycle.

The timer can respond to emulation events from the CPU based on the configuration of the Emulation Suspend Source Register (SUSPSRC) in the System Configuration Module. See the *System Configuration (SYSCFG) Module* chapter for information on SUSPSRC and how it is configured.

**Table 31-7. Timer Emulation Modes Selection**

| FREE | SOFT | Emulation Mode                                                                                              |
|------|------|-------------------------------------------------------------------------------------------------------------|
| 0    | 0    | The timer stops immediately.                                                                                |
| 0    | 1    | The timer stops when the timer counter value increments and reaches the value in the timer period register. |
| 1    | x    | The timer runs free regardless of SOFT bit status.                                                          |

## 31.2 Registers

Table 31-8 lists the memory-mapped registers for the 64-bit Timer Plus. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 31-8 should be considered as reserved locations and the register contents should not be modified.

**Table 31-8. Timer Registers**

| Offset | Acronym    | Register Description                        | Section                                             |

### 31.2.5 Timer Counter Registers (TIM12 and TIM34)

The timer counter register is a 64-bit wide register. This 64-bit register is divided into two 32-bit registers, TIM12 and TIM34.

In the dual 32-bit timer mode, the 64-bit register is divided with TIM12 acting as one 32-bit counter and TIM34 acting as another. These two registers can be configured as chained or unchained.

#### 31.2.5.1 Timer Counter Register 12 (TIM12)

The timer counter register 12 (TIM12) is shown in [Figure 31-17](#) and described in [Table 31-13](#)

**Figure 31-17. Timer Counter Register 12 (TIM12)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-13. Timer Counter Register 12 (TIM12) Field Descriptions**

| Bit  | Field | Value        | Description                                                                   |
|------|-------|--------------|-------------------------------------------------------------------------------|
| 31-0 | TIM12 | 0-FFFF FFFFh | TIM12 count bits. This 32-bit value is the current count of the main counter. |

#### 31.2.5.2 Timer Counter Register 34 (TIM34)

The timer counter register 34 (TIM34) is shown in [Figure 31-18](#) and described in [Table 31-14](#).

**Figure 31-18. Timer Counter Register 34 (TIM34)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-14. Timer Counter Register 34 (TIM34) Field Descriptions**

| Bit  | Field | Value        | Description                                                                   |
|------|-------|--------------|-------------------------------------------------------------------------------|
| 31-0 | TIM34 | 0-FFFF FFFFh | TIM34 count bits. This 32-bit value is the current count of the main counter. |

### 31.2.6 Timer Period Registers (PRD12 and PRD34)

The timer period register is a 64-bit wide register. This 64-bit register is divided into two 32-bit registers, PRD12 and PRD34.

Similar to TIM $n$  in the dual 32-bit timer mode, PRD $n$  can be divided into 2 registers: for timer 1:2, PRD12 and for timer 3:4, PRD34. These two registers can be used in conjunction with the two timer counter registers TIM12 and TIM34.

#### 31.2.6.1 Timer Period Register 12 (PRD12)

The timer period register 12 (PRD12) is shown in [Figure 31-19](#) and described in [Table 31-15](#).

**Figure 31-19. Timer Period Register 12 (PRD12)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 31-15. Timer Period Register (PRD12) Field Descriptions**

| Bit  | Field | Value        | Description                                                                              |
|------|-------|--------------|------------------------------------------------------------------------------------------|
| 31-0 | PRD12 | 0-FFFF FFFFh | PRD12 period bits. This 32-bit value is the number of timer input clock cycles to count. |

#### 31.2.6.2 Timer Period Register 34 (PRD34)

The timer period register 34 (PRD34) is shown in [Figure 31-20](#) and described in [Table 31-16](#).

**Figure 31-20. Timer Period Register 34 (PRD34)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 31-16. Timer Period Register (PRD34) Field Descriptions**

| Bit  | Field | Value        | Description                                                                              |
|------|-------|--------------|------------------------------------------------------------------------------------------|
| 31-0 | PRD34 | 0-FFFF FFFFh | PRD34 period bits. This 32-bit value is the number of timer input clock cycles to count. |

### 31.2.7 Timer Control Register (TCR)

The timer control register (TCR) is shown in [Figure 31-21](#) and described in [Table 31-17](#).

**Figure 31-21. Timer Control Register (TCR)**

|           |    |             |               |               |           |

### 31.2.8 Timer Global Control Register (TGCR)

The timer global control register (TGCR) is shown in [Figure 31-22](#) and described in [Table 31-18](#).

**Figure 31-22. Timer Global Control Register (TGCR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-18. Timer Global Control Register (TGCR) Field Descriptions**

| Bit   | Field    | Value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0                           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 15-12 | TDDR34   | 0-Fh                        | Timer linear divide-down ratio specifies the timer divide-down ratio for timer 3:4. When the timer is enabled, TDDR34 increments every timer clock. The TIM34 counter increments on the cycle after TDDR34 matches PSC34. TDDR34 resets to 0 and continues. When TIM34 matches PRD34, timer 3:4 stops, if timer 3:4 is enabled one time; TIM34 resets to 0 on the cycle after matching PRD34 and timer 3:4 continues, if timer 3:4 is enabled continuously. |
| 11-8  | PSC34    | 0-Fh                        | TIM34 pre-scalar counter specifies the count for timer 3:4.                                                                                                                                                                                                                                                                                                                                                                                                 |

| 1     | TIM34RS  | 0<br>1                      | Timer 3:4 reset.<br>Timer 3:4 is in reset.<br>Timer 3:4 is not in reset. Timer 3:4 can be used as a 32-bit timer. Note that for the timer to function properly in 64-bit timer mode, both TIM34RS and TIM12RS must be set to 1. Changing this bit does not affect the timer, if the timer is in the watchdog active state.                                                                                                                                  |
| 0     | TIM12RS  | 0<br>1                      | Timer 1:2 reset.<br>Timer 1:2 is in reset.<br>Timer 1:2 is not in reset. Timer 1:2 can be used as a 32-bit timer. Note that for the timer to function properly in 64-bit timer mode, both TIM34RS and TIM12RS must be set to 1. Changing this bit does not affect the timer, if the timer is in the watchdog active state.                                                                                                                                  |

### 31.2.9 Watchdog Timer Control Register (WDTCR)

The watchdog timer control register (WDTCR) is shown in [Figure 31-23](#) and described in [Table 31-19](#).

**Figure 31-23. Watchdog Timer Control Register (WDTCR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-19. Watchdog Timer Control Register (WDTCR) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                           |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | WDKEY    | 0-FFFFh | 16-bit watchdog timer service key. Only the sequence of an A5C6h followed by a DA7Eh services the watchdog. Not applicable in regular timer mode.                                                                     |
| 15    | WDFLAG   | 0<br>1  | Watchdog flag bit. WDFLAG can be cleared by enabling the watchdog timer, by device reset, or being written with 1. It is set by a watchdog time-out.<br>No watchdog time-out occurred.<br>Watchdog time-out occurred. |
| 14    | WDEN     | 0<br>1  | Watchdog timer enable bit.<br>Disable watchdog timer<br>Enable watchdog timer                                                                                                                                         |
| 13-12 | Reserved | 0       | Reserved. This bit field must be written as 00b.                                                                                                                                                                      |
| 11-0  | Reserved | 0       | Reserved                                                                                                                                                                                                              |

### 31.2.10 Timer Reload Register 12 (REL12)

The timer reload register 12 (REL12) is shown in [Figure 31-24](#) and described in [Table 31-20](#).

**Figure 31-24. Timer Reload Register 12 (REL12)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-20. Timer Reload Register 12 (REL12) Field Descriptions**

| Bit   | Field | Value        | Description         |
|-------|-------|--------------|---------------------|
| 31- 0 | REL12 | 0-FFFF FFFFh | Period reload bits. |

### 31.2.11 Timer Reload Register 34 (REL34)

The timer reload register 34 (REL34) is shown in [Figure 31-25](#) and described in [Table 31-21](#).

**Figure 31-25. Timer Reload Register 34 (REL34)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-21. Timer Reload Register 34 (REL34) Field Descriptions**

| Bit   | Field | Value        | Description         |
|-------|-------|--------------|---------------------|
| 31- 0 | REL34 | 0-FFFF FFFFh | Period reload bits. |

### 31.2.12 Timer Capture Register 12 (CAP12)

The timer capture register 12 (CAP12) is shown in [Figure 31-26](#) and described in [Table 31-22](#).

**Figure 31-26. Timer Capture Register 12 (CAP12)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-22. Timer Capture Register 12 (CAP12) Field Descriptions**

| Bit   | Field | Value        | Description                  |
|-------|-------|--------------|------------------------------|
| 31- 0 | CAP12 | 0-FFFF FFFFh | Captured timer counter bits. |

### 31.2.13 Timer Capture Register 34 (CAP34)

The timer capture register 34 (CAP34) is shown in [Figure 31-27](#) and described in [Table 31-23](#).

**Figure 31-27. Timer Capture Register 34 (CAP34)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-23. Timer Capture Register 34 (CAP34) Field Descriptions**

| Bit   | Field | Value        | Description                  |
|-------|-------|--------------|------------------------------|
| 31- 0 | CAP34 | 0-FFFF FFFFh | Captured timer counter bits. |

### 31.2.14 Timer Interrupt Control and Status Register (INTCTLSTAT)

The timer interrupt control and status register (INTCTLSTAT) is shown in [Figure 31-28](#) and described in [Table 31-24](#).

**Figure 31-28. Timer Interrupt Control and Status Register (INTCTLSTAT)**

|          |    |  |  |  |              |            |       |              |         |            |       |  |  |  |  |  |    |

When PLUSEN = 1 in the timer global control register (TGCR) and the timer is configured in 32-bit unchained mode, TIM12 is compared to all 8 compare registers (CMP0-CMP7). When CMP $n$ matches TIM12, a timer CMP $n$ interrupt and DMA event are generated. A CMP $n$ match will not affect the TIM12 count or behavior. |

## ***Universal Asynchronous Receiver/Transmitter (UART)***

This chapter describes the universal asynchronous receiver/transmitter (UART) peripheral. See your device-specific data manual to determine how many UARTs are available on your device.

| Topic                                    | Page        |
|------------------------------------------|-------------|

| <b>32.3 Registers .....</b>              | <b>1532</b> |

## 32.1 Introduction

### 32.1.1 Purpose of the Peripheral

The UART peripheral is based on the industry standard TL16C550 asynchronous communications element, which in turn is a functional upgrade of the TL16C450. Functionally similar to the TL16C450 on power up (single character or TL16C450 mode), the UART can be placed in an alternate FIFO (TL16C550) mode. This relieves the CPU of excessive software overhead by buffering received and transmitted characters. The receiver and transmitter FIFOs store up to 16 bytes including three additional bits of error status per byte for the receiver FIFO.

The UART performs serial-to-parallel conversions on data received from a peripheral device and parallel-to-serial conversion on data received from the CPU. The CPU can read the UART status at any time. The UART includes control capability and a processor interrupt system that can be tailored to minimize software management of the communications link.

The UART includes a programmable baud generator capable of dividing the UART input clock by divisors from 1 to 65535 and producing a 16× reference clock or a 13× reference clock for the internal transmitter and receiver logic. For detailed timing and electrical specifications for the UART, see your device-specific data manual.

### 32.1.2 Features

Check your device-specific data manual to see the list of features that are supported and that are not supported by the UART.

### 32.1.3 Functional Block Diagram

A functional block diagram of the UART is shown in [Figure 32-1](#).

### 32.1.4 Industry Standard(s) Compliance Statement

The UART peripheral is based on the industry standard TL16C550 asynchronous communications element, which is a functional upgrade of the TL16C450. The information in this chapter assumes you are familiar with these standards.

**Figure 32-1. UART Block Diagram**

NOTE: The value *n* indicates the applicable UART; that is, UART0, UART1, and so on.

## 32.2 Peripheral Architecture

### 32.2.1 Clock Generation and Control

The UART bit clock is derived from an input clock to the UART. See your device-specific data manual to check the maximum data rate supported by the UART.

Figure 32-2 is a conceptual clock generation diagram for the UART. The processor clock generator receives a signal from an external clock source and produces a UART input clock with a programmed frequency. The UART contains a programmable baud generator that takes an input clock and divides it by a divisor in the range between 1 and  $(2^{16} - 1)$  to produce a baud clock (BCLK). The frequency of BCLK is sixteen times ( $16\times$ ) the baud rate (each received or transmitted bit lasts 16 BCLK cycles) or thirteen times ( $13\times$ ) the baud rate (each received or transmitted bit lasts 13 BCLK cycles). When the UART is receiving, the bit is sampled in the 8th BCLK cycle for  $16\times$  over sampling mode and on the 6th BCLK cycle for  $13\times$  over-sampling mode. The  $16\times$  or  $13\times$  reference clock is selected by configuring the OSM\_SEL bit in the mode definition register (MDR). The formula to calculate the divisor is:

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 16} \quad [\text{MDR.OSM\_SEL} = 0]$$

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 13} \quad [\text{MDR.OSM\_SEL} = 1]$$

Two 8-bit register fields (DLH and DLL), called divisor latches, hold this 16-bit divisor. DLH holds the most significant bits of the divisor, and DLL holds the least significant bits of the divisor. For information about these register fields, see Section 32.3. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Figure 32-3 summarizes the relationship between the transferred data bit, BCLK, and the UART input clock. Note that the timing relationship depicted in Figure 32-3 shows that each bit lasts for 16 BCLK cycles. This is in case of  $16\times$  over-sampling mode. For  $13\times$  over-sampling mode each bit lasts for 13 BCLK cycles.

Example baud rates and divisor values relative to a 150-MHz UART input clock and  $16\times$  over-sampling mode are shown in Table 32-1.

Figure 32-2. UART Clock Generation Diagram

### 32.2.2 Signal Descriptions

The UARTs utilize a minimal number of signal connections to interface with external devices. The UART signal descriptions are included in [Table 32-3](#). Note that the number of UARTs and their supported features vary on each device, see your device-specific data manual for more details.

**Table 32-3. UART Signal Descriptions**

| Signal Name <sup>(1)</sup> | Signal Type | Function                           |
|----------------------------|-------------|------------------------------------|
| UARTn_TXD                  | Output      | Serial data transmit               |
| UARTn_RXD                  | Input       | Serial data receive                |
| UARTn_CTS <sup>(2)</sup>   | Input       | Clear-to-Send handshaking signal   |
| UARTn_RTS <sup>(2)</sup>   | Output      | Request-to-Send handshaking signal |

<sup>(1)</sup> The value *n* indicates the applicable UART; that is, UART0, UART1, etc.

<sup>(2)</sup> This signal is not supported in all UARTs. See your device-specific data manual to check if it is supported.

### 32.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. See your device-specific data manual to determine how pin multiplexing affects the UART.

### 32.2.4 Protocol Description

#### 32.2.4.1 Transmission

The UART transmitter section includes a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

#### 32.2.4.2 Reception

The UART receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Receiver section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

### 32.2.4.3 Data Format

The UART transmits in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + STOP bit (1, 1.5, 2)

It transmits 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1, 1.5, or 2 STOP bits, depending on the STOP bit selection.

The UART receives in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + 1 STOP bit

It receives 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1 STOP bit.

The protocol formats are shown in [Figure 32-4](#).

**Figure 32-4. UART Protocol Formats**

Transmit/Receive for 5-bit data, parity Enable, 1 STOP bit

Transmit/Receive for 6-bit data, parity Enable, 1 STOP bit

Transmit/Receive for 7-bit data, parity Enable, 1 STOP bit

Transmit/Receive for 8-bit data, parity Enable, 1 STOP bit

## 32.2.5 Operation

### 32.2.5.1 Transmission

The UART transmitter section includes a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

THR receives data from the internal data bus, and when TSR is ready, the UART moves the data from THR to TSR. The UART serializes the data in TSR and transmits the data on the UARTn\_TXD pin.

In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled in the interrupt enable register (IER), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register (IIR) is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or IIR is read.

### 32.2.5.2 Reception

The UART receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16× receiver clock. Receiver section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

RSR receives the data bits from the UARTn\_RXD pin. Then RSR concatenates the data bits and moves the resulting value into RBR (or the receiver FIFO). The UART also stores three bits of error status information next to each received character, to record a parity error, framing error, or break.

In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled in the interrupt enable register (IER), an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register (FCR), and it is cleared when the FIFO contents drop below the trigger level.

### 32.2.5.3 FIFO Modes

The following two modes can be used for servicing the receiver and transmitter FIFOs:

- FIFO interrupt mode. The FIFO is enabled and the associated interrupts are enabled. Interrupts are sent to the CPU to indicate when specific events occur.
- FIFO poll mode. The FIFO is enabled but the associated interrupts are disabled. The CPU polls status bits to detect specific events.

Because the receiver FIFO and the transmitter FIFO are controlled separately, either one or both can be placed into the interrupt mode or the poll mode.

#### 32.2.5.3.1 FIFO Interrupt Mode

When the receiver FIFO is enabled in the FIFO control register (FCR) and the receiver interrupts are enabled in the interrupt enable register (IER), the interrupt mode is selected for the receiver FIFO. The following are important points about the receiver interrupts:

- The receiver data-ready interrupt is issued to the CPU when the FIFO has reached the trigger level that is programmed in FCR. It is cleared when the CPU or the DMA controller reads enough characters from the FIFO such that the FIFO drops below its programmed trigger level.
- The receiver line status interrupt is generated in response to an overrun error, a parity error, a framing error, or a break. This interrupt has higher priority than the receiver data-ready interrupt. For details, see [Section 32.2.8](#).
- The data-ready (DR) bit in the line status register (LSR) indicates the presence or absence of characters in the receiver FIFO. The DR bit is set when a character is transferred from the receiver shift register (RSR) to the empty receiver FIFO. The DR bit remains set until the FIFO is empty again.
- A receiver time-out interrupt occurs if all of the following conditions exist:
  - At least one character is in the FIFO,
  - The most recent character was received more than four continuous character times ago. A character time is the time allotted for 1 START bit,  $n$  data bits, 1 PARITY bit, and 1 STOP bit, where  $n$  depends on the word length selected with the WLS bits in the line control register (LCR). See [Table 32-4](#).
  - The most recent read of the FIFO has occurred more than four continuous character times before.
- Character times are calculated by using the baud rate.
- When a receiver time-out interrupt has occurred, it is cleared and the time-out timer is cleared when the CPU or the EDMA controller reads one character from the receiver FIFO. The interrupt is also cleared if a new character is received in the FIFO or if the URRST bit is cleared in the power and emulation management register (PWREMU\_MGMT).
- If a receiver time-out interrupt has not occurred, the time-out timer is cleared after a new character is received or after the CPU or EDMA reads the receiver FIFO.

When the transmitter FIFO is enabled in FCR and the transmitter holding register empty (THRE) interrupt is enabled in IER, the interrupt mode is selected for the transmitter FIFO. The THRE interrupt occurs when the transmitter FIFO is empty. It is cleared when the transmitter hold register (THR) is loaded (1 to 16 characters may be written to the transmitter FIFO while servicing this interrupt) or the interrupt identification register (IIR) is read.

**Table 32-4. Character Time for Word Lengths**

| Word Length ( $n$ ) | Character Time   | Four Character Times |
|---------------------|------------------|----------------------|
| 5                   | Time for 8 bits  | Time for 32 bits     |
| 6                   | Time for 9 bits  | Time for 36 bits     |
| 7                   | Time for 10 bits | Time for 40 bits     |
| 8                   | Time for 11 bits | Time for 44 bits     |

### 32.2.5.3.2 FIFO Poll Mode

When the receiver FIFO is enabled in the FIFO control register (FCR) and the receiver interrupts are disabled in the interrupt enable register (IER), the poll mode is selected for the receiver FIFO. Similarly, when the transmitter FIFO is enabled and the transmitter interrupts are disabled, the transmitted FIFO is in the poll mode. In the poll mode, the CPU detects events by checking bits in the line status register (LSR):

- The RXFIFOE bit indicates whether there are any errors in the receiver FIFO.
- The TEMT bit indicates that both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
- The THRE bit indicates when THR is empty.
- The BI (break), FE (framing error), PE (parity error), and OE (overrun error) bits specify which error or errors have occurred.
- The DR (data-ready) bit is set as long as there is at least one byte in the receiver FIFO.

Also, in the FIFO poll mode:

- The interrupt identification register (IIR) is not affected by any events because the interrupts are disabled.
- The UART does not indicate when the receiver FIFO trigger level is reached or when a receiver time-out occurs.

### 32.2.5.4 Autoflow Control

The UART can employ autoflow control by connecting the  $\overline{\text{UARTn\_CTS}}$  and  $\overline{\text{UARTn\_RTS}}$  signals. Note that all UARTs do not support autoflow control, see your device-specific data manual for supported features. The  $\overline{\text{UARTn\_CTS}}$  input must be active before the transmitter FIFO can transmit data. The  $\overline{\text{UARTn\_RTS}}$  becomes active when the receiver needs more data and notifies the sending device. When  $\overline{\text{UARTn\_RTS}}$  is connected to  $\overline{\text{UARTn\_CTS}}$ , data transmission does not occur unless the receiver FIFO has space for the data. Therefore, when two UARTs are connected as shown in Figure 32-5 with autoflow enabled, overrun errors are eliminated.

**Figure 32-5. UART Interface Using Autoflow Diagram**

### 32.2.5.4.1 UARTn\_RTS Behavior

UARTn\_RTS data flow control originates in the receiver block (see [Figure 32-1](#)). When the receiver FIFO level reaches a trigger level of 1, 4, 8, or 14 (see [Figure 32-6](#)), UARTn\_RTS is deasserted. The sending UART may send an additional byte after the trigger level is reached (assuming the sending UART has another byte to send), because it may not recognize the deassertion of UARTn\_RTS until after it has begun sending the additional byte. For trigger level 1, 4, and 8, UARTn\_RTS is automatically reasserted once the receiver FIFO is emptied. For trigger level 14, UARTn\_RTS is automatically reasserted once the receiver FIFO drops below the trigger level.

**Figure 32-6. Autoflow Functional Timing Waveforms for UARTn\_RTS**

- (1) N = Receiver FIFO trigger level.
- (2) The two blocks in dashed lines cover the case where an additional byte is sent.

### 32.2.5.4.2 UARTn\_CTS Behavior

The transmitter checks UARTn\_CTS before sending the next data byte. If UARTn\_CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, UARTn\_CTS must be released before the middle of the last STOP bit that is currently being sent (see [Figure 32-7](#)). When flow control is enabled, UARTn\_CTS level changes do not trigger interrupts because the device automatically controls its own transmitter. Without autoflow control, the transmitter sends any data present in the transmitter FIFO and a receiver overrun error may result.

**Figure 32-7. Autoflow Functional Timing Waveforms for UARTn\_CTS**

- (1) When UARTn\_CTS is active (low), the transmitter keeps sending serial data out.
- (2) When UARTn\_CTS goes high before the middle of the last STOP bit of the current byte, the transmitter finishes sending the current byte but it does not send the next byte.
- (3) When UARTn\_CTS goes from high to low, the transmitter begins sending data again.

### 32.2.5.5 Loopback Control

The UART can be placed in the diagnostic mode using the LOOP bit in the modem control register (MCR), which internally connects the UART output back to the UART input. In this mode, the transmit and receive data paths, the transmitter and receiver interrupts, and the modem control interrupts can be verified without connecting to another UART.

## 32.2.6 Reset Considerations

### 32.2.6.1 Software Reset Considerations

Two bits in the power and emulation management register (PWREMU\_MGMT) control resetting the parts of the UART:

- The UTRST bit controls resetting the transmitter only. If UTRST = 1, the transmitter is active; if UTRST = 0, the transmitter is in reset.
- The URRST bit controls resetting the receiver only. If URRST = 1, the receiver is active; if URRST = 0, the receiver is in reset.

In each case, putting the receiver and/or transmitter in reset will reset the state machine of the affected portion but does not affect the UART registers.

### 32.2.6.2 Hardware Reset Considerations

When the processor RESET pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the UART state machine is reset and the UART registers are forced to their default states. The default states of the registers are shown in [Section 32.3](#).

## 32.2.7 Initialization

The following steps are required to initialize the UART:

1. Perform the necessary device pin multiplexing setup (see your device-specific data manual).
2. Set the desired baud rate by writing the appropriate clock divisor values to the divisor latch registers (DLL and DLH).
3. If the FIFOs will be used, select the desired trigger level and enable the FIFOs by writing the appropriate values to the FIFO control register (FCR). The FIFOEN bit in FCR must be set first, before the other bits in FCR are configured.
4. Choose the desired protocol settings by writing the appropriate values to the line control register (LCR).
5. If autoflow control is desired, write appropriate values to the modem control register (MCR). Note that all UARTs do not support autoflow control, see your device-specific data manual for supported features.
6. Choose the desired response to emulation suspend events by configuring the FREE bit and enable the UART by setting the UTRST and URRST bits in the power and emulation management register (PWREMU\_MGMT).

## 32.2.8 Interrupt Support

### 32.2.8.1 Interrupt Events and Requests

The UART generates the interrupt requests described in [Table 32-5](#). All requests are multiplexed through an arbiter to a single UART interrupt request to the CPU, as shown in [Figure 32-8](#). Each of the interrupt requests has an enable bit in the interrupt enable register (IER) and is recorded in the interrupt identification register (IIR).

If an interrupt occurs and the corresponding enable bit is set to 1, the interrupt request is recorded in IIR and is forwarded to the CPU. If an interrupt occurs and the corresponding enable bit is cleared to 0, the interrupt request is blocked. The interrupt request is neither recorded in IIR nor forwarded to the CPU.

### 32.2.8.2 Interrupt Multiplexing

The UARTs have dedicated interrupt signals to the CPU and the interrupts are not multiplexed with any other interrupt source.

**Table 32-5. UART Interrupt Requests Descriptions**

| UART Interrupt Request | Interrupt Source                                                                                                                                                                                                                                          | Comment                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| THREINT                | THR-empty condition: The transmitter holding register (THR) or the transmitter FIFO is empty. All of the data has been copied from THR to the transmitter shift register (TSR).                                                                           | If THREINT is enabled in IER, by setting the ETBEI bit, it is recorded in IIR.<br>As an alternative to using THREINT, the CPU can poll the THRE bit in the line status register (LSR).                                                                                                                                                                                                       |
| RDAINT                 | Receive data available in non-FIFO mode or trigger level reached in the FIFO mode.                                                                                                                                                                        | If RDAINT is enabled in IER, by setting the ERBI bit, it is recorded in IIR.<br>As an alternative to using RDAINT, the CPU can poll the DR bit in the line status register (LSR). In the FIFO mode, this is not a functionally equivalent alternative because the DR bit does not respond to the FIFO trigger level. The DR bit only indicates the presence or absence of unread characters. |
| RTOINT                 | Receiver time-out condition (in the FIFO mode only): No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 32-4), and there is at least one character in the receiver FIFO during this time. | The receiver time-out interrupt prevents the UART from waiting indefinitely, in the case when the receiver FIFO level is below the trigger level and thus does not generate a receiver data-ready interrupt.<br>If RTOINT is enabled in IER, by setting the ERBI bit, it is recorded in IIR.<br>There is no status bit to reflect the occurrence of a time-out condition.                    |
| RLSINT                 | Receiver line status condition: An overrun error, parity error, framing error, or break has occurred.                                                                                                                                                     | If RLSINT is enabled in IER, by setting the ELSI bit, it is recorded in IIR.<br>As an alternative to using RLSINT, the CPU can poll the following bits in the line status register (LSR): overrun error indicator (OE), parity error indicator (PE), framing error indicator (FE), and break indicator (BI).                                                                                 |

**Figure 32-8. UART Interrupt Request Enable Paths**

### 32.2.9 DMA Event Support

In the FIFO mode, the UART generates the following two DMA events:

- **Receive event (URXEVT):** The trigger level for the receiver FIFO (1, 4, 8, or 14 characters) is set with the RXFIFTL bit in the FIFO control register (FCR). Every time the trigger level is reached or a receiver time-out occurs, the UART sends a receive event to the EDMA controller. In response, the EDMA controller reads the data from the receiver FIFO by way of the receiver buffer register (RBR). Note that the receive event is not asserted if the data at the top of the receiver FIFO is erroneous even if the trigger level has been reached.
- **Transmit event (UTXEVT):** When the transmitter FIFO is empty (when the last byte in the transmitter FIFO has been copied to the transmitter shift register), the UART sends an UTXEVT signal to the EDMA controller. In response, the EDMA controller refills the transmitter FIFO by way of the transmitter holding register (THR). The UTXEVT signal is also sent to the DMA controller when the UART is taken out of reset using the UTRST bit in the power and emulation management register (PWREMU\_MGMT).

Activity in DMA channels can be synchronized to these events. In the non-FIFO mode, the UART generates no DMA events. Any DMA channel synchronized to either of these events must be enabled at the time the UART event is generated. Otherwise, the DMA channel will miss the event and, unless the UART generates a new event, no data transfer will occur.

### 32.2.10 Power Management

The UART peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the UART peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 32.2.11 Emulation Considerations

The FREE bit in the power and emulation management register (PWREMU\_MGMT) determines how the UART responds to an emulation suspend event such as an emulator halt or breakpoint. If FREE = 0 and a transmission is in progress, the UART halts after completing the one-word transmission; if FREE = 0 and a transmission is not in progress, the UART halts immediately. If FREE = 1, the UART does not halt and continues operating normally.

Note also that most emulator accesses are transparent to UART operation. Emulator read operations do not affect any register contents, status bits, or operating states, with the exception of the interrupt identification register (IIR). Emulator writes, however, may affect register contents and may affect UART operation, depending on what register is accessed and what value is written.

The UART registers can be read from or written to during emulation suspend events, even if the UART activity has stopped.

### 32.2.12 Exception Processing

#### 32.2.12.1 Divisor Latch Not Programmed

Since the processor reset signal has no effect on the divisor latch, the divisor latch will have an unknown value after power up. If the divisor latch is not programmed after power up, the baud clock (BCLK) will not operate and will instead be set to a constant logic 1 state.

The divisor latch values should always be reinitialized following a processor reset.

#### 32.2.12.2 Changing Operating Mode During Busy Serial Communication

Since the serial link characteristics are based on how the control registers are programmed, the UART will expect the control registers to be static while it is busy engaging in a serial communication. Therefore, changing the control registers while the module is still busy communicating with another serial device will most likely cause an error condition and should be avoided.

### 32.3 Registers

The system programmer has access to and control over any of the UART registers that are listed in [Table 32-6](#). These registers, which control UART operations, receive data, and transmit data, are available at 32-bit addresses in the device memory map. See your device-specific data manual for the memory address of these registers.

- RBR, THR, and DLL share one address. When the DLAB bit in LCR is 0, reading from the address gives the content of RBR, and writing to the address modifies THR. When DLAB = 1, all accesses at the address read or modify DLL. DLL can also be accessed with address offset 20h.
- IER and DLH share one address. When DLAB = 0, all accesses read or modify IER. When DLAB = 1, all accesses read or modify DLH. DLH can also be accessed with address offset 24h.
- IIR and FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of IIR, and writing modifies FCR.

**Table 32-6. UART Registers**

| Offset | Acronym     | Register Description                          | Section                         |
|--------|-------------|-----------------------------------------------|---------------------------------|

### 32.3.1 Receiver Buffer Register (RBR)

The receiver buffer register (RBR) is shown in [Figure 32-9](#) and described in [Table 32-7](#).

The UART receiver section consists of a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16x receiver clock or 13x receiver clock by programming OSM\_SEL bit field of MDR register. Receiver section control is a function of the line control register (LCR).

RSR receives serial data from the UARTn\_RXD pin. Then RSR concatenates the data and moves it into RBR (or the receiver FIFO). In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled (DR = 1 in IER), an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register (FCR), and it is cleared when the FIFO contents drop below the trigger level.

#### Access considerations:

RBR, THR, and DLL share one address. To read RBR, write 0 to the DLAB bit in LCR, and read from the shared address. When DLAB = 0, writing to the shared address modifies THR. When DLAB = 1, all accesses at the shared address read or modify DLL.

DLL also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that RBR and THR are always selected at the shared address.

**Figure 32-9. Receiver Buffer Register (RBR)**

LEGEND: R = Read only; -n = value after reset

**Table 32-7. Receiver Buffer Register (RBR) Field Descriptions**

| Bit  | Field    | Value | Description   |
|------|----------|-------|---------------|
| 31-8 | Reserved | 0     | Reserved      |
| 7-0  | DATA     | 0-FFh | Received data |

### 32.3.2 Transmitter Holding Register (THR)

The transmitter holding register (THR) is shown in [Figure 32-10](#) and described in [Table 32-8](#).

The UART transmitter section consists of a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the line control register (LCR).

THR receives data from the internal data bus and when TSR is idle, the UART moves the data from THR to TSR. The UART serializes the data in TSR and transmits the data on the TX pin. In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled (ETBEI = 1 in IER), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register (IIR) is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or IIR is read.

#### Access considerations:

RBR, THR, and DLL share one address. To load THR, write 0 to the DLAB bit of LCR, and write to the shared address. When DLAB = 0, reading from the shared address gives the content of RBR. When DLAB = 1, all accesses at the address read or modify DLL.

DLL also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that RBR and THR are always selected at the shared address.

**Figure 32-10. Transmitter Holding Register (THR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 32-8. Transmitter Holding Register (THR) Field Descriptions**

| Bit  | Field    | Value | Description      |
|------|----------|-------|------------------|
| 31-8 | Reserved | 0     | Reserved         |
| 7-0  | DATA     | 0-FFh | Data to transmit |

### 32.3.3 Interrupt Enable Register (IER)

The interrupt enable register (IER) is used to individually enable or disable each type of interrupt request that can be generated by the UART. Each interrupt request that is enabled in IER is forwarded to the CPU. IER is shown in [Figure 32-11](#) and described in [Table 32-9](#).

**Access considerations:**

IER and DLH share one address. To read or modify IER, write 0 to the DLAB bit in LCR. When DLAB = 1, all accesses at the shared address read or modify DLH.

DLH also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that IER is always selected at the shared address.

### Figure 32-11. Interrupt Enable Register (IER)

### 32.3.4 Interrupt Identification Register (IIR)

The interrupt identification register (IIR) is a read-only register at the same address as the FIFO control register (FCR), which is a write-only register. When an interrupt is generated and enabled in the interrupt enable register (IER), IIR indicates that an interrupt is pending in the IPEND bit and encodes the type of interrupt in the INTID bits. Reading IIR clears any THR empty (THRE) interrupts that are pending.

IIR is shown in [Figure 32-12](#) and described in [Figure 32-12](#).

The UART has an on-chip interrupt generation and prioritization capability that permits flexible communication with the CPU. The UART provides three priority levels of interrupts:

- Priority 1 - Receiver line status (highest priority)
- Priority 2 - Receiver data ready or receiver timeout
- Priority 3 - Transmitter holding register empty

The FIFOEN bit in IIR can be checked to determine whether the UART is in the FIFO mode or the non-FIFO mode.

#### Access consideration:

IIR and FCR share one address. Regardless of the value of the DLAB bit in LCR, reading from the address gives the content of IIR, and writing to the address modifies FCR.

**Figure 32-12. Interrupt Identification Register (IIR)**

| 3              | 0        | 0 | 1 | 0 | Transmitter holding register empty | Non-FIFO mode: Transmitter holding register (THR) is empty.<br>FIFO mode: Transmitter FIFO is empty.                                                                                                                                  | A character is written to the transmitter holding register (THR) or the interrupt identification register (IIR) is read.                                                                                                                                                                              |

<sup>(1)</sup> In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

### 32.3.5 FIFO Control Register (FCR)

The FIFO control register (FCR) is a write-only register at the same address as the interrupt identification register (IIR), which is a read-only register. Use FCR to enable and clear the FIFOs and to select the receiver FIFO trigger level FCR is shown in [Figure 32-13](#) and described in [Table 32-12](#). The FIFOEN bit must be set to 1 before other FCR bits are written to or the FCR bits are not programmed.

#### Access consideration:

IIR and FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of IIR, and writing to the address modifies FCR.

#### CAUTION

For proper communication between the UART and the EDMA controller, the DMAMODE1 bit must be set to 1. Always write a 1 to the DMAMODE1 bit, and after a hardware reset, change the DMAMODE1 bit from 0 to 1.

**Figure 32-13. FIFO Control Register (FCR)**

LEGEND: R = Read only; W = Write only; W1C = Write 1 to clear (writing 0 has no effect); -n = value after reset

<sup>(1)</sup> Always write 1 to the DMAMODE1 bit. After a hardware reset, change the DMAMODE1 bit from 0 to 1. DMAMODE = 1 is required for proper communication between the UART and the DMA controller.

**Table 32-12. FIFO Control Register (FCR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                      |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                         |
| 7-6  | RXFIFTL  | 0-3h  | Receiver FIFO trigger level. RXFIFTL sets the trigger level for the receiver FIFO. When the trigger level is reached, a receiver data-ready interrupt is generated (if the interrupt request is enabled). Once the FIFO drops below the trigger level, the interrupt is cleared. |
|      |          | 0     | 1 byte                                                                                                                                                                                                                                                                           |
|      |          | 1h    | 4 bytes                                                                                                                                                                                                                                                                          |
|      |          | 2h    | 8 bytes                                                                                                                                                                                                                                                                          |
|      |          | 3h    | 14 bytes                                                                                                                                                                                                                                                                         |
| 5-4  | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                         |
| 3    | DMAMODE1 |       | DMA MODE1 enable if FIFOs are enabled. Always write 1 to DMAMODE1. After a hardware reset, change DMAMODE1 from 0 to 1. DMAMOD1 = 1 is a requirement for proper communication between the UART and the EDMA controller.                                                          |
|      |          | 0     | DMA MODE1 is disabled.                                                                                                                                                                                                                                                           |
|      |          | 1     | DMA MODE1 is enabled.                                                                                                                                                                                                                                                            |
| 2    | TXCLR    |       | Transmitter FIFO clear. Write a 1 to TXCLR to clear the bit.                                                                                                                                                                                                                     |
|      |          | 0     | No effect.                                                                                                                                                                                                                                                                       |
|      |          | 1     | Clears transmitter FIFO and resets the transmitter FIFO counter. The shift register is not cleared.                                                                                                                                                                              |
| 1    | RXCLR    |       | Receiver FIFO clear. Write a 1 to RXCLR to clear the bit.                                                                                                                                                                                                                        |
|      |          | 0     | No effect.                                                                                                                                                                                                                                                                       |
|      |          | 1     | Clears receiver FIFO and resets the receiver FIFO counter. The shift register is not cleared.                                                                                                                                                                                    |
| 0    | FIFOEN   |       | Transmitter and receiver FIFOs mode enable. FIFOEN must be set before other FCR bits are written to or the FCR bits are not programmed. Clearing this bit clears the FIFO counters.                                                                                              |
|      |          | 0     | Non-FIFO mode. The transmitter and receiver FIFOs are disabled, and the FIFO pointers are cleared.                                                                                                                                                                               |
|      |          | 1     | FIFO mode. The transmitter and receiver FIFOs are enabled.                                                                                                                                                                                                                       |

### 32.3.6 Line Control Register (LCR)

The line control register (LCR) is shown in [Figure 32-14](#) and described in [Table 32-13](#).

The system programmer controls the format of the asynchronous data communication exchange by using LCR. In addition, the programmer can retrieve, inspect, and modify the content of LCR; this eliminates the need for separate storage of the line characteristics in system memory.

**Figure 32-14. Line Control Register (LCR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-13. Line Control Register (LCR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                          |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                             |
| 7    | DLAB     | 0     | Divisor latch access bit. The divisor latch registers (DLL and DLH) can be accessed at dedicated addresses or at addresses shared by RBR, THR, and IER. Using the shared addresses requires toggling DLAB to change which registers are selected. If you use the dedicated addresses, you can keep DLAB = 0.         |
|      |          | 0     | Allows access to the receiver buffer register (RBR), the transmitter holding register (THR), and the interrupt enable register (IER) selected. At the address shared by RBR, THR, and DLL, the CPU can read from RBR and write to THR. At the address shared by IER and DLH, the CPU can read from and write to IER. |
|      |          | 1     | Allows access to the divisor latches of the baud generator during a read or write operation (DLL and DLH). At the address shared by RBR, THR, and DLL, the CPU can read from and write to DLL. At the address shared by IER and DLH, the CPU can read from and write to DLH.                                         |
| 6    | BC       | 0     | Break control.                                                                                                                                                                                                                                                                                                       |
|      |          | 0     | Break condition is disabled.                                                                                                                                                                                                                                                                                         |
|      |          | 1     | Break condition is transmitted to the receiving UART. A break condition is a condition where the UARTn_TXD signal is forced to the spacing (cleared) state.                                                                                                                                                          |
| 5    | SP       | 0     | Stick parity. The SP bit works in conjunction with the EPS and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in <a href="#">Table 32-14</a> .                                                                                                                                           |
|      |          | 0     | Stick parity is disabled.                                                                                                                                                                                                                                                                                            |
|      |          | 1     | Stick parity is enabled. <ul style="list-style-type: none"> <li>When odd parity is selected (EPS = 0), the PARITY bit is transmitted and checked as set.</li> <li>When even parity is selected (EPS = 1), the PARITY bit is transmitted and checked as cleared.</li> </ul>                                           |
| 4    | EPS      | 0     | Even parity select. Selects the parity when parity is enabled (PEN = 1). The EPS bit works in conjunction with the SP and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in <a href="#">Table 32-14</a> .                                                                                |
|      |          | 0     | Odd parity is selected (an odd number of logic 1s is transmitted or checked in the data and PARITY bits).                                                                                                                                                                                                            |
|      |          | 1     | Even parity is selected (an even number of logic 1s is transmitted or checked in the data and PARITY bits).                                                                                                                                                                                                          |
| 3    | PEN      | 0     | Parity enable. The PEN bit works in conjunction with the SP and EPS bits. The relationship between the SP, EPS, and PEN bits is summarized in <a href="#">Table 32-14</a> .                                                                                                                                          |
|      |          | 0     | No PARITY bit is transmitted or checked.                                                                                                                                                                                                                                                                             |
|      |          | 1     | Parity bit is generated in transmitted data and is checked in received data between the last data word bit and the first STOP bit.                                                                                                                                                                                   |

**Table 32-13. Line Control Register (LCR) Field Descriptions (continued)**

| Bit | Field | Value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|-------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | STB   | 0<br>1                      | <p>Number of STOP bits generated. STB specifies 1, 1.5, or 2 STOP bits in each transmitted character. When STB = 1, the WLS bit determines the number of STOP bits. The receiver clocks only the first STOP bit, regardless of the number of STOP bits selected. The number of STOP bits generated is summarized in <a href="#">Table 32-15</a>.</p> <p>1 STOP bit is generated.</p> <p>WLS bit determines the number of STOP bits:</p> <ul style="list-style-type: none"> <li>When WLS = 0, 1.5 STOP bits are generated.</li> <li>When WLS = 1h, 2h, or 3h, 2 STOP bits are generated.</li> </ul> |

**Table 32-14. Relationship Between ST, EPS, and PEN Bits in LCR**

| ST Bit | EPS Bit | PEN Bit | Parity Option                                                            |
|--------|---------|---------|--------------------------------------------------------------------------|
| x      | x       | 0       | Parity disabled: No PARITY bit is transmitted or checked                 |
| 0      | 0       | 1       | Odd parity selected: Odd number of logic 1s                              |
| 0      | 1       | 1       | Even parity selected: Even number of logic 1s                            |
| 1      | 0       | 1       | Stick parity selected with PARITY bit transmitted and checked as set     |
| 1      | 1       | 1       | Stick parity selected with PARITY bit transmitted and checked as cleared |

**Table 32-15. Number of STOP Bits Generated**

| STB Bit | WLS Bits | Word Length Selected with WLS Bits | Number of STOP Bits Generated | Baud Clock (BCLK) Cycles |
|---------|----------|------------------------------------|-------------------------------|--------------------------|
| 0       | x        | Any word length                    | 1                             | 16                       |
| 1       | 0h       | 5 bits                             | 1.5                           | 24                       |
| 1       | 1h       | 6 bits                             | 2                             | 32                       |
| 1       | 2h       | 7 bits                             | 2                             | 32                       |
| 1       | 3h       | 8 bits                             | 2                             | 32                       |

### 32.3.7 Modem Control Register (MCR)

The modem control register (MCR) is shown in Figure 32-15 and described in Table 32-16. The modem control register provides the ability to enable/disable the autoflow functions, and enable/disable the loopback function for diagnostic purposes.

**Figure 32-15. Modem Control Register (MCR)**

|          |          |  |  |  |  |                    |       |       |       |                    |       |     |  |  |  |    |

| 0    | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 32.3.8 Line Status Register (LSR)

The line status register (LSR) is shown in [Figure 32-16](#) and described in [Table 32-17](#). LSR provides information to the CPU concerning the status of data transfers. LSR is intended for read operations only; do not write to this register. Bits 1 through 4 record the error conditions that produce a receiver line status interrupt.

LEGEND: R = Read only; -n = value after reset

**Table 32-17. Line Status Register (LSR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                          |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                             |
| 7    | RXFIFOE  | 0     | Receiver FIFO error.<br><b>In non-FIFO mode:</b><br>There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver buffer register (RBR).                                                                                                            |
|      |          | 1     | There is a parity error, framing error, or break indicator in the receiver buffer register (RBR).                                                                                                                                                                                                    |
|      |          | 0     | <b>In FIFO mode:</b><br>There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver FIFO and there are no more errors in the receiver FIFO.                                                                                                       |
|      |          | 1     | At least one parity error, framing error, or break indicator in the receiver FIFO.                                                                                                                                                                                                                   |
| 6    | TEMT     | 0     | Transmitter empty (TEMT) indicator.<br><b>In non-FIFO mode:</b><br>Either the transmitter holding register (THR) or the transmitter shift register (TSR) contains a data character.                                                                                                                  |
|      |          | 1     | Both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.                                                                                                                                                                                                      |
|      |          | 0     | <b>In FIFO mode:</b><br>Either the transmitter FIFO or the transmitter shift register (TSR) contains a data character.                                                                                                                                                                               |
|      |          | 1     | Both the transmitter FIFO and the transmitter shift register (TSR) are empty.                                                                                                                                                                                                                        |
| 5    | THRE     | 0     | Transmitter holding register empty (THRE) indicator. If the THRE bit is set and the corresponding interrupt enable bit is set (ETBEI = 1 in IER), an interrupt request is generated.<br><b>In non-FIFO mode:</b><br>Transmitter holding register (THR) is not empty. THR has been loaded by the CPU. |
|      |          | 1     | Transmitter holding register (THR) is empty (ready to accept a new character). The content of THR has been transferred to the transmitter shift register (TSR).                                                                                                                                      |
|      |          | 0     | <b>In FIFO mode:</b><br>Transmitter FIFO is not empty. At least one character has been written to the transmitter FIFO. You can write to the transmitter FIFO if it is not full.                                                                                                                     |
|      |          | 1     | Transmitter FIFO is empty. The last character in the FIFO has been transferred to the transmitter shift register (TSR).                                                                                                                                                                              |

**Table 32-17. Line Status Register (LSR) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | BI    |       | Break indicator. The BI bit is set whenever the receive data input (UARTn_RXD) was held low for longer than a full-word transmission time. A full-word transmission time is defined as the total time to transmit the START, data, PARITY, and STOP bits. If the BI bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.                                                                         |
|     |       |       | <b>In non-FIFO mode:</b>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|     |       | 0     | No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver buffer register (RBR).                                                                                                                                                                                                                                                                                                                    |
|     |       | 1     | A break has been detected with the character in the receiver buffer register (RBR).                                                                                                                                                                                                                                                                                                                                                                            |
|     |       |       | <b>In FIFO mode:</b>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|     |       | 0     | No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver FIFO and the next character to be read from the FIFO has no break indicator.                                                                                                                                                                                                                                                              |
|     |       | 1     | A break has been detected with the character at the top of the receiver FIFO.                                                                                                                                                                                                                                                                                                                                                                                  |
|     |       |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3   | FE    |       | Framing error (FE) indicator. A framing error occurs when the received character does not have a valid STOP bit. In response to a framing error, the UART sets the FE bit and waits until the signal on the RX pin goes high. Once the RX signal goes high, the receiver is ready to detect a new START bit and receive new data. If the FE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated. |

| 1   | OE    |       | Overrun error (OE) indicator. An overrun error in the non-FIFO mode is different from an overrun error in the FIFO mode. If the OE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.                                                                                                                                                                                                          |
|     |       |       | <b>In non-FIFO mode:</b>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|     |       | 0     | No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR).                                                                                                                                                                                                                                                                                                                              |
|     |       | 1     | Overrun error has been detected. Before the character in the receiver buffer register (RBR) could be read, it was overwritten by the next character arriving in RBR.                                                                                                                                                                                                                                                                                           |
|     |       |       | <b>In FIFO mode:</b>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|     |       | 0     | No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR).                                                                                                                                                                                                                                                                                                                              |
|     |       | 1     | Overrun error has been detected. If data continues to fill the FIFO beyond the trigger level, an overrun error occurs only after the FIFO is full and the next character has been completely received in the shift register. An overrun error is indicated to the CPU as soon as it happens. The new character overwrites the character in the shift register, but it is not transferred to the FIFO.                                                          |
|     |       |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 32-17. Line Status Register (LSR) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                         |
|-----|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | DR    |       | Data-ready (DR) indicator for the receiver. If the DR bit is set and the corresponding interrupt enable bit is set (ERBI = 1 in IER), an interrupt request is generated.                                                                                            |
|     |       |       | <b>In non-FIFO mode:</b>                                                                                                                                                                                                                                            |
|     |       | 0     | Data is not ready, or the DR bit was cleared because the character was read from the receiver buffer register (RBR).                                                                                                                                                |
|     |       | 1     | Data is ready. A complete incoming character has been received and transferred into the receiver buffer register (RBR).                                                                                                                                             |
|     |       |       | <b>In FIFO mode:</b>                                                                                                                                                                                                                                                |
|     |       | 0     | Data is not ready, or the DR bit was cleared because all of the characters in the receiver FIFO have been read.                                                                                                                                                     |
|     |       | 1     | Data is ready. There is at least one unread character in the receiver FIFO. If the FIFO is empty, the DR bit is set as soon as a complete incoming character has been received and transferred into the FIFO. The DR bit remains set until the FIFO is empty again. |

### 32.3.9 Modem Status Register (MSR)

The Modem status register (MSR) is shown in [Figure 32-17](#) and described in [Table 32-18](#). MSR provides information to the CPU concerning the status of modem control signals. MSR is intended for read operations only; do not write to this register.

**Figure 32-17. Modem Status Register (MSR)**

|          |  |  |  |  |  |  |  |   |     |     |     |     |     |      |      |      |     |

LEGEND: R = Read only; -n = value after reset

**Table 32-18. Modem Status Register (MSR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                    |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                       |
| 7    | CD       | 0     | Complement of the Carrier Detect input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 3 (OUT2).                                                                                                                                                                    |
| 6    | RI       | 0     | Complement of the Ring Indicator input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 2 (OUT1).                                                                                                                                                                    |
| 5    | DSR      | 0     | Complement of the Data Set Ready input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 0 (DTR).                                                                                                                                                                     |
| 4    | CTS      | 0     | Complement of the Clear To Send input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 1 (RTS).                                                                                                                                                                      |
| 3    | DCD      | 0     | Change in DCD indicator bit. DCD indicates that the DCD input has changed state since the last time it was read by the CPU. When DCD is set and the modem status interrupt is enabled, a modem status interrupt is generated.                                                                                                  |
| 2    | TERI     | 0     | Trailing edge of RI (TERI) indicator bit. TERI indicates that the RI input has changed from a low to a high. When TERI is set and the modem status interrupt is enabled, a modem status interrupt is generated.                                                                                                                |
| 1    | DDSR     | 0     | Change in DSR indicator bit. DDSR indicates that the DSR input has changed state since the last time it was read by the CPU. When DDSR is set and the modem status interrupt is enabled, a modem status interrupt is generated.                                                                                                |
| 0    | DCTS     | 0     | Change in CTS indicator bit. DCTS indicates that the CTS input has changed state since the last time it was read by the CPU. When DCTS is set (autoflow control is not enabled and the modem status interrupt is enabled), a modem status interrupt is generated. When autoflow control is enabled, no interrupt is generated. |

### 32.3.10 Scratch Pad Register (SCR)

The Scratch Pad register (SCR) is shown in [Figure 32-18](#) and described in [Table 32-19](#). SCR is intended for programmer's use as a scratch pad. It temporarily holds the programmer's data without affecting UART operation.

**Figure 32-18. Scratch Pad Register (SCR)**

LEGEND: R = Read only; -n = value after reset

**Table 32-19. Scratch Pad Register (MSR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                                                                                   |
| 7-0  | SCR      | 0     | These bits are intended for the programmer's use as a scratch pad in the sense that it temporarily holds the programmer's data without affecting any other UART operation. |

### 32.3.11 Divisor Latches (DLL and DLH)

Two 8-bit register fields (DLL and DLH), called divisor latches, store the 16-bit divisor for generation of the baud clock in the baud generator. The latches are in DLH and DLL. DLH holds the most-significant bits of the divisor, and DLL holds the least-significant bits of the divisor. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

#### Access considerations:

- RBR, THR, and DLL share one address. When DLAB = 1 in LCR, all accesses at the shared address are accesses to DLL. When DLAB = 0, reading from the shared address gives the content of RBR, and writing to the shared address modifies THR.
- IER and DLH share one address. When DLAB = 1 in LCR, accesses to the shared address read or modify to DLH. When DLAB = 0, all accesses at the shared address read or modify IER.

DLL and DLH also have dedicated addresses. If you use the dedicated addresses, you can keep the DLAB bit cleared, so that RBR, THR, and IER are always selected at the shared addresses.

The divisor LSB latch (DLL) is shown in [Figure 32-19](#) and described in [Table 32-20](#). The divisor MSB latch (DLH) is shown in [Figure 32-20](#) and described in [Table 32-21](#).

### 32.3.12 Revision Identification Registers (REVID1 and REVID2)

The revision identification registers (REVID1 and REVID2) contain peripheral identification data for the peripheral. REVID1 is shown in [Figure 32-21](#) and described in [Table 32-22](#). REVID2 is shown in [Figure 32-22](#) and described in [Table 32-23](#).

| 0     | FREE     | 0<br>1 | Free-running enable mode bit. This bit determines the emulation mode functionality of the UART. When halted, the UART can handle register read/write requests, but does not generate any transmission/reception, interrupts or events.<br>If a transmission is not in progress, the UART halts immediately. If a transmission is in progress, the UART halts after completion of the one-word transmission.<br>Free-running mode is enabled; UART continues to run normally. |

### 32.3.14 Mode Definition Register (MDR)

The Mode Definition register (MDR) determines the over-sampling mode for the UART. MDR is shown in [Figure 32-24](#) and described in [Table 32-25](#).

**Figure 32-24. Mode Definition Register (MDR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-25. Mode Definition Register (MDR) Field Descriptions**

|      |          | 1     | 13× over-sampling.                               |

## ***Universal Parallel Port (uPP)***

---

---

This chapter describes the universal parallel port (uPP).

| Topic                          | Page        |
|--------------------------------|-------------|
| <b>33.1 Introduction .....</b> | <b>1552</b> |
| <b>33.2 Architecture .....</b> | <b>1555</b> |
| <b>33.3 Registers .....</b>    | <b>1572</b> |

## 33.1 Introduction

### 33.1.1 Purpose of the Peripheral

The universal parallel port (uPP) peripheral is a multichannel, high-speed parallel interface with dedicated data lines and minimal control signals. It is designed to interface cleanly with high-speed analog-to-digital converters (ADCs) or digital-to-analog converters (DACs) with up to 16-bit data width (per channel). It may also be interconnected with field-programmable gate arrays (FPGAs) or other uPP devices to achieve high-speed digital data transfer. It can operate in receive mode, transmit mode, or duplex mode, in which its individual channels operate in opposite directions.

The uPP peripheral includes an internal DMA controller to maximize throughput and minimize CPU overhead during high-speed data transmission. All uPP transactions use the internal DMA to feed data to or retrieve data from the I/O channels. The DMA controller includes two DMA channels, which typically service separate I/O channels. The uPP peripheral also supports data interleave mode, in which all DMA resources service a single I/O channel. In this mode, only one I/O channel may be used.

### 33.1.2 Features

For more information on the features and performance supported by the uPP peripheral, see your device-specific data manual.

### 33.1.3 Functional Block Diagram

[Figure 33-1](#) provides a high-level view of the uPP peripheral internal logic. Note that this figure shows one particular configuration: Channel A receives and Channel B transmits. In general, each channel may operate in either direction.

[Figure 33-2](#), [Figure 33-3](#), [Figure 33-4](#), and [Figure 33-5](#) show simplified data paths through the uPP peripheral for various configurations. Note that these figures are examples and do not represent all possible configurations. More information on these and other modes of operation is given in subsequent sections.

**Figure 33-1. uPP Functional Block Diagram**

**Figure 33-2. Data Flow for Single-Channel Receive Mode**

**Figure 33-3. Data Flow for Single-Channel Transmit Mode**

**Figure 33-4. Data Flow for Digital Loopback (DLB) Mode (Duplex Mode 0)**

**Figure 33-5. Data Flow for Single-Channel Transmit with Data Interleave**

## 33.2 Architecture

### 33.2.1 Clock Generation and Control

The uPP peripheral uses two separate clocks: a module clock that controls its internal logic, and a transmit clock that runs either interface channel in transmit mode. The source for each of these clocks may be configurable; see the *Device Clocking* chapter for more information. Neither the module clock nor the transmit clock can be faster than one-half the device CPU clock speed.

Each channel's CLOCK pin, or I/O clock, is obtained independently based on its operating direction.

#### 33.2.1.1 Transmit Mode (Single Data Rate)

The channel drives a clock signal on its CLOCK pin. The uPP transmit clock is divided by a fixed value of 2, then divided again by a user-specified value between 1 and 16 (UPICR.CLKDIV $_n$  + 1). The resulting signal then drives the CLOCK pin. The following formula determines the final I/O clock speed:

$$I/O \text{ Clock} = \text{Transmit Clock} / (2 \times (\text{UPICR.CLKDIV}_n + 1))$$

The fixed divisor restricts the maximum speed of the I/O clock to one-fourth the device CPU clock speed.

Figure 33-6 shows the clock generation system for a channel configured in transmit mode.

**Figure 33-6. Clock Generation for a Channel Configured in Transmit Mode**

#### 33.2.1.2 Receive Mode (Single Data Rate)

The channel requires an external clock to drive its CLOCK pin. The incoming clock is not divided, and its maximum allowed speed is one fourth ( $\frac{1}{4}$ ) the device CPU clock speed.

Figure 33-7 shows the clock generation system for a channel configured in receive mode.

**Figure 33-7. Clock Generation for a Channel Configured in Receive Mode**

### 33.2.1.3 Double Data Rate

The uPP peripheral supports two I/O clocking schemes. The first, single data rate (SDR), clocks data from the DATA pins on either the rising edge or the falling edge (depending on UPICR.CLKINV<sub>n</sub>) of the I/O clock.

The second clocking scheme is double data rate (DDR). In this mode, data is clocked on both the rising and falling edges of the I/O clock. However, DDR mode imposes a lower I/O clock speed limit of one eighth (1/8) the device CPU clock for both transmit and receive modes. The operating speed for transmit mode with various divisors in each data rate are summarized in [Table 33-1](#) (in this table, a data word is defined as the data represented on the DATA pins; uPP supports data words in the 8-bit to 16-bit range). In receive mode, a channel I/O clock is generated by an external source, but the same speed limit applies.

**Table 33-1. I/O Clock Speeds for Channel in Transmit Mode Given 150 MHz Transmit Clock**

| UPICR.CLKDIV <sub>n</sub> | I/O Clock (MHz) | Word Rate (Mw/s) |                  |
|---------------------------|-----------------|------------------|------------------|
|                           |                 | Single Data Rate | Double Data Rate |
| 0                         | 75.00           | 75.00            | ...              |
| 1                         | 37.50           | 37.50            | 75.00            |
| 2                         | 25.00           | 25.00            | 50.00            |
| 3                         | 18.75           | 18.75            | 37.50            |
| ...                       | ...             | ...              | ...              |
| 15                        | 4.69            | 4.69             | 9.38             |

Additional restrictions may apply, check the device datasheet to see if your particular uPP peripheral has any additional clock requirements.

## 33.2.2 Signal Description

Each uPP channel has its own set of control and data signals. [Table 33-2](#) lists every signal and briefly describes their functions. [Section 33.2.5](#) explains the uPP protocol.

**Table 33-2. uPP Signal Descriptions**

| Signal      | I/O Channel | Type (Transmit) | Type (Receive) | Description                                                |
|-------------|-------------|-----------------|----------------|------------------------------------------------------------|
| DATA[15:0]  | —           | Output          | Input          | Parallel data bus                                          |
| XDATA[15:0] | —           | Output          | Input          | Extended parallel data bus                                 |
| CHA_START   | A           | Output          | Input          | Indicates first data word per line of data                 |
| CHA_ENABLE  | A           | Output          | Input          | Indicates data transmission active                         |
| CHA_WAIT    | A           | Input           | Output         | Requests transmitter halt temporarily                      |
| CHA_CLOCK   | A           | Output          | Input          | Source-synchronous clock signal                            |
| CHB_START   | B           | Output          | Input          | Indicates first data word per line of data                 |
| CHB_ENABLE  | B           | Output          | Input          | Indicates data transmission active                         |
| CHB_WAIT    | B           | Input           | Output         | Requests transmitter halt temporarily                      |
| CHB_CLOCK   | B           | Output          | Input          | Source-synchronous clock signal                            |
| UPP_2TXCLK  | —           | Input           | —              | Optional external source for transmit clock <sup>(1)</sup> |

<sup>(1)</sup> This clock can only be used in transmit mode, and must be twice the speed of your desired I/O clock. See [Section 33.2.1](#) and the *Device Clocking* chapter for more information.

Note that the DATA and XDATA pins are not dedicated to a single I/O channel in the same way as the control signals. For practical reasons, uPP data pin channel assignments are not static. Instead, the data pins used by each I/O channel (A, B) depend on the operating mode of the uPP peripheral. [Table 33-3](#) summarizes the assignment of the DATA and XDATA pins to each channel for various operating modes, along with the relevant register settings. For more information on these pins, see your device-specific data manual.

**Table 33-3. DATA and XDATA Pin Assignments to Channels A and B According to Operating Mode**

| uPP Channel Control Register (UPCTL) Bit |     |     | Assigned Channel |           |             |            |
|------------------------------------------|-----|-----|------------------|-----------|-------------|------------|
| CHN                                      | IWA | IWB | DATA[15:8]       | DATA[7:0] | XDATA[15:8] | XDATA[7:0] |
| 0                                        | 0   | x   | —                | A[7:0]    | —           | —          |
| 0                                        | 1   | x   | A[15:8]          | A[7:0]    | —           | —          |
| 1                                        | 0   | 0   | B[7:0]           | A[7:0]    | —           | —          |
| 1                                        | 0   | 1   | B[7:0]           | A[7:0]    | B[15:8]     | —          |
| 1                                        | 1   | 0   | B[7:0]           | A[7:0]    | —           | A[15:8]    |
| 1                                        | 1   | 1   | B[7:0]           | A[7:0]    | B[15:8]     | A[15:8]    |

### 33.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. To determine how pin multiplexing affects the uPP peripheral, see your device-specific data manual.

### 33.2.4 Internal DMA Controller Description

The uPP peripheral includes an internal DMA controller separate from any device-level DMA, such as EDMA. The internal DMA controller consists of two DMA channels, I and Q, which move data to/from the uPP peripheral interface (I/O) channels in all operating modes. This section describes how to program the internal DMA channels.

#### 33.2.4.1 DMA Programming Concepts

The uPP internal DMA controller uses a simplified programming model similar to 2D transfers performed by the EDMA (see the *Enhanced Direct Memory Access (EDMA3) Controller* chapter for more information). Each DMA channel may be configured with four parameters: window address, byte count, line count, and line offset address. [Figure 33-8](#) shows a typical DMA window defined by these parameters.

- **Window Address** (UPxD0.ADDR) – The location in memory of the first byte in the data buffer. When the uPP operates in receive mode, the DMA channel begins writing to this address as it takes incoming data from the uPP I/O channel. When the uPP operates in transmit mode, the DMA channel begins reading from this address and pass the data to the uPP I/O channel. The window address can reside in any available memory space (including EMIF), but it must be aligned to a 64-bit boundary (that is, the 3 LSBs must equal 0). Nonaligned addresses are automatically adjusted to a properly aligned value when written to UPxD0.
- **Byte Count** (UPxD1.BCNT) – The number of bytes per line. The byte count must be an even number.
- **Line Count** (UPxD1.LNCNT) – The number of lines per window. The total number of bytes transferred equals  $B \times L$ , where B is the byte count per line and L is the line count.
- **Line Offset Address** (UPxD2.LNOFFSET) – The offset address between the first byte in successive lines. The line offset address cannot exceed 65528 (FFF8h) bytes, and must be aligned to a 64-bit boundary in memory (that is, the 3 LSBs must equal 0).

**Figure 33-8. Structure of DMA Window and Lines in Memory**

Certain values of the line offset address have special implications on the structure of the data buffer:

- **Line Offset Address = Byte Count** – Data buffer is a contiguous block in memory with size equal to (Line Count) × (Byte Count).
- **Line Offset Address = 0** – Data buffer consists of a single line, with total size equal to Byte Count. If the I/O channel is configured in transmit mode, this line is transmitted (Line Count) consecutive times before the DMA transfer completes. If the I/O channel is configured in receive mode, the buffer is repeatedly written and overwritten by incoming data.

To program a DMA transfer, write the appropriate fields in the DMA channel descriptor registers, UPID<sub>n</sub> for DMA Channel I or UPQD<sub>n</sub> for DMA Channel Q. If the associated I/O channel is initialized and idle, the DMA transfer and I/O transaction begins immediately. [Section 33.2.6](#) describes a step-by-step process for configuring the I/O and DMA channels and starting a uPP transfer.

Each DMA channel allows a second descriptor to be queued while the previously programmed DMA transfer is still running. The UPxS2.PEND bit reports whether a new set of DMA parameters may be written to the DMA descriptor registers. Each DMA channel can have at most one active transfer and one queued transfer. This allows each I/O channel to perform uninterrupted, consecutive transactions across DMA transfer boundaries.

The internal DMA controller does not support automatically reloading DMA transfer descriptors. Each successive descriptor set must be explicitly written to the UPxD<sub>n</sub> registers by software.

All uPP interrupt events originate in the internal DMA controller. [Section 33.2.8](#) lists and explains all uPP interrupt events.

The internal DMA controller always writes data in bursts of 64 bytes. However, DMA read operations have configurable burst size, which may be set per channel using the RDSIZEI and RDSIZEQ bits in the uPP threshold configuration register (UPTCR). A DMA channel waits until the specified number of bytes leaves its internal buffer before performing another burst read from memory.

Note that the TXSIZEA and TXSIZEB bits in UPTCR are not DMA parameters; instead, they control transmit thresholds for the uPP interface channels.

### 33.2.4.2 Data Interleave Mode

The data interleave mode is a special configuration that maps both DMA channels to a single interface channel. Since there are only two DMA channels in the uPP peripheral, data interleave mode can only be used when the uPP peripheral is operated in single-channel mode. There are two variants on data interleave mode, each with special conditions:

- Single Data Rate (SDR) Interleave – Transmit Only
  - UPCTL.CHN = 0 (single-channel mode)
  - UPCTL.DRA = 0 (single data rate)
  - UPCTL.MODE = 1 (transmit mode)
  - UPCTL.SDRTXIL = 1 (enable SDR transmit interleave)
  - UPCTL.DDRDEMUX = 0 (disable DDR interleave)
- Double Data Rate (DDR) Interleave – Transmit or Receive
  - UPCTL.CHN = 0 (single-channel mode)
  - UPCTL.DRA = 1 (double data rate)
  - UPCTL.MODE = 0 or 1 (receive or transmit mode; not duplex)
  - UPCTL.SDRTXIL = 0 (disable SDR transmit interleave)
  - UPCTL.DDRDEMUX = 1 (enable DDR interleave)

[Section 33.2.1](#) describes the differences between single data rate (SDR) and double data rate (DDR).

In data interleave mode, only I/O Channel A is used. This single channel is associated with two data buffers, each serviced by its own DMA channel (I and Q). In SDR interleave mode, the START signal is used as a buffer selection line: START = 1 indicates that the current word comes from DMA Channel I; START = 0 indicates that the current word comes from DMA Channel Q. In DDR Interleave mode, the data buffers alternate every word beginning with Channel I: Channel I Word 0, Channel Q Word 0, Channel I Word 1, Channel Q Word 1, etc. [Section 33.2.5](#) shows signal diagrams for both data interleave modes.

### 33.2.4.3 Interface and DMA Channel Mapping

Typically, DMA Channels I and Q are mapped to interface Channels A and B, respectively. Data interleave mode is the exception, since it allocates both DMA channels to service interface Channel A. [Table 33-4](#) summarizes DMA channel mapping for various modes of operation.

**Table 33-4. Interface and DMA Channel Mapping for Various Operating Modes**

| Operating Mode                  | I/O Channel Serviced |       |
|---------------------------------|----------------------|-------|
|                                 | DMA I                | DMA Q |
| 1-Channel Receive               | A                    | —     |
| 1-Channel Transmit              | A                    | —     |
| 2-Channel Receive               | A                    | B     |
| 2-Channel Transmit              | A                    | B     |
| 2-Channel Duplex                | A                    | B     |
| 1-Channel Transmit (Interleave) | A                    | A     |
| 1-Channel Receive (Interleave)  | A                    | A     |

### 33.2.5 Protocol Description

The uPP peripheral consists of two independent channels, each possessing its own data lines and control signals. A channel may be configured to run in transmit or receive mode and to use either 8 or 16 data lines (8-bit or 16-bit mode) using the uPP channel control register (UPCTL). A channel may also be configured to ignore certain control signals using the uPP interface configuration register (UPICR). Each uPP defaults to 8-bit mode and uses all four control signals, unless otherwise configured. [Table 33-5](#) summarizes the signals that are required for basic operation in receive and transmit modes. The following subsections describe the role of each signal.

**Table 33-5. Required Signals for Various Modes**

| Signal Name | Signal Required? |              |
|-------------|------------------|--------------|
|             | Transmit Mode    | Receive Mode |
| DATA[7:0]   | √                | √            |
| DATA[15:8]  |                  |              |
| START       | √                |              |
| ENABLE      | √                |              |
| WAIT        |                  | √            |
| CLOCK       | √                | √            |

#### 33.2.5.1 DATA[7:0] Signals

In 8-bit mode, DATA[7:0] comprise the channel's entire data bus. In 16-bit mode, DATA[7:0] comprise the least-significant bits of the 16-bit word. The channel's data width is selected using the IWx bit in UPCTL.

In transmit mode, these pins are outputs that transmit data supplied by the channel's associated DMA channel. While the channel is idle, their behavior depends on the TRISx bit in UPICR. These pins can be configured to drive an idle value (TRISx = 0, VALx field in the uPP interface idle value register (UPIVR)) or be in a high-impedance state while idle (TRISx = 1).

In receive mode, these pins are inputs that provide data to the channel's associated DMA channel.

Note that the DATA signals map differently to the DATA and XDATA pins for various uPP configurations, see [Section 33.2.2](#) for more information.

#### 33.2.5.2 DATA[15:8] Signals

In 8-bit mode, DATA[15:8] are not used. In 16-bit mode, DATA[15:8] comprise the most-significant bits of the 16-bit word. The channel's data width is selected using the IWx bit in UPCTL. A channel may be further configured to use only part of its DATA[15:8] pins, which allows any total data width from 8 to 16 bits. [Section 33.2.5.8](#) describes data format and packing in the 9-bit to 15-bit configurations.

While in use, the direction and behavior of DATA[15:8] in transmit and receive modes are the same as the direction and behavior of DATA[7:0].

Note that the DATA signals map differently to the DATA and XDATA pins for various uPP configurations, see [Section 33.2.2](#) for more information.

#### 33.2.5.3 START Signal

The uPP transmitter asserts the START signal when it transfers the first word of a data line. A line is defined in terms of the channel's associated DMA channel; for more on DMA programming concepts, see [Section 33.2.4](#). The START signal is active-high by default, but its polarity is controlled by the STARTPOLx bit in UPICR.

In transmit mode, START is an output signal and is always driven; in receive mode, START is an input signal and may be disabled using the STARTx bit in UPICR.

When the channel is configured in transmit mode with data interleave enabled ( $SDRTXIL = 1$  in  $UPCTL$ ), the START signal function changes completely. The START signal now asserts on every data word that is provided by DMA Channel I. See [Section 33.2.5.7](#) for this alternative behavior.

### 33.2.5.4 ENABLE Signal

The uPP transmitter asserts the ENABLE signal when it transfers a valid data word. The ENABLE signal is active-high by default, but its polarity is controlled by the  $ENAPOLx$  bit in  $UPICR$ .

In transmit mode, ENABLE is an output signal and is always driven; in receive mode, ENABLE is an input signal and may be disabled using the  $ENAx$  bit in  $UPICR$ .

### 33.2.5.5 WAIT Signal

The WAIT signal allows the receiver to request a temporary halt in data transmission. When the receiver asserts WAIT, the transmitter responds by stopping transmission (starting with the next word) until WAIT is released. The receiver ignores all incoming data until WAIT is released. Once WAIT is released, the transmitter can resume transmission on the next word. [Figure 33-10](#) shows WAIT signal timing. The WAIT signal is active-high by default, but its polarity is controlled by the  $WAITPOLx$  bit in  $UPICR$ .

In transmit mode, WAIT is an input signal and may be disabled using the  $WAITx$  bit in  $UPICR$ ; in receive mode, WAIT is an output signal.

### 33.2.5.6 CLOCK Signal

The uPP transmitter drives the CLOCK signal to align all other uPP signals. By default, other signals align on the rising edge of CLOCK, but its polarity is controlled by the  $CLKINVx$  bit in  $UPICR$ . The active edge(s) of CLOCK should always slightly precede transitions of other uPP signals.

In transmit mode, CLOCK is an output signal; in receive mode, CLOCK is an input signal. See [Section 33.2.1](#) for more information on clock generation and allowed frequencies.

### 33.2.5.7 Signal Timing Diagrams

In the following diagrams, signals are marked (i) to indicate that they are inputs to the uPP peripheral and (o) to indicate that they are outputs from the uPP peripheral. Data words from a single DMA channel are designated  $Dx$ , while data words that must come from a specific DMA channel are designated  $Ix$  or  $Qx$  to indicate DMA Channel I or Q, respectively. For more information on DMA channels and data interleave mode, see [Section 33.2.4](#).

All signal diagrams are drawn with signal polarities in their default states. All signals except DATA are independently configurable in the uPP interface configuration register ( $UPICR$ ).

**Figure 33-9. Signal Timing for uPP Channel in Receive Mode with Single Data Rate**

**Figure 33-10. Signal Timing for uPP Channel in Transmit Mode with Single Data Rate**

**Figure 33-11. Signal Timing for uPP Channel in Receive Mode with Double Data Rate**

**Figure 33-12. Signal Timing for uPP Channel in Transmit Mode with Double Data Rate**

**Figure 33-13. Signal Timing for uPP Channel in Receive Mode with Double Data Rate and Data Interleave Enabled (via UPCTL.DDRDEMUX)**

**Figure 33-14. Signal Timing for uPP Channel in Transmit Mode with Double Data Rate and Data Interleave Enabled (via UPCTL.DDRDEMUX)**

**Figure 33-15. Signal Timing for uPP Channel in Transmit Mode with Single Data Rate and Data Interleave Enabled (via UPCTL.SDRTXIL)**

NOTE: START asserts on every data word from DMA Channel I.

### 33.2.5.8 Data Format

The uPP peripheral supports any data word width between 8 to 16 bits using the IWx and DPWx bits in the uPP channel control register (UPCTL). For 8-bit operation, uPP reads/writes 8-bit words in memory; for 16-bit operation, uPP reads/writes 16-bit words in memory.

For N-bit operation ( $8 < N < 16$ ), the uPP peripheral reads/writes 16-bit words in memory. The “extra” bits are filled by the uPP according to a data packing scheme, selected by the DFWx bit in UPCTL. There are three selectable data packing modes:

- Right-Justify, Zero Extend – Data occupies N LSBs. The  $(16 - N)$  MSBs are cleared to 0.
- Right-Justify, Sign Extend – Data occupies N LSBs. The  $(16 - N)$  MSBs are the same value as the  $(N - 1)$  bit.
- Left-Justify, Zero Fill – Data occupies N MSBs. The  $(16 - N)$  LSBs are cleared to 0.

Table 33-6 lists some example data for  $N = 12$  (that is, 12-bit operation). In transmit mode, the packed version of each data word from memory is transmitted using all 16 data pins allotted to the uPP channel. In receive mode, the packed version of each incoming data word (using only N data pins) is stored in memory.

**Table 33-6. Data Packing Examples for 12-Bit Data Words**

| 12-Bit Data Word | Right-Justify, Zero Extend | Right-Justify, Sign Extend | Left-Justify, Zero Fill |
|------------------|----------------------------|----------------------------|-------------------------|
| 123h             | 0123h                      | 0123h                      | 1230h                   |
| ABCh             | 0ABCh                      | FABCh                      | ABC0h                   |
| 000h             | 0000h                      | 0000h                      | 0000h                   |
| 800h             | 0800h                      | F800h                      | 8000h                   |
| FFFh             | 0FFFh                      | FFFFh                      | FFF0h                   |

## 33.2.6 Initialization and Operation

### 33.2.6.1 Step-by-Step Procedure

---

**NOTE:** When initializing the uPP peripheral, the uPP interface configuration register (UPICR) must be programmed using a single, 32-bit write. Writing UPICR fields one-by-one can lead to unexpected results.

---

This section provides step-by-step instructions for initializing and running the uPP peripheral in various modes. These instructions are given assuming that the device has just come out of a power-on reset (POR) state.

1. Apply the appropriate pin multiplexing settings. See the *System Configuration (SYSCFG) Module* chapter, your device-specific data manual, and/or pin multiplexing utility for more information.
2. Enable the power and clocks to the uPP peripheral. See the *Device Clocking* chapter for more information.
3. Set the SWRST bit in the uPP peripheral control register (UPPCR) to 1 to place uPP in software reset.
4. Wait at least 200 device clock cycles, then clear the SWRST bit to 0 to bring the module out of reset.
5. Program the uPP configuration registers: UPCTL, UPICR, UPIVR, UPTCR, and UPDLB. The basic function of each register is summarized here; for more information, see [Section 33.3](#).
  - (a) UPCTL – Transmit/receive selection (see [Table 33-7](#)), data width, data format, data rate, data interleave enable
  - (b) UPICR – Signal enable, signal inversion, clock divisor (transmit only)
  - (c) UPIVR – Idle value (transmit only)
  - (d) UPTCR – I/O transmit threshold (transmit only), DMA read burst size
  - (e) UPDLB – Digital loopback (see [Table 33-7](#))
6. Program the uPP interrupt enable set register (UPIES) to interrupt generation for the desired events. Register an interrupt service routine (ISR) if desired; otherwise, polling is required.
7. Set the EN bit in the uPP peripheral control register (UPPCR) to 1 to turn on the uPP peripheral.
8. Allocate and/or initialize data buffers for use with uPP.
9. Program the DMA channels with their first transfers using the uPP DMA channel descriptor registers: UPID0-2 and/or UPQD0-2.
10. Watch for interrupt events. Reprogram the DMA as necessary (checking that the PEND bit in the uPP DMA channel status register (UPxS2) is 0).
  - (a) If polling, check UPIES. Reading a bit as 1 indicates the corresponding event has occurred. Write the corresponding bit with 1 to clear.
  - (b) If using ISR, check UPIES inside your ISR. Structure your ISR according to the pseudo-code in [Section 33.2.6.4](#).

### 33.2.6.2 Sample Configuration Settings

The uPP peripheral is flexible, with several orthogonal configuration choices. [Table 33-7](#) summarizes selecting the fundamental operating mode of the module.

**NOTE:** Digital loopback (DLB) mode is a configuration that the uPP peripheral internally routes data and control signals from one channel to the other. DLB can only be used when the peripheral is configured in duplex mode (that is, UPCTL.MODE = 2h or 3h). DLB is primarily useful for debug purposes, and requires no physical connections between channels. The standard uPP pin multiplexing must be applied, however, even though the pins are not used.

**Table 33-7. Basic Operating Mode Selection**

| Operating Mode           | uPP Channel Control Register (UPCTL) Bit |      | uPP Digital Loopback Register (UPDLB) Bit |    |
|--------------------------|------------------------------------------|------|-------------------------------------------|----|
|                          | CHN                                      | MODE | AB                                        | BA |
| 1-Channel Transmit       | 0                                        | 1    | 0                                         | 0  |
| 1-Channel Receive        | 0                                        | 0    | 0                                         | 0  |
| 2-Channel Transmit       | 1                                        | 1    | 0                                         | 0  |
| 2-Channel Receive        | 1                                        | 0    | 0                                         | 0  |
| 2-Channel Duplex 0       | 1                                        | 2h   | 0                                         | 0  |
| 2-Channel Duplex 1       | 1                                        | 3h   | 0                                         | 0  |
| 2-Channel Duplex 0 (DLB) | 1                                        | 2h   | 0                                         | 1  |
| 2-Channel Duplex 1 (DLB) | 1                                        | 3h   | 1                                         | 0  |

Other than [Table 33-7](#), there are several more choices to make (per channel):

- Data width – 8-bit, 9-bit to 16-bit
- Data packing – 9-bit to 15-bit data width only
- Data rate – single, double
- Data interleave –single channel only
- Clock divisor – transmit only
- Individual control signal enable
- Individual control signal polarity
- Idle value – transmit only
- Transmit threshold – transmit only
- DMA read burst size

Table 33-8 lists an example set of uPP parameters for duplex mode 0. This configuration places the uPP peripheral in duplex mode with Channel A receiving and Channel B transmitting. Each channel uses a 16-bit interface with a different data format.

**Table 33-8. Sample uPP Parameters for Duplex Mode 0**

| Register | Register Field <sup>(1)</sup> | Setting | Description                                          |
|----------|-------------------------------|---------|------------------------------------------------------|
| UPCTL    | DPFB                          | 2h      | Data packing: left-justified, zero fill              |
|          | DPWB                          | 4h      | 12-bit data format                                   |
|          | IWB                           | 1       | 16-bit                                               |
|          | DRB                           | 0       | Single data rate                                     |
|          | DPFA                          | —       | Unused                                               |
|          | DPWA                          | 0       | 16-bit data format                                   |
|          | IWA                           | 1       | 16-bit                                               |
|          | DRA                           | 0       | Single data rate                                     |
|          | CHN                           | 1       | 2-Channel                                            |
|          | MODE                          | 2h      | Duplex 0: A receive, B transmit                      |
| UPICR    | CLKDIVB                       | 1       | Divide by 2 (total division of transmit clock: 4)    |
|          | CLKDIVA                       | —       | Unused                                               |
| UPIVR    | VALB                          | 0BBBh   | Note idle value is 12-bit data format; 4 MSBs unused |
|          | VALA                          | —       | Unused                                               |
| UPIES    | EOLQ                          | 1       | Turn on EOL interrupt for Channel B (DMA Channel Q)  |
|          | EOWQ                          | 1       | Turn on EOW interrupt for Channel B (DMA Channel Q)  |
|          | EOLI                          | 1       | Turn on EOL interrupt for Channel A (DMA Channel I)  |
|          | EOWI                          | 1       | Turn on EOW interrupt for Channel A (DMA Channel I)  |

<sup>(1)</sup> Unlisted register fields are left at their default values (typically 0), see [Section 33.3](#).

### 33.2.6.3 System Tuning Tips

The uPP peripheral can operate at high speed and transfer data at a very high rate. When operating the uPP near its upper limits, tuning certain parameters can help decrease the incidence of errors and the software overhead incurred servicing uPP data. [Table 33-9](#) lists several parameters that can be useful in system tuning. A parameter is defined as a “coarse” adjustment, if changing the parameter directly alters the peripheral throughput. A “fine” adjustment does not change the peripheral throughput, but it does affect general system performance.

**Table 33-9. uPP Parameters Useful for System Tuning**

| Parameter            | Register | Register Field     | Edge Value | Safe Value | Description                                                                                                                                                                                                                                             |
|----------------------|----------|--------------------|------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data Rate            | UPCTL    | DRB<br>DRA         | 1          | 0          | Double data rate increases data transfer by a factor of 2 and greatly increases system loading for the same clock divisor. This is a coarse adjustment and is probably fixed due to design constraints.                                                 |
| Clock Division       | UPICR    | CLKDIVB<br>CLKDIVA | 0          | 1+         | Increasing clock division is the most straight-forward way to decrease system loading. This is a coarse adjustment; the difference between CLKDIVx = 0 and 1 is the same (in terms of data rate) as the difference between single and double data rate. |
| DMA Read Burst Size  | UPTCR    | RDSIZEQ<br>RDSIZEI | 0          | 3h         | Increasing the DMA read threshold decreases system loading by generating fewer, larger DMA events. This is a fine adjustment.                                                                                                                           |
| DMA Line Size, Count | UPxD1    | LNCNT<br>BCNT      |            | (1)(1)     | Condensing uPP transfers into fewer, larger lines generates fewer end-of-line interrupts and, thus, invokes fewer ISR calls. This is a fine adjustment.                                                                                                 |
| Total Transfer Size  | UPxD1    | LNCNT<br>BCNT      | (1)        | (1)        | Performing many small uPP transfers can require excessive software overhead (programming DMA descriptors, handling interrupts, etc.) at high data rates. This is a fine adjustment.                                                                     |
| System Priority      |          |                    | (2)(2)     | (2)        | When the uPP operates in parallel with other data masters, such as EDMA, assigning higher priority to the uPP may help the uPP avoid underflow or overflow conditions. This is a fine adjustment.                                                       |

(1) These values vary per application. One example could be a 16-KB transfer. The same total data could be transferred as 16 1-KB lines or 2 8-KB lines.

(2) System priority settings are not set within the uPP peripheral. See the *System Configuration (SYSCFG) Module* chapter for more information.

### 33.2.6.4 Sample Interrupt Service Routine

The following pseudo-code serves as a template for writing a uPP interrupt service routing (ISR) function. Note that the uPP combines all events into a single CPU interrupt, and a new interrupt does not call the ISR if the previous interrupt still has not returned from the ISR. To allow future ISR calls, the uPP end-of-interrupt register (UPEOI) must be written with a zero value. Thus, the ISR should check for multiple events, and should continue rechecking after handling each individual event until no more events are found. Then, it must write UPEOI = 0 before returning.

```

Function upp_isr
{
    interrupt_status = UPIER
    while (interrupt_status != 0)
    {
        if (interrupt_status.EOLI)
        {
            UPIER.EOLI = 1      // clear EOLI
            // Handle EOLI...
        }
        if (interrupt_status.EOWI)
        {
            UPIER.EOWI = 1      // clear EOWI
            // Handle EOWI...
        }
        if (interrupt_status.ERRI)
        {
            UPIER.ERRI = 1      // clear ERRI
            // Handle ERRI...
        }
        if (interrupt_status.UORI)
        {
            UPIER.UORI = 1      // clear UORI
            // Handle UORI...
        }
        if (interrupt_status.DPEI)
        {
            UPIER.DPEI = 1      // clear DPEI
            // Handle DPEI...
        }
        if (interrupt_status.EOLQ)
        {
            UPIER.EOLQ = 1      // clear EOLQ
            // Handle EOLQ...
        }
        if (interrupt_status.EOWQ)
        {
            UPIER.EOWQ = 1      // clear EOWQ
            // Handle EOWQ...
        }
        if (interrupt_status.ERRQ)
        {
            UPIER.ERRQ = 1      // clear ERRQ
            // Handle ERRQ...
        }
        if (interrupt_status.UORQ)
        {
            UPIER.UORQ = 1      // clear UORQ
            // Handle UORQ...
        }
        if (interrupt_status.DPEQ)
        {
            UPIER.DPEQ = 1      // clear DPEQ
            // Handle DPEQ...
        }

        // loop again if any interrupts are left
        interrupt_status = UPIER
    } // end of while

    // write end of interrupt vector to allow future calls
    UPEOI = 0
} // end of function

```

### 33.2.7 Reset Considerations

#### 33.2.7.1 Software Reset

Software reset clears the uPP internal state machines but does not reset the contents of the uPP registers. The following procedure performs a software reset on the uPP peripheral.

1. Write the EN bit in the uPP peripheral control register (UPPCR) to 0 (disables the uPP).
2. Poll the DB bit in UPPCR for activity; wait until DMA controller is inactive/idle.
3. Write the SWRST bit UPPCR to 1 (places uPP in software reset).
4. Write the SWRST bit UPPCR to 0 to (brings uPP out of software reset).

#### 33.2.7.2 Hardware Reset

When the processor RESET pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the uPP state machines are reset, and the uPP registers are forced to their default states (see [Section 33.3](#)).

### 33.2.8 Interrupt Support

The uPP peripheral generates eight interrupt events, all tied to internal DMA Channels I and Q. The uPP peripheral automatically combines all interrupt events into a single chip-level (CPU) interrupt. Individual events may be enabled using the uPP interrupt enable set register (UPIES) and disabled using the uPP interrupt enable clear register (UPIEC). Only enabled events generate interrupts and assert bits in the interrupt enabled status register (UPIER). Disabled events do not generate interrupts but do assert bits in the interrupt raw status register (UPISR).

An interrupt service routine (ISR) may be assigned to handle uPP CPU-level interrupts using the interrupt controller module. If uPP events occur in close proximity to one another, a single CPU interrupt (and a single call to the ISR) may represent multiple interrupt events. Thus, the uPP ISR must meet certain structural requirements:

- The ISR must be able to handle multiple events before returning.
- The ISR must handle any subsequent events that occur after it is called but before it returns.
- The ISR must write 00h to the uPP end-of-interrupt register (UPEOI) just before it returns. This allows future uPP events to generate a CPU interrupt.

[Section 33.2.6](#) provides a sample ISR that demonstrates these requirements.

#### 33.2.8.1 End of Line (EOL) Event

This event occurs each time that the DMA channel reaches the end of a line in the data window. Note that if the associated uPP interface channel is operating in transmit mode, this event may occur before the line's final bytes are actually transmitted over the data pins.

For small line size and fast data transfer, it is possible to “miss” EOL events if they occur faster than the user's code can handle them. This does not hinder uPP operation; the uPP peripheral continue processing data uninterrupted until the EOW event or some error condition is encountered.

#### 33.2.8.2 End of Window (EOW) Event

This event occurs when the DMA channel reaches the end of its current data window. Note that if the associated uPP interface channel is operating in transmit mode, this event may occur shortly before the window's final bytes are actually transmitted over the data pins.

When an EOW event occurs, the DMA channel automatically begins the next DMA transfer if one has been pre-programmed into the channel descriptor registers. If no new transfer is preprogrammed, the DMA channel becomes idle. For small window size and fast data transfer, code overhead may make it impossible to maintain a constant flow of data through the uPP interface channel. This problem can be solved by increasing the DMA window size or decreasing the peripheral clock speed.

### 33.2.8.3 Internal Bus Error (ERR) Event

This event occurs when the uPP peripheral or its internal DMA controller encounters an internal bus error. After encountering this error, the uPP peripheral should be reset to avoid further problem.

### 33.2.8.4 Underrun or Overflow (UOR) Event

This event occurs when the DMA channel fails to keep up with incoming or outgoing data on its associated interface channel. Typically, this error indicates that background system activity has interfered with normal operation of the peripheral. It does not occur simply when a channel is allowed to idle. After encountering this error, the uPP peripheral should be reset when this event occurs.

This error should primarily occur when operating the uPP at high speed with significant system loading. To avoid this error, run the uPP at slower speeds or reduce background activity, such as non-uPP peripheral or DMA transactions. Additional tuning tips are given in [Section 33.2.6.3](#).

### 33.2.8.5 DMA Programming Error (DPE) Event

This event occurs when the DMA channel descriptors are programmed while its PEND bit in the uPP DMA channel status register (UPxS2) is set to 1. A channel's descriptors should only be programmed while the channel's PEND bit is cleared to 0.

## 33.2.9 Power Management

The uPP peripheral can be placed in reduced-power modes to conserve power during periods of inactivity. For information on power management, see the *Power Management* chapter.

### 33.2.10 Emulation Considerations

The uPP peripheral stops running if any of three conditions are met:

- Peripheral Disable – EN bit in the uPP peripheral control register (UPPCR) is 0.
- Clock Stop – uPP acknowledges a clock stop request from the device power management module.
- Emulation Suspend – JTAG emulator halts chip while FREE = 0 and SOFT = 1 in UPPCR.

For other settings of FREE and SOFT, the uPP peripheral continues running during emulation halt.

When the uPP encounters a stop condition, it completes the current DMA burst transaction (if one is active) before stopping.

An I/O channel configured in transmit mode immediately places its pins in a high-impedance state and preserves the state of its internal state machines. Unless some reset event occurs (see [Section 33.2.7](#)), the channel can resume where it left off when the stop condition is cleared.

An I/O channel configured in receive mode immediately asserts its WAIT signal (see [Section 33.2.5.5](#)) and captures one additional data word. Further incoming data words are ignored as long as the stop condition persists.

### 33.2.11 Transmit and Receive FIFOs

Each of the uPP peripheral I/O channels has a 512-byte FIFO. In receive mode, the FIFO is divided into eight 64-byte blocks. In transmit mode, the FIFO is divided into blocks that can be set to 64, 128, or 256 bytes, configured by the TXSIZEA or TXSIZEB field in the uPP threshold configuration register (UPTCR). Transmission will not begin until the channel has loaded enough data to fill at least one full FIFO block.

The internal DMA channels may also be configured to use a read threshold of 64, 128, or 256 bytes using the RDSIZEI or RDSIZEQ field in UPTCR. The DMA write threshold is fixed at 64 bytes.

### 33.3 Registers

The system programmer has access to and control over any of the uPP registers that are listed in [Table 33-10](#). These registers, which control uPP I/O and DMA operations, are available at 32-bit addresses in the device memory-map. The device-specific data sheet lists the base memory address of these registers.

**Table 33-10. uPP Registers**

| Address Offset | Acronym | Register Description                    | Section                         |
|----------------|---------|-----------------------------------------|---------------------------------|
| 0              | UPPID   | uPP Peripheral Identification Register  | <a href="#">Section 33.3.1</a>  |
| 4h             | UPPCR   | uPP Peripheral Control Register         | <a href="#">Section 33.3.2</a>  |

| 78h            | UPQS2   | uPP DMA Channel Q Status 2 Register     | <a href="#">Section 33.3.24</a> |

#### 33.3.1 uPP Peripheral Identification Register (UPPID)

The uPP peripheral identification register (UPPID) reports the revision ID of the uPP peripheral. The UPPID is shown in [Figure 33-16](#) and described in [Table 33-11](#).

**Figure 33-16. uPP Peripheral Identification Register (UPPID)**

LEGEND: R = Read only; -n = value after reset

**Table 33-11. uPP Peripheral Identification Register (UPPID) Field Descriptions**

| Bit  | Field | Value      | Description                       |
|------|-------|------------|-----------------------------------|
| 31-0 | REVID | 4423 1100h | Peripheral identification number. |

### 33.3.2 uPP Peripheral Control Register (UPPCR)

The uPP peripheral control register (UPPCR) controls certain peripheral-level configuration settings for the uPP peripheral. Among these are global enable and reset states and rules governing its behavior during CPU emulation halt. This register also reports the current activity state of the uPP internal DMA controller. The UPPCR is shown in [Figure 33-17](#) and described in [Table 33-12](#).

**Figure 33-17. uPP Peripheral Control Register (UPPCR)**

### 33.3.3 uPP Digital Loopback Register (UPDLB)

The uPP digital loopback register (UPDLB) enables or disables the use of internal digital loopback in the uPP peripheral. Internal loopback may be used to transfer data from one uPP interface channel to another when the peripheral is configured in duplex mode. The interface Channel A and Channel B pins do not need to be connected for this operation, but the proper pin multiplexing must still be applied. The UPDLB is shown in [Figure 33-18](#) and described in [Table 33-13](#).

**Figure 33-18. uPP Digital Loopback Register (UPDLB)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### 33.3.4 uPP Channel Control Register (UPCTL)

The uPP channel control register (UPCTL) controls uPP interface channel settings. This includes global settings, such as the channel count and data interleave, and channel-specific settings such as bit width and data rate.

The UPCTL also controls data formatting for 9-bit to 15-bit operating modes. For a channel with an N-bit interface, the 16 – N MSBs are written or replaced (in receive or transmit mode, respectively) according to the DPFB and DPFA fields. The uPP peripheral performs no data formatting for 8-bit and 16-bit modes. The UPCTL is shown in [Figure 33-19](#) and described in [Table 33-14](#).

**Figure 33-19. uPP Channel Control Register (UPCTL)**

| 17    | IWA      |       | Channel A interface width. Controls whether Channel A performs 8-bit or 16-bit transactions. |
|       |          | 0     | 8-bit interface                                                                              |
|       |          | 1     | 16-bit interface                                                                             |
| 16    | DRA      |       | Channel A data rate. Controls whether Channel A operates at single or double rate.           |
|       |          | 0     | Single data rate                                                                             |
|       |          | 1     | Double data rate                                                                             |
| 15-5  | Reserved | 0     | Reserved                                                                                     |
| 4     | DDRDEMUX |       | Double data rate demultiplexing mode. Only applies when DRA = 1.                             |
|       |          | 0     | Disable. Each peripheral channel is associated with its own DMA channel.                     |
|       |          | 1     | Enable. Both DMA channels service peripheral Channel A. Requires CHN = 0 and MODE = 0 or 1.  |
| 3     | SDRTXIL  |       | Single data rate transmit interleave mode. Only applies when DRA = 0.                        |
|       |          | 0     | Disable. Each peripheral channel is associated with its own DMA channel.                     |
|       |          | 1     | Enable. Both DMA channels service peripheral Channel A. Requires CHN = 0 and MODE = 1.       |
| 2     | CHN      |       | Interface channel number. Controls whether one or both interface channels (A, B) are active. |
|       |          | 0     | Single channel mode. Only Channel A is active.                                               |
|       |          | 1     | Dual channel mode. Channel A and Channel B are both active.                                  |
| 1-0   | MODE     | 0-3h  | Operating mode. Controls the direction each active interface channel operates.               |
|       |          | 0     | All receive mode                                                                             |
|       |          | 1h    | All transmit mode                                                                            |
|       |          | 2h    | Duplex Mode 0. Channel A receives and Channel B transmits. Requires CHN = 1.                 |
|       |          | 3h    | Duplex Mode 1. Channel A transmits and Channel B receives. Requires CHN = 1.                 |

### 33.3.5 uPP Interface Configuration Register (UPICR)

The uPP interface configuration register (UPICR) controls the enable state and polarity of each uPP interface channel's pins. The polarity selection applies regardless of channel direction. The signal enable states only apply in either receive or transmit mode, but never both. The UPICR is shown in [Figure 33-20](#) and described in [Table 33-15](#).

**NOTE:** When initializing the uPP peripheral, the uPP interface configuration register (UPICR) must be programmed using a single, 32-bit write. Writing UPICR fields one-by-one can lead to unexpected results.

**Figure 33-20. uPP Interface Configuration Register (UPICR)**

| 29    | TRISB    | 0<br>1 | Channel B high-impedance state. Controls interface Channel B while idle in transmit mode. Only applies when Channel B is configured in transmit mode using the MODE bit in the uPP channel control register (UPCTL).<br>Channel B drives value from the VALB bit in the uPP interface idle value register (UPIVR) while idle.<br>Channel B data pins are in a high-impedance state while idle.            |
| 28    | CLKINVB  | 0<br>1 | Channel B clock inversion. Controls clock signal polarity for interface Channel B.<br>Clock is not inverted. Channel B signals align on rising edge of clock.<br>Clock is inverted. Channel B signals align on falling edge of clock.                                                                                                                                                                     |
| 27-24 | CLKDIVB  | 0-Fh   | Clock divisor for Channel B. Only used when interface Channel B is configured in transmit mode using the MODE bit in the uPP channel control register (UPCTL). Applied divisor equals CLKDIVB + 1.                                                                                                                                                                                                        |
| 23-22 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                  |
| 21    | WAITB    | 0<br>1 | Channel B WAIT signal enable. Controls use of WAIT signal for interface Channel B. Only applied when Channel B is configured in transmit mode using the MODE bit in the uPP channel control register (UPCTL). In receive mode, WAIT is always driven low.<br>WAIT signal is disabled. Channel B ignores WAIT in transmit mode.<br>WAIT signal is enabled. Channel B honors WAIT in transmit mode.         |
| 20    | ENAB     | 0<br>1 | Channel B ENABLE Signal Enable. Controls use of ENABLE signal for interface Channel B. Only applied when Channel B is configured in receive mode using the MODE bit in the uPP channel control register (UPCTL). In transmit mode, ENABLE is always driven.<br>ENABLE signal is disabled. Channel B ignores ENABLE in receive mode.<br>ENABLE signal is enabled. Channel B honors ENABLE in receive mode. |

**Table 33-15. uPP Interface Configuration Register (UPICR) Field Descriptions (continued)**

| Bit   | Field     | Value | Description                                                                                                                                                                                                                                                 |
|-------|-----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19    | STARTB    |       | Channel B START Signal Enable. Controls use of START signal for interface Channel B. Only applied when Channel B is configured in receive mode using the MODE bit in the uPP channel control register (UPCTL). In transmit mode, STARTB is always driven.   |
|       |           | 0     | START signal is disabled. Channel B ignores START in receive mode.                                                                                                                                                                                          |
|       |           | 1     | START signal is enabled. Channel B honors START in receive mode.                                                                                                                                                                                            |
| 18    | WAITPOLB  |       | Channel B WAIT Signal Polarity. Controls polarity of WAIT signal for interface Channel B.                                                                                                                                                                   |
|       |           | 0     | WAIT is active-high for Channel B.                                                                                                                                                                                                                          |
|       |           | 1     | WAIT is active-low for Channel B.                                                                                                                                                                                                                           |
| 17    | ENAPOLB   |       | Channel B ENABLE Signal Polarity. Controls polarity of ENABLE signal for interface Channel B.                                                                                                                                                               |
|       |           | 0     | ENABLE is active-high for Channel B.                                                                                                                                                                                                                        |
|       |           | 1     | ENABLE is active-low for Channel B.                                                                                                                                                                                                                         |
| 16    | STARTPOLB |       | Channel B START Signal Polarity. Controls polarity of START signal for interface Channel B.                                                                                                                                                                 |
|       |           | 0     | START is active-high for Channel B.                                                                                                                                                                                                                         |
|       |           | 1     | START is active-low for Channel B.                                                                                                                                                                                                                          |
| 15-14 | Reserved  | 0     | Reserved                                                                                                                                                                                                                                                    |
| 13    | TRISA     |       | Channel A high-impedance state. Controls interface Channel A while idle in transmit mode. Only applies when Channel A is configured in transmit mode using the MODE bit in the uPP channel control register (UPCTL).                                        |
|       |           | 0     | Channel A drives value from the VALA bit in the uPP interface idle value register (UPIVR) while idle.                                                                                                                                                       |
|       |           | 1     | Channel A data pins are in a high-impedance state while idle.                                                                                                                                                                                               |
| 12    | CLKINVA   |       | Channel A clock inversion. Controls clock signal polarity for interface Channel A.                                                                                                                                                                          |
|       |           | 0     | Clock is not inverted. Channel A signals align on rising edge of clock.                                                                                                                                                                                     |
|       |           | 1     | Clock is inverted. Channel A signals align on falling edge of clock.                                                                                                                                                                                        |
| 11-8  | CLKDIVA   | 0-Fh  | Clock divisor for Channel A. Only used when interface Channel A is configured in transmit mode using the MODE bit in the uPP channel control register (UPCTL). Applied divisor equals CLKDIVA + 1.                                                          |
| 7-6   | Reserved  | 0     | Reserved                                                                                                                                                                                                                                                    |
| 5     | WAITA     |       | Channel A WAIT signal enable. Controls use of WAIT signal for interface Channel A. Only applied when Channel A is configured in transmit mode using the MODE bit in the uPP channel control register (UPCTL). In receive mode, WAIT is always driven low.   |
|       |           | 0     | WAIT signal is disabled. Channel A ignores WAIT in transmit mode.                                                                                                                                                                                           |
|       |           | 1     | WAIT signal is enabled. Channel A honors WAIT in transmit mode.                                                                                                                                                                                             |
| 4     | ENAA      |       | Channel A ENABLE Signal Enable. Controls use of ENABLE signal for interface Channel B. Only applied when Channel A is configured in receive mode using the MODE bit in the uPP channel control register (UPCTL). In transmit mode, ENABLE is always driven. |
|       |           | 0     | ENABLE signal is disabled. Channel A ignores ENABLE in receive mode.                                                                                                                                                                                        |
|       |           | 1     | ENABLE signal is enabled. Channel A honors ENABLE in receive mode.                                                                                                                                                                                          |
| 3     | STARTA    |       | Channel A START Signal Enable. Controls use of START signal for interface Channel A. Only applied when Channel A is configured in receive mode using the MODE bit in the uPP channel control register (UPCTL). In transmit mode, STARTA is always driven.   |
|       |           | 0     | START signal is disabled. Channel A ignores START in receive mode.                                                                                                                                                                                          |
|       |           | 1     | START signal is enabled. Channel A honors START in receive mode.                                                                                                                                                                                            |
| 2     | WAITPOLA  |       | Channel A WAIT Signal Polarity. Controls polarity of WAIT signal for interface Channel A.                                                                                                                                                                   |
|       |           | 0     | WAIT is active-high for Channel A.                                                                                                                                                                                                                          |
|       |           | 1     | WAIT is active-low for Channel A.                                                                                                                                                                                                                           |
| 1     | ENAPOLA   |       | Channel A ENABLE Signal Polarity. Controls polarity of ENABLE signal for interface Channel A.                                                                                                                                                               |
|       |           | 0     | ENABLE is active-high for Channel A.                                                                                                                                                                                                                        |
|       |           | 1     | ENABLE is active-low for Channel A.                                                                                                                                                                                                                         |
| 0     | STARTPOLA |       | Channel A START Signal Polarity. Controls polarity of START signal for interface Channel A.                                                                                                                                                                 |
|       |           | 0     | START is active-high for Channel A.                                                                                                                                                                                                                         |
|       |           | 1     | START is active-low for Channel A.                                                                                                                                                                                                                          |

### 33.3.6 uPP Interface Idle Value Register (UPIVR)

The uPP interface idle value register (UPIVR) controls the value that each interface channel transmits while idle. Note that this only applies when the associated channel is configured in transmit mode and also depends on the value of the TRISA and TRISB bits in the uPP interface configuration register (UPICR). The UPIVR is shown in [Figure 33-21](#) and described in [Table 33-16](#).

**Figure 33-21. uPP Interface Idle Value Register (UPIVR)**

**Table 33-16. uPP Interface Idle Value Register (UPIVR) Field Descriptions**

| Bit   | Field | Value   | Description                                                                                                                                                                                                                                                  |
|-------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | VALB  | 0-FFFFh | Channel B idle value. Sets idle value for interface Channel B. This value is output on the Channel B data pins when the channel is idle, configured in transmit mode, and the TRISB bit in the uPP interface configuration register (UPICR) is cleared to 0. |
| 15-0  | VALA  | 0-FFFFh | Channel A idle value. Sets idle value for interface Channel A. This value is output on the Channel A data pins when the channel is idle, configured in transmit mode, and the TRISA bit in the uPP interface configuration register (UPICR) is cleared to 0. |

### 33.3.7 uPP Threshold Configuration Register (UPTCR)

The uPP threshold configuration register (UPTCR) controls the transmit threshold for each interface channel and the read threshold for each DMA channel. Using larger thresholds can decrease internal bus traffic and increase performance, especially when the uPP is operating in a loaded system. The UPTCR is shown in Figure 33-22 and described in Table 33-17.

**Figure 33-22. uPP Threshold Configuration Register (UPTCR)**

### 33.3.8 uPP Interrupt Raw Status Register (UPISR)

The uPP interrupt raw status register (UPISR) reports the raw interrupt status for various conditions. Each status bit reads 1 when the associated event occurs, even if that interrupt event is disabled in the uPP interrupt enable clear register (UPIEC). Writing 1 to any bit simulates the associated interrupt event; writing 0 has no effect. The UPISR is shown in [Figure 33-23](#) and described in [Table 33-18](#).

### 33.3.9 uPP Interrupt Enabled Status Register (UPIER)

The uPP interrupt enabled status register (UPIER) reports the enabled interrupt status for various conditions. Each status bit reads 1, if the associated event occurs while that event is enabled in the uPP interrupt enabled set register (UPIES). If the interrupt event is disabled in the uPP interrupt enable clear register (UPIEC), the associated status bit always reads 0. Writing 1 to any bit clears the associated interrupt event; writing 0 has no effect. The UPIER is shown in [Figure 33-24](#) and described in [Table 33-19](#).

### 33.3.10 uPP Interrupt Enable Set Register (UPIES)

The uPP interrupt enabled set register (UPIES) controls whether individual interrupt events generate a CPU interrupt. Writing 1 to any bit enables CPU interrupt generation for the associated uPP event; writing 0 has no effect.

Reads from both UPIES and the uPP interrupt enable clear register (UPIEC) access the same internal interrupt enable register, and a value of 1 indicates that the corresponding interrupt is enabled. The UPIES is shown in [Figure 33-25](#) and described in [Table 33-20](#).

**Figure 33-25. uPP Interrupt Enable Set Register (UPIES)**

### 33.3.11 uPP Interrupt Enable Clear Register (UPIEC)

The uPP interrupt enable clear register (UPIEC) controls whether individual interrupt events generate a CPU interrupt. Writing 1 to any bit disables CPU interrupt generation for the associated uPP event; writing 0 has no effect.

Reads from both UPIEC and the uPP interrupt enabled set register (UPIES) access the same internal interrupt enable register, and a value of 1 indicates that the corresponding interrupt is enabled. The UPIEC is shown in [Figure 33-26](#) and described in [Table 33-21](#).

**Figure 33-26. uPP Interrupt Enable Clear Register (UPIEC)**

### 33.3.12 uPP End of Interrupt Register (UPEOI)

The uPP end of interrupt register (UPEOI) acknowledges CPU interrupts generated from uPP events. The EOI bit field must be written with 00h at the end of the interrupt service routine (ISR) that handles uPP interrupts. Until this acknowledgement occurs, no uPP event can generate another CPU interrupt. The UPEOI is shown in [Figure 33-27](#) and described in [Table 33-22](#).

**Figure 33-27. uPP End of Interrupt Register (UPEOI)**

### 33.3.13 uPP DMA Channel I Descriptor 0 Register (UPID0)

The uPP DMA channel I descriptor 0 register (UPID0) programs the starting address of the data buffer, or window, for DMA Channel I. The address is programmed by writing a 32-bit value to the entire register. Note that the 3 lower bits are read-only and always equal 0, so that data buffers are properly aligned in memory. The UPID0 is shown in [Figure 33-28](#) and described in [Table 33-23](#).

**Figure 33-28. uPP DMA Channel I Descriptor 0 Register (UPID0)**

| 15-0  | BCNT  | 0-FFFFh | DMA Byte Number. Reports the current byte position within the current line of the DMA Channel I transfer. |

### 33.3.18 uPP DMA Channel I Status 2 Register (UPIS2)

The uPP DMA channel I status register 2 (UPIS2) reports the status of the current DMA Channel I transfer. The PEND bit is used to determine when a new transfer may be programmed into the uPP DMA channel I descriptor registers (UPIDn). The UPIS2 is shown in [Figure 33-33](#) and described in [Table 33-28](#).

**Figure 33-33. uPP DMA Channel I Status 2 Register (UPIS2)**

This field should not be used to determine whether the DMA Channel I descriptors are programmable; use the PEND bit instead.<br>DMA is inactive.<br>DMA is active.                                                                                                         |

### 33.3.19 uPP DMA Channel Q Descriptor 0 Register (UPQD0)

The uPP DMA channel Q descriptor 0 register (UPQD0) programs the starting address of the data buffer, or window, for DMA Channel Q. The address can be programmed by simply writing a 32-bit value to the entire register. Note that the 3 lower bits are read-only and always equal to 0, so that data buffers must be properly aligned in memory. The UPQD0 is shown in [Figure 33-34](#) and described in [Table 33-29](#).

**Figure 33-34. uPP DMA Channel Q Descriptor 0 Register (UPQD0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 33-29. uPP DMA Channel Q Descriptor 0 Register (UPQD0) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                           |
|------|-------|--------------|-------------------------------------------------------------------------------------------------------|
| 31-3 | ADDRH | 0-1FFF FFFFh | Window Address MSBs. Sets the 29 most-significant bits of starting address for DMA Channel Q window.  |
| 2-0  | ADDR  | 0            | Window Address LSBs. Forces window address to align to multiple of 8 bytes (64-bit buffer alignment). |

### 33.3.20 uPP DMA Channel Q Descriptor 1 Register (UPQD1)

The uPP DMA channel Q descriptor 1 register (UPQD1) programs the line count per window and byte count per line for DMA Channel Q. The line count (LNCNT) may be set to any number from 1 to 65 535 (FFFFh), but must not be cleared to 0. The byte count (BCNT) may only be set to an even number. For a simple transfer, LNCNT may be set to 1, and BCNT may be set to  $N \gg 1$ , where N is the desired byte count of the entire DMA transfer. Note that the lower bit is read-only and is always equal 0, so that N is an even number. The UPQD1 is shown in [Figure 33-35](#) and described in [Table 33-30](#).

**Figure 33-35. uPP DMA Channel Q Descriptor 1 Register (UPQD1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 33-30. uPP DMA Channel Q Descriptor 1 Register (UPQD1) Field Descriptions**

| Bit   | Field | Value        | Description                                                                                                                      |
|-------|-------|--------------|----------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | LNCNT | 1-FFFFh<br>0 | Line Count. Sets the number of lines in the DMA Channel Q window.<br>Invalid value                                               |
| 15-1  | BCNTH | 1-7FFFh<br>0 | Byte Count MSBs. Sets the 15 most-significant bits of the number of bytes per line in the DMA Channel Q window.<br>Invalid value |
| 0     | BCNT  | 0            | Byte Count LSB. Forces the number of bytes per line to an even value (multiple of 2 bytes).                                      |

### 33.3.21 uPP DMA Channel Q Descriptor 2 Register (UPQD2)

The uPP DMA channel Q descriptor 2 register (UPQD2) programs the offset address between lines within the DMA Channel Q window. Note that the 3 lower bits are read-only and always equal 0, so that the line offset address is aligned to a multiple of 8 bytes, similar to the window address in UPQD0. Writing a value of 0 to UPQD2 effectively repeats the same (first) line *UPQD1.LNCNT* times. The UPQD2 is shown in [Figure 33-36](#) and described in [Table 33-31](#).

**Figure 33-36. uPP DMA Channel Q Descriptor 2 Register (UPID2)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 33-31. uPP DMA Channel Q Descriptor 2 Register (UPID2) Field Descriptions**

| Bit   | Field     | Value   | Description                                                                                                                                                                   |
|-------|-----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved  | 0       | Reserved                                                                                                                                                                      |
| 15-3  | LNOFFSETH | 0-1FFFh | Line Offset Address MSBs. Sets the 13 most-significant bits of the offset address (in bytes) between lines in the DMA Channel Q window. This is a signed 2s-complement value. |
| 2-0   | LNOFFSET  | 0       | Line Offset Address LSBs. Forces the line offset address to align to a multiple of 8 bytes (64-bit alignment).                                                                |

### 33.3.22 uPP DMA Channel Q Status 0 Register (UPQS0)

The uPP DMA channel Q status 0 register (UPQS0) reports the current address of the DMA Channel Q transfer. The UPQS0 is shown in [Figure 33-37](#) and described in [Table 33-32](#).

**Figure 33-37. uPP DMA Channel Q Status 0 Register (UPQS0)**

LEGEND: R = Read only; -n = value after reset

**Table 33-32. uPP DMA Channel Q Status 0 Register (UPQS0) Field Descriptions**

| Bit  | Field | Value        | Description                                                                     |
|------|-------|--------------|---------------------------------------------------------------------------------|
| 31-0 | ADDR  | 0-FFFF FFFFh | DMA Current Address. Reports the current address of the DMA Channel Q transfer. |

### 33.3.23 uPP DMA Channel Q Status 1 Register (UPQS1)

The uPP DMA channel Q status 1 register (UPQS1) reports the current line number and the byte position within the current line of the DMA Channel Q transfer. The UPQS1 is shown in [Figure 33-38](#) and described in [Table 33-33](#).

**Figure 33-38. uPP DMA Channel Q Status 1 Register (UPQS1)**

|-------|-------|---------|-----------------------------------------------------------------------------------------------------------|
| 31-16 | LNCNT | 0-FFFFh | DMA Current Line Number. Reports the current line number of the DMA Channel Q transfer.                   |
| 15-0  | BCNT  | 0-FFFFh | DMA Byte Number. Reports the current byte position within the current line of the DMA Channel Q transfer. |

### 33.3.24 uPP DMA Channel Q Status 2 Register (UPQS2)

The uPP DMA channel Q status 2 register (UPQS2) reports the status of the current DMA Channel Q transfer. The PEND bit is used to determine when a new transfer may be programmed into the into the uPP DMA channel Q descriptor registers (UPQDn). The UPQS2 is shown in [Figure 33-39](#) and described in [Table 33-34](#).

**Figure 33-39. uPP DMA Channel Q Status 2 Register (UPQS2)**

## 34.1 Introduction

### 34.1.1 Purpose of the Peripheral

The USB1.1 OHCI host controller (HC) is a single port controller that communicates with USB devices at the USB low-speed (1.5M bit-per-second maximum) and full-speed (12M bit-per-second maximum) data rates. It is compatible with the *Universal Serial Bus Specification Revision 2.0* and the *Open HCI—Open Host Controller Interface Specification for USB, Release 1.0a*, available through the Compaq Computer Corporation web site, and hereafter called the *OHCI Specification for USB*. It is assumed that users of the USB1.1 host controller are already familiar with the *USB Specification* and *OHCI Specification for USB*.

The USB1.1 host controller implements the register set and makes use of the memory data structures defined in the *OHCI Specification for USB*. These registers and data structures are the mechanisms by which a USB host controller driver software package can control the USB1.1 host controller. The *OHCI Specification for USB* also defines how the USB host controller implementation must interact with those registers and data structures in system memory.

To reduce processor software and interrupt overhead, the USB1.1 host controller generates USB traffic based on data structures and data buffers stored in system memory. The USB1.1 host controller accesses these data structures without direct intervention by the processor using its bus master port. These data structures and data buffers can be located in internal or external system RAM.

The USB1.1 host controller provides an interrupt to both the ARM and DSP.

## 34.2 Architecture

### 34.2.1 Clock and Reset

The USB1.1 module requires that several different clocks are present before it can be accessed:

1. Internal system bus clocks for accesses by the ARM or (Device SYSCLK2 and SYSCLK4)
2. Local bus clock to the USB1.1 host controller (derived from SYSCLK4)
3. USB bus side 48-MHz reference clock must be present. Several options are available to source this clock.

#### 34.2.1.1 Internal System Bus Clocks Needed

The internal system bus clocks SYSCLK2 and SYSCLK4 are normally configured during the device reset process; as the device PLL controller is initialized. The USB1.1 host controller operates in the SYSCLK4 domain but most of the device level bus infrastructure operates on the SYSCLK2 domain. Normally one or both of the host CPU clock domains (SYSCLK6 for the ARM and SYSCLK1 for the DSP) are enabled as well.

#### 34.2.1.2 Local Bus Clock and Local Reset

The USB1.1 host controller actually operates from a local (gated) version of SYSCLK4. This allows the module be put into a low power state when not in use. The module also has its own local reset that is asserted during a device level reset and remains asserted until released by software. Additionally software can at any time assert a hardware reset on the USB1.1 host controller individually, causing it to reinitialize without affecting any of the other peripherals on the device.

Both the local clock and local reset of the USB1.1 host controller are under the control of the device level power sleep controller 1 (PSC1) module. This module controls many local power sleep controller modules, and local power sleep controller 2 (LPSC2) of PSC1 controls the USB1.1 OHCI host controller.

#### 34.2.1.3 48-MHz Reference Clock

This device includes an integrated USB 1.1 Phy for the OHCI Host Controller's Root Hub (Port 0). This Phy requires a 48-MHz reference clock for proper operation. Two options are available to provide this reference clock:

- Use the reference clock generated by the USB0 module integrated high-speed phy. The high-speed phy includes a phase locked loop (PLL) that is capable of generating a 48-MHz reference clock from multiple different input clock options. This method is probably the most convenient as it does not require an externally sourced clock, and the PLL in the USB0 module has flexibility in the frequency of its input clock. However when using this option, the USB0 phy must be operating in order to use the USB1.1 OHCI host controller. (This does not mean that the USB2.0 module must be running, only that its phy needs to be configured properly and enabled).
- Provide the 48 MHz clock externally, on the USB\_REFCLKIN pin.

For details on device-level configuration of the 48-MHz reference clock, see the *Device Clocking* chapter.

The USB1.1 host controller completes its reset after the host controller clock is transitioned from disabled to enabled and the host controller reset is removed. After system software turns on the clock to the USB1.1 host controller and removes it from reset, it is necessary to wait until the USB1.1 host controller internal reset completes. To ensure that the USB1.1 host controller has completely reset, system software must wait until reads of both the HCREVISION register and the HCHCCA register return their correct reset default values.

## 34.2.2 Open Host Controller Interface Functionality

### 34.2.2.1 OHCI Controller Overview

The *Open HCI—Open Host Controller Interface Specification for USB, Release 1.0a* defines a set of registers and data structures stored in system memory that control how a USB host controller interfaces to system software. This specification, in conjunction with the *Universal Serial Bus Specification Version 2.0*, defines most of the USB functionality that the USB1.1 host controller provides.

The *OHCI Specification for USB* focuses on two main aspects of the USB host controller hardware implementation: its register set and the memory data structures that define the appearance of USB bus activity. Other topics include interrupt generation, USB host controller state, USB frame management, and the hardware methods used to process the lists of data structures in system memory.

This document does not duplicate the information presented in the *OHCI Specification for USB* or the *USB Specification*. USB1.1 host controller users can refer to the *USB Specification* and the *OHCI Specification for USB* for detailed discussions of USB requirements and OHCI controller operation.

### 34.2.3 Differences From OHCI Specification for USB

The USB1.1 module OHCI compatible host controller implementation does not implement every aspect of the functionality defined in the *OHCI Specification for USB*. The differences focus on power switching, overcurrent reporting, and the OHCI ownership change interrupt. Other restrictions are imposed by the effects of the pin multiplexing options.

#### 34.2.3.1 Power Switching Output Pins Not Supported

The device does not provide pins that can be controlled directly by the USB1.1 host controller OHCI port power control features. The OHCI RHPORTSTATUS register port power control bits can be programmed by the USB1.1 host controller driver software, but this does not have any direct effect on any VBUS switching implemented on the board.

You can use software control of GPIO pins or other implementation-specific control mechanisms to control VBUS switching.

#### 34.2.3.2 Overcurrent Protection Input Pins Not Supported

The device does not provide any pins that allow the USB1.1 host controller OHCI RHPORTSTATUS overcurrent protection status bits to be directly controlled by external hardware.

You can use software monitoring of GPIO pins or other implementation-specific control mechanisms to report port overcurrent information to the USB1.1 host controller driver.

#### 34.2.3.3 No Ownership Change Interrupt

The USB1.1 host controller does not implement the OHCI ownership change interrupt.

## 34.2.4 Implementation of OHCI Specification for USB1.1

### 34.2.4.1 USB1.1 Host Controller Endpoint Descriptor (ED) List Head Pointers

The *OHCI Specification for USB* provides a specific sequence of operations for the host controller driver to perform when setting up the host controller. Failure to follow that sequence can result in malfunction. As a specific example, the HCCONTROLHEADED and HCBULKHEADED pointer registers and the 32 HCCAINERRUPTABLE pointers must all point to valid physical addresses of valid endpoint descriptors.

The USB1.1 host controller does not check HCCONTROLHEADED registers, HCBULKHEADED registers, or the values in the 32 HCCAINERRUPTABLE pointers before using them to access EDs. In particular if any of these pointers are NULL when the corresponding list enable bit is set, the USB1.1 host controller attempts to access using the physical address of 0, which is not a valid memory region for the USB1.1 host controller to access.

### 34.2.4.2 OHCI USB Suspend State

The USB1.1 host controller ignores upstream traffic from downstream devices for about 3 ms after the host controller state (HCCONTROL.HCFS) changes from USB resume state to USB operational state. If any TDs cause generation of downstream packets during that time, the downstream packets are sent, but downstream device responses are ignored. Any such TDs are aborted with completion codes marked as Device Not Responding. TDs on any of the lists (periodic, control, bulk, and isochronous) can cause such an occurrence.

The *USB Specification* requires that system software must provide a 10-ms resume recovery time (TRSMRCY) after a bus segment transitions from resume signaling to normal operational mode. During that time, only start of frame packets are to be sent on the bus segment. The system software should disable all list enable bits (HCCONTROL.PLE, HCCONTROL.IE, HCCONTROL.CLE, and HCCONTROL.BLE) and then wait for at least 1 ms before setting the host controller into USB suspend state (via HCCONTROL.HCFS). When restoring from suspend, system software must set the host controller into USB resume state, and wait for the host controller to transition into USB operational state. System software must then wait 10 ms before enabling the host controller list enable bits.

When the host controller has been placed into the USB suspend state under software control, but is brought out by a remote wake-up, system software must monitor the HCRHPORTSTATUS[x].PSS and HCRHPORTSTATUS[x].PSSC bits. The HCRHPORTSTATUS[x].PSS bit changes to 0 only after completion of resume signaling on the bus segment, and completion of the 3-ms period (packets from downstream devices are ignored).

When using port-specific suspend, it is not necessary to disable the host controller lists, as long as there are no active EDs and TDs directed toward devices that are downstream of the suspended port. For port-specific suspend operations, the host controller does not issue a root hub status change interrupt (HCRHPORTSTATUS[n].PSSC bit = 1 and HCRHPORTSTATUS[n].PSS = 0), until the end of the approximately 3-ms delay after the resume signaling completes.

When using port-specific suspend, system software must ensure that there are no active EDs for devices that are downstream of the suspended port before setting the port into suspend mode. While the port is in suspend or being resumed, system software must not enable any EDs for any devices downstream of the suspended port. Once the root hub status change interrupt occurs as a result of the suspended port PSS bit changing to 0, EDs can be enabled for devices downstream of the operational port.

### 34.2.5 OHCI Interrupts

The USB1.1 host controller is controlled by either the ARM or the DSP. It has the ability to interrupt either processor.

### 34.2.6 USB1.1 Host Controller Access to System Memory

The USB1.1 module needs to access system memory to read and write the OHCI data structures and data buffers associated with USB traffic. The switch fabric allows the USB1.1 host controller to access system memory.

### 34.2.7 Physical Addressing

Transactions on the internal bus use physical addresses, so all system memory accesses initiated by the USB1.1 host controller must use physical addresses. The CPU can be configured to use virtual addressing. In this case, software manipulates virtual addresses that may or may not be identical to physical addresses. When virtual addressing is used, system software must perform the appropriate virtual address to physical address and physical address to virtual address conversions when manipulating the USB1.1 host controllers data structures and pointers to those data structures.

Figure 34-1 shows the virtual address to physical address conversion.

**Figure 34-1. Relationships Between Virtual Address Physical Address**

### 34.3 Registers

Most of the host controller (HC) registers are OHCI operational registers, defined by the *OHCI Specification for USB*. Four additional registers not specified by the *OHCI Specification for USB* provide additional information about the USB1.1 host controller state. The USB1.1 host controller registers can be accessed in user and supervisor modes.

To enhance code reusability with possible future versions of the USB1.1 host controller, reads and writes to reserved USB1.1 host controller register addresses are to be avoided. Unless otherwise specified, when writing registers that have reserved bits, read-modify-write operations must be used so that the reserved bits are written with their previous values.

The USB1.1 host controller registers are listed in [Table 34-1](#).

**Table 34-1. USB1.1 Host Controller Registers**

| Address    | Acronym            | Register Description                                 | Section                         |
|------------|--------------------|------------------------------------------------------|---------------------------------|
| 01E2 5000h | HCREVISION         | OHCI Revision Number Register                        | <a href="#">Section 34.3.1</a>  |

<sup>(1)</sup> Restrictions apply to the physical addresses used in these registers (see [Section 34.2.7](#)).

<sup>(2)</sup> Connected to the integrated USB1.1 phy pins (DM, DP).

<sup>(3)</sup> Although the controller implements two ports, the second port cannot be used.

### 34.3.1 OHCI Revision Number Register (HCREVISION)

The OHCI revision number register (HCREVISION) is shown in [Figure 34-2](#) and described in [Table 34-2](#).

**Figure 34-2. OHCI Revision Number Register (HCREVISION)**

LEGEND: R = Read only; -n = value after reset

**Table 34-2. OHCI Revision Number Register (HCREVISION) Field Descriptions**

| Bit  | Field    | Value | Description           |
|------|----------|-------|-----------------------|
| 31-8 | Reserved | 0     | Reserved              |
| 7-0  | REV      | 10h   | OHCI revision number. |

### 34.3.2 HC Operating Mode Register (HCCONTROL)

The HC operating mode register (HCCONTROL) controls the operating mode of the USB1.1 host controller. HCCONTROL is shown in [Figure 34-3](#) and described in [Table 34-3](#).

**Figure 34-3. HC Operating Mode Register (HCCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-3. HC Operating Mode Register (HCCONTROL) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-11 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 10    | RWE      | 0-1   | Remote wake-up enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 9     | RWC      | 0-1   | Remote wake-up connected.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8     | IR       | 0     | Interrupt routing. The USB1.1 host controller does not provide an SMI interrupt. This bit must be 0 to allow the USB1.1 host controller interrupt to propagate to the MPU level 2 interrupt controller.                                                                                                                                                                                                                                                               |
| 7-6   | HCFS     | 0-3h  | Host controller functional state. A transition to USB operational causes SOF generation to begin in 1 ms. The USB1.1 host controller can automatically transition from USB suspend to USB resume, if a downstream resume is received. The USB1.1 host controller enters USB suspend after a software reset. The USB1.1 host controller enters USB reset after a hardware reset. The USB reset state resets the root hub and causes downstream signaling of USB reset. |
|       |          | 0     | USB reset                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 34.3.4 HC Interrupt and Status Register (HCINTERRUPTSTATUS)

The HC interrupt and status register (HCINTERRUPTSTATUS) reports the status of the USB1.1 host controller internal interrupt sources. HCINTERRUPTSTATUS is shown in [Figure 34-5](#) and described in [Table 34-5](#).

**Figure 34-5. HC Interrupt and Status Register (HCINTERRUPTSTATUS)**

### 34.3.5 HC Interrupt Enable Register (HCINTERRUPTENABLE)

The HC interrupt enable register (HCINTERRUPTENABLE) enables various OHCI interrupt sources to generate interrupts to the level 2 interrupt controller. HCINTERRUPTENABLE is shown in [Figure 34-6](#) and described in [Table 34-6](#).

**Figure 34-6. HC Interrupt Enable Register (HCINTERRUPTENABLE)**

| 4    | UE       | 0<br>1 | Unrecoverable error. Read always returns 0.<br>No effect.<br>Clears the UE bit in the HC interrupt enable register (HCINTERRUPTENABLE).      |
| 3    | RD       | 0<br>1 | Resume detected. Read always returns 0.<br>No effect.<br>Clears the RD bit in the HC interrupt enable register (HCINTERRUPTENABLE).          |
| 2    | SF       | 0<br>1 | Start of frame. Read always returns 0.<br>No effect.<br>Clears the SF bit in the HC interrupt enable register (HCINTERRUPTENABLE).           |
| 1    | WDH      | 0<br>1 | Write done head. Read always returns 0.<br>No effect.<br>Clears the WDH bit in the HC interrupt enable register (HCINTERRUPTENABLE).         |
| 0    | SO       | 0<br>1 | Scheduling overrun. Read always returns 0.<br>No effect.<br>Clears the SO bit in the HC interrupt enable register (HCINTERRUPTENABLE).       |

### 34.3.7 HC HCAA Address Register (HCHCCA)

The HC HCAA address register (HCHCCA) defines the physical address of the beginning of the HCCA. HCHCCA is shown in [Figure 34-8](#) and described in [Table 34-8](#).

**Figure 34-8. HC HCAA Address Register (HCHCCA)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-8. HC HCAA Address Register (HCHCCA) Field Descriptions**

| Bit  | Field    | Value      | Description                                    |
|------|----------|------------|------------------------------------------------|
| 31-8 | HCCA     | 0-FF FFFFh | Physical address of the beginning of the HCCA. |
| 7-0  | Reserved | 0          | Reserved                                       |

### 34.3.8 HC Current Periodic Register (HCPERIODCURRENTED)

The HC current periodic register (HCPERIODCURRENTED) defines the physical address of the next endpoint descriptor (ED) on the periodic ED list. HCPERIODCURRENTED is shown in [Figure 34-9](#) and described in [Table 34-9](#).

**Figure 34-9. HC Current Periodic Register (HCPERIODCURRENTED)**

LEGEND: R = Read only; -n = value after reset

**Table 34-9. HC Current Periodic Register (HCPERIODCURRENTED) Field Descriptions**

| Bit  | Field    | Value       | Description                                                                                                                                                                                                                                                                                                                                          |
|------|----------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | PCED     | 0-FFF FFFFh | Physical address of the current ED on the periodic ED list. This field represents bits 31-4 of the physical address of the next ED on the periodic ED list. EDs are assumed to begin on a 16-byte aligned address, so bits 3-0 of this pointer are assumed to be 0. For the restrictions on physical addresses, see <a href="#">Section 34.2.7</a> . |
| 3-0  | Reserved | 0           | Reserved                                                                                                                                                                                                                                                                                                                                             |

### 34.3.9 HC Head Control Register (HCCONTROLHEADED)

The HC head control register (HCCONTROLHEADED) defines the physical address of the head endpoint descriptor (ED) on the control ED list. HCCONTROLHEADED is shown in [Figure 34-10](#) and described in [Table 34-10](#).

**Figure 34-10. HC Head Control Register (HCCONTROLHEADED)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-10. HC Head Control Register (HCCONTROLHEADED) Field Descriptions**

| Bit  | Field    | Value       | Description                                                                                                                                                                                                                                                                                                                                     |
|------|----------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | CHED     | 0-FFF FFFFh | Physical address of the head ED on the control ED list. This field represents bits 31-4 of the physical address of the head ED on the control ED list. EDs are assumed to begin on a 16-byte aligned address, so bits 3-0 of this pointer are assumed to be 0. For the restrictions on physical addresses, see <a href="#">Section 34.2.7</a> . |
| 3-0  | Reserved | 0           | Reserved                                                                                                                                                                                                                                                                                                                                        |

### 34.3.10 HC Current Control Register (HCCONTROLCURRENTED)

The HC current control register (HCCONTROLCURRENTED) defines the physical address of the next endpoint descriptor (ED) on the control ED list. HCCONTROLCURRENTED is shown in [Figure 34-11](#) and described in [Table 34-11](#).

**Figure 34-11. HC Current Control Register (HCCONTROLCURRENTED)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-11. HC Current Control Register (HCCONTROLCURRENTED) Field Descriptions**

| Bit  | Field    | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|----------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | CCED     | 0-FFF FFFFh | Physical address of the current ED on the control ED list. This field represents bits 31-4 of the physical address of the next ED on the control ED list. EDs are assumed to begin on a 16-byte aligned address, so bits 3-0 of this pointer are assumed to be 0. For the restrictions on physical addresses, see <a href="#">Section 34.2.7</a> .<br><br>A value of 0 indicates that the USB1.1 host controller has reached the end of the control ED list without finding any transfers to process. This register is automatically updated by the USB1.1 host controller. |
| 3-0  | Reserved | 0           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 34.3.11 HC Head Bulk Register (HCBULKHEADED)

The HC head bulk register (HCBULKHEADED) defines the physical address of the head endpoint descriptor (ED) on the bulk ED list. HCBULKHEADED is shown in [Figure 34-12](#) and described in [Table 34-12](#).

**Figure 34-12. HC Head Bulk Register (HCBULKHEADED)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-12. HC Head Bulk Register (HCBULKHEADED) Field Descriptions**

| Bit  | Field    | Value       | Description                                                                                                                                                                                                                                                                                                                               |
|------|----------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | BHED     | 0-FFF FFFFh | Physical address of the head ED on the bulk ED list. This field represents bits 31-4 of the physical address of the head ED on the bulk ED list. EDs are assumed to begin on a 16-byte aligned address, so bits 3-0 of this pointer are assumed to be 0. For the restrictions on physical addresses, see <a href="#">Section 34.2.7</a> . |
| 3-0  | Reserved | 0           | Reserved                                                                                                                                                                                                                                                                                                                                  |

### 34.3.12 HC Current Bulk Register (HCBULKCURRENTED)

The HC current bulk register (HCBULKCURRENTED) defines the physical address of the next endpoint descriptor (ED) on the bulk ED list. HCBULKCURRENTED is shown in [Figure 34-13](#) and described in [Table 34-13](#).

**Figure 34-13. HC Current Bulk Register (HCBULKCURRENTED)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-13. HC Current Bulk Register (HCBULKCURRENTED) Field Descriptions**

| Bit  | Field    | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | BCED     | 0-FFF FFFFh | Physical address of the current ED on the bulk ED list. This field represents bits 31-4 of the physical address of the next ED on the bulk ED list. EDs are assumed to begin on a 16-byte aligned address, so bits 3-0 of this pointer are assumed to be 0. For the restrictions on physical addresses, see <a href="#">Section 34.2.7</a> .<br><br>A value of 0 indicates that the USB1.1 host controller has reached the end of the bulk ED list without finding any transfers to process. This register is automatically updated by the USB1.1 host controller. |
| 3-0  | Reserved | 0           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 34.3.13 HC Head Done Register (HCDONEHEAD)

The HC head done register (HCDONEHEAD) defines the physical address of the current head of the done TD queue. HCDONEHEAD is shown in [Figure 34-14](#) and described in [Table 34-14](#).

**Figure 34-14. HC Head Done Register (HCDONEHEAD)**

LEGEND: R = Read only; -n = value after reset

**Table 34-14. HC Head Done Register (HCDONEHEAD) Field Descriptions**

| Bit  | Field    | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | DH       | 0-FFF FFFFh | Physical address of the last TD that has added to the done queue. This field represents bits 31-4 of the physical address of the top TD on the done TD queue. TDs are assumed to begin on a 16-byte aligned address, so bits 3-0 of this pointer are assumed to be 0.<br>A value of 0 indicates that there are no TDs on the done queue. This register is automatically updated by the USB1.1 host controller. |
| 3-0  | Reserved | 0           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                       |

### 34.3.14 HC Frame Interval Register (HCFMINTERVAL)

The HC frame interval register (HCFMINTERVAL) defines the number of 12-MHz clock pulses in each USB frame. HCFMINTERVAL is shown in [Figure 34-15](#) and described in [Table 34-15](#).

**Figure 34-15. HC Frame Interval Register (HCFMINTERVAL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 34-15. HC Frame Interval Register (HCFMINTERVAL) Field Descriptions**

| Bit   | Field         | Value   | Description                                                                                                                                                                                                                                            |
|-------|---------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | FIT           | 0-1     | Frame interval toggle. The host controller driver must toggle this bit any time it changes the frame interval field.                                                                                                                                   |
| 30-16 | FSMPS         | 0-7FFFh | Largest data packet. Largest data packet size allowed for full-speed packets, in bit times.                                                                                                                                                            |
| 15-14 | Reserved      | 0       | Reserved                                                                                                                                                                                                                                               |
| 13-0  | FRAMEINTERVAL | 0-3FFFh | Frame interval. Number of 12-MHz clocks in the USB frame. Nominally, this is set to 11,999 (2EDFh) to give a 1-ms frame. The host controller driver can make minor changes to this field to attempt to manually synchronize with another clock source. |

### 34.3.15 HC Frame Remaining Register (HCFMREMAINING)

The HC frame remaining register (HCFMREMAINING) reports the number of full-speed bit times remaining in the current frame. HCFMREMAINING is shown in [Figure 34-16](#) and described in [Table 34-16](#).

**Figure 34-16. HC Frame Remaining Register (HCFMREMAINING)**

|          |    |          |    |

**Table 34-16. HC Frame Remaining Register (HCFMREMAINING) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                   |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | FRT      | 0-1     | Frame remaining toggle. This bit is loaded with the frame interval toggle bit every time the USB1.1 host controller loads the frame interval field into the frame remaining field.                                                            |
| 30-14 | Reserved | 0       | Reserved                                                                                                                                                                                                                                      |
| 13-0  | FR       | 0-3FFFh | Frame remaining. The number of full-speed bit times remaining in the current frame. This field is automatically reloaded with the frame interval (FI) value in the HC frame interval register (HCFMINTERVAL) at the beginning of every frame. |

### 34.3.16 HC Frame Number Register (HCFMNUMBER)

The HC frame number register (HCFMNUMBER) reports the current USB frame number. HCFMNUMBER is shown in [Figure 34-17](#) and described in [Table 34-17](#).

**Figure 34-17. HC Frame Number Register (HCFMNUMBER)**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 15-0  | FN       | 0-FFFFh | Frame number. This field reports the current USB frame number. It is incremented when the frame remaining field is reloaded with the frame interval (FI) value in the HC frame interval register (HCFMINTERVAL). Frame number automatically rolls over from FFFFh to 0. After frame number is incremented, its new value is written to the HCCA and the USB1.1 host controller sets the SOF interrupt status bit and begins processing the ED lists. |

### 34.3.17 HC Periodic Start Register (HCPERIODICSTART)

The HC periodic start register (HCPERIODICSTART) defines the position within the USB frame where endpoint descriptors (EDs) on the periodic list have priority over EDs on the bulk and control lists. HCPERIODICSTART is shown in [Figure 34-18](#) and described in [Table 34-18](#).

Figure 34-18. HC Periodic Start Register (HCPERIODICSTART)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Table 34-18. HC Periodic Start Register (HCPERIODICSTART) Field Descriptions

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                 |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-14 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                    |
| 13-0  | PS       | 0-3FFFh | Periodic start. The host controller driver must program this value to be about 10% less than the frame interval (FI) value in the HC frame interval register (HCFMINTERVAL), so that control and bulk EDs have priority for the first 10% of the frame; then periodic EDs have priority for the remaining 90% of the frame. |

### 34.3.18 HC Low-Speed Threshold Register (HCLSTHRESHOLD)

The HC low-speed threshold register (HCLSTHRESHOLD) defines the latest time in a frame that the USB1.1 host controller can begin a low-speed packet. HCLSTHRESHOLD is shown in [Figure 34-19](#) and described in [Table 34-19](#).

**Figure 34-19. HC Low-Speed Threshold Register (HCLSTHRESHOLD)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 34-19. HC Low-Speed Threshold Register (HCLSTHRESHOLD) Field Descriptions

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-14 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 13-0  | LST      | 0-3FFFh | <p>Low-speed threshold. This field defines the number of full-speed bit times in the frame after which the USB1.1 host controller cannot start an 8-byte low-speed packet. The USB1.1 host controller only begins a low-speed transaction if the frame remaining (FR) value in the HC frame remaining register (HCFMREMAINING) is greater than the low-speed threshold.</p> <p>The host controller driver must set this field to a value that ensures that an 8-byte low-speed TD completes before the end of the frame. When set, the host controller driver must not change the value.</p> |

### 34.3.19 HC Root Hub A Register (HCRHDESCRIPTORA)

The HC root hub A register (HCRHDESCRIPTORA) defines several aspects of the USB1.1 host controller root hub functionality. HCRHDESCRIPTORA is shown in [Figure 34-20](#) and described in [Table 34-20](#).

**Figure 34-20. HC Root Hub A Register (HCRHDESCRIPTORA)**

| 31-24 | POTPG    | 0-FFh | Power-on to power-good time. Defines the minimum amount of time (2 ms × POTPG) between the USB1.1 host controller turning on power to a downstream port and when the USB1.1 host can access the downstream device. This field has no effect on USB1.1 host controller operation. After turning on power to a port, the USB1.1 host controller driver must delay the amount of time implied by POTPG before attempting to reset an attached downstream device. The required amount of time is implementation-specific and must be calculated based on the amount of time the VBUS supply takes to provide valid VBUS to a worst-case downstream USB function controller. The implementation-specific value must be computed and then written to this register before the USB1.1 host controller driver is initialized. Because the device does not provide a direct control from the USB1.1 host controller to switch VBUS on and off, this value must take into account any delays caused by other methods of controlling VBUS externally. This field has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding. |

| 12    | NOCP     | 1     | No overcurrent protection. Because the device does not provide signals to allow connection of external overcurrent indication signals to the USB1.1 host controller, this bit defaults to 1 that indicates that the USB1.1 host controller does not implement overcurrent protection inputs. This bit has no relationship to the OTG controller register bits that relate to VBUS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 11    | OCPM     | 0     | Overcurrent protection mode. Because the device does not provide host controller overcurrent protection input signals, this bit has no effect. This bit has no relationship to the OTG controller register bits that relate to VBUS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 10    | DT       | 0     | Device type. This bit is always 0, which indicates that the USB1.1 host controller implemented is not a compound device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 9     | NPS      | 1     | No power switching. Because the device does not provide connections from the USB1.1 host controller to control external VBUS switching, this bit defaults to 1 that indicates that VBUS power switching is not supported and that power is available to all downstream ports when the USB1.1 host controller is powered. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 8     | PSM      | 0     | Power switching mode. Because the device does not provide signals from the USB1.1 host controller to control external VBUS switching, this bit defaults to 0 that indicates that all ports are powered at the same time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7-0   | NDP      | 0-FFh | Number of downstream ports. The USB signal multiplexing mode and top-level pin multiplexing features can place the device in a mode where 0, 1, 2, or 3 of the USB1.1 host controller downstream ports are usable. This register reports three ports, regardless of USB signal multiplexing mode and top-level pin multiplexing mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 34.3.20 HC Root Hub B Register (HCRHDESCRIPTORB)

The HC root hub B register (HCRHDESCRIPTORB) defines several aspects of the USB1.1 host controller root hub functionality. HCRHDESCRIPTORB is shown in [Figure 34-21](#) and described in [Table 34-21](#).

**NOTE:** The device does not provide connections from the USB1.1 host controller to pins to provide external port power switching. Systems that implement port power switching must use other mechanisms to control port power.

**Table 34-21. HC Root Hub B Register (HCRHDESCRIPTORB) Field Descriptions**

| Bit   | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | PPCM[15-4] | 0      | Port power control mask. PPCM[15] through PPCM[4] are reserved.                                                                                                                                                                                                                                                                                                                                                  |
| 19    | PPCM[3]    | 0<br>1 | Port power control mask. PPCM[3] is the port power control mask for downstream port 3. Defines whether downstream port 3 has port power controlled by the global power control. System software can update these bits to simplify host controller driver and/or OTG driver coding.<br>Global power control is implemented for downstream port 3.<br>Per-port power control is implemented for downstream port 3. |
| 18    | PPCM[2]    | 0<br>1 | Port power control mask. PPCM[2] is the port power control mask for downstream port 2. Defines whether downstream port 2 has port power controlled by the global power control. System software can update these bits to simplify host controller driver and/or OTG driver coding.<br>Global power control is implemented for downstream port 2.<br>Per-port power control is implemented for downstream port 2. |
| 17    | PPCM[1]    | 0<br>1 | Port power control mask. PPCM[1] is the port power control mask for downstream port 1. Defines whether downstream port 1 has port power controlled by the global power control. System software can update these bits to simplify host controller driver and/or OTG driver coding.<br>Global power control is implemented for downstream port 1.<br>Per-port power control is implemented for downstream port 1. |
| 16    | PPCM[0]    | 0      | Port power control mask. PPCM[0] is reserved.                                                                                                                                                                                                                                                                                                                                                                    |
| 15-4  | DR[15-4]   | 0      | Device removable. DR[15] through DR[4] are reserved.                                                                                                                                                                                                                                                                                                                                                             |
| 3     | DR[3]      | 0<br>1 | Device removable. DR[3] is the device removable bit for downstream port 3. Defines whether downstream port 3 has a removable or nonremovable device.<br>Downstream port 3 may have a removable device attached.<br>Downstream port 3 has a nonremovable device attached.                                                                                                                                         |
| 2     | DR[2]      | 0<br>1 | Device removable. DR[2] is the device removable bit for downstream port 2. Defines whether downstream port 2 has a removable or nonremovable device.<br>Downstream port 2 may have a removable device attached.<br>Downstream port 2 has a nonremovable device attached.                                                                                                                                         |
| 1     | DR[1]      | 0<br>1 | Device removable. DR[1] is the device removable bit for downstream port 1. Defines whether downstream port 1 has a removable or nonremovable device.<br>Downstream port 1 may have a removable device attached.<br>Downstream port 1 has a nonremovable device attached.                                                                                                                                         |
| 0     | DR[0]      | 0      | Device removable. DR[0] is reserved.                                                                                                                                                                                                                                                                                                                                                                             |

### 34.3.21 HC Root Hub Status Register (HCRHSTATUS)

The HC root hub status register (HCRHSTATUS) reports the USB1.1 host controller root hub status. HCRHSTATUS is shown in [Figure 34-22](#) and described in [Table 34-22](#).

**Figure 34-22. HC Root Hub Status Register (HCRHSTATUS)**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | CRWE     | 0<br>1 | Clear remote wake-up enable.<br>No effect..<br>Clears the device remote wake-up enable bit.                                                                                                                                                                                                                                                                                                                                                                                                |
| 30-18 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 17    | OCIC     | 0<br>1 | Overcurrent indication change. This bit is automatically set when the overcurrent indicator bit changes. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.<br>No effect.<br>Clears this bit.                                                                                                                                                     |
| 16    | LPSC     | 0      | Local power status change. Because the root hub does not support the local power status feature, this bit defaults to 0 and has no effect. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.                                                                                                                                                     |
| 15    | DRWE     | 0<br>1 | Device remote wake-up enable.<br>When 1, this bit enables a connect status change event to be treated as a resume event, which causes a transition from USB suspend to USB resume state and sets the resume detected interrupt status bit. When 0, connect status change events do not cause a transition from USB suspend to USB resume state and the resume detected interrupt is not changed.<br>A write of 0 has no effect.<br>A write of 1 sets the device remote wake-up enable bit. |
| 14-2  | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 1     | OCI      | 0      | Overcurrent indicator. Because the device does not provide signals for external hardware to report overcurrent status to the USB1.1 host controller, this bit is always 0. This bit has no relationship to the OTG controller register bits that relate to VBUS.                                                                                                                                                                                                                           |
| 0     | LPS      | 0      | Local power status. Because the root hub does not support the local power status feature, this bit defaults to 0 and has no effect. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.                                                                                                                                                            |

### 34.3.22 HC Port 1 Status and Control Register (HCRHPORTSTATUS1)

The HC port 1 status and control register (HCRHPORTSTATUS1) reports and controls the state of USB1.1 host port 1. HCRHPORTSTATUS1 is shown in [Figure 34-23](#) and described in [Table 34-23](#).

| 20    | PRSC     | 0     | Port 1 reset status change. A write of 1 clears this bit; a write of 0 has no effect.<br>Port 1 port reset status bit has not changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | Port 1 port reset status bit has changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 19    | OCIC     | 0     | Port 1 overcurrent indicator change. Because the device does not provide inputs for signaling external overcurrent indication to the USB1.1 host controller, this bit is always 0. Overcurrent monitoring, if required, must be handled through some other mechanism. This bit has no relationship to the OTG controller register bits that relate to VBUS.                                                                                                                                                                                                                                                                                                   |
| 18    | PSSC     | 0     | Port 1 suspend status change. A write of 1 clears this bit; a write of 0 has no effect.<br>Port 1 port suspend status has not changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | Port 1 port suspend status has changed. Suspend status is considered to have changed only after the resume pulse, low-speed EOP, and 3-ms synchronization delays have been completed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 17    | PESC     | 0     | Port 1 enable status change. A write of 1 clears this bit; a write of 0 has no effect.<br>Port 1 port enable status has not changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|       |          | 1     | Port 1 port enable status has changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 16    | CSC      | 0     | Port 1 connect status change. If the DR[1] bit in the HC root hub B register (HCRHDESCRIPTORB) is set to 1 to indicate a nonremovable USB device on port 1, this bit is set only after a root hub reset to inform the system that the device is attached. A write of 1 clears this bit; a write of 0 has no effect.<br>Port 1 current connect status has not changed.                                                                                                                                                                                                                                                                                         |
|       |          | 1     | Port 1 current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, then this bit is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 15-10 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 9     | LSDA/CPP | 0     | Port 1 low-speed device attached/clear port power. This bit is valid only when port 1 current connect status is 1. The host controller driver can write a 1 to this bit to clear the port 1 port power status bit; a write of 0 has no effect. The USB1.1 host controller does not control external port power using OHCI mechanisms, so, if required, USB1.1 host port power must be controlled through other means. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.<br>Full-speed device is attached to port 1. |
|       |          | 1     | Low-speed device is attached to port 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 34-23. HC Port 1 Status and Control Register (HCRHPORTSTATUS1) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | PPS/SPP  | 0<br>1 | Port 1 port power status/set port power. The host controller driver can write a 1 to this bit to set the port 1 port power status bit; a write of 0 has no effect. The device does not provide signals from the USB1.1 host controller to control external port power, so if required, USB1.1 host port power control signals must be controlled through other means. Software can track the current power state using the port power status bit and other power control bits, but those bits have no direct effect on external port power control. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.<br>Port 1 power is disabled.<br>Port 1 power is enabled. |
| 7-5 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 4   | PRS/SPR  | 0<br>1 | Port 1 port reset status/set port reset. A write of 1 to this bit sets the port 1 port reset status bit and causes the USB1.1 host controller to begin signaling USB reset to port 1; a write of 0 has no effect.<br>USB reset is not being sent to port 1.<br>Port 1 is signaling the USB reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 3   | POCI/CSS | 0<br>1 | Port 1 port overcurrent indicator/clear suspend status. A write of 1 to this bit when port 1 port suspend status is 1 causes resume signaling on port 1; a write of 1 when port 1 port suspend status is 0 has no effect; a write of 0 has no effect. The device does not provide inputs for signaling external overcurrent indication to the USB1.1 host controller. Overcurrent monitoring, if required, must be handled through some other mechanism.<br>Port 1 port overcurrent condition has not occurred.<br>Port 1 port overcurrent condition has occurred.                                                                                                                                                                                                                                       |
| 2   | PSS/SPS  | 0<br>1 | Port 1 port suspend status/set port suspend. A write of 1 to this bit when port 1 current connect status is 1 sets the port 1 port suspend status bit and places port 1 in USB suspend state; a write of 1 when port 1 current connect status is 0 sets the connect status change to inform the USB1.1 host controller driver software of an attempt to suspend a disconnected device; a write of 0 has no effect. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence.<br>Port 1 is not in the USB suspend state.<br>Port 1 is in the USB suspend state or is in the resume sequence.                                                                                                                                                 |
| 1   | PES/SPE  | 0<br>1 | Port 1 port enable status/set port enable. A write of 1 to this bit when port 1 current connect status is 1 sets the port 1 port enable status bit; a write of 1 when port 1 current connect status is 0 has no effect; a write of 0 has no effect. This bit is automatically set at completion of port 1 USB reset, if it was not already set before the USB reset completed; and this bit is automatically set at the end of a USB suspend, if the port was not enabled when the USB resume completed.<br>Port 1 is disabled.<br>Port 1 is enabled.                                                                                                                                                                                                                                                    |
| 0   | CCS/CPE  | 0<br>1 | Port 1 current connection status/clear port enable. If the DR[1] bit in the HC root hub B register (HCRHDESCRIPTORB) is set to 1 to indicate a nonremovable USB device on port 1, this bit is set after a root hub reset to inform the system that the device is attached. A write of 1 clears this bit; a write of 0 has no effect.<br>No USB device is attached to port 1.<br>USB device is attached to port 1.                                                                                                                                                                                                                                                                                                                                                                                        |

### 34.3.23 HC Port 2 Status and Control Register (HCRHPORTSTATUS2)

The HC port 2 status and control register (HCRHPORTSTATUS2) reports and controls the state of USB1.1 host port 2. HCRHPORTSTATUS2 is shown in [Figure 34-24](#) and described in [Table 34-24](#).

**Figure 34-24. HC Port 2 Status and Control Register (HCRHPORTSTATUS2)**

Table 34-24. HC Port 2 Status and Control Register (HCRHPORTSTATUS2) Field Descriptions

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-21 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 20    | PRSC     | 0     | Port 2 reset status change. A write of 1 clears this bit; a write of 0 has no effect.                                                                                                                                                                                                                                                                                                                                       |
|       |          | 0     | Port 2 port reset status bit has not changed.                                                                                                                                                                                                                                                                                                                                                                               |
|       |          | 1     | Port 2 port reset status bit has changed.                                                                                                                                                                                                                                                                                                                                                                                   |
| 19    | OCIC     | 0     | Port 2 overcurrent indicator change. Because the device does not provide inputs for signaling external overcurrent indication to the USB1.1 host controller, this bit is always 0. Overcurrent monitoring, if required, must be handled through some other mechanism. This bit has no relationship to the OTG controller register bits that relate to VBUS.                                                                 |
| 18    | PSSC     | 0     | Port 2 suspend status changed. A write of 1 clears this bit; a write of 0 has no effect.                                                                                                                                                                                                                                                                                                                                    |
|       |          | 0     | Port 2 port suspend status has not changed.                                                                                                                                                                                                                                                                                                                                                                                 |
|       |          | 1     | Port 2 port suspend status has changed. Suspend status is considered to have changed only after the resume pulse, low-speed EOP, and 3-ms synchronization delays have been completed.                                                                                                                                                                                                                                       |
| 17    | PESC     | 0     | Port 2 enable status change. A write of 1 clears this bit; a write of 0 has no effect.                                                                                                                                                                                                                                                                                                                                      |
|       |          | 0     | Port 2 port enable status has not changed.                                                                                                                                                                                                                                                                                                                                                                                  |
|       |          | 1     | Port 2 port enable status has changed.                                                                                                                                                                                                                                                                                                                                                                                      |
| 16    | CSC      | 0     | Port 2 connect status change. If the DR[2] bit in the HC root hub B register (HCRHDESCRIPTORB) is set to 1 to indicate a nonremovable USB device on port 2, this bit is set only after a root hub reset to inform the system that the device is attached. A write of 1 clears this bit; a write of 0 has no effect.                                                                                                         |
|       |          | 0     | Port 2 current connect status has not changed.                                                                                                                                                                                                                                                                                                                                                                              |
|       |          | 1     | Port 2 current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, then this bit is set.                                                                                                                                                                                                              |
| 15-10 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 9     | LSDA/PPP | 0     | Port 2 low-speed device attached/clear port power. This bit indicates, when read as 1, that a low-speed device is attached to port 2. A 0 in this bit indicates a full-speed device. This bit is valid only when port 2 current connect status is 1. The USB1.1 host controller does not control external port power using OHCI mechanisms, so, if required, USB1.1 host port power must be controlled through other means. |
|       |          | 0     | A write of 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                     |
|       |          | 1     | The host controller driver can write a 1 to this bit to clear the port 2 port power status.                                                                                                                                                                                                                                                                                                                                 |

**Table 34-24. HC Port 2 Status and Control Register (HCRHPORTSTATUS2) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | PPS/SPP  | 0<br>1 | Port 2 port power status/set port power. This bit indicates, when read as 1, that the port 2 power is enabled. When read as 0, port 2 power is not enabled. The device does not provide signals from the USB1.1 host controller to control external port power, so, if required, USB1.1 host port power control signals must be controlled through other means. Software can track the current power state using the port power status bit and other power control bits, but those bits have no direct effect on external port power control. This bit has no relationship to the OTG controller register bits that relate to VBUS. System software can update this register to simplify host controller driver and/or OTG driver coding.<br>A write of 0 has no effect.<br>A write of 1 to this bit sets the port 2 port power status bit. |
| 7-5 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4   | PRS/SPR  | 0<br>1 | Port 2 port reset status/set port reset. When read as 1, indicates that port 2 is sending a USB reset. When read as 0, USB reset is not being sent to port 2.<br>A write of 0 to this bit has no effect.<br>A write of 1 to this bit sets the port 2 port reset status bit and causes the USB1.1 host controller to begin signaling USB reset to port 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3   | POCI/CSS | 0<br>1 | Port 2 port overcurrent indicator/clear suspend status. When read as 1, indicates that a port 2 port overcurrent condition has occurred. When 0, no port 2 port overcurrent condition has occurred. The device does not provide inputs for signaling external overcurrent indication to the USB1.1 host controller. Overcurrent monitoring, if required, must be handled through some other mechanism. This bit has no relationship to the OTG controller register bits that relate to VBUS.<br>A write of 0 has no effect.<br>A write of 1 to this bit when port 2 port suspend status is 1 causes resume signaling on port 2. A write of 1 when port 2 port suspend status is 0 has no effect.                                                                                                                                            |
| 2   | PSS/SPS  | 0<br>1 | Port 2 port suspend status/set port suspend. When read as 1, indicates that port 2 is in the USB suspend state, or is in the resume sequence. When 0, indicates that port 2 is not in the USB suspend state. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence.<br>A write of 0 to this bit has no effect.<br>If port 2 current connect status is 1, a write of 1 to this bit sets the port 2 port suspend status bit and places port 2 in USB suspend state. If current connect status is 0, a write of 1 instead sets connect status change to inform the USB1.1 host controller driver software of an attempt to suspend a disconnected device.                                                                                                                      |
| 1   | PES/SPE  | 0<br>1 | Port 2 port enable status/set port enable. When read as 1, indicates that port 2 is enabled. When read as 0, this bit indicates that port 2 is not enabled. This bit is automatically set at completion of port 2 USB reset if it was not already set before the USB reset completed and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed.<br>A write of 0 has no effect.<br>A write of 1 to this bit when port 2 current connect status is 1 sets the port 2 port enable status bit. A write of 1 when port 2 current connect status is 0 has no effect.                                                                                                                                                                                                                         |
| 0   | CCS/CPE  | 0<br>1 | Port 2 current connection status/clear port enable. When read as 1, indicates that port 2 currently has a USB device attached. When 0, indicates that no USB device is attached to port 2. This bit is set to 1 after root hub reset if the HCRHDESCRIPTORB.DR[2] bit is set to indicate a non-removable device on port 2.<br>A write of 0 to this bit has no effect.<br>A write of 1 to this bit clears the port 2 port enable bit.                                                                                                                                                                                                                                                                                                                                                                                                        |

## ***Universal Serial Bus 2.0 (USB) Controller***

This chapter describes the universal serial bus (USB) controller.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>35.1 Introduction .....</b> | <b>1624</b> |
| <b>35.2 Architecture .....</b> | <b>1625</b> |
| <b>35.3 Use Cases.....</b>     | <b>1692</b> |
| <b>35.4 Registers .....</b>    | <b>1704</b> |

## 35.1 Introduction

The controller complies with the USB 2.0 standard high-speed and full-speed functions and low-speed, full-speed, and high-speed limited host mode operations. It also includes support for the Session Request and Host Negotiation Protocols used in point-to-point communications, details of which are given in the USB On-The-Go supplement to the USB 2.0 specification. In addition, the four test modes for high-speed operation described in the USB 2.0 specification are supported. It also allows options that allow the USB controller to be forced into full-speed mode, high-speed mode, or host mode that may be used for debug purposes.

### 35.1.1 Purpose of the Peripheral

The USB controller provides a low-cost connectivity solution for consumer portable devices by providing a mechanism for data transfer between USB devices up to 480 Mbps. Its support for a dual-role feature allows for additional versatility supporting operation capability as a host or peripheral.

### 35.1.2 Features

The USB has the following features:

- Operating as a host, it complies with the USB 2.0 standard for high-speed (480 Mbps), full-speed (12 Mbps), and low-speed (1.5 Mbps) operations with a peripheral
- Operating as a peripheral, it complies with the USB 2.0 standard for high-speed (480 Mbps) and full-speed (12 Mbps) operation with a host.
- Supports USB extensions for Session Request (SRP) and Host Negotiation (HNP) – OTG
- Supports 4 simultaneous RX and TX endpoints, in addition to control endpoint, more devices can be supported by dynamically switching endpoints states
- Each endpoint (other than endpoint 0) can support all transfer types (control, bulk, interrupt, and isochronous)
- Includes a 4K endpoint FIFO RAM, and supports programmable FIFO sizes
- External 5V power supply for VBUS, when operating as host, enabled directly by the USB controller through a dedicated signal
- Includes a DMA controller that supports 4 TX and 4 RX DMA channels
- Includes four types of Communications Port Programming Interface (CPPI) 4.1 DMA compliant transfer modes, Transparent, Generic RNDIS, RNDIS, and Linux CDC mode of DMA for accelerating RNDIS type protocols using short packet termination over USB.
- DMA supports single data transfer size up to 4Mbytes

### 35.1.3 Functional Block Diagram

The USB functional block diagram is shown in [Figure 35-1](#).

**Figure 35-1. Functional Block Diagram**

### 35.1.4 Industry Standard(s) Compliance Statement

This device conforms to USB 2.0 Specification.

## 35.2 Architecture

### 35.2.1 Clock Control

Figure 35-2 shows the clock connections for the USB2.0 module. Note that there is no built-in oscillator. The USB2.0 subsystem requires a reference clock for its internal PLL. This reference clock can be sourced from either the USB\_REFCLKIN pin or from the AUXCLK of the system PLL. The reference clock input to the USB2.0 subsystem is selected by programming the USB0PHYCLKMUX bit in the chip configuration 2 register (CFGCHIP2) of the System Configuration Module. The USB\_REFCLKIN source should be selected when it is not possible (such as when specific audio rates are required) to operate the device at one of the allowed input frequencies to the USB2.0 subsystem. The USB2.0 subsystem peripheral bus clock is sourced from SYSCLK2. Table 35-1 determines the source origination as well as the source input frequency to the USB 2.0 PHY. Once the clock source origination (internal/external) and its frequency is determined, the firmware should program the PHY PLL with the correct input frequency via CFGCHIP2.USB0REF\_FREQ (see Table 35-2).

---

**NOTE:** Prior to accessing any of the device configuration registers, including CFGCHIP2, in order to avoid inadvertent access, two Access Key Registers (KICK0R and KICK1R) should be written with key values. For more information on the device configuration registers, see your device-specific data manual.

---

**Table 35-1. USB Clock Multiplexing Options**

| CFGCHIP2.<br>USB0PHYCLKMUX<br>bit | CFGCHIP2.<br>USB1PHYCLKMUX<br>bit | USB2.0<br>Clock<br>Source | USB1.1<br>Clock<br>Source          | Additional Conditions                                                                                                                                                                           |
|-----------------------------------|-----------------------------------|---------------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                 | 0                                 | USB_REFCLKIN              | CLK48MHz output<br>from USB2.0 PHY | USB_REFCLKIN must be 12, 24, 48, 19.2, 38.4, 13, 26, 20, or 40 MHz. The PLL inside the USB2.0 PHY can be configured to accept any of these input clock frequencies.                             |
| 0                                 | 1                                 | USB_REFCLKIN              | USB_REFCLKIN                       | USB_REFCLKIN must be 48 MHz. The PLL inside the USB2.0 PHY can be configured to accept this input clock frequency.                                                                              |
| 1                                 | 0                                 | PLL0_AUXCLK               | CLK48MHz output<br>from USB2.0 PHY | PLL0_AUXCLK must be 12, 24, 48, 19.2, 38.4, 13, 26, 20, or 40 MHz. The PLL inside the USB2.0 PHY can be configured to accept any of these input clock frequencies.                              |
| 1                                 | 1                                 | PLL0_AUXCLK               | USB_REFCLKIN                       | PLL0_AUXCLK must be 12, 24, 48, 19.2, 38.4, 13, 26, 20, or 40 MHz. The PLL inside the USB2.0 PHY can be configured to accept any of these input clock frequencies. USB_REFCLKIN must be 48 MHz. |

**Table 35-2. PHY PLL Clock Frequencies Supported**

| CFGCHIP2.USB0REF_FREQ bit | Frequency |
|---------------------------|-----------|
| 1h                        | 12.0 MHz  |
| 2h                        | 24.0 MHz  |
| 3h                        | 48.0 MHz  |
| 4h                        | 19.2 MHz  |
| 5h                        | 38.4 MHz  |
| 6h                        | 13.0 MHz  |
| 7h                        | 26.0 MHz  |
| 8h                        | 20.0 MHz  |
| 9h                        | 40.0 MHz  |

### 35.2.2 Signal Descriptions

The USB controller provides the I/O signals listed in [Table 35-3](#).

**Table 35-3. USB Terminal Functions**

| Name         | I/O <sup>(1)</sup> | Description                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB0_DP      | A I/O/Z            | USB0 D+ (differential signal pair)                                                                                                                                                                                                                                                                                                                                           |
| USB0_DM      | A I/O/Z            | USB0 D- (differential signal pair)                                                                                                                                                                                                                                                                                                                                           |
| USB0_ID      | A I/O              | USB0 operating mode identification pin. For OTG mode or device only mode of operation, do NOT connect the USB0_ID pin, that is, leave the pin floating. For host only mode of operation, connect the USB0_ID pin to ground via a 0 ohm resistor or connect the pin directly to ground.                                                                                       |
| USB0_VBUS    | A I/O/Z            | 5 volt input that signifies that VBUS is connected. The OTG section of the PHY can also pull-up/pull-down on this signal for HNP and SRP. For device or host only mode of operation, pull-up this pin to 5V. For host mode of operation, also pull-up the USB power signal on the USB connector to 5V. For mixed host/device mode of operation, tie this to the charge pump. |
| USB0_DRVVBUS | I/O/Z              | Digital output to control external 5-V supply                                                                                                                                                                                                                                                                                                                                |
| USB0_VDDA33  | I/O/Z              | USB0 PHY 3.3V supply                                                                                                                                                                                                                                                                                                                                                         |
| USB0_VDDA18  | I/O/Z              | USB0 PHY 1.8V supply input                                                                                                                                                                                                                                                                                                                                                   |
| USB_REFCLKIN | I/O/Z              | External clock input for USB PHY                                                                                                                                                                                                                                                                                                                                             |
| USB0_VDDA12  | I/O/Z              | USB PHY 1.2V LD0 output for bypass CAP                                                                                                                                                                                                                                                                                                                                       |

<sup>(1)</sup> A = Analog signal; I = Input; O = Output; Z = High impedance

### 35.2.3 Indexed and Non-Indexed Registers

The USB controller provides two mechanisms of accessing the endpoint control and status registers:

- Indexed Endpoint Control/Status Registers: These registers are memory-mapped at offset 410h to 41Fh. The endpoint is selected by programming the INDEX register of the controller.
- Non-indexed Endpoint Control/Status Registers: These registers are memory-mapped at offset 500h to 54Fh. Registers at offset 500h to 50Fh map to Endpoint 0; at offset 510h to 51Fh map to Endpoint 1, and so on.

For detailed information about the USB controller registers, see [Section 35.4](#).

### 35.2.4 USB PHY Initialization

Two boot configuration registers, pin multiplexing control registers, and chip configuration 2 register (CFGCHIP2) are used to configure the multiplexed pins for USB 2.0 uses. See the *System Configuration (SYSCFG) Module* chapter for more information on the pin multiplexing control registers and CFGCHIP2.

The general procedure for USB PHY initialization starts by releasing the PHY from reset and programming the corresponding bits within the pin multiplexing control registers and CFGCHIP2, for achieving the multiplexed pins for the use of the USB2.0. Next, configuring PHY input clock related information and other PHY general configuration attributes.

When the USB2.0 controller assumes the role of a host, it is tasked to source the required 5V supply via USB0\_VBUS (must be at least  $\geq 4.75V$ ) pin. The USB2.0 controller makes use of an external charge pump or logic by enabling and disabling the external power logic from the USB2.0 controller core level. It uses the USB0\_DRVVBUS for controlling the enable/disable state of the external power logic. In order to achieve this task, the pin multiplexing control registers should be configured accordingly to map the USB0\_DRVVBUS pin to be used for USB2.0 purposes. In addition, the source (internal or external) and frequency of the PHY clock should be identified and should be configured by the firmware. This is achieved using CFGCHIP2. Other PHY related fields within CFGCHIP2 should be programmed as: USB0PHYPWDN and USB0OTGPWRDN should be cleared to 0 and USB0DATPOL, USB0SESNDEN, and USB0VBDTCEN should be set to 1. This will configure the PHY for normal operation as well as also turn on the PHYs VBUS comparator logic. The final task is to turn on the PHY PLL and wait until it locks. You should wait for the PHY clock good status to be set prior to ending the PHY initialization process.

### 35.2.5 VBUS Voltage Sourcing Control

When the USB controller assumes the role of a host, it is required to supply 5V power to an attached device through its VBUS line. In order to achieve this task, the USB controller requires the use of an external logic (or charge pump) capable of sourcing 5V power. A USB\_DRVVBUS is used as a control signal to enable/disable the external logic to either source or disable power on the VBUS line. This control is automatic and is handled by the controller. The USB controller drives the USB\_DRVVBUS signal high when it assumes the role of a host while the controller is in Session. When assuming the role of a device, the controller drives the USB\_DRVVBUS signal low disabling the external charge pump; hence, no power is driven on the VBUS line.

### 35.2.6 Dynamic FIFO Sizing

The USB controller supports a total of 4K RAM to dynamically allocate FIFO to all endpoints. The allocation of FIFO space to the different endpoints requires the specification for each Tx and Rx endpoint of:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required.

These details are specified through four registers, which are added to the indexed area of the memory map. That is, the registers for the desired endpoint are accessed after programming the INDEX register with the desired endpoint value. [Section 35.4.55](#), [Section 35.4.56](#), [Section 35.4.57](#), and [Section 35.4.58](#) provide details of these registers.

---

**NOTE:** The option of dynamically setting FIFO sizes only applies to Endpoints 1-4. The Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location (start address 0).

It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints that are active in the current USB configuration have a block of RAM assigned exclusively to that endpoint. The RAM must be at least as large as the maximum packet size set for that endpoint.

---

### 35.2.7 USB Controller Host and Peripheral Modes Operation

The USB controller can be used in a range of different environments. It can be used as either a high-speed or a full-speed USB peripheral device attached to a conventional USB host (such as a PC). It can be used as either a host or a peripheral device in a point-to-point type of setup/arrangement or it can be used as a host connecting to a range of peripheral devices in a multi-point setup (that is, using a hub).

The USB2.0 controller role adaptation of a host or peripheral (device) is dependent upon the state of the USB0\_ID pin on its mini-AB receptacle. If the USB0\_ID pin state is not driven by the connector or is left floating, the USB2.0 controller would assume the role of a peripheral; if the USB0\_ID pin state is driven low or is grounded, the USB2.0 controller would assume the role of a host. The state of the USB ID pin is controlled by the type of USB plug attached to the mini-AB connector. A mini/micro-B plug (peripheral) would leave the USB0\_ID pin floating and a mini/micro-A plug (host) grounds the USB0\_ID pin low. The procedure for the USB2.0 controller determining its operating modes (role of a host or a peripheral) starts when the USB 2.0 controller is in session. The USB 2.0 controller is in session when either it senses a voltage on the USB0\_VBUS pin or when the firmware sets the DEVCTL[SESSION] bit.

Usually, the firmware sets the SESSION bit, when it assumes that it will be operating as a host. When the SESSION bit is set, the controller will start sensing the state of the USB0\_ID pin. If the USB0\_ID pin has been grounded low, then the USB2.0 controller will assume the role of a host; however, if the USB0\_ID pin is left floating, then the USB2.0 controller will assume the role of a device. Upon determining its role as a host, it will drive the USB0\_DRVVBUS pin high to enable the external power logic so that it start sourcing the required 5V power (must be  $\geq 4.75V$ ). The USB2.0 controller will then wait for the voltage of the USB0\_VBUS goes high. If it does not see the power on the USB0\_VBUS pin greater than Vbus Valid (4.4V), it will generate an interrupt to the user indicating the existence of a problem. Assuming that the voltage level of the USB0\_VBUS is found to be above Vbus Valid, then the USB 2.0 controller will wait for a device to connect, that is, for it to see one of its data lines USB0\_DP/DM to be pulled high.

When assuming the role of a peripheral, assuming that the firmware has set the POWER[SOFTCONN] bit and has enabled the data lines and there is an external host sourcing power on the USB0\_VBUS line, the USB2.0 controller will transition to session when it sees power (must be greater or equal to 4.01V) on the USB0\_VBUS pin. The USB 2.0 controller will then set the SESSION bit upon detecting the power on the USB0\_VBUS line. This will force the USB2.0 controller to sense the state of the USB0\_ID pin. If the USB0\_ID pin has been left floating, it will know that it has to assume the role of a device and will enable its 1.5 kohm pull-up resistor to signify to the attached external host that it is a Full-Speed device. Note that even when operating as a High-Speed; it has to first come up as Full-Speed. The USB2.0 controller will then await for a reset signal from the host.

The USB controller interrupts the CPU on completion of the data transfer on any of the endpoints or on detecting reset, resume, suspend, connect, disconnect, or SOF on the bus.

When the CPU is interrupted with a USB interrupt, it needs to read the interrupt status register to determine the endpoints that have caused the interrupt and jump to the appropriate routine. If multiple endpoints have caused the interrupt, endpoint 0 should be serviced first, followed by the other endpoints. The suspend interrupt should be serviced last.

The flowchart in [Figure 35-3](#) describes the interrupt service routine for the USB module.

The following sections describe the programming of USB controller in Peripheral mode and Host mode. DMA operations and interrupt handler mechanisms are common to both peripheral and host mode operations and are discussed after the programming in peripheral and Host mode.

**Figure 35-3. Interrupt Service Routine Flow Chart**

### 35.2.7.1 USB Controller Peripheral Mode Operation

- *Soft connect* - After a reset, the SOFTCONN bit of POWER register (bit 6) is cleared to 0. The controller will therefore appear disconnected until the software has set the SOFTCONN bit to 1. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB.

Once the SOFTCONN bit has been set, the software can also simulate a disconnect by clearing this bit to 0.

- *Entry into suspend mode* - When operating as a peripheral device, the controller monitors activity on the bus and when no activity has occurred for 3 ms, it goes into Suspend mode. If the Suspend interrupt has been enabled, an interrupt will be generated at this time.

At this point, the controller can then be left active (and hence able to detect when Resume signaling occurs on the USB), or the application may arrange to disable the controller by stopping its clock. However, the controller will not then be able to detect Resume signaling on the USB. As a result, some external hardware will be needed to detect Resume signaling (by monitoring the DM and DP signals), so that the clock to the controller can be restarted.

- *Resume Signaling* - When resume signaling occurs on the bus, first the clock to the controller must be restarted if necessary. Then the controller will automatically exit Suspend mode. If the Resume interrupt is enabled, an interrupt will be generated.
- *Initiating a remote wakeup* - If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should write to the Power register to set the RESUME bit to 1. The software should leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0.

---

**NOTE:** No resume interrupt will be generated when the software initiates a remote wakeup.

---

- *Reset Signaling* - When reset signaling occurs on the bus, the controller performs the following actions:
  - Clears FADDR register to 0
  - Clears INDEX register to 0
  - Flushes all endpoint FIFOs
  - Clears all control/status registers
  - Generates a reset interrupt.

If the HSENA bit in the POWER register (bit 5) was set, the controller also tries to negotiate for high-speed operation.

Whether high-speed operation is selected is indicated by HSMODE bit of POWER register (bit 4).

When the application software receives a reset interrupt, it should close any open pipes and wait for bus enumeration to begin.

### 35.2.7.1.1 Control Transactions

Endpoint 0 is the main control endpoint of the core. The software is required to handle all the standard device requests that may be sent or received via endpoint 0. These are described in Universal Serial Bus Specification, Revision 2.0, Chapter 9. The protocol for these device requests involves different numbers and types of transactions per transfer. To accommodate this, the software needs to take a state machine approach to command decoding and handling.

The Standard Device Requests received by a USB peripheral device can be divided into three categories: Zero Data Requests (in which all the information is included in the command), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

This section looks at the sequence of actions that the software must perform to process these different types of device request.

---

**NOTE:** The Setup packet associated with any standard device request should include an 8-byte command. Any setup packet containing a command field of anything other than 8 bytes will be automatically rejected by the controller.

---

#### 35.2.7.1.1.1 Zero Data Requests

Zero data requests have all their information included in the 8-byte command and require no additional data to be transferred. Examples of Zero Data standard device requests are:

- SET\_FEATURE
- CLEAR\_FEATURE
- SET\_ADDRESS
- SET\_CONFIGURATION
- SET\_INTERFACE

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPkTRDY bit of PERI\_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO, decoded and the appropriate action taken.

For example, if the command is SET\_ADDRESS, the 7-bit address value contained in the command should be written to the FADDR register. The PERI\_CSR0 register should then be written to set the SERV\_RXPkTRDY bit (bit 6) (indicating that the command has been read from the FIFO) and to set the DATAEND bit (bit 3) (indicating that no further data is expected for this request). The interval between setting SERV\_RXPkTRDY bit and DATAEND bit should be very small to avoid getting a SetupEnd error condition.

When the host moves to the status stage of the request, a second endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software. The second interrupt is just a confirmation that the request completed successfully. For SET\_ADDRESS command, the address should be set in FADDR register only after the status stage interrupt is received.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI\_CSR0 register should be written to set the SERV\_RXPkTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host moves to the status stage of the request, the controller will send a STALL to tell the host that the request was not executed. A second endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI\_CSR0) will be set.

If the host sends more data after the DATAEND bit has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI\_CSR0) will be set.

---

**NOTE:** DMA is not supported for endpoint 0, so the command should be read by accessing the endpoint 0 FIFO register.

---

### 35.2.7.1.1.2 Write Requests

Write requests involve an additional packet (or packets) of data being sent from the host after the 8-byte command. An example of a Write standard device request is: SET\_DESCRIPTOR.

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI\_CSR0 will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO and decoded.

As with a zero data request, the PERI\_CSR0 register should then be written to set the SERV\_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) but in this case the DATAEND bit (bit 3) should not be set (indicating that more data is expected).

When a second endpoint 0 interrupt is received, the PERI\_CSR0 register should be read to check the endpoint status. The RXPKTRDY bit of PERI\_CSR0 should be set to indicate that a data packet has been received. The COUNT0 register should then be read to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO.

If the length of the data associated with the request (indicated by the wLength field in the command) is greater than the maximum packet size for endpoint 0, further data packets will be sent. In this case, PERI\_CSR0 should be written to set the SERV\_RXPKTRDY bit, but the DATAEND bit should not be set.

When all the expected data packets have been received, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit and to set the DATAEND bit (indicating that no more data is expected).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software, the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host sends more data, the controller will send a STALL to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

If the host sends more data after the DATAEND has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

### 35.2.7.1.1.3 Read Requests

Read requests have a packet (or packets) of data sent from the function to the host after the 8-byte command. Examples of Read Standard Device Requests are:

- GET\_CONFIGURATION
- GET\_INTERFACE
- GET\_DESCRIPTOR
- GET\_STATUS
- SYNCH\_FRAME

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI\_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO and decoded. The PERI\_CSR0 register should then be written to set the SERV\_RXPKTRDY bit (bit 6) (indicating that the command has read from the FIFO).

The data to be sent to the host should then be written to the endpoint 0 FIFO. If the data to be sent is greater than the maximum packet size for endpoint 0, only the maximum packet size should be written to the FIFO. The PERI\_CSR0 register should then be written to set the TXPKTRDY bit (bit 1) (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, another endpoint 0 interrupt will be generated and the next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, the PERI\_CSR0 register should be written to set the TXPKTRDY bit and to set the DATAEND bit (bit 3) (indicating that there is no more data after this packet).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software: the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI\_CSR0 register should be written to set the SERV\_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host requests data, the controller will send a STALL to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

If the host requests more data after DATAEND (bit 3) has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI\_CSR0 (bit 2) will be set.

### 35.2.7.1.1.4 Endpoint 0 States

When the USB controller is operating as a peripheral device, the endpoint 0 control needs three modes – IDLE, TX and RX – corresponding to the different phases of the control transfer and the states endpoint 0 enters for the different phases of the transfer (described in later sections).

The default mode on power-up or reset should be IDLE. RXPKTRDY bit of PERI\_CSR0 (bit 0) becoming set when endpoint 0 is in IDLE state indicates a new device request. Once the device request is unloaded from the FIFO, the controller decodes the descriptor to find whether there is a data phase and, if so, the direction of the data phase of the control transfer (in order to set the FIFO direction). See [Figure 35-4](#).

Depending on the direction of the data phase, endpoint 0 goes into either TX state or RX state. If there is no Data phase, endpoint 0 remains in IDLE state to accept the next device request.

The actions that the CPU needs to take at the different phases of the possible transfers (for example, loading the FIFO, setting TXPKTRDY) are indicated in [Figure 35-5](#).

---

**NOTE:** The controller changes the FIFO direction, depending on the direction of the data phase independently of the CPU.

---

**Figure 35-4. CPU Actions at Transfer Phases**

**Figure 35-5. Sequence of Transfer**

### 35.2.7.1.1.5 Endpoint 0 Service Routine

An Endpoint 0 interrupt is generated when:

- The controller sets the RXPkTRDY bit of PERI\_CSR0 (bit 0) after a valid token has been received and data has been written to the FIFO.
- The controller clears the TXPKTRDY bit of PERI\_CSR0 (bit 1) after the packet of data in the FIFO has been successfully transmitted to the host.
- The controller sets the SENTSTALL bit of PERI\_CSR0 (bit 2) after a control transaction is ended due to a protocol violation.
- The controller sets the SETUPEND bit of PERI\_CSR0 (bit 4) because a control transfer has ended before DATAEND (bit 3 of PERI\_CSR0) is set.

Whenever the endpoint 0 service routine is entered, the software must first check to see if the current control transfer has been ended due to either a STALL condition or a premature end of control transfer. If the control transfer ends due to a STALL condition, the SENTSTALL bit would be set. If the control transfer ends due to a premature end of control transfer, the SETUPEND bit would be set. In either case, the software should abort processing the current control transfer and set the state to IDLE.

Once the software has determined that the interrupt was not generated by an illegal bus state, the next action taken depends on the endpoint state. [Figure 35-6](#) shows the flow of this process.

*If endpoint 0 is in IDLE state*, the only valid reason an interrupt can be generated is as a result of the controller receiving data from the bus. The service routine must check for this by testing the RXPkTRDY bit of PERI\_CSR0 (bit 0). If this bit is set, then the controller has received a SETUP packet. This must be unloaded from the FIFO and decoded to determine the action the controller must take. Depending on the command contained within the SETUP packet, endpoint 0 will enter one of three states:

- If the command is a single packet transaction (SET\_ADDRESS, SET\_INTERFACE etc.) without any data phase, the endpoint will remain in IDLE state.
- If the command has an OUT data phase (SET\_DESCRIPTOR etc.), the endpoint will enter RX state.
- If the command has an IN data phase (GET\_DESCRIPTOR etc.), the endpoint will enter TX state.

*If the endpoint 0 is in TX state*, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The software must respond to this either by placing more data in the FIFO if the host is still expecting more data or by setting the DATAEND bit to indicate that the data phase is complete. Once the data phase of the transaction has been completed, endpoint 0 should be returned to IDLE state to await the next control transaction.

---

**NOTE:** All command transactions include a field that indicates the amount of data the host expects to receive or is going to send.

---

*If the endpoint is in RX state*, the interrupt indicates that a data packet has been received. The software must respond by unloading the received data from the FIFO. The software must then determine whether it has received all of the expected data. If it has, the software should set the DATAEND bit and return endpoint 0 to IDLE state. If more data is expected, the firmware should set the SERV\_RXPKTRDY bit of PERI\_CSR0 (bit 6) to indicate that it has read the data in the FIFO and leave the endpoint in RX state.

**Figure 35-6. Service Endpoint 0 Flow Chart**

\* By default

### 35.2.7.1.1.5.1 IDLE Mode

IDLE mode is the mode the endpoint 0 control must select at power-on or reset and is the mode to which the endpoint 0 control should return when the RX and TX modes are terminated. It is also the mode in which the SETUP phase of control transfer is handled (as outlined in [Figure 35-7](#)).

**Figure 35-7. IDLE Mode Flow Chart**

### 35.2.7.1.1.5.2 TX Mode

When the endpoint is in TX state all arriving IN tokens need to be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the TX state, this will cause a SetupEnd condition to occur as the core expects only IN tokens. See [Figure 35-8](#).

Three events can cause TX mode to be terminated before the expected amount of data has been sent:

1. The host sends an invalid token causing a SETUPEND condition (bit 4 of PERI\_CSR0 set).
2. The software sends a packet containing less than the maximum packet size for endpoint 0.
3. The software sends an empty data packet.

Until the transaction is terminated, the software simply needs to load the FIFO when it receives an interrupt that indicates a packet has been sent from the FIFO. (An interrupt is generated when TXPKTRDY is cleared.)

When the software forces the termination of a transfer (by sending a short or empty data packet), it should set the DATAEND bit of PERI\_CSR0 (bit 3) to indicate to the core that the data phase is complete and that the core should next receive an acknowledge packet.

**Figure 35-8. TX Mode Flow Chart**

### 35.2.7.1.1.5.3 RX Mode

In RX mode, all arriving data should be treated as part of a data phase until the expected amount of data has been received. If either a SETUP or an IN token is received while the endpoint is in RX state, a SetupEnd condition will occur as the controller expects only OUT tokens.

Three events can cause RX mode to be terminated before the expected amount of data has been received as shown in Figure 35-9:

1. The host sends an invalid token causing a SETUPEND condition (setting bit 4 of PERI\_CSR0).
2. The host sends a packet which contains less than the maximum packet size for endpoint 0.
3. The host sends an empty data packet.

Until the transaction is terminated, the software unloads the FIFO when it receives an interrupt that indicates new data has arrived (setting RXPkTRDY bit of PERI\_CSR0) and to clear RXPkTRDY by setting the SERV\_RXPKTRDY bit of PERI\_CSR0 (bit 6).

When the software detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it should set the DATAEND bit (bit 3 of PERI\_CSR0) to indicate to the controller that the data phase is complete and that the core should receive an acknowledge packet next.

**Figure 35-9. RX Mode Flow Chart**

#### 35.2.7.1.1.5.4 Error Handling

A control transfer may be aborted due to a protocol error on the USB, the host prematurely ending the transfer, or if the software wishes to abort the transfer (for example, because it cannot process the command).

The controller automatically detects protocol errors and sends a STALL packet to the host under the following conditions:

- The host sends more data during the OUT Data phase of a write request than was specified in the command. This condition is detected when the host sends an OUT token after the DATAEND bit (bit 3 of PERI\_CSR0) has been set.
- The host requests more data during the IN Data phase of a read request than was specified in the command. This condition is detected when the host sends an IN token after the DATAEND bit in the PERI\_CSR0 register has been set.
- The host sends more than Max Packet Size data bytes in an OUT data packet.
- The host sends a non-zero length DATA1 packet during the STATUS phase of a read request.

When the controller has sent the STALL packet, it sets the SENTSTALL bit (bit 2 of PERI\_CSR0) and generates an interrupt. When the software receives an endpoint 0 interrupt with the SENTSTALL bit set, it should abort the current transfer, clear the SENTSTALL bit, and return to the IDLE state.

If the host prematurely ends a transfer by entering the STATUS phase before all the data for the request has been transferred, or by sending a new SETUP packet before completing the current transfer, then the SETUPEND bit (bit 4 of PERI\_CSR0) will be set and an endpoint 0 interrupt generated. When the software receives an endpoint 0 interrupt with the SETUPEND bit set, it should abort the current transfer, set the SERV\_SETUPEND bit (bit 7 of PERI\_CSR0), and return to the IDLE state. If the RXPCKTRDY bit (bit 0 of PERI\_CSR0) is set this indicates that the host has sent another SETUP packet and the software should then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it should set the SENDSTALL bit (bit 5 of PERI\_CSR0). The controller will then send a STALL packet to the host, set the SENTSTALL bit (bit 2 of PERI\_CSR0) and generate an endpoint 0 interrupt.

#### 35.2.7.1.1.5.5 Additional Conditions

When working as a peripheral device, the controller automatically responds to certain conditions on the USB bus or actions by the host. The details are:

- Stall Issued to Control Transfers
  - The host sends more data during an OUT Data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an OUT token (instead of an IN token) after the software has unloaded the last OUT packet and set DataEnd.
  - The host requests more data during an IN data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an IN token (instead of an OUT token) after the software has cleared TXPKTRDY and set DataEnd in response to the ACK issued by the host to what should have been the last packet.
  - The host sends more than MaxPktSize data with an OUT data token.
  - The host sends the wrong PID for the OUT Status phase of a Control transfer.
  - The host sends more than a zero length data packet for the OUT Status phase.
- Zero Length Out Data Packets In Control Transfer
  - A zero length OUT data packet is used to indicate the end of a Control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred (i.e., after the software has set DataEnd). If, however, the host sends a zero length OUT data packet before the entire length of device request has been transferred, this signals the premature end of the transfer. In this case, the controller will automatically flush any IN token loaded by software ready for the Data phase from the FIFO and set SETUPEND bit (bit 4 of PERI\_CSR0).

### 35.2.7.1.2 Bulk Transactions

#### 35.2.7.1.2.1 Bulk IN Transactions

A Bulk IN transaction is used to transfer non-periodic data from the USB peripheral device to the host.

The following optional features are available for use with a Tx endpoint used in peripheral mode for Bulk IN transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.

##### 35.2.7.1.2.1.1 Setup

In configuring a TX endpoint for bulk transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint and the PERI\_TXCSR register should be set as shown in [Table 35-4](#) when using DMA:

**Table 35-4. PERI\_TXCSR Register Bit Configuration for Bulk IN Transactions**

| Bit Position | Bit Field Name | Configuration                                                                                         |
|--------------|----------------|-------------------------------------------------------------------------------------------------------|
| Bit 14       | ISO            | Cleared to 0 for bulk mode operation.                                                                 |
| Bit 13       | MODE           | Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint). |
| Bit 12       | DMAEN          | Set to 1 if DMA requests must be enabled.                                                             |
| Bit 11       | FRCDATATOG     | Cleared to 0 to allow normal data toggle operations.                                                  |
| Bit 10       | DMAMODE        | Set to 1 when DMA is enabled.                                                                         |

When the endpoint is first configured (following a SET\_CONFIGURATION or SET\_INTERFACE command on Endpoint 0), the lower byte of PERI\_TXCSR should be written to set the CLRDATATOG bit (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state.

Also if there are any data packets in the FIFO, indicated by the FIFONOTEMPTY bit (bit 1 of PERI\_TXCSR) being set, they should be flushed by setting the FLUSHFIFO bit (bit 3 of PERI\_TXCSR).

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

##### 35.2.7.1.2.1.2 Operation

When data is to be transferred over a Bulk IN pipe, a data packet needs to be loaded into the FIFO and the PERI\_TXCSR register written to set the TXPKTRDY bit (bit 0). When the packet has been sent, the TXPKTRDY bit will be cleared by the USB controller and an interrupt generated so that the next packet can be loaded into the FIFO. If double packet buffering is enabled, then after the first packet has been loaded and the TXPKTRDY bit set, the TXPKTRDY bit will immediately be cleared by the USB controller and an interrupt generated so that a second packet can be loaded into the FIFO. The software should operate in the same way, loading a packet when it receives an interrupt, regardless of whether double packet buffering is enabled or not.

In the general case, the packet size must not exceed the size specified by the lower 11 bits of the TXMAXP register. This part of the register defines the payload (packet size) for transfers over the USB and is required by the USB Specification to be either 8, 16, 32, 64 (Full-Speed or High-Speed) or 512 bytes (High-Speed only).

The host may determine that all the data for a transfer has been sent by knowing the total amount of data that is expected. Alternatively it may infer that all the data has been sent when it receives a packet which is smaller than the stated payload (TXMAXP[10-0]). In the latter case, if the total size of the data block is a multiple of this payload, it will be necessary for the function to send a null packet after all the data has been sent. This is done by setting TXPKTRDY when the next interrupt is received, without loading any data into the FIFO.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

### 35.2.7.1.2.1.3 Error Handling

If the software wants to shut down the Bulk IN pipe, it should set the SENDSTALL bit (bit 4 of PERI\_TXCSR). When the controller receives the next IN token, it will send a STALL to the host, set the SENTSTALL bit (bit 5 of PERI\_TXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 5 of PERI\_TXCSR) set, it should clear the SENTSTALL bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk IN pipe.

---

**NOTE:** If the host failed to receive the STALL packet for some reason, it will send another IN token, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk IN pipe. When a pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit in the PERI\_TXCSR register (bit 6).

---

### 35.2.7.1.2.2 Bulk OUT Transactions

A Bulk OUT transaction is used to transfer non-periodic data from the host to the function controller.

The following optional features are available for use with an Rx endpoint used in peripheral mode for Bulk OUT transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of the RXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

#### 35.2.7.1.2.2.1 Setup

In configuring an Rx endpoint for Bulk OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI\_RXCSR register should be set as shown in [Table 35-5](#).

**Table 35-5. PERI\_RXCSR Register Bit Configuration for Bulk OUT Transactions**

| Bit Position | Bit Field Name | Configuration                                                                                  |
|--------------|----------------|------------------------------------------------------------------------------------------------|
| Bit 14       | ISO            | Cleared to 0 to enable Bulk protocol.                                                          |
| Bit 13       | DMAEN          | Set to 1 if a DMA request is required for this endpoint.                                       |
| Bit 12       | DISNYET        | Cleared to 0 to allow normal PING flow control. This will affect only high speed transactions. |
| Bit 11       | DMAMODE        | Always clear this bit to 0.                                                                    |

When the endpoint is first configured (following a SET\_CONFIGURATION or SET\_INTERFACE command on Endpoint 0), the lower byte of PERI\_RXCSR should be written to set the CLRDATATOG bit (bit 7). This will ensure that the data toggle (which is handled automatically by the USB controller) starts in the correct state.

Also if there are any data packets in the FIFO (indicated by the RXPKTRDY bit (bit 0 of PERI\_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit (bit 4 of PERI\_RXCSR).

---

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

---

### 35.2.7.1.2.2.2 Operation

When a data packet is received by a Bulk Rx endpoint, the RXPKTRDY bit (bit 0 of PERI\_RXCSR) is set and an interrupt is generated. The software should read the RXCOUNT register for the endpoint to determine the size of the data packet. The data packet should be read from the FIFO, then the RXPKTRDY bit should be cleared.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host). When a block of data larger than wMaxPacketSize needs to be sent to the function, it will be sent as multiple packets. All the packets will be wMaxPacketSize in size, except the last packet which will contain the residue. The software may use an application specific method of determining the total size of the block and hence when the last packet has been received. Alternatively it may infer that the entire block has been received when it receives a packet which is less than wMaxPacketSize in size. (If the total size of the data block is a multiple of wMaxPacketSize, a null data packet will be sent after the data to signify that the transfer is complete.)

In the general case, the application software will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

### 35.2.7.1.2.2.3 Error Handling

If the software wants to shut down the Bulk OUT pipe, it should set the SENDSTALL bit (bit 5 of PERI\_RXCSR). When the controller receives the next packet it will send a STALL to the host, set the SENTSTALL bit (bit 6 of PERI\_RXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 6 of PERI\_RXCSR) set, it should clear this bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk OUT pipe.

---

**NOTE:** If the host failed to receive the STALL packet for some reason, it will send another packet, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk OUT pipe. When a Bulk OUT pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit (bit 7) in the PERI\_RXCSR register.

---

### 35.2.7.1.3 Peripheral Mode: Interrupt Transactions

An Interrupt IN transaction uses the same protocol as a Bulk IN transaction and can be used the same way. Similarly, an Interrupt OUT transaction uses almost the same protocol as a Bulk OUT transaction and can be used the same way.

Tx endpoints in the USB controller have one feature for Interrupt IN transactions that they do not support in Bulk IN transactions. In Interrupt IN transactions, the endpoints support continuous toggle of the data toggle bit.

This feature is enabled by setting the FRCDATATOG bit in the PERI\_TXCSR register (bit 11). When this bit is set, the controller will consider the packet as having been successfully sent and toggle the data bit for the endpoint, regardless of whether an ACK was received from the host.

Another difference is that interrupt endpoints do not support PING flow control. This means that the controller should never respond with a NYET handshake, only ACK/NAK/STALL. To ensure this, the DISNYET bit in the PERI\_RXCSR register (bit 12) should be set to disable the transmission of NYET handshakes in high-speed mode.

Though DMA can be used with an interrupt OUT endpoint, it generally offers little benefit as interrupt endpoints are usually expected to transfer all their data in a single packet.

### 35.2.7.1.4 Isochronous Transactions

#### 35.2.7.1.4.1 Peripheral Mode: Isochronous IN Transactions

An Isochronous IN transaction is used to transfer periodic data from the function controller to the host.

The following optional features are available for use with a Tx endpoint used in Peripheral mode for Isochronous IN transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

---

**NOTE:** Double packet buffering is generally advisable for Isochronous transactions in order to avoid Underrun errors as described in later section.

---

- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI\_TXCSR register needs to be accessed following every packet to check for Underrun errors.

When DMA is enabled and DMAMODE bit of PERI\_TXCSR is set, endpoint interrupt will not be generated for completion of packet transfer. Endpoint interrupt will be generated only in the error conditions.

#### 35.2.7.1.4.1.1 Setup

In configuring a Tx endpoint for Isochronous IN transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint) and the PERI\_TXCSR register should be set as shown in [Table 35-6](#).

**Table 35-6. PERI\_TXCSR Register Bit Configuration for Isochronous IN Transactions**

| Bit Position | Bit Field Name | Configuration                                                                                      |
|--------------|----------------|----------------------------------------------------------------------------------------------------|
| Bit 14       | ISO            | Set to 1 to enable Isochronous transfer protocol.                                                  |
| Bit 13       | MODE           | Set to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint). |
| Bit 12       | DMAEN          | Set to 1 if DMA Requests have to be enabled.                                                       |
| Bit 11       | FRCDATATOG     | Ignored in Isochronous mode.                                                                       |
| Bit 10       | DMAMODE        | Set to 1 when DMA is enabled.                                                                      |

### 35.2.7.1.4.1.2 Operation

An Isochronous endpoint does not support data retries, so if data underrun is to be avoided, the data to be sent to the host must be loaded into the FIFO before the IN token is received. The host will send one IN token per frame (or microframe in High-speed mode), however the timing within the frame (or microframe) can vary. If an IN token is received near the end of one frame and then at the start of the next frame, there will be little time to reload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is sent to the host and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the PERI\_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame(/microframe) before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using either the SOF interrupt or the external SOF\_PULSE signal from the controller to trigger the loading of the next data packet. The SOF\_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF\_PULSE when the SOF packet has been lost.) The interrupts may still be used to set the TXPKTRDY bit in PERI\_TXCSR (bit 0) and to check for data overruns/underruns.

Starting up a double-buffered Isochronous IN pipe can be a source of problems. Double buffering requires that a data packet is not transmitted until the frame(/microframe) after it is loaded. There is no problem if the function loads the first data packet at least a frame(/microframe) before the host sets up the pipe (and therefore starts sending IN tokens). But if the host has already started sending IN tokens by the time the first packet is loaded, the packet may be transmitted in the same frame(/microframe) as it is loaded, depending on whether it is loaded before, or after, the IN token is received. This potential problem can be avoided by setting the ISOUPDATE bit in the POWER register (bit 7). When this bit is set, any data packet loaded into an Isochronous Tx endpoint FIFO will not be transmitted until after the next SOF packet has been received, thereby ensuring that the data packet is not sent too early.

### 35.2.7.1.4.1.3 Error Handling

If the endpoint has no data in its FIFO when an IN token is received, it will send a null data packet to the host and set the UNDERRUN bit in the PERI\_TXCSR register (bit 2). This is an indication that the software is not supplying data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the software is loading one packet per frame(/microframe) and it finds that the TXPKTRDY bit in the PERI\_TXCSR register (bit 0) is set when it wants to load the next packet, this indicates that a data packet has not been sent (perhaps because an IN token from the host was corrupted). It is up to the application how it handles this condition: it may choose to flush the unsent packet by setting the FLUSHFIFO bit in the PERI\_TXCSR register (bit 3), or it may choose to skip the current packet.

### 35.2.7.1.4.2 Peripheral Mode: Isochronous OUT Transactions

An Isochronous OUT transaction is used to transfer periodic data from the host to the function controller.

Following optional features are available for use with an Rx endpoint used in Peripheral mode for Isochronous OUT transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).

**NOTE:** Double packet buffering is generally advisable for Isochronous transactions in order to avoid Overrun errors.

- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI\_RXCSR register needs to be accessed following every packet to check for Overrun or CRC errors.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

#### 35.2.7.1.4.2.1 Setup

In configuring an Rx endpoint for Isochronous OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI\_RXCSR register should be set as shown in [Table 35-7](#).

**Table 35-7. PERI\_RXCSR Register Bit Configuration for Isochronous OUT Transactions**

| Bit Position | Bit Field Name | Configuration                                            |
|--------------|----------------|----------------------------------------------------------|
| Bit 14       | ISO            | Set to 1 to enable isochronous protocol.                 |
| Bit 13       | DMAEN          | Set to 1 if a DMA request is required for this endpoint. |
| Bit 12       | DISNYET        | Ignored in isochronous transfers.                        |
| Bit 11       | DMAMODE        | Always clear this bit to 0.                              |

#### 35.2.7.1.4.2.2 Operation

An Isochronous endpoint does not support data retries so, if a data overrun is to be avoided, there must be space in the FIFO to accept a packet when it is received. The host will send one packet per frame (or microframe in High-speed mode); however, the time within the frame can vary. If a packet is received near the end of one frame(/microframe) and another arrives at the start of the next frame, there will be little time to unload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is received from the host and the software may use this interrupt to unload the packet from the FIFO and clear the RXPKTRDY bit in the PERI\_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame(/microframe) before unloading the FIFO. This can be done by using either the SOF interrupt or the external SOF\_PULSE signal from the controller to trigger the unloading of the data packet. The SOF\_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF\_PULSE when the SOF packet has been lost.) The interrupts may still be used to clear the RXPKTRDY bit in PERI\_RXCSR and to check for data overruns/underruns.

### 35.2.7.1.4.2.3 Error Handling

If there is no space in the FIFO to store a packet when it is received from the host, the **OVERRUN** bit in the **PERI\_RXCSR** register (bit 2) will be set. This is an indication that the software is not unloading data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the controller finds that a received packet has a CRC error, it will still store the packet in the FIFO and set the **RXPkTRDY** bit (bit 0 of **PERI\_RXCSR**) and the **DATAERROR** bit (bit 3 of **PERI\_RXCSR**). It is left up to the application how this error condition is handled.

### 35.2.7.2 USB Controller Host Mode Operation

- *Entry into Suspend mode.* When operating as a host, the controller can be prompted to enter Suspend mode by setting the **SUSPENDM** bit in the **POWER** register. When this bit is set, the controller will complete the current transaction then stop the transaction scheduler and frame counter. No further transactions will be started and no SOF packets will be generated. If the **ENSUSPM** bit (bit 0 of **POWER** register) is set, **PHY** will go into low-power mode when the controller enters Suspend mode.
- *Sending Resume Signaling.* When the application requires the controller to leave Suspend mode, it must clear the **SUSPENDM** bit in the **POWER** register (bit 1), set the **RESUME** bit (bit 2) and leave it set for 20ms. While the **RESUME** bit is high, the controller will generate Resume signaling on the bus. After 20 ms, the application should clear the Resume bit, at which point the frame counter and transaction scheduler will be started.
- *Responding to Remote Wake-up.* If Resume signaling is detected from the target while the controller is in Suspend mode, the **PHY** will be brought out of low-power mode. The controller will then exit Suspend mode and automatically set the **RESUME** bit in the **POWER** register (bit 2) to take over generating the Resume signaling from the target. If the Resume interrupt is enabled, an interrupt will be generated.
- *Reset Signaling.* If the **RESET** bit in the **POWER** register (bit 3) is set while the controller is in Host mode, it will generate Reset signaling on the bus. If the **HSENAB** bit in the **POWER** register (bit 5) was set, it will also try to negotiate for high-speed operation. The software should keep the **RESET** bit set for at least 20 ms to ensure correct resetting of the target device. After the software has cleared the bit, the controller will start its frame counter and transaction scheduler. Whether high-speed operation is selected will be indicated by **HSMODE** bit of **POWER** register (bit 4).

#### 35.2.7.2.1 Control Transactions

Host Control Transactions are conducted through Endpoint 0 and the software is required to handle all the Standard Device Requests that may be sent or received via Endpoint 0 (as described in Universal Serial Bus Specification, Revision 2.0).

As for a USB peripheral device, there are three categories of Standard Device Requests to be handled: Zero Data Requests (in which all the information is included in the command), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

1. Zero Data Requests consist of a **SETUP** command followed by an **IN Status Phase**
2. Write Requests consist of a **SETUP** command, followed by an **OUT Data Phase** which is in turn followed by an **IN Status Phase**
3. Read Requests consist of a **SETUP** command, followed by an **IN Data Phase** which is in turn followed by an **OUT Status Phase**

A timeout may be set to limit the length of time for which the controller will retry a transaction which is continually **NAKed** by the target. This limit can be between 2 and 215 frames/ microframes and is set through the **HOST\_NAKLIMIT0** register. The following sections describe the CPU actions required for these different types of requests by examining the steps to take in the different Control Transaction phases.

### 35.2.7.2.1.1 Setup Phase

For the SETUP Phase of a control transaction ([Figure 35-10](#)), the software driving the USB host device needs to:

1. Load the 8 bytes of the required Device request command into the Endpoint 0 FIFO.
2. Set SETUPPKT and TXPKTRDY (bits 3 and 1 of HOST\_CSR0, respectively).

---

**NOTE:** These bits must be set together.

---

The controller then proceeds to send a SETUP token followed by the 8-byte command to Endpoint 0 of the addressed device, retrying as necessary. (On errors, controller retries the transaction three times.)

3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK\_TIMEOUT bit (bit 7) has been set.

If RXSTALL is set, it indicates that the target did not accept the command (for example, because it is not supported by the target device) and so has issued a STALL response.

If ERROR is set, it means that the controller has tried to send the SETUP Packet and the following data packet three times without getting any response.

If NAK\_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the SETUP packet, for longer than the time set in HOST\_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.

4. If none of RXSTALL, ERROR or NAK\_TIMEOUT is set, the SETUP Phase has been correctly ACKed and the software should proceed to the following IN Data Phase, OUT Data Phase or IN Status Phase specified for the particular Standard Device Request.

**Figure 35-10. Setup Phase of a Control Transaction Flow Chart**

### 35.2.7.2.1.2 IN Data Phase

For the IN Data Phase of a control transaction ([Figure 35-11](#)), the software driving the USB host device needs to:

1. Set REQPKT bit of HOST\_CSR0 (bit 5).
2. Wait while the controller sends the IN token and receives the required data back.
3. When the controller generates the Endpoint 0 interrupt, read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK\_TIMEOUT bit (bit 7) or RXPBKTRDY bit (bit 0) has been set.

If RXSTALL is set, it indicates that the target has issued a STALL response.

If ERROR is set, it means that the controller has tried to send the required IN token three times without getting any response.

If NAK\_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in HOST\_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by clearing REQPKT before clearing the NAK\_TIMEOUT bit.

4. If RXPBKTRDY has been set, the software should read the data from the Endpoint 0 FIFO, then clear RXPBKTRDY.
5. If further data is expected, the software should repeat Steps 1-4.

When all the data has been successfully received, the CPU should proceed to the OUT Status Phase of the Control Transaction.

**Figure 35-11. IN Data Phase Flow Chart**

### 35.2.7.2.1.3 OUT Data Phase

For the OUT Data Phase of a control transaction ([Figure 35-12](#)), the software driving the USB host device needs to:

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the TXPKTRDY bit of HOST\_CSR0 (bit 1). The controller then proceeds to send an OUT token followed by the data from the FIFO to Endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK\_TIMEOUT bit (bit 7) has been set.

If RXSTALL bit is set, it indicates that the target has issued a STALL response.

If ERROR bit is set, it means that the controller has tried to send the OUT token and the following data packet three times without getting any response.

If NAK\_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the HOST\_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.

If none of RXSTALL, ERROR or NAKLIMIT is set, the OUT data has been correctly ACKed.

4. If further data needs to be sent, the software should repeat Steps 1-3.

When all the data has been successfully sent, the software should proceed to the IN Status Phase of the Control Transaction.

**Figure 35-12. OUT Data Phase Flow Chart**

#### 35.2.7.2.1.4 IN Status Phase (following SETUP Phase or OUT Data Phase)

For the IN Status Phase of a control transaction (Figure 35-13), the software driving the USB Host device needs to:

1. Set the STATUSPKT and REQPKT bits of HOST\_CSR0 (bit 6 and bit 5, respectively).
2. Wait while the controller sends an IN token and receives a response from the USB peripheral device.
3. When the controller generates the Endpoint 0 interrupt, read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK\_TIMEOUT bit (bit 7) or RXPkTRDY bit (bit 0) has been set.

If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.

If ERROR bit is set, it means that the controller has tried to send the required IN token three times without getting any response.

If NAK\_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST\_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by clearing REQPKT bit and STATUSPKT bit before clearing the NAK\_TIMEOUT bit.

4. If RxPktRdy has been set, the CPU should simply clear RxPktRdy.

**Figure 35-13. Completion of SETUP or OUT Data Phase Flow Chart**

### 35.2.7.2.1.5 OUT Status Phase (following IN Data Phase)

For the OUT Status Phase of a control transaction (Figure 35-14), the CPU driving the host device needs to:

1. Set STATUSPKT and TXPKTRDY bits of HOST\_CSR0 (bit 6 and bit 1, respectively).

---

**NOTE:** These bits need to be set together.

---

2. Wait while the controller sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST\_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK\_TIMEOUT bit (bit 7) has been set.  
If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.  
If ERROR bit is set, it means that the controller has tried to send the STATUS Packet and the following data packet three times without getting any response.  
If NAK\_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST\_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK\_TIMEOUT bits is set, the STATUS Phase has been correctly ACKed.

**Figure 35-14. Completion of IN Data Phase Flow Chart**

### 35.2.7.2.2 Bulk Transactions

#### 35.2.7.2.2.1 Bulk IN Transactions

A Bulk IN transaction may be used to transfer non-periodic data from the external USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in host mode to receive the data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

- AutoRequest: When the AutoRequest feature is enabled, the REQPKT bit of HOST\_RXCSR (bit 5) will be automatically set when the RXPKT RDY bit is cleared.

This feature is applicable only when DMA is enabled. To enable AutoRequest feature, set the AUTOREQ register for the DMA channel associated for the endpoint.

##### 35.2.7.2.2.1.1 Setup

Before initiating any Bulk IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint. (RXFUNCADDR register is available for all endpoints from EP0 to EP4.)
- The HOST\_RXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 10 (binary value) in the PROT field for bulk transfer.
  - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_RXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or set to zero if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_RXCSR register should be set as:
  - Set DMAEN (bit 13) to 1 if a DMA request is required for this endpoint.
  - Clear DSINYET (bit 12) to 0 to allow normal PING flow control. This will affect only High Speed transactions.
  - Always clear DMAMODE (bit 11) to 0.
- If DMA is enabled, the AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn\_AUTOREQ (where n is the endpoint number) with binary value 01 or 11.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN and DATATOG bits of HOST\_RXCSR (bit 10 and bit 9) to toggle the current setting or by setting the CLRDATATOG bit of HOST\_RXCSR (bit 7). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also if there are any data packets in the FIFO (indicated by the RXPKT RDY bit (bit 0 of HOST\_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit of HOST\_RXCSR (bit 4).

---

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

---

#### **35.2.7.2.2.1.2 Operation**

When Bulk data is required from the USB peripheral device, the software should set the REQPKT bit in the corresponding HOST\_RXCSR register (bit 5). The controller will then send an IN token to the selected peripheral endpoint and waits for data to be returned.

If data is correctly received, RXPkTRDY bit of HOST\_RXCSR (bit 0) is set. If the USB peripheral device responds with a STALL, RXSTALL bit (bit 6 of HOST\_RXCSR) is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the POLINTVL\_NAKLIMIT set in the HOST\_RXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting the ERROR bit of HOST\_RXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST\_RXCSR register to determine whether the RXPkTRDY, RXSTALL, ERROR or DATAERR\_NAKTIMEOUT bit is set and act accordingly. If the DATAERR\_NAKTIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the DATAERR\_NAKTIMEOUT bit or to abort the transaction by clearing REQPKT bit before clearing the DATAERR\_NAKTIMEOUT bit.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host).

In the general case, the application software will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

#### **35.2.7.2.2.1.3 Error Handling**

If the target wants to shut down the Bulk IN pipe, it will send a STALL response to the IN token. This will result in the RXSTALL bit of HOST\_RXCSR (bit 6) being set.

### 35.2.7.2.2.2 Host Mode: Bulk OUT Transactions

A Bulk OUT transaction may be used to transfer non-periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.

When DMA is enabled and DMAMODE bit in HOST\_TXCSR register is set, an endpoint interrupt will not be generated for completion of packet reception. An endpoint interrupt will be generated only in the error conditions.

#### 35.2.7.2.2.2.1 Setup

Before initiating any bulk OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint. (TXFUNCADDR register is available for all endpoints from EP0 to EP4.)
- The HOST\_TXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 10b in the PROT field for bulk transfer.
  - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_TXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or set to zero if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_TXCSR register should be set as:
  - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
  - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint.
  - Clear the FRCDATATOG bit (bit 11) to 0 to allow normal data toggle operations.
  - Set the DMAMODE bit (bit 10) to 1 when DMA is enabled.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN bit and DATATOG bit of HOST\_TXCSR (bit 9 and bit 8) to toggle the current setting or by setting the CLRDATATOG bit of HOST\_TXCSR (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also, if there are any data packets in the FIFO (indicated by the FIFONOTEMPTY bit of HOST\_TXCSR register (bit 1) being set), they should be flushed by setting the FLUSHFIFO bit (bit 3 of HOST\_TXCSR).

---

**NOTE:** It may be necessary to set this bit twice in succession if double buffering is enabled.

---

#### **35.2.7.2.2.2 Operation**

When Bulk data is required to be sent to the USB peripheral device, the software should write the first packet of the data to the FIFO (or two packets if double-buffered) and set the TXPKTRDY bit in the corresponding HOST\_TXCSR register (bit 0). The controller will then send an OUT token to the selected peripheral endpoint, followed by the first data packet from the FIFO.

If data is correctly received by the peripheral device, an ACK should be received whereupon the controller will clear TXPKTRDY bit of HOST\_TXCSR (bit 0). If the USB peripheral device responds with a STALL, the RXSTALL bit (bit 5) of HOST\_TXCSR is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the NAK limit set in the HOST\_TXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting ERROR bit in HOST\_TXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST\_TXCSR register to determine whether the RXSTALL (bit 5), ERROR (bit 2) or NAK\_TIMEOUT (bit 7) bit is set and act accordingly. If the NAK\_TIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT bit.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

#### **35.2.7.2.2.3 Error Handling**

If the target wants to shut down the Bulk OUT pipe, it will send a STALL response. This is indicated by the RXSTALL bit of HOST\_TXCSR register (bit 5) being set.

#### **35.2.7.2.3 Interrupt Transactions**

When the controller is operating as the host, interactions with an Interrupt endpoint on the USB peripheral device are handled in very much the same way as the equivalent Bulk transactions (described in previous sections).

The principal difference as far as operational steps are concerned is that the PROT field of HOST\_RXTYPE and HOST\_TXTYPE (bits 5-4) need to be set (binary value) to represent an Interrupt transaction. The required polling interval also needs to be set in the HOST\_RXINTERVAL and HOST\_TXINTERVAL registers.

### 35.2.7.2.4 Isochronous Transactions

#### 35.2.7.2.4.1 Isochronous IN Transactions

An Isochronous IN transaction is used to transfer periodic data from the USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in Host mode to receive this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention. However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

- AutoRequest: When the AutoRequest feature is enabled, the REQPKT bit of HOST\_RXCSR (bit 5) will be automatically set when the RXPKT RDY bit is cleared.

This feature is applicable only when DMA is enabled. To enable AutoRequest feature, set the AUTOREQ register for the DMA channel associated for the endpoint.

##### 35.2.7.2.4.1.1 Setup

Before initiating an Isochronous IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint (RXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST\_RXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 01 (binary value) in the PROT field for isochronous transfer.
  - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_RXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_RXCSR register should be set as:
  - Set the DMAEN bit (bit 13) to 1 if a DMA request is required for this endpoint.
  - Clear the DISNYET it (bit 12) to 0 to allow normal PING flow control. This will only affect High Speed transactions.
  - Always clear the DMAMODE bit (bit 11) to 0.
- If DMA is enabled, AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn\_AUTOREQ (where *n* is the endpoint number) with binary value 01 or 11.

##### 35.2.7.2.4.1.2 Operation

The operation starts with the software setting REQPKT bit of HOST\_RXCSR (bit 5). This causes the controller to send an IN token to the target.

When a packet is received, an interrupt is generated which the software may use to unload the packet from the FIFO and clear the RXPkTRDY bit in the HOST\_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame before unloading the FIFO. This can be done by using the SOF\_PULSE signal from the controller to trigger the unloading of the data packet. The SOF\_PULSE is generated once per frame(/microframe). The interrupts may still be used to clear the RXPkTRDY bit in HOST\_RXCSR.

#### 35.2.7.2.4.1.3 Error Handling

If a CRC or bit-stuff error occurs during the reception of a packet, the packet will still be stored in the FIFO but the DATAERR\_NAKTIMEOUT bit of HOST\_RXCSR (bit 3) is set to indicate that the data may be corrupt.

#### 35.2.7.2.4.2 Isochronous OUT Transactions

An Isochronous OUT transaction may be used to transfer periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

When DMA is enabled and DMAMODE bit in HOST\_TXCSR register is set, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

##### 35.2.7.2.4.2.1 Setup

Before initiating any Isochronous OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint (TXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST\_TXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 01 (binary value) in the PROT field for isochronous transfer.
  - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST\_TXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST\_TXCSR register should be set as:
  - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
  - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint.
  - The FRCDATATOG bit (bit 12) is ignored for isochronous transactions.

- Set the DMAMODE bit (bit 10) to 1 when DMA is enabled.

### 35.2.7.2.4.2.2 Operation

The operation starts when the software writes to the FIFO and sets TXPKTRDY bit of HOST\_TXCSR (bit 0). This triggers the controller to send an OUT token followed by the first data packet from the FIFO.

An interrupt is generated whenever a packet is sent and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the HOST\_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame, depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using the SOF\_PULSE signal from the controller to trigger the loading of the next data packet. The SOF\_PULSE is generated once per frame(/microframe). The interrupts may still be used to set the TXPKTRDY bit in HOST\_TXCSR.

## 35.2.8 Communications Port Programming Interface (CPPI) 4.1 DMA Overview

The CPPI DMA module supports the transmission and reception of USB packets. The CPPI DMA is designed to facilitate the segmentation and reassembly of CPPI compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each networking port. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be effectively performed in parallel (but not actually simultaneously). The DMA controller maintains state information for each of the ports/channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

The CPPI (version 4.1) DMA controller sub-module is a common 4 dual-port DMA controller. It supports 4 Tx and 4 Rx Ports and each port attaches to the associated endpoint in the controller. Port 1 maps to endpoint 1 and Port 2 maps to endpoint 2 and Port 3 maps to endpoint 3 and Port 4 maps to endpoint 4, while endpoint 0 can not utilize the DMA and the firmware is responsible to load or offload the endpoint 0 FIFO via CPU.

Figure 35-15 displays the USB controller block diagram.

Figure 35-15. USB Controller Block Diagram

- Host**— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.
- Main Memory**— The area of data storage managed by the CPU. The CPPI DMA (CDMA) reads and writes CPPI packets from and to main memory. This memory can exist internal or external from the device.
- Queue Manager (QM)**— The QM is responsible for accelerating management of a variety of Packet Queues and Free Descriptor / Buffer Queues. It provides status indications to the CDMA Scheduler when queues are empty or full.
- CPPI DMA (CDMA)**— The CDMA is responsible for transferring data between the CPPI FIFO and Main Memory. It acquires free Buffer Descriptor from the QM (Receive Submit Queue) for storage of received data, posts received packets pointers to the Receive Completion Queue, transmits packets stored on the Transmit Submit Queue (Transmit Queue) , and posts completed transmit packets to the Transmit Completion Queue.
- CDMA Scheduler (CDMAS)**— The CDMAS is responsible for scheduling CDMA transmit and receive operations. It uses Queue Indicators from the QM and the CDMA to determine the types of operations to schedule.
- CPPI FIFO**— The CPPI FIFO provides 8 FIFO interfaces (one for each of the 4 transmit and receive endpoints). Each FIFO contains two 64-byte memory storage elements (ping-pong buffer storage).
- Transfer DMA (XDMA)**— The XDMA receives DMA requests from the Mentor USB 2.0 Core and initiates DMAs to the CPPI FIFO.
- Endpoint FIFOs**— The Endpoint FIFOs are the USB packet storage elements used by the Mentor USB 2.0 Core for packet transmission or reception. The XDMA transfers data between the CPPI FIFO and the Endpoint FIFOs for transmit operations and between the Endpoint FIFOs and the CPPI FIFO for receive operations.
- Mentor USB 2.0 Core**— This controller is responsible for processing USB bus transfers (control, bulk, interrupt, and isochronous). It supports 4 transmit and 4 receive endpoints in addition to endpoint 0 (control).

### 35.2.8.1 CPPI Terminology

The following terms are important in the discussion of DMA CPPI.

- Port**— A port is the communications module (peripheral hardware) that contains the control logic for Direct Memory Access for a single transmit/receive interface or set of interfaces. Each port may have multiple communication channels that transfer data using homogenous or heterogeneous protocols. A port is usually subdivided into transmit and receive pairs which are independent of each other. Each endpoint, excluding endpoint 0, has its own dedicated port.
- Channel**— A channel refers to the sub-division of information (flows) that is transported across ports. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (example: CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). All four ports have dedicated single channels, channel 0, associated for their use in a USB application.
- Data Buffer**— A data buffer is a single data structure that contains payload information for transmission to or reception from a port. A data buffer is a byte aligned contiguous block of memory used to store packet payload data. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 32-bit memory space. The Buffer Length field of the packet descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.
- Host Buffer Descriptor**— A buffer descriptor is a single data structure that contains information about one or more data buffers. This type of descriptor is required when more than one descriptor is needed to define an entire packet, i.e., it either defines the middle of a packet or end of a packet.

**Host Packet Descriptor**— A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. This type of descriptor is always used to define a packet since it provides packet level information that is useful to both the ports and the Host in order to properly process the packet. It is the only descriptor used when single descriptor solely defines a packet. When multiple descriptors are needed to define a packet, the packet descriptor is the first descriptor used to define a packet.

**Free Descriptor/Buffer Queue**— A free descriptor/buffer queue is a hardware managed list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Queue Manager.

**Teardown Descriptor**— Teardown Descriptor is a special structure which is not used to describe either a packet or a buffer but is instead used to describe the completion of a channel halt and teardown event. Channel teardown is an important function because it ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the Host without the possibility of losing buffer or descriptor references (which results in a memory leak).

**Packet Queue**— A packet queue is hardware managed list of valid (i.e. populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes.

**Queue Manager**— The queue manager is a hardware module that is responsible for accelerating management of the packet queues. Packets are added to a packet queue by writing the 32-bit descriptor address to a particular memory mapped location in the Queue Manager module. Packets are de-queued by reading the same location for that particular queue. A single Queue Manager is used for a USB application.

---

**NOTE:** All descriptors (regardless of type) must be allocated at addresses that are naturally aligned to the smallest power of 2 that is equal to or greater than the descriptor size.

---

### 35.2.8.2 Host Packet Descriptor (SOP Descriptor)

Host Packet Descriptors are designed to be used when USB like application requires support for true, unlimited fragment count scatter/gather type operations. The Host Packet Descriptor is the first descriptor on multiple descriptors setup or the only descriptor in a single descriptors setup. The Host Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Host Packet Descriptor (always 10h)
- Source and Destination Tags (Reserved)
- Packet Type
- Packet Length
- Protocol Specific Region Size
- Protocol Specific Control/Status Bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet

Host Packet Descriptors can vary in size of their defined fields from 32 bytes up to 104 bytes. Within this range, Host Packet Descriptors always contain 32 bytes of required information and may also contain 8 bytes of software specific tagging information and up to 64 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent.

The Host Packet Descriptor layout is shown in [Figure 35-16](#) and described in [Table 35-8](#) to [Table 35-15](#).

**Figure 35-16. Host Packet Descriptor Layout**

**Table 35-8. Host Packet Descriptor Word 0 (HPD Word 0)**

| Bits  | Name                               | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Descriptor Type                    | The Host Packet Descriptor Type is 16 decimal (10h). The CPU initializes this field.                                                                                                                                                                                                                                                                                                  |
| 26-22 | Protocol Specific Valid Word Count | This field indicates the valid number of 32-bit words in the protocol specific region. The CPU initializes this field. This is encoded in increments of 4 bytes as:<br>0 = 0 byte<br>1 = 4 bytes<br>...<br>16 = 64 bytes<br>17-31 = Reserved                                                                                                                                          |
| 21-0  | Packet Length                      | The length of the packet in bytes. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is an error. The valid range for the packet length is 0 to (4M - 1) bytes. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-9. Host Packet Descriptor Word 1 (HPD Word 1)**

| Bits  | Name                      | Description                                                                                                                                                                                       |
|-------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Source Tag: Port #        | This field indicates the port number (0-31) from which the packet originated. The DMA overwrites this field on packet reception. This is the RX Endpoint number from which the packet originated. |
| 26-21 | Source Tag: Channel #     | This field indicates the channel number within the port from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0-67.                           |
| 20-16 | Source Tag: Sub-channel # | This field indicates the sub-channel number (0-31) within the channel from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0.                |
| 15-0  | Destination Tag           | This field is application specific. This field is always 0.                                                                                                                                       |

**Table 35-10. Host Packet Descriptor Word 2 (HPD Word 2)**

| Bits  | Name                         | Description                                                                                                                                                                                                                                                                                                                                                         |
|-------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | Packet Error                 | This bit indicates if an error occurred during reception of this packet (0 = No error occurred, 1 = Error occurred). The DMA overwrites this field on packet reception. Additional information about different errors may be encoded in the protocol specific fields in the descriptor.                                                                             |
| 30-26 | Packet Type                  | This field indicates the type of this packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. This field is encoded as:<br>5 = USB<br>8-31 = Reserved                                                                                                                                                    |
| 25-20 | Reserved                     | Reserved                                                                                                                                                                                                                                                                                                                                                            |
| 19    | Zero-length packet indicator | If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit is set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller. |
| 18-16 | Protocol Specific            | This field contains protocol specific flags/information that can be assigned based on the packet type. Not used for USB.                                                                                                                                                                                                                                            |
| 15    | Return Policy                | This field indicates the return policy for this packet. The CPU initializes this field.<br>0 = Entire packet (still linked together) should be returned to the queue specified in bits 13-0.<br>1 = Each buffer should be returned to the queue specified in bits 13-0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.   |
| 14    | On-chip                      | This field indicates whether or not this descriptor is in a region which is in on-chip memory space (1) or in external memory (0).                                                                                                                                                                                                                                  |
| 13-12 | Packet Return Queue Mgr #    | This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU. There is only 1 Queue Manager in the USB HS/FS Device Controller, this field must always be 0.                                      |
| 11-0  | Packet Return Queue #        | This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.                                                                                                               |

**Table 35-11. Host Packet Descriptor Word 3 (HPD Word 3)**

| Bits  | Name            | Description                                                                                                                                                                               |
|-------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22 | Reserved        | Reserved                                                                                                                                                                                  |
| 21-0  | Buffer 0 Length | The Buffer Length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-12. Host Packet Descriptor Word 4 (HPD Word 4)**

| Bits | Name             | Description                                                                                                                                                                                                           |
|------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | Buffer 0 Pointer | The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-13. Host Packet Descriptor Word 5 (HPD Word 5)**

| Bits | Name                    | Description                                                                                                                                                                                                                                                                                    |
|------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | Next Descriptor Pointer | The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current buffer is the last buffer in the packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-14. Host Packet Descriptor Word 6 (HPD Word 6)**

| Bits  | Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22 | Reserved                 | Reserved                                                                                                                                                                                                                                                                                                                                                                                                |
| 21-0  | Original Buffer 0 Length | The Buffer Length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information. |

**Table 35-15. Host Packet Descriptor Word 7 (HPD Word 7)**

| Bits  | Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22 | Reserved                  | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 21-0  | Original Buffer 0 Pointer | The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. |

### 35.2.8.3 Host Buffer Descriptor (Non-SOP Descriptor)

The Host Buffer Descriptor is identical in size and organization to a Host Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. The packet level fields is not needed since the SOP descriptor contain this information and additional copy of this data is not needed/necessary.

Host Buffer Descriptors are designed to be linked onto a Host Packet Descriptor or another Host Buffer Descriptor to provide support for unlimited scatter / gather type operations. Host Buffer Descriptors provide information about a single corresponding data buffer. Every Host buffer descriptor stores the following information:

- Pointer to the first valid byte in the data buffer
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Host Buffer Descriptors always contain 32 bytes of required information. Since it is a requirement that it is possible to convert a Host descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Host Buffer Descriptors will be allocated using the same sizes as Host Packet Descriptors. In addition, since the 5 LSBs of the Descriptor Pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is always 32 bytes. (For more information on Descriptor Size, see [Section 35.4.87](#)).

The Host Buffer Descriptor layout is shown in [Figure 35-17](#) and described in [Table 35-16](#) to [Table 35-23](#).

**Figure 35-17. Host Buffer Descriptor Layout**

| 31-0 | Reserved | Reserved    |

**Table 35-18. Host Buffer Descriptor Word 2 (HBD Word 2)**

| Bits  | Name                      | Description                                                                                                                                                                                                                                                                                                                    |
|-------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-15 | Reserved                  | Reserved                                                                                                                                                                                                                                                                                                                       |
| 14    | On-chip                   | This field indicates whether or not this descriptor is in a region which is in on-chip memory space (1) or in external memory (0).                                                                                                                                                                                             |
| 13-12 | Packet Return Queue Mgr # | This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU. There is only 1 Queue Manager in the USB HS/FS Device Controller, this field must always be 0. |
| 11-0  | Packet Return Queue #     | This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.                                                                          |

**Table 35-19. Host Buffer Descriptor Word 3 (HBD Word 3)**

| Bits  | Name            | Description                                                                                                                                                                               |
|-------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22 | Reserved        | Reserved                                                                                                                                                                                  |
| 21-0  | Buffer 0 Length | The Buffer Length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-20. Host Buffer Descriptor Word 4 (HBD Word 4)**

| Bits | Name             | Description                                                                                                                                                                                                           |
|------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | Buffer 0 Pointer | The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-21. Host Buffer Descriptor Word 5 (HBD Word 5)**

| Bits | Name                    | Description                                                                                                                                                                                                                                                                                            |
|------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | Next Descriptor Pointer | The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current descriptor is the last descriptor in the packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. |

**Table 35-22. Host Buffer Descriptor Word 6 (HBD Word 6)**

| Bits  | Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22 | Reserved                 | Reserved                                                                                                                                                                                                                                                                                                                                                                                                |
| 21-0  | Original Buffer 0 Length | The Buffer Length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information. |

**Table 35-23. Host Buffer Descriptor Word 7 (HBD Word 7)**

| Bits | Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | Original Buffer 0 Pointer | The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. |

#### 35.2.8.4 Teardown Descriptor

The Teardown Descriptor is not like the Host Packet or Buffer Descriptors since it is not used to describe either a packet or a buffer. The Teardown Descriptor is always 32 bytes long and is comprised of 4 bytes of actual teardown information and 28 bytes of pad. The Teardown Descriptor layout is shown in [Figure 35-18](#) and described in [Table 35-24](#) and [Table 35-25](#). Since the 5 LSBs of the Descriptor Pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is 32 bytes.

The Teardown Descriptor is used to describe a channel halt and teardown event. Channel teardown ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the Host without the possibility of losing buffer or descriptor references (which results in a memory leak).

The Teardown Descriptor contains the following information:

- Indicator which identifies the descriptor as a Teardown Packet Descriptor
- DMA Controller Number where teardown occurred
- Channel number within DMA where teardown occurred
- Indicator of whether this teardown was for the Tx or Rx channel

**Figure 35-18. Teardown Descriptor Layout**

**Table 35-24. Teardown Descriptor Word 0**

| Bits  | Name            | Description                                                     |
|-------|-----------------|-----------------------------------------------------------------|
| 31-27 | Descriptor Type | The teardown descriptor type is 19 decimal (13h).               |
| 26-17 | Reserved        | Reserved                                                        |
| 16    | TX_RX           | Indicates whether teardown is a TX (0) or RX (1).               |
| 15-10 | DMA Number      | Indicates the DMA number for this teardown.                     |
| 9-6   | Reserved        | Reserved                                                        |
| 5-0   | Channel Number  | Indicates the channel number within the DMA that was torn down. |

**Table 35-25. Teardown Descriptor Words 1-7**

| Bits | Name     | Description |
|------|----------|-------------|
| 31-0 | Reserved | Reserved    |

Teardown operation of an endpoint requires three operations. The teardown register in the CPPI DMA must be written, the corresponding endpoint bit in TEARDOWN of the USB module must be set, and the FlushFIFO bit in the Mentor USB controller Tx/RxCSR register must be set.

The following is the Transmit teardown procedure highlighting the steps required to be followed.

1. Set the TX\_TEARDOWN bit in the CPPI DMA TX channel *n* global configuration register (TXGCR<sub>*n*</sub>).
2. Set the appropriate TX\_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Write Tx Endpoint Number to teardown to TEARDOWN[TX\_TDOWN] field.
3. Check if the teardown descriptor has been received on the teardown queue: The completion queue (Queues 24 or 25) is usually used as the Teardown queue when the Teardown descriptor has been received, the descriptor address will be loaded onto CTRLD[24/25] register:
  - (a) If not, go to step 2.
  - (b) If so, go to step 4.
4. Set the appropriate TX\_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Set the bit corresponding to the Channel Number within TEARDOWN[TX\_TDOWN] field.
5. Flush the TX FIFO in the Mentor OTG core: Set PERI\_TXCSR[FLUSHFIFO] for the corresponding Endpoint.

6. Re-enable the Tx DMA channel:
  - (a) Clear TXGCRn[TX\_TEARDOWN and TX\_ENABLE] bit.
  - (b) Set TXGCRn[TX\_ENABLE] bit.

### 35.2.8.5 Queues

Several types of queues exist (a total of 64 queues) within the CPPI 4.1 DMA. Regardless of the type of queue a queue is, queues are used to hold pointers to host or buffer packet descriptors while they are being passed between the Host and / or any of the ports in the system. All queues are maintained within the Queue Manager module.

The following type of Queues exist:

- Receive Free Descriptor/Buffer Queue
- Receive Completion (Return) Queue
- Transmit Submit Queue (also referred as Transmit Queue)
- Transmit Completion (Return) Queue
- Free Descriptor Queue (Unassigned: Can be used for Completion or Application Specific purposes)

Table 35-26 displays the allocation (partition) of the available Queues.

**Table 35-26. Allocation of Queues**

| Starting Queue Number | Number of Queues | Function                                    |
|-----------------------|------------------|---------------------------------------------|
| 0                     | 16               | RX + Free Descriptor/Buffer (submit) queues |
| 16                    | 2                | USB Endpoint 1 TX (submit) queues           |
| 18                    | 2                | USB Endpoint 2 TX (submit) queues           |
| 20                    | 2                | USB Endpoint 3 TX (submit) queues           |
| 22                    | 2                | USB Endpoint 4 TX (submit) queues           |
| 24                    | 2                | TX Completion (return) queues               |
| 26                    | 2                | RX Completion (return) queues               |
| 28                    | 36               | Unassigned (application-defined) queues     |

#### 35.2.8.5.1 Queuing Packets

Prior to queuing packets, the host/firmware should construct data buffer as well host packet/buffer descriptors within memory that is external to the CPPI 4.1 DMA module.

Queuing of packets onto a packet queue is accomplished by writing a pointer to the Packet Descriptor into a specific address within the selected queue (Register D of Queue N). Packet is always queued onto the tail of the queue. The Queue Manager provides a unique set of addresses for adding packets for each queue that it manages.

#### 35.2.8.5.2 De-Queuing Packets

De-queuing of packets from a packet queue is accomplished by reading the head packet pointer from a specific address within the selected queue (Register D of Queue N). After the head pointer has been read, the Queue Manager will invalidate the head pointer and will replace it with the next packet pointer in the queue. This functionality which is implemented in the Queue Manager prevents the ports from needing to traverse linked lists and allows for certain optimizations to be performed within the Queue Manager.

#### 35.2.8.5.3 Type of Queues

Several types of queues exist and all are managed by the Queue Manager which is part of the CPPI 4.1 DMA. All accesses to the queues are through memory mapped registers and no external memory setup is required by the firmware.

### **35.2.8.5.3.1 Receive Free Descriptor/Buffer (Submit) Queue**

Receive ports use queues referred to as "receive free descriptor / buffer queues" to forward completed receive packets to the host or another peer port entity. The entries on the Free Descriptor / Buffer Queues have pre-attached empty buffers whose size and location are described in the "original buffer information" fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding (submitting) a descriptor to one of the available receive free descriptor / buffer queue. The first 16 queues (Queue 0 up to Queue 15) are reserved for all four receive ports to handle incoming packets.

### **35.2.8.5.3.2 Transmit (Submit) Queue**

Transmit ports use packet queues referred to as "transmit (submit) queues" to store the packets that are waiting to be transmitted. Each port has dedicated queues (2 queues per port) that are reserved exclusively for a use by a single port. Multiple queues per port/channel are allocated to facilitate Quality of Service (QoS) for applications that require QoS. Queue 16 and 17 are allocated for port 1, Queue 18 and 19 are allocated for port 2 and Queue 20 and Queue 21 are allocated for port 3 and Queue 22 and 23 are allocated for port 4.

### **35.2.8.5.3.3 Transmit Completion Queue**

Transmit ports also use packet queues referred to as "transmit completion queues" to return packets to the host after they have been transmitted. Even though, non-allocated queues can be used for this purpose, a total of two dedicated queues (Queue 24 and Queue 25), that is to be shared amongst all four transmit ports, have been reserved for returning transmit packets after end of transmit operation when the firmware desires to receive interrupt when transmission completes.

### **35.2.8.5.3.4 Receive Completion Queue**

Receive ports also use packet queues referred to as "receive completion queues" to return packets to the port after they have been received. Even though, non-allocated queues can be used for this purpose, a total of two dedicated queues (Queue 26 and Queue 27), that is to be shared amongst all four transmit ports, have been reserved for returning received packets to the receive ports after end of receive operation when the firmware desires to receive interrupt when transmission completes.

### **35.2.8.5.3.5 Unassigned (Application Defined) Queue**

Thirty-six additional queues (Queue 28 to Queue 63) exist that have not been dedicated for exclusive use. The user can use these queues as a Completion Queues or Free Descriptor/Buffer queue.

When these queues are used as Completion Queues, interrupt will not be generated. However, the queues will have the list of descriptor pointers for the packets that have completed transmission or reception. The firmware can use polling method by continually performing the de-queuing technique onto the particular unassigned queue used to identify if the reception or transmission has completed.

When unassigned queues are used as free descriptor/buffer queue, the user can use these queues to queue/store available descriptors for future receive and transmit operations by the firmware popping the respective assigned queue and retrieving and populating descriptor prior to submitting the updated descriptor.

### **35.2.8.5.3.6 Teardown Queue**

The Teardown Queue is used by the DMA to communicate a completion of a channel teardown after a channel teardown is invoked on to a channel. The pointer to the teardown descriptor is written to the teardown queue, which is also the Completion Queue, when the channel teardown completes.

### **35.2.8.5.3.7 Diverting Queue Packets from one Queue to Another**

The host can move the entire contents of one queue to another queue by writing the source queue number and the destination queue number to the Queue Diversion Register. When diverting packets, the host can choose whether the source queue contents should be pushed onto the tail of the destination queue.

### 35.2.8.6 Memory Regions and Linking RAM

In addition to allocating memory for raw data, the host is responsible for allocating additional memory for exclusive use of the CPPI DMA Queue Manager to be used as a scratch PAD RAM. The Queue Manager uses this memory to manage states of Descriptors submitted within the submit queues. In other words, this memory needs not to be managed by your software and your software responsibility is only for allocation of memory. The allocated memory can be a single block of memory that is contiguous or two blocks of memory that are not contiguous. These two blocks of memory are referred as a Linking RAM Regions and should not be confused with Memory Regions that are used to store Descriptors and the use of the term Region should be used in the context of its use.

The physical size of the Linking RAM region(s) to be allocated depends on the total number of Descriptors defined within all memory regions. A minimum of four bytes of memory needs to be allocated for each Descriptor defined within all 16 Memory Regions.

The Queue Manager has the capability of managing up to 16 Memory Regions. These Memory Regions are used to store descriptors of variable sizes. The total number of Descriptors that can be managed by the Queue Manager should not exceed 16K. Each Memory Region has Descriptors of one configurable size, that is, Descriptors with different sizes cannot be housed within a single Memory Region. These 16K Descriptors are referenced internally in the Queue Manager by a 16-bit quantity index.

The information about the Linking RAM regions and the size that are allocated is communicated to the CPPI DMA via three registers dedicated for this purpose. Two of the three registers are used to store the 32-bit aligned start addresses of the Linking RAM regions. The remaining one register is used to store the size of the first Linking RAM. The size value stored here is the number of Descriptors that is to be managed by the Queue Manager within that region not the physical size of the buffer, which is four times the number of descriptors.

Note that you are not required to use both Linking RAM Regions, if the size of the Linking RAM for the first Region is large enough to accommodate all Descriptors defined. No Linking RAM size register for Linking RAM Region 2 exists. The size of the second Linking RAM, when used, is indirectly computed from the total number of Descriptors defined less the number of Descriptors managed by the first Linking RAM.

**Figure 35-19. Relationship Between Memory Regions and Linking RAM**

### 35.2.8.7 Zero Length Packets

A special case is the handling of null packets with the CPPI 4.1 compliant DMA controller. Upon receiving a zero length USB packet, the XFER DMA will send a data block to the DMA controller with byte count of zero and the zero byte packet bit of INFO Word 2 set. The DMA controller will then perform normal End of Packet termination of the packet, without transferring data.

If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.

### 35.2.8.8 CPPI DMA Scheduler

The CPPI DMA scheduler is responsible for controlling the rate and order between the different Tx and Rx threads that are provided in the CPPI DMA controller. The scheduler table RAM exists within the scheduler.

#### 35.2.8.8.1 CPPI DMA Scheduler Initialization

Before the scheduler can be used, the host is required to initialize and enable the block. This initialization is performed as follows:

1. The Host initializes entries within an internal memory array in the scheduler. This array contains up to 256 entries (4 entries per table word  $n$ ) and each entry consists of a DMA channel number and a bit indicating if this is a Tx or Rx opportunity. These entries represent both the order and frequency that various Tx and Rx channels will be processed. A table size of 256 entries allows channel bandwidth to be allocated with a maximum precision of 1/256th of the total DMA bandwidth. The more entries that are present for a given channel, the bigger the slice of the bandwidth that channel will be given. Larger tables can be accommodated to allow for more precision. This array can only be written by the Host, it cannot be read.
2. If the application does not need to use the entire 256 entries, firmware can initialize the portion of the 256 entries and indicate the size of the entries used by writing onto an internal register in the scheduler which sets the actual size of the array (it can be less than 256 entries).
3. The host writes an internal register bit to enable the scheduler. The scheduler is not required to be disabled in order to change the scheduler array contents.

#### 35.2.8.8.2 Example of Scheduler Programming

Consider a three endpoints use on a system with the following configurations: EP1-Tx, EP2-Rx, and EP2-Tx. Two assumptions are considered:

**Case 1:** Assume that you would like to service each enabled endpoints (EP1-Tx, EP2-Rx, and EP2-Tx) with equal priority.

The scheduler handles the rate at which an endpoint is serviced by the number of credits programmed (entries) for that particular endpoint within the scheduler Table Words. The scheduler has up to 256 credits that it can grant and for this example the number of entries/credits could be anywhere from 3 to 256. However, the optimum and direct programming for this scenario would be programming only the first three entries of the scheduler via scheduler Table WORD[0]. Since this case expects the Scheduler to use only the first three entries, you communicate that by programming DMA\_SCHED\_CTRL.LAST\_ENTRY with 2 (that is, 3 - 1). The Enabled Endpoint numbers and the data transfer direction is then communicated by programming the first three entries of WORD[0] (ENTRY0\_CHANNEL = 1: ENTRY0\_RXTX = 0; ENTRY1\_CHANNEL = 2: ENTRY1\_RXTX = 1; ENTRY2\_CHANNEL = 2: ENTRY2\_RXTX = 0). With this programming, the Scheduler will only service the first three entries in a round-robin fashion, checking each credited endpoint for transfer one after the other, and servicing the endpoint that has data to transfer.

**Case 2:** Enabled endpoint EP1-Tx is serviced at twice the rate as the other enabled endpoints (EP2-Rx and EP2-Tx).

The number of entries/credit that has to be awarded to EP1-Tx has to be twice as much of the others. Since only four entries/credits are required, two for EP1-Tx, one for EP2-Rx, and one for EP2-Tx, the use of scheduler Table WORD[0] would still suffice. Even though several scenarios exist to programming the order of service for this case, one scenario would be to allow EP1-Tx to be serviced back-to-back followed by the other enabled endpoints. Program DMA\_SCHED\_CTRL.LAST\_ENTRY with 3 (that is, 4 - 1). Program WORD[0] (ENTRY0\_CHANNEL = 1: ENTRY0\_RXTX = 0; ENTRY1\_CHANNEL = 1: ENTRY1\_RXTX = 0; ENTRY2\_CHANNEL = 2: ENTRY2\_RXTX = 1; ENTRY3\_CHANNEL = 2: ENTRY3\_RXTX = 0).

### 35.2.8.8.3 Scheduler Operation

Once the scheduler is enabled it will begin processing the entries in the table and when appropriate passing credits to the DMA controller to perform a Tx or Rx operation. The operation of the DMA controller is as follows:

1. After the DMA scheduler is enabled it begins with the table index set to 0.
2. The scheduler reads the entry pointed to by the index and checks to see if the channel in question is currently in a state where a DMA operation can be accepted. The following must both be true:
  - The DMA channel must be enabled.
  - The CPPI FIFO that the channel talks to has free space on TX (FIFO full signal is not asserted) or a valid block on Rx (FIFO empty signal is not asserted).
3. If the DMA channel is capable of processing a credit to transfer a block, the DMA scheduler will issue that credit via the DMA scheduling interface. These are the steps:
  - (a) The DMA controller may not be ready to accept the credit immediately and is provided a sched\_ready signal which is used to stall the scheduler until it can accept the credit. The DMA controller only asserts the sched\_ready signal when it is in the IDLE state.
  - (b) Once a credit has been accepted (indicated by sched\_req and sched\_ready both asserted), the scheduler will increment the index to the next entry and will start at step 2.
4. If the channel in question is not currently capable of processing a credit, the scheduler will increment the index in the scheduler table to the next entry and will start at step 2.
5. When the scheduler attempts to increment its index to the value programmed in the table size register, the index will reset to 0.

### 35.2.8.9 CPPI DMA Transfer Interrupt Handling

The CPPI DMA 4.1 Interrupt handling mechanism does not go through the PDR interrupt handler built into the core. The DMA interrupt line is directly routed to the Interrupt Dispatcher in a PDR compliant manner. The DMA interrupt is not maskable. The firmware needs to use queues reserved by hardware as Completion Queues, if required for the DMA interrupt to be generated on a completion of a transfer.

Queues 24 and 25 are reserved by hardware for DMA transmit operations and queues 26 and 27 are reserved by hardware for DMA receive operations. If firmware uses these queues as Completion Queues, an interrupt will be generated when the transfer completes. If you need not to generate an interrupt, firmware is required to use queues that are not reserved as Completion Queues.

### 35.2.8.10 DMA State Registers

The port must store and maintain state information for each transmit and receive port/channel. The state information is referred to as the Tx DMA State and Rx DMA State.

#### 35.2.8.10.1 Transmit DMA State Registers

The Tx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures and transmit packets. Each transmit channel has two queues. Each queue has a one head descriptor pointer and one completion pointer. There are four Tx DMA State registers; one for each port/channel.

The following information is stored in the Tx DMA State:

- Tx Queue Head Descriptor Pointer(s)
- Tx Completion Pointer(s)
- Protocol specific control/status (port scratchpad)

#### 35.2.8.10.2 Receive DMA State Registers

The Rx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures in order to receive packets. Each receive channel has only one queue. Each channel queue has one head descriptor pointer and one completion pointer. There are four Rx DMA State registers; one for each port/channel.

The following information is stored in the Rx DMA State:

- Rx Queue Head Descriptor Pointer
- Rx Queue Completion Pointer
- Rx Buffer Offset

### 35.2.8.11 USB DMA Protocols Supported

Four different type of DMA transfers are supported by the CPPI 4.1 DMA; Transparent, RNDIS, Generic RNDIS, and Linux CDC. The following sections will outline the details on these DMA transfer types.

#### 35.2.8.11.1 Transparent DMA

Transparent Mode DMA operation is the default DMA mode where DMA interrupt is generated whenever a DMA packet is transferred. In the transparent mode, DMA packet size cannot be greater than USB MaxPktSize for the endpoint. This transfer type is ideal for transfer (not packet) sizes that are less than a max packet size.

##### Transparent DMA Transfer Setup

The following will configure all four ports/channels for Transparent DMA Transfer type.

- Make sure that RNDIS Mode is disabled globally. RNDIS bit in the control register (CTRLR) is cleared to 0.
- Configure the DMA Mode Register (MODE) for the Endpoint field in use is programmed for Transparent Mode. MODE = 0000 0000h

#### 35.2.8.11.2 RNDIS

RNDIS mode DMA is used for large transfers (i.e., total data size to be transferred is greater than USB MaxPktSize where the MzxPktSize is a multiple of 64 bytes) that requires multiple USB packets. This is accomplished by breaking the larger packet into smaller packets, where each packet size being USB MaxPktSize except the last packet where its size is less than USB MaxPktSize, including zero bytes. This implies that multiple USB packets of MaxPktSize will be received and transferred together as a single large DMA transfer and the DMA interrupt is generated only at the end of the complete reception of DMA transfer. The protocol defines the end of the complete transfer by receiving a short USB packet (smaller than USB MaxPktSize as mentioned in USB specification 2.0). If the DMA packet size is an exact multiple of USB MaxPktSize, the DMA controller waits for a zero byte packet at the end of complete transfer to signify the completion of the transfer.

---

**NOTE:** RNDIS Mode DMA is supported only when USB MaxPktSize is an integral multiple of 64 bytes.

---

##### RNDIS DMA Transfer Setup

The following will configure all four ports/channels for RNDIS DMA Transfer type. If all endpoints are to be configured with the same RNDIS DMA transfer type, then you can enable for RNDIS mode support from the Control Register and the content of the Mode Register will be ignored.

If you need to enable RNDIS support globally.

- Enable RNDIS Mode globally. RNDIS bit in the control register (CTRLR) is set to 1.

If you need to enable RNDIS support at the port/channel (endpoint) level.

- Disable RNDIS Mode globally. RNDIS bit in the control register (CTRLR) is cleared to 0.
- Configure the DMA Mode Register (MODE) for the Endpoint field in use is programmed for RNDIS Mode. MODE = 1111 1111h

The above two setups yield the same result.

### 35.2.8.11.3 Generic RNDIS

Generic RNDIS DMA transfer mode is identical to the normal RNDIS mode in nearly all respects, except for the exception case where the last packet of the transfer can either be a short packet or the MaxPktSize. Generic RNDIS transfer makes use of a RNDIS EP Size register (there exists a register for each endpoint) that must be programmed with a value that is an integer multiple of the endpoint size for the DMA to know the end of the transfer when the last packet size is equal to the USB MaxPktSize. For example, if the Tx/RxMaxP is programmed with a value of 64, the Generic RNDIS EP Size register for that endpoint must be programmed with a value that is an integer multiple of 64 (for example, 64, 128, 192, 256, etc.).

In other words, when using Generic RNDIS mode and the DMA is tasked to transfer data transfer size that is less than a value programmed within the RNDIS EP Size register and this transfer will be resulting with a short packet, the DMA will terminate the transfer when encountering the short packet behaving exactly as the RNDIS DMA transfer type.

This means that Generic RNDIS mode will perform data transfer in the same manner as RNDIS mode, closing the CPPI packet when a USB packet is received that is less than the USB MaxPktSize size. Otherwise, the packet will be closed when the value in the Generic RNDIS EP Size register is reached.

Using RNDIS EP Size register, a packet of up to 64K bytes can be transferred. This is to allow the host software to program the USB module to transfer data that is an exact multiple of the USB MaxPktSize (Tx/RxMaxP programmed value) without having to send an additional short packet to terminate.

---

**NOTE:** As in RNDIS mode, the USB max packet size of any Generic RNDIS mode enabled endpoints must be a multiple of 64 bytes. Generic RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

---

#### Generic RNDIS DMA Transfer Setup

The following will configure all four ports/channels for Generic RNDIS DMA Transfer type.

- Disable RNDIS Mode globally. RNDIS bit in the control register (CTRLR) is cleared to 0.
- Configure the DMA Mode Register (MODE) for the Endpoint field in use is programmed for Generic RNDIS Mode. MODE = 3333 3333h

### 35.2.8.11.4 Linux CDC

Linux CDC DMA transfer mode acts in the same manner as RNDIS packets, except for the case where the last data matches the max USB packet size. If the last data packet of a transfer is a short packet where the data size is greater than zero and less the USB MaxPktSize, then the behavior of the Linux CDC DMA transfer type is identical with the RNDIS DMA transfer type. The only exception is when the short packet length terminating the transfer is a Null Packet. In this case, instead of transferring the Null Packet, it will transfer a data packet of size 1 byte with the data value of 0x00.

In transmit operation, if an endpoint is configured or CDC Linux mode, upon receiving a Null Packet from the CPPI DMA, the XFER DMA will then generate a packet containing 1 byte of data, whose value is 0x00, indicating the end of the transfer. During receive operation, the XFER DMA will recognize the one byte zero packet as a termination of the data transfer, and sends a block of data with the EOP indicator set and a byte count of one to the CPPI DMA controller. The CPPI DMA realizing the end of the transfer termination will not update/increase the packet size count of the Host Packet Descriptor.

#### Linux CDC DMA Transfer Setup

The following will configure all four ports/channels for Linux CDC DMA Transfer type.

- Disable RNDIS Mode globally. RNDIS bit in the control register (CTRLR) is cleared to 0.
- Configure the DMA Mode Register (MODE) for the Endpoint field in use is programmed for Linux CDC Mode. MODE = 2222 2222h

### 35.2.8.12 USB Data Flow Using DMA

The necessary steps required to perform a USB data transfer using the CPPI 4.1 DMA is expressed using an example for both transmit and receive cases. Assume a device is ready to perform a data transfer of size 608 bytes (see [Figure 35-20](#)).

**Figure 35-20. High-Level Transmit and Receive Data Transfer Example**

Example assumptions:

- The CPPI data buffers are 256 bytes in length.
- The USB endpoint 1 Tx and Rx endpoint 1 size are 512 bytes.
- A single transfer length is 608 bytes.
- The SOP offset is 0.

This translates to the following:

- Transmit Case:
  - 1 Host Packet Descriptor with Packet Length field of 608 bytes and a Data Buffer of size 256 Bytes linked to the 1st Host Buffer Descriptor.
  - First Host Buffer Descriptor with a Data Buffer size of 256 Bytes linked to the 2nd Buffer Descriptor.
  - Second Host Buffer Descriptor with a Data Buffer size of 96 bytes (can be greater, the Packet Descriptor contain the size of the packet) linked with its link word set to Null.
- Receive Case:
  - Two Host Buffer Descriptors with 256 bytes of Data Buffer Size
  - One Host Buffer Descriptor with 96 bytes (can be greater) of Data Buffer size

Within the rest of this section, the following nomenclature is used.

**BD**— Host Buffer Descriptor

**DB**— Data Buffer Size of 256 Bytes

**PBD**— Pointer to Host Buffer Descriptor

**PD**— Host Packet Descriptor

**PPD**— Pointer to Host Packet Descriptor

**RXCQ**— Receive Completion Queue or Receive Return Queue (for all Rx EPs, use 26 or 27)

**RXSQ**— Receive Free Packet/Buffer Descriptor Queue or Receive Submit Queue. (for all Rx EPs, use 0 to 15)

**TXCQ**— Transmit Completion Queue or Transmit Return Queue (for all Tx EPs, use 24 or 25)

**TXSQ**— Transmit Queue or Transmit Submit Queue (for EP1, use 16 or 17)

### 35.2.8.12.1 Transmit USB Data Flow Using DMA

The transmit descriptors and queue status configuration prior to the transfer taking place is shown in [Figure 35-21](#). An example of initialization for a transmit USB data flow is shown in [Figure 35-22](#).

**Figure 35-21. Transmit Descriptors and Queue Status Configuration**

**Figure 35-22. Transmit USB Data Flow Example (Initialization)**

**Step 1 (Initialization for Tx):**

1. The CPU initializes Queue Manager with the Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. The CPU creates PD, BDs, and DBs in main memory and link as indicated in [Figure 35-22](#).
3. It then initializes and configures the Queue Manager, Channel Setup, DMA Scheduler, and Mentor USB 2.0 Core.
4. It then adds (pushes) the PPD and the two PBDs to the TXSQ

**NOTE:** You can create more BD/DB pairs and push them on one of the unassigned queues. The firmware can pop a BD/DP pair from this chosen queue and can create its HPD or HBDs and pre link them prior to submitting the pointers to the HPD and HBD on to the TXSQ.

**Step 2 (CDMA and XDMA transfers packet data into Endpoint FIFO for Tx):**

1. The Queue Manager informs the CDMAS that the TXSQ is not empty.
2. CDMAS checks that the CPPI FIFO FIFO\_full is not asserted, then issues a credit to the CDMA.
3. CDMA reads the packet descriptor pointer and descriptor size hint from the Queue Manager.
4. CMDA reads the packet descriptor from memory.
5. For each 64-byte block of data in the packet data payload:
  - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
  - (b) The XDMA sees FIFO\_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
  - (c) The CDMA performs the above 2 steps 3 more times since the data size of the HPD is 256 bytes.
6. The CDMA reads the first buffer descriptor pointer.
7. CDMA reads the buffer descriptor from memory.
8. For each 64-byte block of data in the packet data payload:
  - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.

- (b) The XDMA sees FIFO\_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
- (c) The CDMA performs the above 2 steps 2 more times since data size of the HBD is 256 bytes.
9. The CDMA reads the second buffer descriptor pointer.
10. CDMA reads the buffer descriptor from memory.
11. For each 64-byte block of data in the packet data payload:
  - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
  - (b) The XDMA sees FIFO\_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
  - (c) The CDMA transfers the last remaining 32-byte from the data to be transferred in main memory to the CPPI FIFO.
  - (d) The XDMA sees FIFO\_empty not asserted and transfers 32-byte block from CPPI FIFO to Endpoint FIFO.

Step 3 (Mentor USB 2.0 Core transmits USB packets for Tx):

1. Once the XDMA has transferred enough 64-byte blocks of data from the CPPI FIFO to fill the Endpoint FIFO, it signals the Mentor USB 2.0 Core that a TX packet is ready (sets the endpoint's TxPktRdy bit).
2. The Mentor USB 2.0 Core will transmit the packet from the Endpoint FIFO out on the USB BUS when it receives a corresponding IN request from the attached USB Host.
3. After the USB packet is transferred, the Mentor USB 2.0 Core issues a TX DMA\_req to the XDMA.
4. This process is repeated until the entire packet has been transmitted. The XDMA will also generate the required termination packet depending on the termination mode configured for the endpoint.

An example of the completion for a transmit USB data flow is shown in [Figure 35-23](#).

**Figure 35-23. Transmit USB Data Flow Example (Completion)**

Step 4 (Return packet to completion queue and interrupt CPU for Tx):

1. After all data for the packet has been transmitted (as specified by the packet size field), the CDMA will write the pointer to the packet descriptor to the TX Completion Queue specified in the return queue manager / queue number fields of the packet descriptor.

- The Queue Manager then indicates the status of the TXSQ (empty) to the CDMAS and the TXCQ to the CPU via an interrupt.

### 35.2.8.12.2 Receive USB Data Flow Using DMA

The receive descriptors and queue status configuration prior to the transfer taking place is shown in [Figure 35-24](#). An example of initialization for a receive USB data flow is shown in [Figure 35-25](#).

**Figure 35-24. Receive Descriptors and Queue Status Configuration**

**Figure 35-25. Receive USB Data Flow Example (Initialization)**

Step 1 (Initialization for Rx):

1. The CPU initializes Queue Manager with the Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. The CPU creates BDs, and DBs in main memory and link them as indicated in [Figure 35-25](#).
3. It then initializes the RXCQ queue and configures the Queue Manager, Channel Setup, DMA Scheduler, and Mentor USB 2.0 Core.
4. It then adds (pushes) the address of the three PHDs into the RXSQ.

Step 2 (Mentor USB 2.0 Core receives a packet, XDMA starts data transfer for Receive):

1. The Mentor USB 2.0 Core receives a USB packet from the USB Host and stores it in the Endpoint FIFO.
2. It then asserts a DMA\_req to the XDMA informing it that data is available in the Endpoint FIFO.
3. The XDMA verifies the corresponding CPPI FIFO is not full via the FIFO\_full signal, then starts transferring 64-byte data blocks from the Endpoint FIFO into the CPPI FIFO.

Step 3 (CDMA transfers data from SSRAM / PPU to main memory for Receive):

1. The CDMA sees FIFO\_empty de-asserted (there is RX data in the FIFO) and issues a transaction credit to the CDMA.
2. The CDMA begins packet reception by fetching the first PBD from the Queue Manager using the Free Descriptor / Buffer Queue 0 (Rx Submit Queue) index that was initialized in the RX port DMA state for that channel.
3. The CDMA will then begin writing the 64-byte block of packet data into this DB.
4. The CDMA will continue filling the buffer with additional 64-byte blocks of data from the CPPI FIFO and will fetch additional PBD as needed using the Free Descriptor / Buffer Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet. After each buffer is filled, the CDMA writes the buffer descriptor to main memory.

An example of the completion for a receive USB data flow is shown in [Figure 35-26](#).

**Figure 35-26. Receive USB Data Flow Example (Completion)**

Step 4 (CDMA completes the packet transfer for Receive):

1. After the entire packet has been received, the CDMA writes the packet descriptor to main memory.
2. The CDMA then writes the packet descriptor to the RXCQ specified in the Queue Manager / Queue Number fields in the RX Global Configuration Register.
3. The Queue Manager then indicates the status of the RXCQ to the CPU via an interrupt.
4. The CPU can then process the received packet by popping the received packet information from the RXCQ and accessing the packet's data from main memory.

### 35.2.8.13 Interrupt Handling

Table 35-27 lists the interrupts generated by the USB controller.

**Table 35-27. Interrupts Generated by the USB Controller**

| Interrupt         | Description                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------|
| Tx Endpoint [4-0] | Tx endpoint ready or error condition. For endpoints 4 to 0. (Rx and Tx for endpoint 0)                        |
| Rx Endpoint [4-1] | Rx endpoint ready or error condition. For endpoints 4 to 1. (Endpoint 0 has interrupt status in Tx interrupt) |
| USB Core[8-0]     | Interrupts for 9 USB conditions                                                                               |

Whenever any of these interrupt conditions are generated, the host processor is interrupted. The software needs to read the different interrupt status registers (discussed in later section) to determine the source of the interrupt.

The nine USB interrupt conditions are listed in Table 35-28.

**Table 35-28. USB Interrupt Conditions**

| Interrupt | Description                                                                     |
|-----------|---------------------------------------------------------------------------------|
| USB[8]    | DRVVBUS level change                                                            |
| USB[7]    | VBus voltage < VBus Valid Threshold (VBus error)                                |
| USB[6]    | SRP detected                                                                    |
| USB[5]    | Device Disconnected (Valid in Host Mode)                                        |
| USB[4]    | Device Connected (Valid in Host Mode)                                           |
| USB[3]    | SOF started                                                                     |
| USB[2]    | Reset Signaling detected (In Peripheral Mode)<br>Babble detected (In Host Mode) |
| USB[1]    | Resume signaling detected                                                       |
| USB[0]    | Suspend Signaling detected                                                      |

#### 35.2.8.13.1 USB Core Interrupts

Interrupt status can be determined using the INTSRCR (interrupt source) register. This register is non-masked. To clear the interrupt source, set the corresponding interrupt bit in INTCLRR register. For debugging purposes, interrupt can be set manually through INTSETR register.

The interrupt controller provides the option of masking the interrupts. A mask can be set using INTMSKSETR register and can be cleared by setting the corresponding bit in the INTMSKCLRR register. The mask can be read from INTMSKR register. The masked interrupt status is determined using the INTMASKEDR register.

The host processor software should write to the End Of Interrupt Register (EOIR) to acknowledge the completion of an interrupt.

---

**NOTE:** While EOIR is not written, the interrupt from the USB controller remains asserted.

---

### 35.2.9 Test Modes

The USB2.0 controller supports the four USB 2.0 test modes defined for high-speed functions. It also supports an additional “FIFO access” test mode that can be used to test the operation of the CPU interface, the DMA controller (if configured), and the RAM block.

The test modes are entered by writing to the TESTMODE register. A test mode is usually requested by the host sending a SET\_FEATURE request to Endpoint 0. When the software receives the request, it should wait until the Endpoint 0 transfer has completed (when it receives the Endpoint 0 interrupt indicating the status phase has completed) then write to the TESTMODE register.

---

**NOTE:** These test modes have no purpose in normal operation.

---

#### 35.2.9.1 TEST\_SE0\_NAK

To enter the Test\_SE0\_NAK test mode, the software should set the TEST\_SE0\_NAK bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it responds to any valid IN token with a NAK.

#### 35.2.9.2 TEST\_J

To enter the Test\_J test mode, the software should set the TEST\_J bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous J on the bus.

#### 35.2.9.3 TEST\_K

To enter the Test\_K test mode, the software should set the TEST\_K bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous K on the bus.

#### 35.2.9.4 TEST\_PACKET

To execute the Test\_Packet, the software should:

1. Start a session (if the core is being used in Host mode).
2. Write the standard test packet (shown below) to the Endpoint 0 FIFO.
3. Write 8h to the TESTMODE register (TEST\_PACKET = 1) to enter Test\_Packet test mode.
4. Set the TxPktRdy bit in the CSR0 register (D1).

The 53 by test packet to load is as follows (all bytes in hex). The test packet only has to be loaded once; the USB controller will keep re-sending the test packet without any further intervention from the software.

This data sequence is defined in Universal Serial Bus Specification Revision 2.0, Section 7.1.20. The USB controller will add the DATA0 PID to the head of the data sequence and the CRC to the end.

|    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|
| 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 |
| 00 | AA | AA | AA | AA | AA | AA | AA |
| AA | EE | EE | EE | EE | EE | EE | EE |
| EE | FE | FF | FF | FF | FF | FF | FF |
| FF | FF | FF | FF | FF | 7F | BF | DF |
| EF | F7 | FB | FD | FC | 7E | BF | DF |
| EF | F7 | FB | FD | 7E |    |    |    |

### 35.2.9.5 FIFO\_ACCESS

The FIFO Access test mode allows you to test the operation of CPU Interface, the DMA controller (if configured), and the RAM block by loading a packet of up to 64 bytes into the Endpoint 0 FIFO and then reading it back out again. Endpoint 0 is used because it is a bidirectional endpoint that uses the same area of RAM for its Tx and Rx FIFOs.

---

**NOTE:** The core does not need to be connected to the USB bus to run this test. If it is connected, then no session should be in progress when the test is run.

---

The test procedure is as follows:

1. Load a packet of up to 64 bytes into the Endpoint 0 Tx FIFO.
2. Set CSR0.TxPktRdy.
3. Write 40h to the TESTMODE register (FIFO\_ACCESS = 1).
4. Unload the packet from the Endpoint Rx FIFO, again.
5. Set CSR0.ServicedRxPktRdy.

Writing 40h to the TESTMODE register causes the following sequence of events:

1. The Endpoint 0 CPU pointer (that records the number of bytes to be transmitted) is copied to the Endpoint 0 USB pointer (that records the number of bytes received).
2. The Endpoint 0 CPU pointer is reset.
3. CSR0.TxPktRdy is cleared.
4. CSR0.RxPktRdy is set.
5. An Endpoint 0 interrupt is generated (if enabled).

The effect of these steps is to make the Endpoint 0 controller act as if the packet loaded into the Tx FIFO has flushed and the same packet received over the USB. The data that was loaded in the Tx FIFO can now be read out of the Rx FIFO.

### 35.2.9.6 FORCE\_HOST

The Force Host test mode enables you to instruct the core to operate in Host mode, regardless of whether it is actually connected to any peripheral; that is, the state of the CID input and the LINESTATE and HOSTDISCON signals are ignored. (While in this mode, the state of the HOSTDISCON signal can be read from the BDEVICE bit in the device control register (DEVCTL).)

This mode, which is selected by writing 80h to the TESTMODE register (FORCE\_HOST = 1), allows implementation of the USB Test\_Force\_Enable (7.1.20). It can also be used for debugging PHY problems in hardware.

While the FORCE\_HOST bit remains set, the core enters the Host mode when the SESSION bit in DEVCTL is set to 1 and remains in the Host mode until the SESSION bit is cleared to 0 even if a connected device is disconnected during the session. The operating speed while in this mode is determined by the FORCE\_HS and FORCE\_FS bits in the TESTMODE register.

### 35.2.10 Reset Considerations

The USB controller has two reset sources: hardware reset and the soft reset.

#### 35.2.10.1 Software Reset Considerations

When the RESET bit in the control register (CTRLR) is set, all the USB controller registers and DMA operations are reset. The bit is cleared automatically.

A software reset on the ARM or DSP CPU does not affect the register values and operation of the USB controller.

#### 35.2.10.2 Hardware Reset Considerations

When a hardware reset is asserted, all the registers are set to their default values.

### 35.2.11 Interrupt Support

The USB peripheral provides the interrupts listed in [Table 35-29](#) to the interrupt distributor module (INTD). For information on the mapping of interrupts, see your device-specific data manual.

**Table 35-29. USB Interrupts**

| Event          | Acronym  | Source             |
|----------------|----------|--------------------|
| ARM Event = 58 | USB0_INT | USB 2.0 Controller |
| DSP Event = 19 | USB0_INT | USB 2.0 Controller |

### 35.2.12 DMA Event Support

The USB is an internal bus master peripheral and does not utilize EDMA events. The USB has its own dedicated DMA, CPPI 4.1 DMA, that it utilizes for DMA driven data transfer.

### 35.2.13 Power Management

The USB controller can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 35.3 Use Cases

The USB supports the following use cases.

#### 35.3.1 User Case 1: Example of How to Initialize the USB Controller

##### Example 35-1. Initializing the USB2.0 Controller

```
void usb_init()
{
    Uint16 I;

    // *****
    // Configure DRVVBUS Pin to be used for USB
    // *****
    // MAKE SURE WRITE ACCESS KEY IS INITIALIZED PRIOR TO ACCESSING ANY OF THE
    // BOOTCFG REGISTERS.

    BootCfg->KICK0R = KICK0KEY;    // Write Access Key 0
    BootCfg->KICK1R = KICK1KEY;    // Write Access Key 1
    /* CONFIGURE THE DRVVBUS PIN HERE.*/
    /* See the System Configuration (SYSCFG) Module chapter for more information on how to set up
    the pinmux. */

    // Reset the USB controller:
    usbRegs->CTRLR |= 0x00000001;

    //Wait until controller is finished with Reset. When done, it will clear the RESET bit field.
    while ((usbRegs->CTRLR & 0x1) == 1);

    // RESET: Hold PHY in Reset
    BootCfg->CFGCHIP2 |= 0x00008000;    // Hold PHY in Reset
    // Drive Reset for few clock cycles
    for (I=0; i<50; I++);
    // RESET: Release PHY from Reset
    BootCfg->CFGCHIP2 &= 0xFFFF7FFF;    // Release PHY from Reset

    /* Configure PHY with the Desired Operation */
    // OTGMODE
    BootCfg->CFGCHIP2 &= 0xFFFF9FFF;    // 00=> Do Not Override PHY Values

    // PHYPWDN
    BootCfg->CFGCHIP2 &= 0xFFFFFBFF;    // 1/0 => PowerdDown/ NormalOperation
    // OTGPWRDN
    BootCfg->CFGCHIP2 &= 0xFFFFFDFF;    // 1/0 => PowerDown/ NormalOperation
    // DATAPOL
    BootCfg->CFGCHIP2 |= 0x00000100;    // 1/0 => Normal/ Reversed
    // SESNDEN
    BootCfg->CFGCHIP2 |= 0x00000020;    // 1/0 => NormalOperation/ SessionEnd
    // VBDTCEN
    BootCfg->CFGCHIP2 |= 0x00000010;    // 1/0 => VBUS Comparator Enable/ Disable

    /* Configure PHY PLL use and Select Source */

## 35.4 Registers

**Table 35-30** lists the memory-mapped registers for the universal serial bus OTG controller (USB0). See your device-specific data manual for the memory address of these registers. The base address is 01E0 0000h.

**NOTE:** In some cases, a single register address can have different names or meanings depending on the mode (host/peripheral) or the setting of the index register. The meaning of some bit fields varies with the mode.

**Table 35-30. Universal Serial Bus OTG (USB0) Registers**

| VBUS Slave Address Offset   | Acronym     | Register Description                                                   | Section                         |

### 35.4.1 Revision Identification Register (REVID)

The revision identification register (REVID) contains the revision for the USB 2.0 OTG controller module. The REVID is shown in [Figure 35-27](#) and described in [Table 35-31](#).

**Figure 35-27. Revision Identification Register (REVID)**

|              |   |
|--------------|---|
| 31           | 0 |
| REV          |   |
| R-4EA1 0800h |   |

LEGEND: R = Read only; -n = value after reset

**Table 35-31. Revision Identification Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description                    |
|------|-------|------------|--------------------------------|
| 31-0 | REV   | 4EA1 0800h | Revision ID of the USB module. |

### 35.4.2 Control Register (CTRLR)

The control register (CTRLR) allows the CPU to control various aspects of the module. The CTRLR is shown in [Figure 35-28](#) and described in [Table 35-32](#).

**Figure 35-28. Control Register (CTRLR)**

|          |   |       |       |          |               |    |
|----------|---|-------|-------|----------|---------------|----|
| 31       |   |       |       |          |               | 16 |
| Reserved |   |       |       |          |               |    |
| R-0      |   |       |       |          |               |    |
| 15       | 5 | 4     | 3     | 2        | 1 0           |    |

| R-0      |   | R/W-0 | R/W-0 | R-0      | R/W-0 R/W-0   |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-32. Control Register (CTRLR) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                     |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0      | Reserved                                                                                                                        |
| 4    | RNDIS    | 0<br>1 | Global RNDIS mode enable for all endpoints.<br>Global RNDIS mode is disabled.<br>Global RNDIS mode is enabled.                  |
| 3    | UINT     | 0<br>1 | USB non-PDR interrupt handler enable.<br>PDR interrupt handler is enabled.<br>PDR interrupt handler is disabled.                |
| 2    | Reserved | 0      | Reserved                                                                                                                        |
| 1    | CLKFACK  | 0<br>1 | Clock stop fast ACK enable.<br>Clock stop fast ACK is disabled.<br>Clock stop fast ACK is enabled.                              |
| 0    | RESET    | 0<br>1 | Soft reset.<br>No effect.<br>Writing a 1 starts a module reset. The USB controller will clear this bit when it completes reset. |

### 35.4.3 Status Register (STATR)

The status register (STATR) allows the CPU to check various aspects of the module. The STATR is shown in [Figure 35-29](#) and described in [Table 35-33](#).

**Figure 35-29. Status Register (STATR)**

LEGEND: R = Read only; -n = value after reset

**Table 35-33. Status Register (STATR) Field Descriptions**

| Bit  | Field    | Value | Description                                         |
|------|----------|-------|-----------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                            |
| 0    | DRVVBUS  | 0     | Current DRVVBUS value.<br>DRVVBUS value is logic 0. |
|      |          | 1     | DRVVBUS value is logic 1.                           |

### 35.4.4 Emulation Register (EMUR)

The emulation register (EMUR) allows the CPU to configure the CBA 3.0 emulation interface. The EMUR is shown in [Figure 35-30](#) and described in [Table 35-34](#).

**Figure 35-30. Emulation Register (EMUR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-34. Emulation Register (EMUR) Field Descriptions**

| Bit  | Field    | Value | Description      |
|------|----------|-------|------------------|
| 31-3 | Reserved | 0     | Reserved         |
| 2    | RT_SEL   | 0     | Real-time enable |
|      |          | 0     | Enable           |
|      |          | 1     | No effect        |
| 1    | SOFT     | 0     | Soft stop        |
|      |          | 0     | No effect        |
|      |          | 1     | Soft stop enable |
| 0    | FREERUN  | 0     | Free run         |
|      |          | 0     | No effect        |
|      |          | 1     | Free run enable  |

### 35.4.5 Mode Register (MODE)

The mode register (MODE) allows the CPU to individually enable RNDIS/Generic/CDC modes for each endpoint. Using the global RNDIS bit in the control register (CTRLR) overrides this register and enables RNDIS mode for all endpoints. The MODE is shown in [Figure 35-31](#) and described in [Table 35-35](#).

**Figure 35-31. Mode Register (MODE)**

|          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |

### 35.4.6 Auto Request Register (AUTOREQ)

The auto request register (AUTOREQ) allows the CPU to enable an automatic IN token request generation for host mode RX operation per each RX endpoint. This feature has the DMA set the REQPKT bit in the control status register for host receive endpoint (HOST\_RXCSR) when it clears the RXPCKTRDY bit after reading out a packet. The REQPKT bit is used by the core to generate an IN token to receive data. By using this feature, the host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU will have to manually set the REQPKT bit for every USB packet.

There are two modes that auto request can function in: always or all except an EOP. The always mode sets the REQPKT bit after every USB packet the DMA receives thus generating a new IN token after each USB packet. The EOP mode sets the REQPKT bit after every USB packet that is not an EOP (end of packet) in the CPPI descriptor. For RNDIS, CDC, and Generic RNDIS modes, the auto request stops when the EOP is received (either via a short packet for RNDIS, CDC, and Generic RNDIS or the count is reached for Generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode, every USB packet is an EOP CPPI packet so the auto request never functions and acts like auto request is disabled.

The AUTOREQ is shown in [Figure 35-32](#) and described in [Table 35-36](#).

### 35.4.7 SRP Fix Time Register (SRPFIXTIME)

The SRP fix time register (SRPFIXTIME) allows the CPU to configure the maximum amount of time the SRP fix logic blocks the Avalid from the PHY to the OTG core. The SRPFIXTIME is shown in [Figure 35-33](#) and described in [Table 35-37](#).

**Figure 35-33. SRP Fix Time Register (SRPFIXTIME)**

| Bit  | Field      | Value        | Description                                                           |
|------|------------|--------------|-----------------------------------------------------------------------|
| 31-0 | SRPFIXTIME | 0-FFFF FFFFh | SRP fix maximum time in 60 MHz cycles. Default is 700 ms (280 DE80h). |

### 35.4.8 Teardown Register (TEARDOWN)

The teardown register (TEARDOWN) controls the tearing down of receive and transmit FIFOs in the USB controller. When a 1 is written to a valid bit in TEARDOWN, the CPPI FIFO pointers for that endpoint are cleared. TEARDOWN must be used in conjunction with the CPPI DMA teardown mechanism. The Host should also write the FLUSHFIFO bits in the TXCSR and RXCSR registers to ensure a complete teardown of the endpoint.

The TEARDOWN is shown in [Figure 35-34](#) and described in [Table 35-38](#).

**Figure 35-34. Teardown Register (TEARDOWN)**

### 35.4.9 USB Interrupt Source Register (INTSRCR)

The USB interrupt source register (INTSRCR) contains the status of the interrupt sources generated by the USB core (not by the DMA). The INTSRCR is shown in [Figure 35-35](#) and described in [Table 35-39](#).

**NOTE:** Other than the USB bit field, to make use of INTSRCR, the PDR interrupt handler must be enabled (the UINT bit in the control register (CTRLR) is cleared to 0). If the UINT bit in CTRLR is set to 1, you need to use the interrupt status/flag from the core register space.

**Figure 35-35. USB Interrupt Source Register (INTSRCR)**

### 35.4.10 USB Interrupt Source Set Register (INTSETR)

The USB interrupt source set register (INTSETR) allows the USB interrupt sources to be manually triggered. A read of this register returns the USB interrupt source register value. The INTSETR is shown in Figure 35-36 and described in Table 35-40.

**NOTE:** Other than the USB bit field, to make use of INTSETR, the PDR interrupt handler must be enabled (the UINT bit in the control register (CTRLR) is cleared to 0). If the UINT bit in CTRLR is set to 1, you need to use the interrupt status/flag from the core register space.

**Figure 35-36. USB Interrupt Source Set Register (INTSETR)**

### 35.4.11 USB Interrupt Source Clear Register (INTCLRR)

The USB interrupt source clear register (INTCLRR) allows the CPU to acknowledge an interrupt source and turn it off. A read of this register returns the USB interrupt source register value. The INTCLRR is shown in [Figure 35-37](#) and described in [Table 35-41](#).

**NOTE:** Other than the USB bit field, to make use of INTCLRR, the PDR interrupt handler must be enabled (the UINT bit in the control register (CTRLR) is cleared to 0). If the UINT bit in CTRLR is set to 1, you need to use the interrupt status/flag from the core register space.

**Figure 35-37. USB Interrupt Source Clear Register (INTCLRR)**

### 35.4.12 USB Interrupt Mask Register (INTMSKR)

The USB interrupt mask register (INTMSKR) contains the masks of the interrupt sources generated by the USB core (not by the DMA). These masks are used to enable or disable interrupt sources generated on the masked source interrupts (the raw source interrupts are never masked). The bit positions are maintained in the same position as the interrupt sources in the USB interrupt source register (INTSRCR).

The INTMSKR is shown in [Figure 35-38](#) and described in [Table 35-42](#).

**NOTE:** Other than the USB bit field, to make use of INTMSKR, the PDR interrupt handler must be enabled (the UINT bit in the control register (CTRLR) is cleared to 0). If the UINT bit in CTRLR is set to 1, you need to use the interrupt status/flag from the core register space.

**Figure 35-38. USB Interrupt Mask Register (INTMSKR)**

### 35.4.13 USB Interrupt Mask Set Register (INTMSKSETR)

The USB interrupt mask set register (INTMSKSETR) allows the USB masks to be individually enabled. A read to this register returns the USB interrupt mask register value. The INTMSKSETR is shown in Figure 35-39 and described in Table 35-43.

**NOTE:** Other than the USB bit field, to make use of INTMSKSETR, the PDR interrupt handler must be enabled (the UINT bit in the control register (CTRLR) is cleared to 0). If the UINT bit in CTRLR is set to 1, you need to use the interrupt status/flag from the core register space.

### 35.4.15 USB Interrupt Source Masked Register (INTMASKEDR)

The USB interrupt source masked register (INTMASKEDR) contains the status of the interrupt sources generated by the USB core masked by the USB interrupt mask register (INTMSKR) values. The INTMASKEDR is shown in [Figure 35-41](#) and described in [Table 35-45](#).

**NOTE:** Other than the USB bit field, to make use of INTMASKEDR, the PDR interrupt handler must be enabled (the UINT bit in the control register (CTRLR) is cleared to 0). If the UINT bit in CTRLR is set to 1, you need to use the interrupt status/flag from the core register space.

**Figure 35-41. USB Interrupt Source Masked Register (INTMASKEDR)**

|       |          | 0      | TXEPn interrupt source is not masked.               |
|       |          | 1      | TXEPn interrupt source is masked.                   |
| 0     | EP0      |        | Endpoint 0 interrupt source masked.                 |
|       |          | 0      | Endpoint 0 interrupt source is not masked.          |
|       |          | 1      | Endpoint 0 interrupt source is masked.              |

### 35.4.16 USB End of Interrupt Register (EOIR)

The USB end of interrupt register (EOIR) allows the CPU to acknowledge completion of a non-DMA interrupt by writing 0 to the EOI\_VECTOR field. The EOIR is shown in [Figure 35-42](#) and described in [Table 35-46](#).

**Figure 35-42. USB End of Interrupt Register (EOIR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

| 7-0  | EOI_VECTOR | 0-FFh | End of Interrupt (EOI) Vector. |

### 35.4.17 Generic RNDIS EP1 Size Register (GENRNDISSZ1)

The generic RNDIS EP1 size register (GENRNDISSZ1) is programmed with a RNDIS packet size in bytes. When EP1 is in Generic RNDIS mode, the received USB packets are collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register have been received, or a *short* packet is received. This register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 10000h, or 65536. The GENRNDISSZ1 is shown in [Figure 35-43](#) and described in [Table 35-47](#).

**Figure 35-43. Generic RNDIS EP1 Size Register (GENRNDISSZ1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-47. Generic RNDIS EP1 Size Register (GENRNDISSZ1) Field Descriptions**

| Bit   | Field    | Value    | Description               |
|-------|----------|----------|---------------------------|
| 31-17 | Reserved | 0        | Reserved                  |
| 16-0  | EP1_SIZE | 0-10000h | Generic RNDIS packet size |

### 35.4.18 Generic RNDIS EP2 Size Register (GENRNDISSZ2)

The generic RNDIS EP2 size register (GENRNDISSZ2) is programmed with a RNDIS packet size in bytes. When EP2 is in Generic RNDIS mode, the received USB packets are collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register have been received, or a *short* packet is received. This register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 10000h, or 65536. The GENRNDISSZ2 is shown in [Figure 35-44](#) and described in [Table 35-48](#).

**Figure 35-44. Generic RNDIS EP2 Size Register (GENRNDISSZ2)**

### 35.4.19 Generic RNDIS EP3 Size Register (GENRNDISSZ3)

The generic RNDIS EP3 size register (GENRNDISSZ3) is programmed with a RNDIS packet size in bytes. When EP3 is in Generic RNDIS mode, the received USB packets are collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a *short* packet is received. This register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 10000h, or 65536. The GENRNDISSZ3 is shown in [Figure 35-45](#) and described in [Table 35-49](#).

**Figure 35-45. Generic RNDIS EP3 Size Register (GENRNDISSZ3)**

### 35.4.20 Generic RNDIS EP4 Size Register (GENRNDISSZ4)

The generic RNDIS EP4 size register (GENRNDISSZ4) is programmed with a RNDIS packet size in bytes. When EP4 is in Generic RNDIS mode, the received USB packets are collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a *short* packet is received. This register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 10000h, or 65536. The GENRNDISSZ4 is shown in [Figure 35-46](#) and described in [Table 35-50](#).

**Figure 35-46. Generic RNDIS EP4 Size Register (GENRNDISSZ4)**

|-----|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 6-0 | FUNCADDR | 0-7Fh | 7_bit address of the peripheral part of the transaction.<br><br>When used in Peripheral mode, this register should be written with the address received through a SET_ADDRESS command, which will then be used for decoding the function address in subsequent token packets.<br><br>When used in Host mode, this register should be set to the value sent in a SET_ADDRESS command during device enumeration as the address for the peripheral device. |

### 35.4.22 Power Management Register (POWER)

The power management register (POWER) is shown in [Figure 35-48](#) and described in [Table 35-52](#).

**Figure 35-48. Power Management Register (POWER)**

| 7         | 6        | 5     | 4      | 3     | 2      | 1        | 0       |
|-----------|----------|-------|--------|-------|--------|----------|---------|
| ISOUPDATE | SOFTCONN | HSEN  | HSMODE | RESET | RESUME | SUSPENDM | ENSUSPM |
| R/W-0     | R/W-0    | R/W-1 | R-0    | R/W-0 | R/W-0  | R/W-0    | R/W-0   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-52. Power Management Register (POWER) Field Descriptions**

| Bit | Field     | Value | Description                                                                                                                                                                                                                                                                                                                  |
|-----|-----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | ISOUPDATE | 0-1   | When set, the USB controller will wait for an SOF token from the time TxPktRdy is set before sending the packet. If an IN token is received before an SOF token, then a zero length data packet will be sent. Note: this is only valid in Peripheral Mode. This bit only affects endpoints performing Isochronous transfers. |
| 6   | SOFTCONN  | 0-1   | If Soft Connect/Disconnect feature is enabled, then the USB D+/D- lines are enabled when this bit is set and tri-stated when this bit is cleared. Note: this is only valid in Peripheral Mode.                                                                                                                               |
| 5   | HSEN      | 0-1   | When set, the USB controller will negotiate for high-speed mode when the device is reset by the hub. If not set, the device will only operate in full-speed mode.                                                                                                                                                            |
| 4   | HSMODE    | 0-1   | This bit is set when the USB controller has successfully negotiated for high-speed mode.                                                                                                                                                                                                                                     |
| 3   | RESET     | 0-1   | This bit is set when Reset signaling is present on the bus. Note: this bit is Read/Write in Host Mode, but read-only in Peripheral Mode.                                                                                                                                                                                     |
| 2   | RESUME    | 0-1   | Set to generate Resume signaling when the controller is in Suspend mode. The bit should be cleared after 10 ms (a maximum of 15 ms) to end Resume signaling. In Host mode, this bit is also automatically set when Resume signaling from the target is detected while the USB controller is suspended.                       |
| 1   | SUSPENDM  | 0-1   | In Host mode, this bit should be set to enter Suspend mode. In Peripheral mode, this bit is set on entry into Suspend mode. It is cleared when the interrupt register is read, or the RESUME bit is set.                                                                                                                     |
| 0   | ENSUSPM   | 0-1   | Set to enable the SUSPENDM output.                                                                                                                                                                                                                                                                                           |

### 35.4.23 Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 4 (INTRTX)

The interrupt register for endpoint 0 plus transmit endpoints 1 to 4 (INTRTX) is shown in [Figure 35-49](#) and described in [Table 35-53](#).

**NOTE:** Unless the UINT bit in the control register (CTRLR) is set to 1 (non-PDR interrupt mode is enabled), do not read this register directly. Performing a read clears the pending interrupt. Use INTRTX only when in the non-PDR interrupt mode, that is, when handling the interrupt directly from the controller.

**Figure 35-49. Interrupt Register for Endpoint 0 Plus Tx Endpoints 1 to 4 (INTRTX)**

LEGEND: R = Read only; -n = value after reset

**Table 35-53. Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 4 (INTRTX)  
Field Descriptions**

| Bit  | Field    | Value | Description                          |
|------|----------|-------|--------------------------------------|
| 15-5 | Reserved | 0     | Reserved                             |
| 4    | EP4TX    | 0-1   | Transmit Endpoint 4 interrupt active |
| 3    | EP3TX    | 0-1   | Transmit Endpoint 3 interrupt active |
| 2    | EP2TX    | 0-1   | Transmit Endpoint 2 interrupt active |
| 1    | EP1TX    | 0-1   | Transmit Endpoint 1 interrupt active |
| 0    | EP0      | 0-1   | Endpoint 0 interrupt active          |

### 35.4.24 Interrupt Register for Receive Endpoints 1 to 4 (INTRRX)

The interrupt register for receive endpoints 1 to 4 (INTRRX) is shown in [Figure 35-50](#) and described in [Table 35-54](#).

**NOTE:** Unless the UINT bit in the control register (CTRLR) is set to 1 (non-PDR interrupt mode is enabled), do not read this register directly. Performing a read clears the pending interrupt. Use INTRRX only when in the non-PDR interrupt mode, that is, when handling the interrupt directly from the controller.

**Figure 35-50. Interrupt Register for Receive Endpoints 1 to 4 (INTRRX)**

LEGEND: R = Read only; -n = value after reset

**Table 35-54. Interrupt Register for Receive Endpoints 1 to 4 (INTRRX) Field Descriptions**

| Bit  | Field    | Value | Description                         |
|------|----------|-------|-------------------------------------|
| 15-5 | Reserved | 0     | Reserved                            |
| 4    | EP4RX    | 0-1   | Receive Endpoint 4 interrupt active |
| 3    | EP3RX    | 0-1   | Receive Endpoint 3 interrupt active |
| 2    | EP2RX    | 0-1   | Receive Endpoint 2 interrupt active |
| 1    | EP1RX    | 0-1   | Receive Endpoint 1 interrupt active |
| 0    | Reserved | 0     | Reserved                            |

### 35.4.25 Interrupt Enable Register for INTRTX (INTRTXE)

The interrupt enable register for INTRTX (INTRTXE) is shown in [Figure 35-51](#) and described in [Table 35-55](#).

**Figure 35-51. Interrupt Enable Register for INTRTX (INTRTXE)**

|          |  |       |  |       |       |       |       |   |
|----------|--|-------|--|-------|-------|-------|-------|---|
| 15       |  |       |  |       |       | 8     |       |   |
| Reserved |  |       |  |       |       |       |       |   |

### 35.4.27 Interrupt Register for Common USB Interrupts (INTRUSB)

The interrupt register for common USB interrupts (INTRUSB) is shown in [Figure 35-53](#) and described in [Table 35-57](#).

**NOTE:** Unless the UINT bit in the control register (CTRLR) is set to 1 (non-PDR interrupt mode is enabled), do not read this register directly. Performing a read clears the pending interrupt. Use INTRUSB only when in the non-PDR interrupt mode, that is, when handling the interrupt directly from the controller.

**Figure 35-53. Interrupt Register for Common USB Interrupts (INTRUSB)**

|         |         |        |      |     |              |        |         |
|---------|---------|--------|------|-----|--------------|--------|---------|
| 7       | 6       | 5      | 4    | 3   | 2            | 1      | 0       |
| VBUSERR | SESSREQ | DISCON | CONN | SOF | RESET_BABBLE | RESUME | SUSPEND |
| R-0     | R-0     | R-0    | R-0  | R-0 | R-0          | R-0    | R-0     |

LEGEND: R = Read only; -n = value after reset

**Table 35-57. Interrupt Register for Common USB Interrupts (INTRUSB) Field Descriptions**

| Bit | Field        | Value | Description                                                                                                                                                                              |
|-----|--------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | VBUSERR      | 0-1   | Set when VBus drops below the VBus valid threshold during a session. Only valid when the USB controller is 'A' device. All active interrupts will be cleared when this register is read. |
| 6   | SESSREQ      | 0-1   | Set when session request signaling has been detected. Only valid when USB controller is 'A' device.                                                                                      |
| 5   | DISCON       | 0-1   | Set in host mode when a device disconnect is detected. Set in peripheral mode when a session ends.                                                                                       |
| 4   | CONN         | 0-1   | Set when a device connection is detected. Only valid in host mode.                                                                                                                       |
| 3   | SOF          | 0-1   | Set when a new frame starts.                                                                                                                                                             |
| 2   | RESET_BABBLE | 0-1   | Set in peripheral mode when reset signaling is detected on the bus set in host mode when babble is detected.                                                                             |
| 1   | RESUME       | 0-1   | Set when resume signaling is detected on the bus while the USB controller is in suspend mode.                                                                                            |
| 0   | SUSPEND      | 0-1   | Set when suspend signaling is detected on the bus only valid in peripheral mode.                                                                                                         |

### 35.4.28 Interrupt Enable Register for INTRUSB (INTRUSBE)

The interrupt enable register for INTRUSB (INTRUSBE) is shown in [Figure 35-54](#) and described in [Table 35-58](#).

**Figure 35-54. Interrupt Enable Register for INTRUSB (INTRUSBE)**

|         |         |        |       |       |              |        |         |
|---------|---------|--------|-------|-------|--------------|--------|---------|
| 7       | 6       | 5      | 4     | 3     | 2            | 1      | 0       |
| VBUSERR | SESSREQ | DISCON | CONN  | SOF   | RESET_BABBLE | RESUME | SUSPEND |
| R/W-0   | R/W-0   | R/W-0  | R/W-0 | R/W-0 | R/W-1        | R/W-1  | R/W-0   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 35-58. Interrupt Enable Register for INTRUSB (INTRUSBE) Field Descriptions**

| Bit | Field        | Value | Description                      |
|-----|--------------|-------|----------------------------------|
| 7   | VBUSERR      | 0-1   | Vbus error interrupt enable      |
| 6   | SESSREQ      | 0-1   | Session request interrupt enable |
| 5   | DISCON       | 0-1   | Disconnect interrupt enable      |
| 4   | CONN         | 0-1   | Connect interrupt enable         |
| 3   | SOF          | 0-1   | Start of frame interrupt enable  |
| 2   | RESET_BABBLE | 0-1   | Reset interrupt enable           |
| 1   | RESUME       | 0-1   | Resume interrupt enable          |
| 0   | SUSPEND      | 0-1   | Suspend interrupt enable         |

### 35.4.29 Frame Number Register (FRAME)

The frame number register (FRAME) is shown in [Figure 35-55](#) and described in [Table 35-59](#).

**Figure 35-55. Frame Number Register (FRAME)**

|          |    |             |   |
|----------|----|-------------|---|

| R-0      |   | R/W-0 |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-60. Index Register for Selecting the Endpoint Status and Control Registers (INDEX) Field Descriptions**

| Bit | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                |
|-----|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-4 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                   |
| 3-0 | EPSEL    | 0-4h  | Each transmit endpoint and each receive endpoint have their own set of control/status registers. EPSEL determines which endpoint control/status registers are accessed. Before accessing an endpoint's control/status registers, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory-map. |

### 35.4.31 Register to Enable the USB 2.0 Test Modes (TESTMODE)

The register to enable the USB 2.0 test modes (TESTMODE) is shown in [Figure 35-57](#) and described in [Table 35-61](#).

**Figure 35-57. Register to Enable the USB 2.0 Test Modes (TESTMODE)**

|            |             |          |          |             |        |        |              |
|------------|-------------|----------|----------|-------------|--------|--------|--------------|
| 7          | 6           | 5        | 4        | 3           | 2      | 1      | 0            |
| FORCE_HOST | FIFO_ACCESS | FORCE_FS | FORCE_HS | TEST_PACKET | TEST_K | TEST_J | TEST_SE0_NAK |
| R/W-0      | W-0         | R/W-0    | R/W-0    | R/W-0       | R/W-0  | R/W-0  | R/W-0        |

LEGEND: R/W = Read/Write; W = Write only; -n = value after reset

**Table 35-61. Register to Enable the USB 2.0 Test Modes (TESTMODE) Field Descriptions**

| Bit | Field        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|--------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | FORCE_HOST   | 0-1   | Set this bit to forcibly put the USB controller into Host mode when SESSION bit is set, regardless of whether it is connected to any peripheral. The controller remains in Host mode until the Session bit is cleared, even if a device is disconnected. And if the FORCE_HOST bit remains set, it will re-enter Host mode next time the SESSION bit is set. The operating speed is determined using the FORCE_HS and FORCE_FS bits. |
| 6   | FIFO_ACCESS  | 0-1   | Set this bit to transfer the packet in EP0 Tx FIFO to EP0 Receive FIFO. It is cleared automatically.                                                                                                                                                                                                                                                                                                                                 |
| 5   | FORCE_FS     | 0-1   | Set this bit to force the USB controller into full-speed mode when it receives a USB reset.                                                                                                                                                                                                                                                                                                                                          |
| 4   | FORCE_HS     | 0-1   | Set this bit to force the USB controller into high-speed mode when it receives a USB reset.                                                                                                                                                                                                                                                                                                                                          |
| 3   | TEST_PACKET  | 0-1   | Set this bit to enter the Test_Packet test mode. In this mode, the USB controller repetitively transmits a 53-byte test packet on the bus, the form of which is defined in the Universal Serial Bus Specification Revision 2.0. Note: The test packet has a fixed format and must be loaded into the Endpoint 0 FIFO before the test mode is entered.                                                                                |
| 2   | TEST_K       | 0-1   | Set this bit to enter the Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.                                                                                                                                                                                                                                                                                                                    |
| 1   | TEST_J       | 0-1   | Set this bit to enter the Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.                                                                                                                                                                                                                                                                                                                    |
| 0   | TEST_SE0_NAK | 0-1   | Set this bit to enter the Test_SE0_NAK test mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK.                                                                                                                                                                                                                                                                        |

### 35.4.32 Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP)

The maximum packet size for peripheral/host transmit endpoint (TXMAXP) is shown in [Figure 35-58](#) and described in [Table 35-62](#).

**Figure 35-58. Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-62. Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP)  
Field Descriptions**

| Bit   | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-11 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 10-0  | MAXPAYLOAD | 0-400h | The maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB Specification on packet sizes for Bulk, Interrupt, and Isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the Standard Endpoint Descriptor for the associated endpoint. A mismatch could cause unexpected results. |

### 35.4.33 Control Status Register for Endpoint 0 in Peripheral Mode (PERI\_CSR0)

The control status register for endpoint 0 in peripheral mode (PERI\_CSR0) is shown in [Figure 35-59](#) and described in [Table 35-63](#).

**Figure 35-59. Control Status Register for Endpoint 0 in Peripheral Mode (PERI\_CSR0)**

|------|---------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-9 | Reserved      | 0     | Reserved                                                                                                                                                                                                                             |
| 8    | FLUSHFIFO     | 0-1   | Set this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPKTRDY bit is cleared.<br>Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPKTRDY is set.         |
| 7    | SERV_SETUPEND | 0-1   | Set this bit to clear the SETUPEND bit. It is cleared automatically.                                                                                                                                                                 |
| 6    | SERV_RXPKTRDY | 0-1   | Set this bit to clear the RXPKTRDY bit. It is cleared automatically.                                                                                                                                                                 |
| 5    | SENDSTALL     | 0-1   | Set this bit to terminate the current transaction. The STALL handshake will be transmitted and then this bit will be cleared automatically.                                                                                          |
| 4    | SETUPEND      | 0-1   | This bit will be set when a control transaction ends before the DATAEND bit has been set. An interrupt will be generated, and the FIFO will be flushed at this time. The bit is cleared by the writing a 1 to the SERV_SETUPEND bit. |
| 3    | DATAEND       | 0-1   | Set this bit to 1:<br>a. When setting TXPKTRDY for the last data packet.<br>b. When clearing RXPKTRDY after unloading the last data packet.<br>c. When setting TXPKTRDY for a zero length data packet. It is cleared automatically.  |
| 2    | SENTSTALL     | 0-1   | This bit is set when a STALL handshake is transmitted. This bit should be cleared.                                                                                                                                                   |
| 1    | TXPKTRDY      | 0-1   | Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.                                       |
| 0    | RXPKTRDY      | 0-1   | This bit is set when a data packet has been received. An interrupt is generated when this bit is set. This bit is cleared by setting the SERV_RXPKTRDY bit.                                                                          |

### 35.4.34 Control Status Register for Endpoint 0 in Host Mode (HOST\_CSR0)

The control status register for endpoint 0 in host mode (HOST\_CSR0) is shown in [Figure 35-60](#) and described in [Table 35-64](#).

**Figure 35-60. Control Status Register for Endpoint 0 in Host Mode (HOST\_CSR0)**

|             |  |           |  |        |  |         |  |             |  |         |  |           |  |

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 35-64. Control Status Register for Endpoint 0 in Host Mode (HOST\_CSR0)  
Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                                                                                                            |
|-------|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-12 | Reserved    | 0     | Reserved                                                                                                                                                                                                                               |
| 11    | DISPING     | 0-1   | The CPU writes a 1 to the DSPING bit to instruct the core not to issue PING tokens in the data and status phases of a high-speed control transfer (for use with devices that do not respond to PING).                                  |
| 10    | DATATOGWREN | 0-1   | Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.                                                                                               |
| 9     | DATATOG     | 0-1   | When read, this bit indicates the current state of the EP0 data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored. |
| 8     | FLUSHFIFO   | 0-1   | Write 1 to this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPkTRDY bit is cleared.<br>Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPkTRDY is set.    |
| 7     | NAK_TIMEOUT | 0-1   | This bit will be set when Endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the NAKLIMIT0 register. This bit should be cleared to allow the endpoint to continue.                            |
| 6     | STATUSPKT   | 0-1   | Set this bit at the same time as the TXPKTRDY or REQPKT bit is set, to perform a status stage transaction. Setting this bit ensures that the data toggle is set so that a DATA1 packet is used for the Status Stage transaction.       |
| 5     | REQPKT      | 0-1   | Set this bit to request an IN transaction. It is cleared when RXPkTRDY is set.                                                                                                                                                         |
| 4     | ERROR       | 0-1   | This bit will be set when three attempts have been made to perform a transaction with no response from the peripheral. You should clear this bit. An interrupt is generated when this bit is set.                                      |
| 3     | SETUPPKT    | 0-1   | Set this bit, at the same time as the TXPKTRDY bit is set, to send a SETUP token instead of an OUT token for the transaction.                                                                                                          |
| 2     | RXSTALL     | 0-1   | This bit is set when a STALL handshake is received. You should clear this bit.                                                                                                                                                         |
| 1     | TXPKTRDY    | 0-1   | Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.                                         |
| 0     | RXPkTRDY    | 0-1   | This bit is set when a data packet has been received. An interrupt is generated when this bit is set. Clear this bit by setting the SERV_RXPkTRDY bit.                                                                                 |

### 35.4.35 Control Status Register for Peripheral Transmit Endpoint (PERI\_TXCSR)

The control status register for peripheral transmit endpoint (PERI\_TXCSR) is shown in [Figure 35-61](#) and described in [Table 35-65](#).

**Figure 35-61. Control Status Register for Peripheral Transmit Endpoint (PERI\_TXCSR)**

|            |           |           |           |            |              |          |   |

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 35-65. Control Status Register for Peripheral Transmit Endpoint (PERI\_TXCSR)  
Field Descriptions**

| Bit | Field        | Value  | Description                                                                                                                                                                                                                                                                                                                                                              |
|-----|--------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | AUTOSET      | 0<br>1 | DMA Mode: The CPU needs to set the AUTOSET bit prior to enabling the Tx DMA.<br>CPU Mode: If the CPU sets the AUTOSET bit, the TXPKTRDY bit will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then the TXPKTRDY bit will have to be set manually. |
| 14  | ISO          | 0-1    | Set this bit to enable the Tx endpoint for Isochronous transfers, and clear it to enable the Tx endpoint for Bulk or Interrupt transfers.                                                                                                                                                                                                                                |
| 13  | MODE         | 0-1    | Set this bit to enable the endpoint direction as Tx, and clear the bit to enable it as Rx.<br>Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.                                                                                                                                                        |
| 12  | DMAEN        | 0-1    | Set this bit to enable the DMA request for the Tx endpoint.                                                                                                                                                                                                                                                                                                              |
| 11  | FRCDATATOG   | 0-1    | Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.                                                                                                    |
| 10  | DMAMODE      | 0-1    | This bit should always be set to 1 when the DMA is enabled.                                                                                                                                                                                                                                                                                                              |
| 9-7 | Reserved     | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                 |
| 6   | CLRDATATOG   | 0-1    | Write a 1 to this bit to reset the endpoint data toggle to 0.                                                                                                                                                                                                                                                                                                            |
| 5   | SENTSTALL    | 0-1    | This bit is set automatically when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.                                                                                                                                                                                                                     |
| 4   | SENDSTALL    | 0-1    | Write a 1 to this bit to issue a STALL handshake to an IN token. Clear this bit to terminate the stall condition.<br>Note: This bit has no effect where the endpoint is being used for Isochronous transfers.                                                                                                                                                            |
| 3   | FLUSHFIFO    | 0-1    | Write a 1 to this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit is cleared.<br>Note: FlushFIFO has no effect unless the TXPKTRDY bit is set. Also note that, if the FIFO is double-buffered, FlushFIFO may need to be set twice to completely clear the FIFO.                                 |
| 2   | UNDERRUN     | 0-1    | This bit is set automatically if an IN token is received when TXPKTRDY is not set. You should clear this bit.                                                                                                                                                                                                                                                            |
| 1   | FIFONOTEMPTY | 0-1    | This bit is set when there is at least 1 packet in the Tx FIFO. You should clear this bit.                                                                                                                                                                                                                                                                               |
| 0   | TXPKTRDY     | 0-1    | Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.                                                                                                                                                                             |

### 35.4.36 Control Status Register for Host Transmit Endpoint (HOST\_TXCSR)

The control status register for host transmit endpoint (HOST\_TXCSR) is shown in [Figure 35-62](#) and described in [Table 35-66](#).

**Figure 35-62. Control Status Register for Host Transmit Endpoint (HOST\_TXCSR)**

Field Descriptions**

| Bit | Field        | Value  | Description                                                                                                                                                                                                                                                                                                                                                              |
|-----|--------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | AUTOSET      | 0<br>1 | DMA Mode: The CPU needs to set the AUTOSET bit prior to enabling the Tx DMA.<br>CPU Mode: If the CPU sets the AUTOSET bit, the TXPKTRDY bit will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then the TXPKTRDY bit will have to be set manually. |
| 14  | Reserved     | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                 |
| 13  | MODE         | 0-1    | Set this bit to enable the endpoint direction as Tx, and clear the bit to enable it as Rx.<br>Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.                                                                                                                                                        |
| 12  | DMAEN        | 0-1    | Set this bit to enable the DMA request for the Tx endpoint.                                                                                                                                                                                                                                                                                                              |
| 11  | FRCDATATOG   | 0-1    | Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.                                                                                                    |
| 10  | DMAMODE      | 0-1    | This bit should always be set to 1 when the DMA is enabled.                                                                                                                                                                                                                                                                                                              |
| 9   | DATATOGWREN  | 0-1    | Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.                                                                                                                                                                                                                                 |
| 8   | DATATOG      | 0-1    | When read, this bit indicates the current state of the Tx EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.                                                                                                                                 |
| 7   | NAK_TIMEOUT  | 0-1    | This bit will be set when the Tx endpoint is halted following the receipt of NAK responses for longer than the time set as the NAKLIMIT by the TXINTERVAL register. It should be cleared to allow the endpoint to continue.<br>Note: This is valid only for Bulk endpoints.                                                                                              |
| 6   | CLRDATATOG   | 0-1    | Write a 1 to this bit to reset the endpoint data toggle to 0.                                                                                                                                                                                                                                                                                                            |
| 5   | RXSTALL      | 0-1    | This bit is set when a STALL handshake is received. The FIFO is flushed and the TXPKTRDY bit is cleared (see below). You should clear this bit.                                                                                                                                                                                                                          |
| 4   | SETUPPKT     | 0-1    | Set this bit at the same time as TXPKTRDY is set, to send a SETUP token instead of an OUT token for the transaction.<br>Note: Setting this bit also clears the DATATOG bit.                                                                                                                                                                                              |
| 3   | FLUSHFIFO    | 0-1    | Write a 1 to this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit (below) is cleared.<br>Note: FlushFIFO has no effect unless the TXPKTRDY bit is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.                         |
| 2   | ERROR        | 0-1    | The USB controller sets this bit when 3 attempts have been made to send a packet and no handshake packet has been received. You should clear this bit. An interrupt is generated when the bit is set. This is valid only when the endpoint is operating in Bulk or Interrupt mode.                                                                                       |
| 1   | FIFONOTEMPTY | 0-1    | The USB controller sets this bit when there is at least 1 packet in the Tx FIFO.                                                                                                                                                                                                                                                                                         |
| 0   | TXPKTRDY     | 0-1    | Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.                                                                                                                                                                             |

### 35.4.37 Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP)

The maximum packet size for peripheral host receive endpoint (RXMAXP) is shown in [Figure 35-63](#) and described in [Table 35-67](#).

**Figure 35-63. Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-67. Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP)  
Field Descriptions**

| Bit   | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-11 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 10-0  | MAXPAYLOAD | 0-400h | Defines the maximum amount of data that can be transferred through the selected Receive endpoint in a single frame/microframe (high-speed transfers). The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB Specification on packet sizes for Bulk, Interrupt, and Isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the Standard Endpoint Descriptor for the associated endpoint. A mismatch could cause unexpected results. |

### 35.4.38 Control Status Register for Peripheral Receive Endpoint (PERI\_RXCSR)

The control status register for peripheral receive endpoint (PERI\_RXCSR) is shown in [Figure 35-64](#) and described in [Table 35-68](#).

**Figure 35-64. Control Status Register for Peripheral Receive Endpoint (PERI\_RXCSR)**

**Table 35-68. Control Status Register for Peripheral Receive Endpoint (PERI\_RXCSR)  
Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | AUTOCLEAR  | 0<br>1 | DMA Mode: The CPU sets the AUTOCLEAR bit prior to enabling the Rx DMA.<br>CPU Mode: If the CPU sets the AUTOCLEAR bit, then the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO. When packets of less than the maximum packet size are unloaded, RXPKTRDY will have to be cleared manually.                                                                                                                          |
| 14   | ISO        | 0-1    | Set this bit to enable the Receive endpoint for Isochronous transfers, and clear it to enable the Receive endpoint for Bulk/Interrupt transfers.                                                                                                                                                                                                                                                                                                                                      |
| 13   | DMAEN      | 0-1    | Set this bit to enable the DMA request for the Receive endpoints.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12   | DISNYET    | 0<br>1 | DISNYET: Applies only for Bulk/Interrupt Transactions: The CPU sets this bit to disable the sending of NYET handshakes. When set, all successfully received Rx packets are ACK'd including at the point at which the FIFO becomes full.<br>Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints.<br>PID_ERROR: Applies only for ISO Transactions: The core sets this bit to indicate a PID error in the received packet. |
| 11   | DMAMODE    | 0-1    | Always clear this bit to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 10-8 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7    | CLRDATATOG | 0-1    | Write a 1 to this bit to reset the endpoint data toggle to 0.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 6    | SENTSTALL  | 0-1    | This bit is set when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.                                                                                                                                                                                                                                                                                                                                                |
| 5    | SENDSTALL  | 0-1    | Write a 1 to this bit to issue a STALL handshake. Clear this bit to terminate the stall condition.<br>Note: This bit has no effect where the endpoint is being used for Isochronous transfers.                                                                                                                                                                                                                                                                                        |
| 4    | FLUSHFIFO  | 0-1    | Write a 1 to this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPKTRDY bit is cleared.<br>Note: FLUSHFIFO has no effect unless RXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.                                                                                                                                                        |
| 3    | DATAERROR  | 0-1    | This bit is set when RXPKTRDY is set if the data packet has a CRC or bit-stuff error. It is cleared when RXPKTRDY is cleared.<br>Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.                                                                                                                                                                                                                                       |
| 2    | OVERRUN    | 0-1    | This bit is set if an OUT packet cannot be loaded into the Receive FIFO. You should clear this bit.<br>Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.                                                                                                                                                                                                                                                                 |
| 1    | FIFOFULL   | 0-1    | This bit is set when no more packets can be loaded into the Receive FIFO.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 0    | RXPKTRDY   | 0-1    | This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.                                                                                                                                                                                                                                                                                               |

### 35.4.39 Control Status Register for Host Receive Endpoint (HOST\_RXCSR)

The control status register for host receive endpoint (HOST\_RXCSR) is shown in [Figure 35-65](#) and described in [Table 35-69](#).

**Figure 35-65. Control Status Register for Host Receive Endpoint (HOST\_RXCSR)**

**Table 35-69. Control Status Register for Host Receive Endpoint (HOST\_RXCSR) Field Descriptions**

| Bit | Field              | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|--------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | AUTOCLEAR          | 0<br>1 | DMA Mode: The CPU sets the AUTOCLEAR bit prior to enabling the Rx DMA.<br>CPU Mode: If the CPU sets the AUTOCLEAR bit, then the RXPBKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO. When packets of less than the maximum packet size are unloaded, RXPBKTRDY will have to be cleared manually.                                                |
| 14  | AUTOREQ            | 1      | If the CPU sets the AUTOREQ bit, then the REQPKT bit will be automatically set when the RXPBKTRDY bit is cleared.<br>Note: This bit is automatically cleared when a short packet is received.                                                                                                                                                                                                                 |
| 13  | DMAEN              | 0-1    | Set this bit to enable the DMA request for the Receive endpoints.                                                                                                                                                                                                                                                                                                                                             |
| 12  | DISNYET            | 0-1    | Set this bit to disable the sending of NYET handshakes. When set, all successfully received Receive packets are ACKED including at the point at which the FIFO becomes full.<br>Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints.                                                                                                            |
| 11  | DMAMODE            | 0-1    | Always clear this bit to 0.                                                                                                                                                                                                                                                                                                                                                                                   |
| 10  | DATATOGWREN        | 0-1    | Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.                                                                                                                                                                                                                                                                      |
| 9   | DATATOG            | 0-1    | When read, this bit indicates the current state of the Receive EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.                                                                                                                                                                 |
| 8   | Reserved           | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                      |
| 7   | CLRDATATOG         | 0-1    | Write a 1 to this bit to reset the endpoint data toggle to 0.                                                                                                                                                                                                                                                                                                                                                 |
| 6   | RXSTALL            | 0-1    | When a STALL handshake is received, this bit is set and an interrupt is generated. You should clear this bit.                                                                                                                                                                                                                                                                                                 |
| 5   | REQPKT             | 0-1    | Write a 1 to this bit to request an IN transaction. It is cleared when RXPBKTRDY is set.                                                                                                                                                                                                                                                                                                                      |
| 4   | FLUSHFIFO          | 0-1    | Write a 1 to this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPBKTRDY bit is cleared.<br>Note: FLUSHFIFO has no effect unless RXPBKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.                                                                              |
| 3   | DATAERR_NAKTIMEOUT | 0-1    | When operating in ISO mode, this bit is set when RXPBKTRDY is set if the data packet has a CRC or bit-stuff error and cleared when RXPBKTRDY is cleared. In Bulk mode, this bit will be set when the Receive endpoint is halted following the receipt of NAK responses for longer than the time set as the NAK Limit by the RXINTERVAL register. You should clear this bit to allow the endpoint to continue. |
| 2   | ERROR              | 0-1    | The USB controller sets this bit when 3 attempts have been made to receive a packet and no data packet has been received. You should clear this bit. An interrupt is generated when the bit is set.<br>Note: This bit is only valid when the transmit endpoint is operating in Bulk or Interrupt mode. In ISO mode, it always returns zero.                                                                   |
| 1   | FIFOFULL           | 0-1    | This bit is set when no more packets can be loaded into the Receive FIFO.                                                                                                                                                                                                                                                                                                                                     |

**Table 35-69. Control Status Register for Host Receive Endpoint (HOST\_RXCSR) Field Descriptions (continued)**

| Bit | Field    | Value | Description                                                                                                                                                                             |
|-----|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | RXPKTRDY | 0-1   | This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set. |

### 35.4.40 Count 0 Register (COUNT0)

The count 0 register (COUNT0) is shown in [Figure 35-66](#) and described in [Table 35-70](#).

**Figure 35-66. Count 0 Register (COUNT0)**

|          |   |            |   |
|----------|---|------------|---|
| 15       | 7 | 6          | 0 |
| Reserved |   | EP0RXCOUNT |   |
| R-0      |   | R-0        |   |

LEGEND: R = Read only; -n = value after reset

**Table 35-70. Count 0 Register (COUNT0) Field Descriptions**

| Bit  | Field      | Value | Description                                                                                                                                                                                          |
|------|------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-7 | Reserved   | 0     | Reserved                                                                                                                                                                                             |
| 6-0  | EP0RXCOUNT | 0-7Fh | Indicates the number of received data bytes in the Endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while RXPKTRDY of PERI_CSR0 or HOST_CSR0 is set. |

### 35.4.41 Receive Count Register (RXCOUNT)

The receive count register (RXCOUNT) is shown in [Figure 35-67](#) and described in [Table 35-71](#).

**Figure 35-67. Receive Count Register (RXCOUNT)**

|          |    |           |   |
|----------|----|-----------|---|
| 15       | 13 | 12        | 0 |
| Reserved |    | EPRXCOUNT |   |
| R-0      |    | R-0       |   |

LEGEND: R = Read only; -n = value after reset

**Table 35-71. Receive Count Register (RXCOUNT) Field Descriptions**

| Bit   | Field     | Value   | Description                                                                                                                                                                                                   |
|-------|-----------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-13 | Reserved  | 0       | Reserved                                                                                                                                                                                                      |
| 12-0  | EPRXCOUNT | 0-1FFFh | Holds the number of received data bytes in the packet in the Receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while RXPKTRDY of PERI_RXCSR or HOST_RXCSR is set. |

### 35.4.42 Type Register (Host mode only) (HOST\_TYPE0)

The type register (Host mode only) (HOST\_TYPE0) is shown in [Figure 35-68](#) and described in [Table 35-72](#).

**Figure 35-68. Type Register (Host mode only) (HOST\_TYPE0)**

| 7-0           | POLINTVL_NAKLIMIT        | 0-FFh            | For Interrupt and Isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For Bulk endpoints, sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a transmit interval register for each configured transmit endpoint (except Endpoint 0). In each case, the value that is set defines a number of frames/microframes (High-Speed transfers), as follows: <table border="1" style="margin-top: 10px;"> <thead> <tr> <th>Transfer Type</th><th>Speed</th><th>Valid values (m)</th><th>Interpretation</th></tr> </thead> <tbody> <tr> <td rowspan="2">Interrupt</td><td>Low Speed or Full Speed</td><td>1-255</td><td>Polling interval is m frames</td></tr> <tr> <td>High Speed</td><td>1-16</td><td>Polling interval is <math>2^{(-1)}</math> microframes</td></tr> <tr> <td>Isochronous</td><td>Full Speed or High Speed</td><td>1-16</td><td>Polling interval is <math>2^{(-1)}</math> frames/microframes</td></tr> <tr> <td>Bulk</td><td>Full Speed or High Speed</td><td>2-16</td><td>NAK Limit is <math>2^{(-1)}</math> frames/microframes</td></tr> </tbody> </table><br>Note: A value of 0 or 1 disables the NAK timeout function. | Transfer Type | Speed | Valid values (m) | Interpretation | Interrupt | Low Speed or Full Speed | 1-255 | Polling interval is m frames | High Speed | 1-16 | Polling interval is $2^{(-1)}$ microframes | Isochronous | Full Speed or High Speed | 1-16 | Polling interval is $2^{(-1)}$ frames/microframes | Bulk | Full Speed or High Speed | 2-16 | NAK Limit is $2^{(-1)}$ frames/microframes |
| Transfer Type | Speed                    | Valid values (m) | Interpretation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |               |       |                  |                |           |                         |       |                              |            |      |                                            |             |                          |      |                                                   |      |                          |      |                                            |

| 7-0           | POLINTVL_NAKLIMIT        | 0-FFh            | <p>For Interrupt and Isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For Bulk endpoints, sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a transmit interval register for each configured transmit endpoint (except Endpoint 0). In each case, the value that is set defines a number of frames/microframes (High-Speed transfers), as follows:</p> <table> <tr> <th>Transfer Type</th><th>Speed</th><th>Valid values (m)</th><th>Interpretation</th></tr> <tr> <td rowspan="2">Interrupt</td><td>Low Speed or Full Speed</td><td>1-255</td><td>Polling interval is m frames</td></tr> <tr> <td>High Speed</td><td>1-16</td><td>Polling interval is 2<sup>(-1)</sup> microframes</td></tr> <tr> <td>Isochronous</td><td>Full Speed or High Speed</td><td>1-16</td><td>Polling interval is 2<sup>(-1)</sup> frames/microframes</td></tr> <tr> <td>Bulk</td><td>Full Speed or High Speed</td><td>2-16</td><td>NAK Limit is 2<sup>(-1)</sup> frames/microframes</td></tr> </table> <p>Note: A value of 0 or 1 disables the NAK timeout function.</p> | Transfer Type | Speed | Valid values (m) | Interpretation | Interrupt | Low Speed or Full Speed | 1-255 | Polling interval is m frames | High Speed | 1-16 | Polling interval is 2 <sup>(-1)</sup> microframes | Isochronous | Full Speed or High Speed | 1-16 | Polling interval is 2 <sup>(-1)</sup> frames/microframes | Bulk | Full Speed or High Speed | 2-16 | NAK Limit is 2 <sup>(-1)</sup> frames/microframes |

| 1   | HOSTREQ  | 0-1                                                                    | When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. ('B' device only)                                                                                                                                                                                                                                                                       |
| 0   | SESSION  | 0-1                                                                    | When operating as an 'A' device, you must set or clear this bit start or end a session. When operating as a 'B' device, this bit is set/cleared by the USB controller when a session starts/ends. You must also set this bit to initiate the Session Request Protocol (SRP). When the USB controller is in Suspend mode, you may clear the bit to perform a software disconnect. A special software routine is required to perform SRP. |

### 35.4.55 Transmit Endpoint FIFO Size (TXFIFOSZ)

Section 35.2.6 describes dynamically setting endpoint FIFO sizes. The option of dynamically setting endpoint FIFO sizes only applies to Endpoints 1-4. The Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location (start address 0). It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints that are active in the current USB configuration have a block of RAM assigned exclusively to that endpoint. The RAM must be at least as large as the maximum packet size set for that endpoint.

The transmit endpoint FIFO size (TXFIFOSZ) is shown in Figure 35-81 and described in Table 35-85.

**Figure 35-81. Transmit Endpoint FIFO Size (TXFIFOSZ)**

|          |   |       |     |   |
|----------|---|-------|-----|---|
| 7        | 5 | 4     | 3   | 0 |

| 7-5 | Reserved | 0     | Reserved                                                                                                                                                                                                                                     |
| 4   | DPB      | 0     | Double packet buffering enable                                                                                                                                                                                                               |
|     |          | 0     | Single packet buffering is supported                                                                                                                                                                                                         |
|     |          | 1     | Double packet buffering is enabled                                                                                                                                                                                                           |
| 3-0 | SZ       | 0-Fh  | Maximum packet size to be allowed (before any splitting within the FIFO of Bulk packets prior to transmission). If m = SZ, the FIFO size is calculated as $2^{(m+3)}$ for single packet buffering and $2^{(m+4)}$ for dual packet buffering. |

### 35.4.56 Receive Endpoint FIFO Size (RXFIFOSZ)

Section 35.2.6 describes dynamically setting endpoint FIFO sizes. The option of dynamically setting endpoint FIFO sizes only applies to Endpoints 1-4. The Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location (start address 0). It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints that are active in the current USB configuration have a block of RAM assigned exclusively to that endpoint. The RAM must be at least as large as the maximum packet size set for that endpoint.

The receive endpoint FIFO size (RXFIFOSZ) is shown in Figure 35-82 and described in Table 35-86.

**Figure 35-82. Receive Endpoint FIFO Size (RXFIFOSZ)**

|          |   |       |     |   |
|----------|---|-------|-----|---|

|     |          | 0     | Single packet buffering is supported                                                                                                                                                                                                         |
|     |          | 1     | Double packet buffering is enabled                                                                                                                                                                                                           |
| 3-0 | SZ       | 0-Fh  | Maximum packet size to be allowed (before any splitting within the FIFO of Bulk packets prior to transmission). If m = SZ, the FIFO size is calculated as $2^{(m+3)}$ for single packet buffering and $2^{(m+4)}$ for dual packet buffering. |

### 35.4.57 Transmit Endpoint FIFO Address (TXFIFOADDR)

Section 35.2.6 describes dynamically setting endpoint FIFO sizes.

The transmit endpoint FIFO address (TXFIFOADDR) is shown in Figure 35-83 and described in Table 35-87.

**Figure 35-83. Transmit Endpoint FIFO Address (TXFIFOADDR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-87. Transmit Endpoint FIFO Address (TXFIFOADDR) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                        |
|-------|----------|---------|----------------------------------------------------------------------------------------------------|
| 15-13 | Reserved | 0       | Reserved                                                                                           |
| 12-0  | ADDR     | 0-1FFFh | Start Address of endpoint FIFO in units of 8 bytes<br>If m = ADDR, then the start address is 8 × m |

### 35.4.58 Receive Endpoint FIFO Address (RXFIFOADDR)

Section 35.2.6 describes dynamically setting endpoint FIFO sizes.

The receive endpoint FIFO address (RXFIFOADDR) is shown in Figure 35-84 and described in Table 35-88.

**Figure 35-84. Receive Endpoint FIFO Address (RXFIFOADDR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-88. Receive Endpoint FIFO Address (RXFIFOADDR) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                        |
|-------|----------|---------|----------------------------------------------------------------------------------------------------|
| 15-13 | Reserved | 0       | Reserved                                                                                           |
| 12-0  | ADDR     | 0-1FFFh | Start Address of endpoint FIFO in units of 8 bytes<br>If m = ADDR, then the start address is 8 × m |

### 35.4.59 Hardware Version Register (HWVERS)

The hardware version register (HWVERS) contains the RTL major and minor version numbers for the USB 2.0 OTG controller module. The RTL version number is REVMAJ.REVMIN. The HWVERS is shown in [Figure 35-85](#) and described in [Table 35-89](#).

**Figure 35-85. Hardware Version Register (HWVERS)**

|     |        |    |   |        |
|-----|--------|----|---|--------|
| 15  | 14     | 10 | 9 | 0      |
| RC  | REVMAJ |    |   | REVMIN |
| R-0 | R-0    |    |   | R-0    |

LEGEND: R = Read only; -n = value after reset

**Table 35-89. Hardware Version Register (HWVERS) Field Descriptions**

| Bit   | Field  | Value  | Description                                                                                    |
|-------|--------|--------|------------------------------------------------------------------------------------------------|
| 15    | RC     | 0-1    | Set to 1 if RTL is used from a Release Candidate, rather than from a full release of the core. |
| 14-10 | REVMAJ | 0-1Fh  | Major version of RTL. Range is 0-31.                                                           |
| 9-0   | REVMIN | 0-3E7h | Minor version of RTL. Range is 0-999.                                                          |

### 35.4.60 Transmit Function Address (TXFUNCADDR)

The transmit function address (TXFUNCADDR) is shown in [Figure 35-86](#) and described in [Table 35-90](#).

**Figure 35-86. Transmit Function Address (TXFUNCADDR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-90. Transmit Function Address (TXFUNCADDR) Field Descriptions**

| Bit | Field    | Value | Description                |
|-----|----------|-------|----------------------------|
| 7   | Reserved | 0     | Reserved                   |
| 6-0 | FUNCADDR | 0-7Fh | Address of target function |

### 35.4.61 Transmit Hub Address (TXHUBADDR)

The transmit hub address (TXHUBADDR) is shown in [Figure 35-87](#) and described in [Table 35-91](#).

**Figure 35-87. Transmit Hub Address (TXHUBADDR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-91. Transmit Hub Address (TXHUBADDR) Field Descriptions**

| Bit | Field      | Value | Description                                                                                                            |
|-----|------------|-------|------------------------------------------------------------------------------------------------------------------------|
| 7   | MULT_TRANS | 0-1   | Set to 1 if hub has multiple transaction translators. Cleared to 0 if only single transaction translator is available. |
| 6-0 | HUBADDR    | 0-7Fh | Address of hub                                                                                                         |

### 35.4.62 Transmit Hub Port (TXHUBPORT)

The transmit hub port (TXHUBPORT) is shown in [Figure 35-88](#) and described in [Table 35-92](#).

**Figure 35-88. Transmit Hub Port (TXHUBPORT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-92. Transmit Hub Port (TXHUBPORT) Field Descriptions**

| Bit | Field    | Value | Description            |
|-----|----------|-------|------------------------|
| 7   | Reserved | 0     | Reserved               |
| 6-0 | HUBPORT  | 0-7Fh | Port number of the hub |

### 35.4.63 Receive Function Address (RXFUNCADDR)

The receive function address (RXFUNCADDR) is shown in [Figure 35-89](#) and described in [Table 35-93](#).

**Figure 35-89. Receive Function Address (RXFUNCADDR)**

|          |          |   |
|----------|----------|---|
| 7        | 6        | 0 |
| Reserved | FUNCADDR |   |
| R-0      | R/W-0    |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-93. Receive Function Address (RXFUNCADDR) Field Descriptions**

| Bit | Field    | Value | Description                |
|-----|----------|-------|----------------------------|
| 7   | Reserved | 0     | Reserved                   |
| 6-0 | FUNCADDR | 0-7Fh | Address of target function |

### 35.4.64 Receive Hub Address (RXHUBADDR)

The receive hub address (RXHUBADDR) is shown in [Figure 35-90](#) and described in [Table 35-94](#).

**Figure 35-90. Receive Hub Address (RXHUBADDR)**

|            |         |   |
|------------|---------|---|
| 7          | 6       | 0 |
| MULT_TRANS | HUBADDR |   |
| R/W-0      | R/W-0   |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-94. Receive Hub Address (RXHUBADDR) Field Descriptions**

| Bit | Field      | Value | Description                                                                                                            |
|-----|------------|-------|------------------------------------------------------------------------------------------------------------------------|
| 7   | MULT_TRANS | 0-1   | Set to 1 if hub has multiple transaction translators. Cleared to 0 if only single transaction translator is available. |
| 6-0 | HUBADDR    | 0-7Fh | Address of hub                                                                                                         |

### 35.4.65 Receive Hub Port (RXHUBPORT)

The receive hub port (RXHUBPORT) is shown in [Figure 35-91](#) and described in [Table 35-95](#).

**Figure 35-91. Receive Hub Port (RXHUBPORT)**

|          |         |   |
|----------|---------|---|
| 7        | 6       | 0 |
| Reserved | HUBPORT |   |
| R-0      | R/W-0   |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 35-95. Receive Hub Port (RXHUBPORT) Field Descriptions**

| Bit | Field    | Value | Description        |
|-----|----------|-------|--------------------|
| 7   | Reserved | 0     | Reserved           |
| 6-0 | HUBPORT  | 0-7Fh | Port number of hub |

### 35.4.68 CDMA Emulation Control Register (DMAEMU)

The CDMA emulation controls the behavior of the DMA when the emususp input is asserted. The CDMA emulation control register (DMAEMU) is shown in [Figure 35-94](#) and described in [Table 35-98](#).

**Figure 35-94. CDMA Emulation Control Register (DMAEMU)**

|          |  |   |       |       |
|----------|--|---|-------|-------|

| 31-2 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                   |
| 1    | SOFT     | 0<br>1 | Determines emulation mode functionality. When the FREE bit is cleared to 0, the SOFT bit selects the mode.<br>Upon emulation suspend, operation is not affected.<br>In response to an emulation suspend event, the logic halts after the current transaction is completed. |
| 0    | FREE     | 0<br>1 | Free run emulation control. Determines emulation mode functionality. When the FREE bit is cleared to 0, the SOFT bit selects the mode.<br>The SOFT bit selects the mode.<br>Runs free regardless of the SOFT bit.                                                          |

### 35.4.69 CDMA Transmit Channel *n* Global Configuration Registers (TXGCR[0]-TXGCR[3])

The transmit channel *n* configuration registers (TXGCR[*n*]) initialize the behavior of each of the transmit DMA channels. There are four configuration registers, one for each transmit DMA channels. The transmit channel *n* configuration registers (TXGCR[*n*]) are shown in [Figure 35-95](#) and described in [Table 35-99](#).

**Figure 35-95. CDMA Transmit Channel *n* Global Configuration Registers (TXGCR[*n*])**

|           |                 |                 |    |

| 15        | 14              | 13              | 0  |
| Reserved  | TX_DEFAULT_QMGR | TX_DEFAULT_QNUM |    |
| R-0       | W-0             | W-0             |    |

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 35-99. CDMA Transmit Channel *n* Global Configuration Registers (TXGCR[*n*]) Field Descriptions**

| Bit   | Field           | Value  | Description                                                                                                                                                       |
|-------|-----------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | TX_ENABLE       | 0<br>1 | Channel control. The TX_ENABLE field is cleared after a channel teardown is complete.<br>Disables channel<br>Enables channel                                      |
| 30    | TX_TEARDOWN     | 0-1    | Setting this bit requests the channel to be torn down. The TX_TEARDOWN field remains set after a channel teardown is complete.                                    |
| 29-14 | Reserved        | 0      | Reserved                                                                                                                                                          |
| 13-12 | TX_DEFAULT_QMGR | 0-3h   | Controls the default queue manager number that is used to queue teardown descriptors back to the host.                                                            |
| 11-0  | TX_DEFAULT_QNUM | 0-FFFh | Controls the default queue number within the selected queue manager onto which teardown descriptors are queued back to the host. This is the Tx Completion Queue. |

### 35.4.70 CDMA Receive Channel $n$ Global Configuration Registers (RXGCR[0]-RXGCR[3])

The receive channel  $n$  global configuration registers (RXGCR[ $n$ ]) initialize the global (non-descriptor-type specific) behavior of each of the receive DMA channels. There are four configuration registers, one for each receive DMA channels. If the enable bit is being set, the receive channel  $n$  global configuration register should only be written after all of the other receive configuration registers have been initialized. The receive channel  $n$  global configuration registers (RXGCR[ $n$ ]) are shown in Figure 35-96 are described in Table 35-100.

**Figure 35-96. CDMA Receive Channel  $n$  Global Configuration Registers (RXGCR[ $n$ ])**

| 24    | RX_ERROR_HANDLING    | 0<br>1                   | Controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occur):<br>0<br>Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to.<br>1<br>Starvation errors result in subsequent retry of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving its internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. |
| 23-16 | RX_SOP_OFFSET        | 0-FFh                    | Specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 15-14 | RX_DEFAULT_DESC_TYPE | 0-3h<br>0<br>1h<br>2h-3h | Indicates the default descriptor type to use. The actual descriptor type that is used for reception can be overridden by information provided in the CPPI FIFO data block.<br>Reserved<br>Host<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 13-12 | RX_DEFAULT_RQ_QMGR   | 0-3h                     | Indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 11-0  | RX_DEFAULT_RQ_QNUM   | 0-FFFh                   | Indicates the default receive queue that this channel should use. The actual receive queue that is used for reception can be overridden by information provided in the CPPI FIFO data block. This is the Rx Completion Queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 35.4.71 CDMA Receive Channel $n$ Host Packet Configuration Registers A (RXHPCRA[0]-RXHPCRA[3])

The receive channel  $n$  host packet configuration registers A (RXHPCRA[ $n$ ]) initialize the behavior of each of the receive DMA channels for reception of host type packets. There are four configuration A registers, one for each receive DMA channels. The receive channel  $n$  host packet configuration registers A (RXHPCRA[ $n$ ]) are shown in [Figure 35-97](#) and described in [Table 35-101](#).

| 13-12 | RX_HOST_FDQ0_QMGR | 0-3h   | Specifies which buffer manager should be used for the first receive buffer in a host type packet.                                                                           |
| 11-0  | RX_HOST_FDQ0_QNUM | 0-FFFh | Specifies which free descriptor/buffer pool should be used for the first receive buffer in a host type packet. This is the Rx Submit Queue for the first Incoming Packet.   |

### 35.4.72 CDMA Receive Channel $n$ Host Packet Configuration Registers B (RXHPCRB[0]-RXHPCRB[3])

The receive channel  $n$  host packet configuration registers B (RXHPCRB[ $n$ ]) initialize the behavior of each of the receive DMA channels for reception of host type packets. There are four configuration B registers, one for each receive DMA channels. The receive channel  $n$  host packet configuration registers B (RXHPCRB[ $n$ ]) are shown in [Figure 35-98](#) and described in [Table 35-102](#).

| 27-16 | RX_HOST_FDQ3_QNUM | 0-FFFh | Specifies which free descriptor/buffer pool should be used for the fourth or later receive buffer in a host type packet. This is the Rx Submit Queue for the fourth and remaining Incoming Packet. |
| 15-14 | Reserved          | 0      | Reserved                                                                                                                                                                                           |
| 13-12 | RX_HOST_FDQ2_QMGR | 0-3h   | Specifies which buffer manager should be used for the third receive buffer in a host type packet.                                                                                                  |
| 11-0  | RX_HOST_FDQ2_QNUM | 0-FFFh | Specifies which free descriptor/buffer pool should be used for the third receive buffer in a host type packet. This is the Rx Submit Queue for the third Incoming Packet.                          |

### 35.4.73 CDMA Scheduler Control Register (DMA\_SCHED\_CTRL)

The CDMA scheduler control register (DMA\_SCHED\_CTRL) enables the scheduler and indicates the last entry in the scheduler table. The CDMA scheduler control register (DMA\_SCHED\_CTRL) is shown in [Figure 35-99](#) and described in [Table 35-103](#).

**Figure 35-99. CDMA Scheduler Control Register (DMA\_SCHED\_CTRL)**

**Table 35-103. CDMA Scheduler Control Register (DMA\_SCHED\_CTRL) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                         |
|------|------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | ENABLE     | 0      | This is the enable bit for the scheduler and is encoded as follows:<br>Scheduler is disabled and will no longer fetch entries from the scheduler table or pass credits to the DMA controller                                                                        |
|      |            | 1      | Scheduler is enabled. This bit should only be set after the table has been initialized.                                                                                                                                                                             |
| 30-8 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                            |
| 7-0  | LAST_ENTRY | 0-FFh  | Indicates the last valid entry in the scheduler table. There are 64 words in the table and there are 4 entries in each word. The table can be programmed with any integer number of entries from 1 to 256. The corresponding encoding for this field is as follows: |
|      |            | 0      | 1 entry                                                                                                                                                                                                                                                             |
|      |            | 1h     | 2 entries                                                                                                                                                                                                                                                           |
|      |            | 2h-FFh | 3 entries to 256 entries                                                                                                                                                                                                                                            |

#### 35.4.74 CDMA Scheduler Table Word n Registers (WORD[0]-WORD[63])

The CDMA scheduler table word  $n$  registers (WORD[ $n$ ]) has 4 entries (ENTRY[0] to ENTRY[3]) that provide information about the scheduler. The CDMA scheduler table word  $n$  registers (WORD[ $n$ ]) are shown in [Figure 35-100](#) and described in [Table 35-104](#).

| Bit   | Field          | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27-24 | ENTRY3_CHANNEL | 0-Fh  | Indicates the channel number that is to be given an opportunity to transfer data. If this is a transmit entry, the DMA will be presented with a scheduling credit for that exact transmit channel. If this is a receive entry, the DMA will be presented with a scheduling credit for the receive FIFO that is associated with this channel. For receive FIFOs which carry traffic for more than one receive DMA channel, the exact channel number that is given in the receive credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |
| 23    | ENTRY2_RXTX    | 0     | Transmit channel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|       |                | 1     | Receive channel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 22-20 | Reserved       | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 19-16 | ENTRY2_CHANNEL | 0-Fh  | Indicates the channel number that is to be given an opportunity to transfer data. If this is a transmit entry, the DMA will be presented with a scheduling credit for that exact transmit channel. If this is a receive entry, the DMA will be presented with a scheduling credit for the receive FIFO that is associated with this channel. For receive FIFOs which carry traffic for more than one receive DMA channel, the exact channel number that is given in the receive credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |
| 15    | ENTRY1_RXTX    | 0     | Transmit channel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 6-4   | Reserved       | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3-0   | ENTRY0_CHANNEL | 0-Fh  | Indicates the channel number that is to be given an opportunity to transfer data. If this is a transmit entry, the DMA will be presented with a scheduling credit for that exact transmit channel. If this is a receive entry, the DMA will be presented with a scheduling credit for the receive FIFO that is associated with this channel. For receive FIFOs which carry traffic for more than one receive DMA channel, the exact channel number that is given in the receive credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |

### 35.4.75 Queue Manager Revision Identification Register (QMGRREVID)

The queue manager revision identification register (QMGRREVID) contains the major and minor revisions for the module. The QMGRREVID is shown in [Figure 35-101](#) and described in [Table 35-105](#).

**Figure 35-101. Queue Manager Revision Identification Register (QMGRREVID)**

LEGEND: R = Read only; -n = value after reset

### Table 35-105. Queue Manager Revision Identification Register (QMGRREVID) Field Descriptions

| Bit  | Field | Value      | Description                       |

### 35.4.76 Queue Manager Queue Diversion Register (DIVERSION)

The queue manager queue diversion register (DIVERSION) is used to transfer the contents of one queue onto another queue. It does not support byte accesses. The queue manager queue diversion register (DIVERSION) is shown in [Figure 35-102](#) and described in [Table 35-106](#).

**Figure 35-102. Queue Manager Queue Diversion Register (DIVERSION)**

### 35.4.77 Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)

The free descriptor/buffer queue starvation count register (FDBSC0) provides statistics about how many starvation events are occurring on the receive free descriptor/buffer queues. It does not support byte accesses. The free descriptor/buffer queue starvation count register (FDBSC0) is shown in [Figure 35-103](#) and described in [Table 35-107](#).

**Figure 35-103. Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)**

LEGEND: RC = Cleared on read; -n = value after reset

**Table 35-107. Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)  
Field Descriptions**

| Bit   | Field            | Value | Description                                                                                                                    |
|-------|------------------|-------|--------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | FDBQ3_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 3 is read while it is empty. This field is cleared when read. |
| 23-16 | FDBQ2_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 2 is read while it is empty. This field is cleared when read. |
| 15-8  | FDBQ1_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 1 is read while it is empty. This field is cleared when read. |
| 7-0   | FDBQ0_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 0 is read while it is empty. This field is cleared when read. |

### 35.4.78 Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1)

The free descriptor/buffer queue starvation count register 1 (FDBSC1) provides statistics about how many starvation events are occurring on the receive free descriptor/buffer queues. It does not support byte accesses. The free descriptor/buffer queue starvation count register 1 (FDBSC1) is shown in [Figure 35-104](#) and described in [Table 35-108](#).

**Figure 35-104. Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1)**

|                  |    |                  |    |

|-------|------------------|-------|--------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | FDBQ7_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 7 is read while it is empty. This field is cleared when read. |
| 23-16 | FDBQ6_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 6 is read while it is empty. This field is cleared when read. |
| 15-8  | FDBQ5_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 5 is read while it is empty. This field is cleared when read. |
| 7-0   | FDBQ4_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 4 is read while it is empty. This field is cleared when read. |

### 35.4.79 Queue Manager Free Descriptor/Buffer Starvation Count Register 2 (FDBSC2)

The free descriptor/buffer queue starvation count register 2 (FDBSC2) provides statistics about how many starvation events are occurring on the receive free descriptor/buffer queues. It does not support byte accesses. The free descriptor/buffer queue starvation count register 2 (FDBSC2) is shown in [Figure 35-105](#) and described in [Table 35-109](#).

### 35.4.80 Queue Manager Free Descriptor/Buffer Starvation Count Register 3 (FDBSC3)

The free descriptor/buffer queue starvation count register 3 (FDBSC3) provides statistics about how many starvation events are occurring on the receive free descriptor/buffer queues. It does not support byte accesses. The free descriptor/buffer queue starvation count register 3 (FDBSC3) is shown in [Figure 35-106](#) and described in [Table 35-110](#).

| Bit   | Field             | Value | Description                                                                                                                     |
|-------|-------------------|-------|---------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | FDBQ15_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 15 is read while it is empty. This field is cleared when read. |
| 23-16 | FDBQ14_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 14 is read while it is empty. This field is cleared when read. |
| 15-8  | FDBQ13_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 13 is read while it is empty. This field is cleared when read. |
| 7-0   | FDBQ12_STARVE_CNT | 0-FFh | This field increments each time the Free Descriptor/Buffer Queue 12 is read while it is empty. This field is cleared when read. |

### 35.4.81 Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE)

The queue manager linking RAM region 0 base address register (LRAM0BASE) sets the base address for the first portion of the Linking RAM. This address must be 32-bit aligned. It is used by the Queue Manager to calculate the 32-bit linking address for a given descriptor index. It does not support byte accesses. The queue manager linking RAM region 0 base address register (LRAM0BASE) is shown in [Figure 35-107](#) and described in [Table 35-111](#).

**Figure 35-107. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE)**

**Table 35-111. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE) Field Descriptions**

| Bit  | Field        | Value        | Description                                                                                                                                                                |
|------|--------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | REGION0_BASE | 0-FFFF FFFFh | This field stores the base address for the first region of the linking RAM. This may be anywhere in 32-bit address space but would be typically located in on-chip memory. |

### 35.4.84 Queue Manager Queue Pending Register 0 (PEND0)

The queue pending register 0 (PEND0) can be read to find the pending status for queues 31 to 0. It does not support byte accesses. The queue pending register 0 (PEND0) is shown in [Figure 35-110](#) and described in [Table 35-114](#).

**NOTE:** The pending bit gets set when a Descriptor address is loaded in a Queue. The loading action causes the corresponding bit for that Queue to get set. Similarly, the pending bit gets cleared when the Descriptor address is off-loaded from a Queue by reading it. One way to check if the receive or transmit transfer has completed is by checking the bit that corresponds to the desired Completion Queue for that particular transfer. When the Queue Manager is finished with the transfer, it will load the Descriptor address to the Completion Queue.

**Figure 35-110. Queue Manager Queue Pending Register 0 (PEND0)**

LEGEND: R = Read only; -n = value after reset

**Table 35-114. Queue Manager Queue Pending Register 0 (PEND0) Field Descriptions**

| Bit  | Field  | Value        | Description                                                    |
|------|--------|--------------|----------------------------------------------------------------|
| 31-0 | QPEND0 | 0-FFFF FFFFh | This field indicates the queue pending status for queues 31-0. |

### 35.4.85 Queue Manager Queue Pending Register 1 (PEND1)

The queue pending register 1 (PEND1) can be read to find the pending status for queues 63 to 32. It does not support byte accesses. The queue pending register 1 (PEND1) is shown in [Figure 35-111](#) and described in [Table 35-115](#).

**NOTE:** The pending bit gets set when a Descriptor address is loaded in a Queue. The loading action causes the corresponding bit for that Queue to get set. Similarly, the pending bit gets cleared when the Descriptor address is off-loaded from a Queue by reading it. One way to check if the receive or transmit transfer has completed is by checking the bit that corresponds to the desired Completion Queue for that particular transfer. When the Queue Manager is finished with the transfer, it will load the Descriptor address to the Completion Queue.

LEGEND: R = Read only; -n = value after reset

**Table 35-115. Queue Manager Queue Pending Register 1 (PEND1) Field Descriptions**

| Bit  | Field  | Value        | Description                                                     |
|------|--------|--------------|-----------------------------------------------------------------|
| 31-0 | QPEND1 | 0-FFFF FFFFh | This field indicates the queue pending status for queues 63-32. |

### 35.4.86 Queue Manager Memory Region *R* Base Address Registers (QMEMRBASE[0]-QMEMRBASE[15])

The memory region *R* base address register (QMEMRBASE[*R*]) is written by the host to set the base address of memory region *R*, where *R* is 0-15. This memory region will store a number of descriptors of a particular size as determined by the memory region *R* control register. It does not support byte accesses. The memory region *R* base address register (QMEMRBASE[*R*]) is shown in [Figure 35-112](#) and described in [Table 35-116](#).

**Figure 35-112. Queue Manager Memory Region *R* Base Address Registers (QMEMRBASE[*R*])**

LEGEND: R/W = Read/Write; -*n* = value after reset

| 31-0 | REG   | 0-FFFF FFFFh | This field contains the base address of the memory region <i>R</i> . |

### 35.4.87 Queue Manager Memory Region R Control Registers (QMEMRCTRL[0]-QMEMRCTRL[15])

The memory region *R* control register (QMEMRCTRL[*R*]) is written by the host to configure various parameters of memory region *R*, where *R* is 0-15. It does not support byte accesses. The memory region *R* control register (QMEMRCTRL[*R*]) is shown in [Figure 35-113](#) and described in [Table 35-117](#).

**Figure 35-113. Queue Manager Memory Region *R* Control Registers (QMEMRCTRL[*R*])**

### 35.4.88 Queue Manager Queue N Control Register D (CTRLD[0]-CTRLD[63])

The queue manager queue *N* control register D (CTRLD[*N*]) is written to add a packet to the queue and read to pop a packets off a queue. The packet is only pushed or popped to/from the queue when the queue manager queue *N* control register D is written. It does not support byte accesses. The queue manager queue *N* control register D (CTRLD[*N*]) is shown in [Figure 35-114](#) and described in [Table 35-118](#).

**Figure 35-114. Queue Manager Queue N Control Register D (CTRLD[*N*])**

LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 35-118. Queue Manager Queue N Control Register D (CTRLD[*N*]) Field Descriptions**

| Bit  | Field     | Value  | Description                                                                                              |
|------|-----------|--------|----------------------------------------------------------------------------------------------------------|
| 31-5 | DESC_PTR  | 0      | Descriptor Pointer                                                                                       |
|      |           | 1      | Queue is empty.                                                                                          |
|      |           |        | Indicates a 32-bit aligned address that points to a descriptor.                                          |
| 4-0  | DESC_SIZE | 0-1Fh  | The descriptor size is encoded in 4-byte increments. This field returns a 0 when an empty queue is read. |
|      |           | 0      | 24 bytes                                                                                                 |
|      |           | 1h     | 28 bytes                                                                                                 |
|      |           | 2h     | 32 bytes                                                                                                 |
|      |           | 3h-1Fh | 36 bytes to 148 bytes                                                                                    |

### 35.4.89 Queue Manager Queue N Status Register A (QSTATATA[0]-QSTATATA[63])

The queue manager queue *N* status register A (QSTATATA[*N*]) is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses. The queue manager queue *N* status register A (QSTATATA[*N*]) is shown in [Figure 35-115](#) and described in [Table 35-119](#).

**Figure 35-115. Queue Manager Queue N Status Register A (QSTATATA[*N*])**

LEGEND: R = Read only; -*n* = value after reset

**Table 35-119. Queue Manager Queue N Status Register A (QSTATATA[*N*]) Field Descriptions**

| Bit   | Field             | Value   | Description                                                              |
|-------|-------------------|---------|--------------------------------------------------------------------------|
| 31-14 | Reserved          | 0       | Reserved                                                                 |
| 13-0  | QUEUE_ENTRY_COUNT | 0-3FFFh | This field indicates how many packets are currently queued on the queue. |

### 35.4.90 Queue Manager Queue N Status Register B (QSTATB[0]-QSTATB[63])

The queue manager queue *N* status register B (QSTATB[*N*]) is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. It does not support byte accesses. The queue manager queue *N* status register B (QSTATB[*N*]) is shown in [Figure 35-116](#) and described in [Table 35-120](#).

**Figure 35-116. Queue Manager Queue N Status Register B (QSTATB[*N*])**

LEGEND: R = Read only; -*n* = value after reset

**Table 35-120. Queue Manager Queue N Status Register B (QSTATB[*N*]) Field Descriptions**

| Bit   | Field            | Value       | Description                                                                                                  |
|-------|------------------|-------------|--------------------------------------------------------------------------------------------------------------|
| 31-28 | Reserved         | 0           | Reserved                                                                                                     |
| 27-0  | QUEUE_BYTE_COUNT | 0-FFF FFFFh | Indicates how many bytes total are contained in all of the packets which are currently queued on this queue. |

### 35.4.91 Queue Manager Queue N Status Register C (QSTATC[0]-QSTATC[63])

The queue manager queue N status register C (QSTATC[N]) specifies the packet size for the head element of a queue. It does not support byte accesses. The queue manager queue N status register C (QSTATC[N]) is shown in [Figure 35-117](#) and described in [Table 35-121](#).

**Figure 35-117. Queue Manager Queue N Status Register C (QSTATC[N])**

LEGEND: R = Read only; -n = value after reset

**Table 35-121. Queue Manager Queue N Status Register C (QSTATC[N]) Field Descriptions**

| Bit   | Field       | Value   | Description                                                              |
|-------|-------------|---------|--------------------------------------------------------------------------|
| 31-14 | Reserved    | 0       | Reserved                                                                 |
| 13-0  | PACKET_SIZE | 0-3FFFh | This field indicates how many packets are currently queued on the queue. |

## Video Port Interface (VPIF)

This chapter describes the video port interface (VPIF).

| Topic                          | Page        |
|--------------------------------|-------------|
| <b>36.1 Introduction .....</b> | <b>1776</b> |
| <b>36.2 Architecture .....</b> | <b>1780</b> |
| <b>36.3 Registers .....</b>    | <b>1801</b> |

## 36.1 Introduction

### 36.1.1 Overview

The video port interface (VPIF) has two video input channels and two video output channels. Channels 0 and 1 share the same receive architecture, and channels 2 and 3 share the same transmit architecture. The input and output channel combinations of the VPIF are shown in [Figure 36-1](#).

**Figure 36-1. Input and Output Channels of VPIF**

### 36.1.2 Features

The VPIF is designed to support the following features (note that some device designs may support reduced features because of system-level performance limitations):

- ITU-BT.656 format
- ITU-BT.1120 and SMPTE 296 formats
- Raw data capture
- VBI data storage
- Clipping of output data (to eliminate FFh and 00h values)

### 36.1.3 Features Not Supported

The following functions are not supported:

- ITU-BT.601 format
- Separated synchronization format (requiring vertical sync, horizontal sync, and field ID signals independent of the pixel data) is not supported (except for the raw data capture mode)

### 36.1.4 Functional Block Diagram

A block diagram of the VPIF is shown in [Figure 36-2](#). A block diagram of the internal architecture of the VPIF is shown in [Figure 36-3](#).

**Figure 36-2. Video Port Interface (VPIF) Block Diagram**

**Figure 36-3. VPIF Architecture Block Diagram**

## Supported Use Cases

The following describes supported VPIF use cases. Actual VPIF performance may vary between devices designs because of system-level limitations.

The VPIF module has two input channels and two output channels. All channels can be activated simultaneously (see [Table 36-1](#)). The module uses four 512 byte buffers to cache data.

- Channels 0 and 1 are prepared only for input.
- Channels 2 and 3 are prepared only for output.

As shown in [Table 36-1](#), both NTSC and PAL formats are supported. The supported VBI format is based on ITU-BT.1364. [Table 36-2](#) describes the usage combinations that are supported in the VPIF.

**Table 36-1. Supported Formats on VPIF**

| TV System Format                 | TV Definition Format                               |                                                         |

| Raw capture mode            | √                                      | √                                             | √                                      |
| SDTV input                  | √ (both 1-channel and 2-channel input) | √ (both 1-channel and 2-channel input/output) | √ (both 1-channel and 2-channel input) |
| No input                    | √                                      | √ (both 1-channel and 2-channel output)       |                                        |

## 36.2 Architecture

This section describes the architecture of the video port interface module (VPIF).

### 36.2.1 Clock Control

The VPIF has 4 clock input pins and 2 clock output pins. Each channel has 1 clock input pin with clock edge control using the CLKEDGE bit in the channel  $n$  control register (CnCTRL). VPIF can provide a clock for an external device on channel 2 or 3 using the CLKEN bit in the appropriate C2CTRL or C3CTRL register. The clock generated by VPIF will have the same frequency as the input clock.

### 36.2.2 Signal Descriptions

[Table 36-3](#) describes the pin assignment on the VPIF for receiving video and capturing raw data. Shaded signals in [Table 36-3](#) are synchronization signals that are necessary for capturing raw data.

[Table 36-4](#) describes the pin assignments for transmitting video data.

**Table 36-3. Receive Pin Multiplexing Control**

| Pin Name | Rec. 656  | Rec. 1120 | Raw Data Capture | Pin Name | Rec. 656  | Rec. 1120  | Raw Data Capture |
|----------|-----------|-----------|------------------|----------|-----------|------------|------------------|
| DIN[0]   | data0[0]  | luma[0]   | raw_data[0]      | DIN[8]   | data1[0]  | chroma[0]  | raw_data[8]      |
| DIN[1]   | data0[1]  | luma[1]   | raw_data[1]      | DIN[9]   | data1[1]  | chroma[1]  | raw_data[9]      |

## Interlaced and Progressive Video

VPIF supports both interlaced and progressive video formats.

### Interlaced Video

The components of interlaced video are shown in [Figure 36-4](#).

**Figure 36-4. Interlaced Video**

The values in the table are from the BT.656 and BT.1120 standards. L11 is regarded as the start line of the frame in the VPIF.

All parameters (L1 to L12) for interlaced video are configured through VPIF register settings. Values listed in [Figure 36-4](#) are for NTSC and (PAL).

Interlaced video is divided into eight buffer spaces:

1. Top field VBI data in vertical ancillary area
2. Top field VBI data in horizontal ancillary area
3. Bottom field VBI data in vertical ancillary area
4. Bottom field VBI data in horizontal ancillary area
5. Top field luminance data
6. Top field chrominance data
7. Bottom field luminance data
8. Bottom field chrominance data

## Progressive Video

The components of progressive video are shown in [Figure 36-5](#).

**Figure 36-5. Progressive Video**

|    | Role of each line number                      | HDTV case | F | V |
|----|-----------------------------------------------|-----------|---|---|
| L1 | First line of upper blanking for the frame    | 1         | 0 | 1 |
| L2 | Last line of upper blanking for the frame     | 25        | 0 | 1 |
| L3 | First line of the frame for active video area | 26        | 0 | 0 |
| L4 | Last line of the frame for active video area  | 745       | 0 | 0 |
| L5 | First line of lower blanking for the frame    | 746       | 0 | 1 |
| L6 | Last line of lower blanking for the frame     | 750       | 0 | 1 |

The buffer register configurations are latched at L1 in progressive format. Data on L5 to L6 is stored into a different memory buffer from data on L1 to L2 because the base address is changed at timing of L1.

All parameters (L1 to L6) for progressive video are configured through VPIF register settings.

Progressive video is divided into four buffer spaces:

1. VBI data in vertical ancillary area
2. VBI data in horizontal ancillary area
3. Luminance data
4. Chrominance data

### 36.2.3 Memory Interface

#### DMA Request Size

The DMA burst size between the VPIF module and storage memory is configured through the DMA Request Size Control Register (REQSIZE).

#### Storage Format

The VPIF supports two data buffer memory addressing modes for luminance and chrominance data: Field and Frame, as shown in [Figure 36-6](#). The FIELDFRAME bit (in C0CTRL and C2CTRL) selects which storage method is used. Progressive video must use the Frame storage mode, but interlaced video can use either Field or Frame storage modes.

Figure 36-6. Memory Storage Modes for Interlaced Video

The storage modes are optimized for the following use conditions for interlaced video:

- Field format
  - Top- and bottom-field data-sets are stored in isolated buffers
  - Top- and bottom-field buffer start addresses are independent
  - Address offset per line of data in each top- and bottom-field buffer is equal to hofst ( $CnIMGOFFSET = hofst$ )
- Frame format
  - Top- and bottom-field data-sets are interlaced in memory
  - Top-field buffer start address is coupled with bottom-field buffer start address (Top Start = Bottom Start - hofst)
  - Bottom-field buffer start address is coupled with top-field buffer start address (Bottom Start = Top Start + hofst)
  - Address offset per line of data in each top- or bottom-field buffer is equal to  $hofst \times 2$  ( $CnIMGOFFSET = hofst \times 2$ )

Note that because progressive video only uses top-field buffers, the address offset per line of data is equal to hofst ( $CnIMGOFFSET = hofst$ ).

Note that when capturing 10-bit or 12-bit video in the raw capture mode, the offset per line of data is doubled because of bit padding.

### 36.2.4 Video Transmit

VPIF channels 2 and 3 are used for video transmit.

#### Y/C Mux

For BT.656 video, luminance (Y) and chrominance (C) values are multiplexed into a single byte-stream on one channel (either channel 2 or channel 3).

For BT.1120 video, channels 2 and 3 function as a pair without Y/C multiplexing in the following configuration:

- Channel 2 transmits Y data (C buffer settings for channel 2 are ignored)
- Channel 3 transmits C data (Y buffer settings for channel 3 are ignored)

The Y/C multiplex function for BT.656 video is enabled by setting the YCMUX bit in the channel control registers *CnCTRL*. The YCMUX bit must be the same for both channels 2 and 3.

#### Transmit Clocking

Each transmit channel uses a reference input clock (CLKIN $n$ ) and a video output clock (CLKOUT $n$ ). When transmit is enabled, VPIF will generate CLKOUT $n$  with the same frequency as CLKIN $n$ , and video data will be transmitted synchronously with CLKOUT $n$ .

The CLKOUT $n$  output signal is enabled by setting the CLKEN bit in the channel control register *CnCTRL*; the signal can also be inverted by setting the CLKEDGE bit in the *CnCTRL* register.

When transmitting BT.1120 video data, the two transmit channels operate as a pair. To ensure that video data is transmitted at the same time across both channels, the CLKIN $n$  signals must share the same reference clock source.

#### Video Pixel Enable

The PIXEL bit of the C2CTRL and C3CTRL control registers enables the transmission of video data stored in memory. When the PIXEL bit is set, video data is transmitted normally. When the PIXEL bit is cleared, the VPIF will transmit blank video data (Y = 10h, C = 80h). The PIXEL bit should only be set when the associated VPIF channel is disabled, otherwise the VPIF may output corrupt data and issue an ERROR interrupt for buffer underflow.

### 36.2.5 Video Receive

VPIF channels 0 and 1 are used for video receive.

#### Y/C Mux

For BT.656 video, luminance (Y) and chrominance (C) values are multiplexed into a single byte-stream on one channel (either channel 0 or channel 1).

For BT.1120 video, channels 0 and 1 function as a pair without Y/C multiplexing in the following configuration:

- Channel 0 receives Y data (C buffer settings for channel 0 are ignored)
- Channel 1 receives C data (Y buffer settings for channel 1 are ignored)

The Y/C multiplex function for BT.656 video is enabled by setting the YCMUX bit in the channel control registers *CnCTRL*. The YCMUX bit must be the same for both channels 0 and 1.

#### Receive Clocking

Each receive channel uses an input clock (CLKIN<sub>n</sub>). When receive is enabled, video data is latched synchronously with the rising edge of CLKIN<sub>n</sub>. The VPIF can be reconfigured to latch on the falling edge of CLKIN<sub>n</sub> by setting the CLKEDGE bit in the *CnCTRL* register.

When receiving BT.1120 video data, the two receive channels operate as a pair. To ensure that video data is received at the same time across both channels, the CLKIN<sub>n</sub> signals must share the same reference clock.

#### Capture Mode

The CAPMODE bit of the *C0CTRL* and *C1CTRL* control registers determines what data format will be captured by VPIF. The BT/YC video mode will look for video sync signals that are embedded within the video byte stream (standard for BT video). The CCD/CMOS (Raw Data Capture) mode will look for video sync signals on the dedicated VPIF sync pins (common for CCD and CMOS sensors).

When the CCD/CMOS mode is selected, channels 0 and 1 will work as a pair. Thus, both channels must be enabled before VPIF will capture receive data.

Capture mode settings must be the same for both channels 0 and 1.

### 36.2.6 Raw Data Capture

The VPIF supports raw data capturing. With this function, you can connect a camera AFE output signal directly into an input port of the CPU. Usually, the output format of the camera AFE device is in raw format that consists of an RGB component (sometimes RGrGbB format). The following functions are supported:

- Storing pixel data in memory (no storage of blanking data).
- Data bit widths from 8 bits/pixel, 10 bits/pixel, and 12 bits/pixel mode.
- Selectable polarity for H/V pixel valid signal and field ID signal.
- Separated field storage (top field and bottom field are stored independently) and interleaved field storage (normal frame format) support in memory storage.
- Two kinds of interrupt support. One is asserted once per each configured line size (line\_interrupt through the FRAME1 signal) and the other is asserted at the end of the capture area (frame\_interrupt through the FRAME0 signal). See [Figure 36-7](#). Note that line\_interrupt is only supported in raw mode. In other modes (BT.656, BT.1120, and SMPTE 296M), line\_interrupt is not supported.

The following functions are not supported:

- No support of color space conversion from RGB to YCbCr.
- No CFA interpolation for each raw data pattern (such as Bayer or Foveon).
- No push-storage function on non-byte aligned data format (10 bits/pixel and 12 bits/pixel). Data should be stored in memory in byte-aligned format.

The active period of each synchronization signal is regarded as the blanking area and any other area is regarded as the active video area that is stored in memory. See [Figure 36-7](#).

**Figure 36-7. Functional Image of Raw Data Capturing Mode**

All register configurations related to raw capture mode are reflected with the falling edge of the internal V-sync, which source is raw\_v\_valid, in normal polarity (low = blanking, high = data).

#### 36.2.6.1 Raw Capture Mode Signals

Both interlaced and progressive interface modes are supported. The following signals are assigned to the interface signal of the raw capture mode:

- raw\_h\_valid: horizontal pixel valid signal (regarded as horizontal synchronization signal)
- raw\_v\_valid: vertical line valid signal (regarded as vertical synchronization signal)
- raw\_field\_id: field ID signal
- vin\_data\_raw[11:0]: raw data input (8 bits/pixel, 10 bits/pixel, and 12 bits/pixel)

### 36.2.6.1.1 Progressive CCD Raw Capture Mode

The CCD Raw Capture mode is illustrated in Figure 36-8. In this mode, data within the active periods of both raw\_v\_valid and raw\_h\_valid is captured by VPIF. The falling edges of the two valid signals serve as the vertical and horizontal synchronization signals (the valid signal edge polarity can be configured in the COCTRL register). You have to set the image address offset.

In this mode, without the activated period of raw\_v\_valid, no raw\_h\_valid signal is activated. Only in the period when both raw\_v\_valid and raw\_h\_valid signals are activated, the incoming data is regarded as valid data.

**Figure 36-8. Raw Capture Progressive Mode**

### 36.2.6.1.2 Interlaced CCD Raw Capture Mode

See Figure 36-9. The falling edge of the vertical valid signal (`raw_v_valid`) and the horizontal valid signal (`raw_h_valid`) is regarded as the normal vertical and horizontal synchronization signals, respectively. The field ID (`raw_fid`) is detected at the rising edge of the `raw_v_valid` signal. The description of the detail value in Figure 36-8 is based on the description on the Micron Image sensor device specification sheet.

In this mode, data with an active period of both of `raw_v_valid` and `raw_h_valid` is detected by the VPIF and valid data is stored in extra-VPIF memory. The falling edge of the two signals is regarded as the vertical and horizontal synchronization signals (the valid signal polarity and the field ID polarity can be configured by the channel 0 control register (C0CTRL)). You have to set the image address offset.

Figure 36-9. Raw Capture Interlaced Mode

### 36.2.6.2 Configuration Settings for Raw Capture Mode

In raw capture mode, VPIF automatically detects the incoming image size by using the `raw_h_valid` and `raw_v_valid` signals. Thus, the `CnHCFG`, `CnVCFG0`, `CnVCFG1`, and `CnVSIZE` registers are not required.

### 36.2.6.3 Memory Format on Raw Capture Mode

All active video data is stored in memory outside of VPIF in byte-aligned format. Bit stuffing is performed (as shown in Figure 36-10) when 10 bits/pixel or 12 bits/pixel mode is selected.

Figure 36-10. Stuffing Manner in Storage Memory

|                    |                         |    |         |    |                         |    |         |    |                         |    |         |    |                         |   |         |   |
|--------------------|-------------------------|----|---------|----|-------------------------|----|---------|----|-------------------------|----|---------|----|-------------------------|---|---------|---|
|                    | 63                      | 56 | 55      | 48 | 47                      | 40 | 39      | 32 | 31                      | 24 | 23      | 16 | 15                      | 8 | 7       | 0 |
| 8[bit/pixel] mode  | Pixel 7                 |    | Pixel 6 |    | Pixel 5                 |    | Pixel 4 |    | Pixel 3                 |    | Pixel 2 |    | Pixel 1                 |   | Pixel 0 |   |
| 10[bit/pixel] mode | "000000" & pixel 3[9:0] |    |         |    | "000000" & pixel 2[9:0] |    |         |    | "000000" & pixel 1[9:0] |    |         |    | "000000" & pixel 0[9:0] |   |         |   |
| 12[bit/pixel] mode | "0000" & pixel 3[11:0]  |    |         |    | "0000" & pixel 2[11:0]  |    |         |    | "0000" & pixel 1[11:0]  |    |         |    | "0000" & pixel 0[11:0]  |   |         |   |

### 36.2.7 VBI Ancillary Data

The VPIF can transmit and receive ancillary data in the video blanking interval (VBI) of BT.656 and BT.1120 video streams. The ancillary data regions are referred to as:

- Horizontal Ancillary (HANC) - Data between EAV and SAV (horizontal blanking interval), and
- Vertical Ancillary (VANC) - Data between SAV and EAV (horizontal active video area).

Transmit and receive of ancillary data is enabled by setting the HANC and VANC bits in the C0CTRL and C2CTRL control registers.

#### 36.2.7.1 VBI Ancillary Data Transmit

The ancillary data to be transmitted is prepared by the user outside of VPIF. Ancillary register settings determine the origin position of the ancillary data within the VBI and how much ancillary data is to be transmitted. Note that the user is expected to place valid ancillary data in a memory buffer that is representative of the entire VBI region of interest. However, only the valid ancillary data region needs to be initialized -- the VPIF will automatically transmit blanking data (Y = 10h, C = 80h) for non-valid ancillary data regions.

As shown in Figure 36-11, the vertical-origin of each data region is offset from the falling edge of the vertical synchronization signal, and the horizontal-origin of each data region is offset from the SAV and EAV signals.

The value of the horizontal start position should be a multiple of 8 (HPOS[2:0] = 0) on both the horizontal and vertical ancillary data regions; the horizontal size can be defined as any value that does not exceed the data region.

**Figure 36-11. VBI Result Data Transmit Image for Interlaced Image**

### 36.2.7.2 VBI Ancillary Data Receive

When the VBI receive function is enabled, the VPIF receives all data in the associated blanking region. The VPIF cannot selectively receive sub-regions in the VBI space. The CPU has to receive valid data from this data and you have to prepare for the correct size of data buffer. For example in the NTSC case, the horizontal ancillary data needs 268 bytes × 525 lines and the vertical ancillary data needs 1440 bytes × 38 lines buffer.

The address line offset for the vertical ancillary data uses the channel *n* image data address offset register (CnIMGOFFSET).

#### Processing Method for Specific Ancillary Data

The VPIF has the ability to capture/assert video ancillary data ([Image of Specific Ancillary Data on NTSC](#)) that is not video image data but is VBI data. In most cases, video ancillary data is inserted in the blanking interval for either the horizontal or vertical direction. But in some cases, such as CGMS or closed-caption that is in Japanese and US applications, the line number where these kinds of ancillary data is inserted is in the active video area. In the case that ancillary data is inserted in the active video area, the VPIF regards the incoming (or stored data) as video data.

#### Clipping Function for Output

The clipping function is prepared for avoidance of miss-synchronization on an external device (video encoder), which receives output of the VPIF module. In some cases, the source data for the active video area has a combination of FF-00-00, which is the same as TRC (synchronization code). Some video encoders regard this combination as part of TRC and then the synchronization is failed.

In order to avoid this issue, the VPIF module is capable of clipping the output data value except the TRC within the range of 01~FEh. If this function is activated, the value 00h is clipped to 01h and the value FFh is clipped to FEh. Any other value is passed through.

As shown in [Data Areas and Clipping Function](#), VPIF has two data areas other than TRC: one is blanking data (ancillary data) and the second is video image data. The clipping function can be independently enabled for each data area. Note that field-level control is not supported.

The relationship between register bit assignment and the clipping function is shown in [Register Bit Assignment on Clipping Function](#). Control register bits in [Register Bit Assignment on Clipping Function](#) are prepared for both channel 2 and channel 3. Clipping on the channels is independently activated.

## Data Areas and Clipping Function

## Register Bit Assignment on Clipping Function

### 36.2.8 Reset Considerations

The VPIF does not have a software reset. When a hardware reset is asserted, all VPIF registers are set to their default values.

### 36.2.9 Initialization

The general procedure for VPIF initialization is:

1. Enable the VPIF in the LPSC.
2. Program the corresponding bits in the DMA size control register (REQSIZE) and the channel *n* sub-picture configuration register (CnSUBPIC).
3. Program the Emulation related registers, such as the emulation suspend control register (EMUCTRL) in the VPIF and the emulation suspend source register (SUSPSRC) in the System Module (see [Emulation Considerations](#) for more detail). The default values of SUSPSRC are configured to the ARM as the main processor.

### 36.2.10 Interrupt Support

#### Interrupt Events and Requests

The VPIF sends the following interrupt events to the CPU:

- FRAME0
- FRAME1
- FRAME2
- FRAME3
- ERROR

The ERROR interrupt is generated for the following reasons:

- For channels 0 or 1:
  - Internal buffer overflow
  - Length of EAV2SAV or SAV2EAV is not the same as the configured value
  - Bit error detected on 4th field of TRC
- For channels 2 or 3:
  - Internal buffer overflow

Note that the VPIF peripheral has no mechanism to reissue interrupts that may have been dropped by the CPU so care should be taken when VPIF interrupts are combined at the system level. In a combined interrupt configuration, the CPU may be busy servicing a VPIF interrupt when another VPIF interrupt arrives. If the interrupt controller has no means to count VPIF interrupts, the CPU will drop subsequent VPIF interrupts until servicing of the first VPIF interrupt is complete.

#### Field/Frame Interrupts to CPU

This section describes the conditions of the field/frame based interrupt assertion from the VPIF. The VPIF interrupt is designed to make the processor identify the timing for updating the address register of the VPIF module. The timing of the interrupt from the VPIF module is different from the timing of the V-sync. The interrupt is generated when the last data transfer between the VPIF module and the VBUS is finished.

#### Interrupt Condition

The interrupt signal from the VPIF described in this section means the beginning of a field (or frame). A way to indicate the beginning of a field (or a frame) varies from the function mode; normal YC receive/transmit mode and CCD/CMOS capture mode differ because of the vertical synchronization signal.

The VPIF generates the following events as conditions for interrupt assertion:

- In normal YC receive/transmit mode, EAV on line L1 (and EAV on line L7 in field interrupt for bottom field). Both L1 and L7 are described in [Figure 36-4](#) and [Figure 36-5](#).
- In CCD/CMOS capture mode, starting edge for first line of vertical valid pixel area.

## First Interrupt from VPIF

**NOTE:** The first vertical synchronization signal is defined as the transition from the L10 line to the L11 line in the interlace mode or from the L4 line to the L5 line in the progressive mode.

For raw capture mode, the VPIF immediately starts to capture the data if you enable middle of frame.

In channels 0 and 1, the VPIF starts to capture incoming picture data from the first vertical synchronization signal after the CPU activates the VPIF with register configuration. The interrupt signal from the VPIF is asserted when the vertical synchronization signal is received. So, no incoming data is written in memory when the first interrupt is asserted from the VPIF ([Relationship Between the First Interrupt and Incoming Data](#)).

If the CPU uses this interrupt signal not only for the time interval between each video frame but also for the timing to read the stored data from the defined area in memory. Note that the CPU has to ignore the first interrupt signal from the VPIF.

### Relationship Between the First Interrupt and Incoming Data

In channels 2 and 3, the VPIF starts to assert displaying picture data after the CPU activates the VPIF with register configuration. The output displaying data is asserted from the VPIF just after the VPIF reads the output data from memory ([Relationship Between the First Interrupt and Outgoing Data](#)).

So, any redundant data such as the frame[n - 1] area in [Relationship Between the First Interrupt and Incoming Data](#) is not necessary to be prepared. The relationship between the interrupt pulse activation and the register configuration is the same as for capturing data.

### Relationship Between the First Interrupt and Outgoing Data

If the [Relationship Between the First Interrupt and Outgoing Data](#) described relationship with the CPU activates the VPIF and the incoming data and frame[n] start the L11 line for the interlace mode or the L5 line for the progressive mode, the VPIF starts the data store from frame[n+1] not frame[n]. The first frame interrupt happens after frame[n] (at the 2nd frame interrupt in [Relationship Between the First Interrupt and Outgoing Data](#)), because at the start of the incoming data, there is no first vertical synchronization signal.

## Line Interrupts to CPU

In raw data capture mode (CCD/CMOS capture), VPIF will issue line-interval triggered interrupts using the field/frame interrupt signals. The line-interval is programmable in the C0CTRL register, and it uses the FRAME1 interrupt signal.

## Emulation Considerations

### 36.2.10.1 Emulation Suspend Mode Support

The VPIF supports the emulation suspend signal from the CPU. The emulation suspend signal (a high signal indicates that the CPU is suspended) is asserted by the CPU when the CPU is halted with a breakpoint or any other reason during debug.

Functional performance, when the emulation suspend signal is received, is defined by the register configuration and is different for each use (receiver and transmitter). Because the VPIF has to process real-time incoming (or outgoing) data that has a unit size of 1 frame, the VPIF can be stalled at the nearest end of the present processing frame when the emulation suspend signal is received. The fundamental performance of emulation suspend is shown in [Figure 36-12](#).

**Figure 36-12. Module Performance with Emulation Suspend Signal**

### 36.2.10.1.1 Receiver (Channels 0 and 1)

The VPIF receives input data from an external video device. The input format is BT.656 or BT.1120. If the emulation suspend comes from the CPU during image processing, the VPIF will first try to run at the end of the present frame and then the VPIF will be stalled (see [Figure 36-12](#) (c)).

The VPIF should only have a software stop mode; the hardware stop mode is not supported. If the CPU changes the register configuration during an emulation suspended period, the new configuration should be validated at the first V-sync after the suspended period.

### 36.2.10.1.2 Transmitter (Channels 2 and 3)

The VPIF transmits output data to an external video device. Source data for this output data is stored in SDRAM. The VPIF needs information about the start address of the source data stored in SDRAM. The output format is BT.656 or BT.1120.

In this mode, any suspend function should not be activated because you would like to see a displayed picture, taking usage of this signal into consideration. From a system's stand point, the VPIF should act in the following sequence if the emulation suspend signal is detected:

1. The VPIF continues processing at the end of the present frame.
2. If the present frame is finished, interrupt assertion is stalled.
3. At phase (b), during the active period of the emulation suspend signal, the VPIF continues reading the same frame data from SDRAM (no register change is reflected to module performance during this period).
4. After the CPU returns back to the normal state, the VPIF performs as usual. New register configurations done during an emulation suspend period are reflected in the functional performance at the first V-sync after deassertion of the suspend signal.

If the CPU changes the register configuration during an emulation suspended period, the new configuration should be validated at the first V-sync after the suspended period. Functional performance of this mode is shown in [Figure 36-13](#).

**Figure 36-13. Emulation Suspend Function on Channels 2 and 3 (Transmit)**

## Rules for Module Control

When disabling the VPIF follow the sequence below:

1. Disable ancillary data (HANC and VANC) in the *CnCTRL* control registers.
2. Wait for frame interrupt from the active channel.
3. Clear the channel enable bit of the channel in *CnCTRL*.

The VPIF stops immediately after writing 0 to the *CnEN* bit in the channel *n* control register (*CnCTRL*). Writing to *CnCTRL* takes effect exactly at the same time you write to it, it does not wait to be latched by the VSYNC.

**Figure 36-14. Method for Turning off Module Channel**

## Standard Video Modes

### BT.656 Mode

The input clock source of 27 MHz is used for the source clock of the video output, see [Figure 36-15](#). In BT.656 mode, either channel of the input port on the VPIF is used as the actual input of the data. The VPIF can provide a 27-MHz output to an external PLL device that provides the audio clock synchronized to the video output clock.

### Parameter Configuration for BT.656 Mode

The configuration for each register in BT.656 mode is shown in [Register Configuration on BT.656 Input/Output \(Unit Size = Byte in unsigned\)](#).

**Register Configuration on BT.656 Input/Output (Unit Size = Byte in unsigned)**

| Parameter           | Register       | Bit Name | NTSC | PAL  |
|---------------------|----------------|----------|------|------|
| EAV2SAV             | <i>CnHCFG</i>  | EAV2SAV  | 268  | 280  |
| SAV2EAV             | <i>CnHCFG</i>  | SAV2EAV  | 1440 | 1440 |
| Vertical frame size | <i>CnVSIZE</i> | VSIZE    | 525  | 625  |
| L1                  | <i>CnVCFG0</i> | L1       | 4    | 1    |
| L3                  | <i>CnVCFG0</i> | L3       | 20   | 23   |
| L5                  | <i>CnVCFG1</i> | L5       | 264  | 311  |
| L7                  | <i>CnVCFG1</i> | L7       | 266  | 313  |
| L9                  | <i>CnVCFG2</i> | L9       | 283  | 336  |
| L11                 | <i>CnVCFG2</i> | L11      | 1    | 624  |

Figure 36-15. Clock Control on Video Input and Output with SDTV Encoding

## BT.1120 Mode

The BT.1120 format is necessary to support HDTV input and output for the VPIF. The BT.1120 mode requires an input clock source of 74.25 MHz. Two VPIF channels are necessary to receive (encode) an input image and to display (local decode) the output image. The functional image and clock control is shown in [Figure 36-16](#). In this case, VPIF channels 0 and 1 are used for input and VPIF channels 2 and 3 are used for output.

### Parameter Configuration for BT.1120 Mode (1125/60/2:1 and 1250/50/2:1 system)

The configuration for each register in BT.1120 mode (1125/60/2:1 and 1250/50/2:1 system) is shown in [Register Configuration on BT.1120 \(1125/60/2:1 and 1250/50/2:1 System\) Input/Output](#) (Unit Size = Byte in unsigned).

**Register Configuration on BT.1120 (1125/60/2:1 and 1250/50/2:1 System) Input/Output**  
(Unit Size = Byte in unsigned)

| Parameter           | Register | Bit Name | NTSC | PAL  |
|---------------------|----------|----------|------|------|
| EAV2SAV             | CnHCFG   | EAV2SAV  | 272  | 376  |
| SAV2EAV             | CnHCFG   | SAV2EAV  | 1920 | 1920 |
| Vertical frame size | CnVSIZE  | VSIZE    | 1125 | 1250 |
| L1                  | CnVCFG0  | L1       | 1    | 1    |
| L3                  | CnVCFG0  | L3       | 41   | 45   |
| L5                  | CnVCFG1  | L5       | 558  | 621  |
| L7                  | CnVCFG1  | L7       | 564  | 626  |
| L9                  | CnVCFG2  | L9       | 603  | 670  |
| L11                 | CnVCFG2  | L11      | 1121 | 1246 |

### Parameter Configuration for BT.1120 Mode (1080-30p system)

The configuration for each register in BT.1120 mode (1080-30p system) is shown in [Register Configuration on BT.1120 \(1080-30p System\) Input/Output](#) (Unit Size = Byte in unsigned).

**Register Configuration on BT.1120 (1080-30p System) Input/Output**  
(Unit Size = Byte in unsigned)

| Parameter           | Register | Bit Name | Value |
|---------------------|----------|----------|-------|
| EAV2SAV             | CnHCFG   | EAV2SAV  | 272   |
| SAV2EAV             | CnHCFG   | SAV2EAV  | 1920  |
| Vertical frame size | CnVSIZE  | VSIZE    | 1125  |
| L1                  | CnVCFG0  | L1       | 1     |
| L3                  | CnVCFG0  | L3       | 42    |
| L5                  | CnVCFG1  | L5       | 1122  |

Figure 36-16. Clock Control on Video Input and Output with HDTV Encoding

## SMPTE 296M Mode

The SMPTE 296M mode requires the same clock control for the VPIF module as in BT.656 and BT.1120 modes. The video input clock source is 74.25 MHz. Two VPIFs are necessary to receive an input image and to display the output image. The functional image and clock control is shown in [Figure 36-17](#). In this case, VPIF channels 0 and 1 are used for input and VPIF channels 2 and 3 are used for output.

### Parameter Configuration for SMPTE 296M Mode

The configuration for each register in SMPTE 296M mode is shown in [Register Configuration on SMPTE 296M Input/Output \(Unit Size = Byte in unsigned\)](#).

**Register Configuration on SMPTE 296M Input/Output (Unit Size = Byte in unsigned)**

| Parameter           | Register | Bit Name | Value |
|---------------------|----------|----------|-------|
| EAV2SAV             | CnHCFG   | EAV2SAV  | 362   |
| SAV2EAV             | CnHCFG   | SAV2EAV  | 1280  |
| Vertical frame size | CnVSIZE  | VSIZE    | 750   |
| L1                  | CnVCFG0  | L1       | 1     |
| L3                  | CnVCFG0  | L3       | 26    |
| L5                  | CnVCFG1  | L5       | 746   |

**Figure 36-17. Clock Control on Video Input and Output with HDTV Encoding**

## Raw Capture Mode

The raw capture mode requires the same input clock for VPIF channel 0 and channel 1 (clock skew has to be aligned). A single clock signal should be connected to both VP\_CLKIN0 and VP\_CLKIN1.

### Parameter Configuration for Raw Capture Mode

When the VPIF sets the raw capture mode, the VPIF recognizes the image size automatically using the H/V valid signals. You do not need to configure the image size in the following registers:

- channel  $n$  horizontal data size configuration register (CnHCFG)
- channel  $n$  vertical data size configuration 0 register (CnVCFG0)
- channel  $n$  vertical data size configuration 1 register (CnVCFG1)
- channel  $n$  vertical image size register (CnVSIZE)

However, you still need to configure the storage memory address control related registers.

## 36.3 Registers

All register values should be configured before you set the CnEN bit in the channel  $n$  control register (CnCTRL) to 1. Also note that all register values except the CnEN bit in CnCTRL are detected by the first falling edge of the vertical synchronization signal on each channel as shown in [Relationship Between Register and Data Access](#).

[Table 36-5](#) lists the memory-mapped registers for the video port interface (VPIF). See the device-specific data manual for the memory address of these registers.

**Relationship Between Register and Data Access**

**Table 36-5. Video Port Interface (VPIF) Registers**

| Offset | Acronym    | Register Description               | Section                         |

**Table 36-11. Interrupt Enable Register (INTEN) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                           |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved                                                                                                                                              |
| 4    | ERROR    | 0     | VPIF error interrupt enable. The error interrupt is asserted when a problem is detected in any input/output byte stream data.                         |
|      |          | 1     | Error interrupt is disabled.                                                                                                                          |
|      |          | 1     | Error interrupt is enabled. The ERROR bit in the INTSET register must also be set to activate the ERROR interrupt.                                    |
| 3    | FRAME3   | 0     | Channel 3 frame interrupt enable. Enables the frame interrupt from the VPIF to CPU.                                                                   |
|      |          | 1     | Channel 3 frame interrupt is disabled.                                                                                                                |
|      |          | 1     | Channel 3 frame interrupt is enabled. The FRAME3 bit in the INTSET register must also be set to activate the FRAME3 interrupt.                        |
| 2    | FRAME2   | 0     | Channel 2 frame interrupt enable. Enables the frame interrupt from the VPIF to CPU.                                                                   |
|      |          | 1     | Channel 2 frame interrupt is disabled.                                                                                                                |
|      |          | 1     | Channel 2 frame interrupt is enabled. The FRAME2 bit in the INTSET register must also be set to activate the FRAME2 interrupt.                        |
| 1    | FRAME1   | 0     | Channel 1 frame interrupt enable. Enables the frame interrupt in BT/YC capture mode, or enables the line interval interrupt in CCD/CMOS capture mode. |
|      |          | 1     | Channel 1 frame interrupt is disabled.                                                                                                                |
|      |          | 1     | Channel 1 frame interrupt is enabled. The FRAME1 bit in the INTSET register must also be set to activate the FRAME1 interrupt.                        |
| 0    | FRAME0   | 0     | Channel 0 frame interrupt enable. Enables the frame interrupt from VPIF to CPU for BT/YC and CCD/CMOS capture modes.                                  |
|      |          | 1     | Channel 0 frame interrupt is disabled.                                                                                                                |
|      |          | 1     | Channel 0 frame interrupt is enabled. The FRAME0 bit in the INTSET register must also be set to activate the FRAME0 interrupt.                        |

### 36.3.7 Interrupt Enable Set Register (INTSET)

The interrupt enable set register (INTSET) is shown in [Figure 36-24](#) and described in [Table 36-12](#).

**Figure 36-24. Interrupt Enable Set Register (INTSET)**

LEGEND: R/WS = Read/Write 1 to Set; R = Read only; -n = value after reset

**Table 36-12. Interrupt Enable Set Register (INTSET) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                     |
|------|----------|-------|-------------------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved                                                                                        |
| 4    | ERROR    | 0     | Error interrupt enable set.<br>Interrupt on ERROR is masked (write 0 has no effect).            |
|      |          | 1     | Interrupt on ERROR is activated.                                                                |
| 3    | FRAME3   | 0     | Channel 3 frame interrupt enable set.<br>Interrupt on FRAME3 is masked (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME3 is activated.                                                               |
| 2    | FRAME2   | 0     | Channel 2 frame interrupt enable set.<br>Interrupt on FRAME2 is masked (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME2 is activated.                                                               |
| 1    | FRAME1   | 0     | Channel 1 frame interrupt enable set.<br>Interrupt on FRAME1 is masked (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME1 is activated.                                                               |
| 0    | FRAME0   | 0     | Channel 0 frame interrupt enable set.<br>Interrupt on FRAME0 is masked (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME0 is activated.                                                               |

### 36.3.8 Interrupt Enable Clear Register (INTCLR)

The interrupt enable clear register (INTCLR) is shown in [Figure 36-25](#) and described in [Table 36-13](#).

**Figure 36-25. Interrupt Enable Clear Register (INTCLR)**

LEGEND: R = Read only; W1C = Write 1 to Clear; -n = value after reset

**Table 36-13. Interrupt Enable Clear Register (INTCLR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                   |
|------|----------|-------|-------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved                                                                      |
| 4    | ERROR    | 0     | Error interrupt enable clear.<br>No change (write 0 has no effect).           |
|      |          | 1     | Interrupt on ERROR is masked                                                  |
| 3    | FRAME3   | 0     | Channel 3 frame interrupt enable clear.<br>No change (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME3 is masked.                                                |
| 2    | FRAME2   | 0     | Channel 2 frame interrupt enable clear.<br>No change (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME2 is masked.                                                |
| 1    | FRAME1   | 0     | Channel 1 frame interrupt enable clear.<br>No change (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME1 is masked.                                                |
| 0    | FRAME0   | 0     | Channel 0 frame interrupt enable clear.<br>No change (write 0 has no effect). |
|      |          | 1     | Interrupt on FRAME0 is masked.                                                |

### 36.3.9 Interrupt Status Register (INTSTAT)

The interrupt status register (INTSTAT) is shown in [Figure 36-26](#) and described in [Table 36-14](#).

**Figure 36-26. Interrupt Status Register (INTSTAT)**

LEGEND: R = Read only; -n = value after reset

**Table 36-14. Interrupt Status Register (INTSTAT) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                            |
|------|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                               |
| 4    | ERROR    | 0<br>1 | Error interrupt status. This bit is effective even if the ERROR bit in INTEN is disabled. Use the INTSTATCLR register to clear the status.<br>No error detected.<br>Error detected.                                                                                                    |
| 3    | FRAME3   | 0<br>1 | Channel 3 frame interrupt status. This bit is effective even if the FRAME3 bit in INTEN is disabled. Use the INTSTATCLR register to clear the status.<br>Frame sync on channel 3 not detected.<br>Frame sync on channel 3 detected.                                                    |
| 2    | FRAME2   | 0<br>1 | Channel 2 frame interrupt status. This bit is effective even if the FRAME2 bit in INTEN is disabled. Use the INTSTATCLR register to clear the status.<br>Frame sync on channel 2 not detected.<br>Frame sync on channel 2 detected.                                                    |
| 1    | FRAME1   | 0<br>1 | Channel 1 frame or line interval interrupt status. This bit is effective even if the FRAME1 bit in INTEN is disabled. Use the INTSTATCLR register to clear the status.<br>Frame sync or line interval on channel 1 not detected.<br>Frame sync or line interval on channel 1 detected. |
| 0    | FRAME0   | 0<br>1 | Channel 0 frame or line interval interrupt status. This bit is effective even if the FRAME0 bit in INTEN is disabled. Use the INTSTATCLR register to clear the status.<br>Frame sync or line interval on channel 0 not detected.<br>Frame sync or line interval on channel 0 detected. |

### 36.3.10 Interrupt Status Clear Register (INTSTATCLR)

The interrupt status clear register (INTSTATCLR) is shown in [Figure 36-27](#) and described in [Table 36-15](#).

**Figure 36-27. Interrupt Status Clear Register (INTSTATCLR)**

LEGEND: R = Read only; W1C = Write 1 to Clear; -n = value after reset

**Table 36-15. Interrupt Status Clear Register (INTSTATCLR) Field Descriptions**

| Bit  | Field    | Value | Description                                              |
|------|----------|-------|----------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved                                                 |
| 4    | ERROR    | 0     | Error interrupt status clear.                            |
|      |          | 1     | No change                                                |
| 3    | FRAME3   | 0     | Clear ERROR bit in INTSTAT.                              |
|      |          | 1     | No change                                                |
| 2    | FRAME2   | 0     | Channel 3 frame interrupt status clear.                  |
|      |          | 1     | No change                                                |
| 1    | FRAME1   | 0     | Clear FRAME3 bit in INTSTAT.                             |
|      |          | 1     | No change                                                |
| 0    | FRAME0   | 0     | Channel 2 frame interrupt status clear.                  |
|      |          | 1     | No change                                                |
|      |          | 0     | Channel 1 frame or line interval interrupt status clear. |
|      |          | 1     | No change                                                |
|      |          | 0     | Clear FRAME2 bit in INTSTAT.                             |
|      |          | 1     | No change                                                |
|      |          | 0     | Channel 1 frame or line interval interrupt status clear. |
|      |          | 1     | No change                                                |
|      |          | 0     | Clear FRAME1 bit in INTSTAT.                             |
|      |          | 1     | No change                                                |
|      |          | 0     | Channel 0 frame or line interval interrupt status clear. |
|      |          | 1     | No change                                                |
|      |          | 0     | Clear FRAME0 bit in INTSTAT.                             |
|      |          | 1     | No change                                                |

### 36.3.11 Emulation Suspend Control Register (EMUCTRL)

The emulation suspend control register (EMUCTRL) is shown in [Figure 36-28](#) and described in [Table 36-16](#).

**Figure 36-28. Emulation Suspend Control Register (EMUCTRL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 36-16. Emulation Suspend Control Register (EMUCTRL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                  |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                                                                                     |
| 0    | FREE     | 0     | Controls whether the peripheral responds to the emulation suspend signal.<br>Respond to monitoring emulation suspend signal. |
|      |          | 1     | Ignores any emulation suspend signal (non-stop).                                                                             |

### 36.3.12 DMA Size Control Register (REQSIZE)

The DMA size control register (REQSIZE) is shown in [Figure 36-29](#) and described in [Table 36-17](#).

**Figure 36-29. DMA Size Control Register (REQSIZE)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 36-17. DMA Size Control Register (REQSIZE) Field Descriptions**

| Bit  | Field    | Value     | Description                                      |
|------|----------|-----------|--------------------------------------------------|
| 31-9 | Reserved | 0         | Reserved                                         |
| 8-0  | BYTES    | 0-1FF     | Request size for DMA data transfer from/to VPIF. |
|      |          | 0-1Fh     | Reserved                                         |
|      |          | 20h       | 32 bytes                                         |
|      |          | 21h-3Fh   | Reserved                                         |

### 36.3.13 Channel *n* Top Field Luminance Address Register (CnTLUMA)

The Channel *n* Top Field Luminance Address Register (CnTLUMA) is shown in [Figure 36-30](#) and described in [Table 36-18](#).

**NOTE:** C1TLUMA and C3TLUMA registers are only used in Y/C multiplexed mode.

C0TLUMA is used for the top field of CCD/CMOS raw capture mode.

### Figure 36-30. Channel *n* Top Field Luminance Address Register (CnTLUMA)

LEGEND: R/W = Read/Write; -n = value after reset

Table 36-18. Channel *n* Top Field Luminance Address Register (C<sub>n</sub>TLUMA) Field Descriptions

| Bit  | Field   | Value        | Description                                                                                                                                                                    |
|------|---------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CnTLUMA | 0-FFFF FFFFh | Memory address of the top field luminance buffer.<br><br>The register value points to the beginning of the buffer, and the address must be a multiple of 8 (CnTLUMA[2:0] = 0). |

### 36.3.14 Channel *n* Bottom Field Luminance Address Register (CnBLUMA)

The Channel *n* Bottom Field Luminance Address Register (CnBLUMA) is shown in [Figure 36-31](#) and described in [Table 36-19](#).

**NOTE:** CnBLUMA registers are not used in progressive video mode. C1BLUMA and C3BLUMA registers are only used in Y/C multiplexed mode.

C0BLUMA is used for the bottom field of CCD/CMOS raw capture mode.

**Figure 36-31. Channel *n* Bottom Field Luminance Address Register (CnBLUMA)**

LEGEND: R/W = Read/Write; -n = value after reset

### 36.3.23 Channel *n* Horizontal Size Configuration Register (C0HCFG and C1HCFG)

The Channel *n* Horizontal Size Configuration Register (C*n*HCFG) is shown in Figure 36-40 and described in Table 36-28.

The C*n*HCFG Register determines the number of bytes in the active (SAV2EAV) and inactive (EAV2SAV) video regions. In the BT/YC mode ([Horizontal Distance in Y/C Mode](#)), the video regions are delimited by the embedded EAV and SAV codes (the region size does not include the 4-byte EAV and SAV codes). In the CCD/CMOS mode ([Horizontal Distance in CCD/CMOS Mode](#)), the regions are delimited by the synchronous raw\_h\_valid capture signal.

**Figure 36-40. Channel *n* Horizontal Size Configuration Register (C*n*HCFG)**

| 11-0  | VSIZE    | 0-FFFh | Vertical size of image (total number of lines). |

### 36.3.28 Channel *n* Horizontal Size Configuration Register (C2HCFG and C3HCFG)

The Channel *n* Horizontal Size Configuration Register (C*n*HCFG) is shown in [Figure 36-45](#) and described in [Table 36-33](#).

The C*n*HCFG Register determines the number of bytes in the active (SAV2EAV) and inactive (EAV2SAV) video regions. In the BT/YC mode ([Horizontal Distance in Y/C Mode](#)), the video regions are delimited by the embedded EAV and SAV codes (the region size does not include the 4-byte EAV and SAV codes). In the CCD/CMOS mode ([Horizontal Distance in CCD/CMOS Mode](#)), the regions are delimited by the synchronous raw\_h\_valid capture signal.

**Figure 36-45. Channel *n* Horizontal Size Configuration Register (C*n*HCFG)**

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.

### Products

|                              |                                                                                      |
