

# **OMAP-L138 C6000 DSP+ARM Processor**

## **Technical Reference Manual**

Literature Number: SPRUH77C  
April 2013–Revised September 2016

|                                         |            |
|-----------------------------------------|------------|
| <b>Preface</b>                          | <b>81</b>  |
| <b>1 Overview</b>                       | <b>82</b>  |
| 1.1 Introduction                        | 83         |
| 1.2 DSP Subsystem                       | 83         |
| 1.3 ARM Subsystem                       | 83         |
| <b>2 ARM Subsystem</b>                  | <b>85</b>  |
| 2.1 Introduction                        | 86         |
| 2.2 Operating States/Modes              | 87         |
| 2.3 Processor Status Registers          | 87         |
| 2.4 Exceptions and Exception Vectors    | 88         |
| 2.5 The 16-BIS/32-BIS Concept           | 89         |
| 2.6 16-BIS/32-BIS Advantages            | 89         |
| 2.7 Co-Processor 15 (CP15)              | 90         |
| 2.7.1 Addresses in an ARM926EJ-S System | 90         |
| 2.7.2 Memory Management Unit (MMU)      | 90         |
| 2.7.3 Caches and Write Buffer           | 91         |
| <b>3 DSP Subsystem</b>                  | <b>92</b>  |
| 3.1 Introduction                        | 93         |
| 3.2 TMS320C674x Megamodule              | 94         |
| 3.2.1 Internal Memory Controllers       | 94         |
| 3.2.2 Internal Peripherals              | 94         |
| 3.3 Memory Map                          | 99         |
| 3.3.1 DSP Internal Memory               | 99         |
| 3.3.2 External Memory                   | 99         |
| 3.4 Advanced Event Triggering (AET)     | 99         |
| <b>4 System Interconnect</b>            | <b>100</b> |
| 4.1 Introduction                        | 101        |
| 4.2 System Interconnect Block Diagram   | 102        |
| <b>5 System Memory</b>                  | <b>103</b> |
| 5.1 Introduction                        | 104        |
| 5.2 ARM Memories                        | 104        |
| 5.3 DSP Memories                        | 104        |
| 5.4 Peripherals                         | 105        |
| <b>6 Memory Protection Unit (MPU)</b>   | <b>106</b> |
| 6.1 Introduction                        | 107        |
| 6.1.1 Purpose of the MPU                | 107        |
| 6.1.2 Features                          | 107        |
| 6.1.3 Block Diagram                     | 107        |
| 6.1.4 MPU Default Configuration         | 108        |
| 6.2 Architecture                        | 108        |
| 6.2.1 Privilege Levels                  | 108        |
| 6.2.2 Memory Protection Ranges          | 109        |
| 6.2.3 Permission Structures             | 110        |
| 6.2.4 Protection Check                  | 111        |

|          |                                                                                                              |            |
|----------|--------------------------------------------------------------------------------------------------------------|------------|
| 6.2.5    | DSP L1/L2 Cache Controller Accesses .....                                                                    | 111        |
| 6.2.6    | MPU Register Protection .....                                                                                | 111        |
| 6.2.7    | Invalid Accesses and Exceptions .....                                                                        | 112        |
| 6.2.8    | Reset Considerations .....                                                                                   | 112        |
| 6.2.9    | Interrupt Support .....                                                                                      | 112        |
| 6.2.10   | Emulation Considerations .....                                                                               | 112        |
| 6.3      | MPU Registers .....                                                                                          | 113        |
| 6.3.1    | Revision Identification Register (REVID) .....                                                               | 115        |
| 6.3.2    | Configuration Register (CONFIG) .....                                                                        | 115        |
| 6.3.3    | Interrupt Raw Status/Set Register (IRAWSTAT) .....                                                           | 116        |
| 6.3.4    | Interrupt Enable Status/Clear Register (IENSTAT).....                                                        | 117        |
| 6.3.5    | Interrupt Enable Set Register (IENSET) .....                                                                 | 118        |
| 6.3.6    | Interrupt Enable Clear Register (IENCLR) .....                                                               | 118        |
| 6.3.7    | Fixed Range Start Address Register (FXD_MPSAR).....                                                          | 119        |
| 6.3.8    | Fixed Range End Address Register (FXD_MPEAR).....                                                            | 119        |
| 6.3.9    | Fixed Range Memory Protection Page Attributes Register (FXD_MPPA) .....                                      | 120        |
| 6.3.10   | Programmable Range <i>n</i> Start Address Registers (PROG <sub><i>n</i></sub> _MPSAR) .....                  | 121        |
| 6.3.11   | Programmable Range <i>n</i> End Address Registers (PROG <sub><i>n</i></sub> _MPEAR).....                     | 122        |
| 6.3.12   | Programmable Range <i>n</i> Memory Protection Page Attributes Register (PROG <sub><i>n</i></sub> _MPPA)..... | 123        |
| 6.3.13   | Fault Address Register (FLTADDRR).....                                                                       | 124        |
| 6.3.14   | Fault Status Register (FLTSTAT).....                                                                         | 125        |
| 6.3.15   | Fault Clear Register (FLTCLR) .....                                                                          | 126        |
| <b>7</b> | <b>Device Clocking</b> .....                                                                                 | <b>127</b> |
| 7.1      | Overview .....                                                                                               | 128        |
| 7.2      | Frequency Flexibility .....                                                                                  | 130        |
| 7.3      | Peripheral Clocking .....                                                                                    | 131        |
| 7.3.1    | USB Clocking.....                                                                                            | 131        |
| 7.3.2    | DDR2/mDDR Memory Controller Clocking .....                                                                   | 133        |
| 7.3.3    | EMIFA Clocking .....                                                                                         | 135        |
| 7.3.4    | EMAC Clocking .....                                                                                          | 136        |
| 7.3.5    | uPP Clocking .....                                                                                           | 138        |
| 7.3.6    | McASP Clocking .....                                                                                         | 139        |
| 7.3.7    | I/O Domains .....                                                                                            | 140        |
| <b>8</b> | <b>Phase-Locked Loop Controller (PLLCC) .....</b>                                                            | <b>141</b> |
| 8.1      | Introduction .....                                                                                           | 142        |
| 8.2      | PLL Controllers.....                                                                                         | 142        |
| 8.2.1    | Device Clock Generation .....                                                                                | 144        |
| 8.2.2    | Steps for Programming the PLLs .....                                                                         | 145        |
| 8.3      | PLLCC Registers .....                                                                                        | 147        |
| 8.3.1    | PLLCC0 Revision Identification Register (REVID) .....                                                        | 148        |
| 8.3.2    | PLLCC1 Revision Identification Register (REVID) .....                                                        | 149        |
| 8.3.3    | Reset Type Status Register (RSTYPE).....                                                                     | 149        |
| 8.3.4    | PLLCC0 Reset Control Register (RSCTRL) .....                                                                 | 150        |
| 8.3.5    | PLLCC0 Control Register (PLLCTL) .....                                                                       | 151        |
| 8.3.6    | PLLCC1 Control Register (PLLCTL) .....                                                                       | 152        |
| 8.3.7    | PLLCC0 OBSCLK Select Register (OCSEL) .....                                                                  | 153        |
| 8.3.8    | PLLCC1 OBSCLK Select Register (OCSEL) .....                                                                  | 154        |
| 8.3.9    | PLL Multiplier Control Register (PLLM).....                                                                  | 155        |
| 8.3.10   | PLLCC0 Pre-Divider Control Register (PREDIV).....                                                            | 155        |
| 8.3.11   | PLLCC0 Divider 1 Register (PLLDIV1) .....                                                                    | 156        |
| 8.3.12   | PLLCC1 Divider 1 Register (PLLDIV1) .....                                                                    | 156        |
| 8.3.13   | PLLCC0 Divider 2 Register (PLLDIV2) .....                                                                    | 157        |
| 8.3.14   | PLLCC1 Divider 2 Register (PLLDIV2) .....                                                                    | 157        |

|          |                                                                     |            |
|----------|---------------------------------------------------------------------|------------|
| 8.3.15   | PLLCO Divider 3 Register (PLLDIV3) .....                            | 158        |
| 8.3.16   | PLLCO Divider 3 Register (PLLDIV3) .....                            | 158        |
| 8.3.17   | PLLCO Divider 4 Register (PLLDIV4) .....                            | 159        |
| 8.3.18   | PLLCO Divider 5 Register (PLLDIV5) .....                            | 159        |
| 8.3.19   | PLLCO Divider 6 Register (PLLDIV6) .....                            | 160        |
| 8.3.20   | PLLCO Divider 7 Register (PLLDIV7) .....                            | 160        |
| 8.3.21   | PLLCO Oscillator Divider 1 Register (OSCDIV).....                   | 161        |
| 8.3.22   | PLLCO Oscillator Divider 1 Register (OSCDIV).....                   | 161        |
| 8.3.23   | PLL Post-Divider Control Register (POSTDIV) .....                   | 162        |

| 7-5.  | EMAC Clocking Diagram .....                                                                          | 136 |
| 7-6.  | uPP Clocking Diagram .....                                                                           | 138 |
| 7-7.  | McASP Clocking Diagram .....                                                                         | 139 |
| 8-1.  | PLL Structure .....                                                                                  | 143 |
| 8-2.  | PLL0 Revision Identification Register (REVID) .....                                                  | 148 |
| 8-3.  | PLL1 Revision Identification Register (REVID) .....                                                  | 149 |
| 8-4.  | Reset Type Status Register (RSTYPE) .....                                                            | 149 |
| 8-5.  | Reset Control Register (RCTRL) .....                                                                 | 150 |
| 8-6.  | PLL0 Control Register (PLLCTL) .....                                                                 | 151 |
| 8-7.  | PLL1 Control Register (PLLCTL) .....                                                                 | 152 |
| 8-8.  | PLL0 OBSCLK Select Register (OCSEL) .....                                                            | 153 |
| 8-9.  | PLL1 OBSCLK Select Register (OCSEL) .....                                                            | 154 |
| 8-10. | PLL Multiplier Control Register (PLLM) .....                                                         | 155 |
| 8-11. | PLL0 Pre-Divider Control Register (PREDIV) .....                                                     | 155 |
| 8-12. | PLL0 Divider 1 Register (PLLDIV1) .....                                                              | 156 |
| 8-13. | PLL1 Divider 1 Register (PLLDIV1) .....                                                              | 156 |
| 8-14. | PLL0 Divider 2 Register (PLLDIV2) .....                                                              | 157 |
| 8-15. | PLL1 Divider 2 Register (PLLDIV2) .....                                                              | 157 |
| 8-16. | PLL0 Divider 3 Register (PLLDIV3) .....                                                              | 158 |
| 8-17. | PLL1 Divider 3 Register (PLLDIV3) .....                                                              | 158 |
| 8-18. | PLL0 Divider 4 Register (PLLDIV4) .....                                                              | 159 |

|       |                                                               |     |
|-------|---------------------------------------------------------------|-----|
| 8-19. | PLLC0 Divider 5 Register (PLLDIV5) .....                      | 159 |
| 8-20. | PLLC0 Divider 6 Register (PLLDIV6) .....                      | 160 |
| 8-21. | PLLC0 Divider 7 Register (PLLDIV7) .....                      | 160 |
| 8-22. | PLLC0 Oscillator Divider 1 Register (OSCDIV) .....            | 161 |
| 8-23. | PLLC1 Oscillator Divider 1 Register (OSCDIV) .....            | 161 |
| 8-24. | PLL Post-Divider Control Register (POSTDIV) .....             | 162 |
| 8-25. | PLL Controller Command Register (PLLCMD) .....                | 162 |
| 8-26. | PLL Controller Status Register (PLLSTAT) .....                | 163 |
| 8-27. | PLLC0 Clock Align Control Register (ALNCTL) .....             | 164 |
| 8-28. | PLLC1 Clock Align Control Register (ALNCTL) .....             | 165 |
| 8-29. | PLLC0 PLLDIV Ratio Change Status Register (DCHANGE) .....     | 166 |
| 8-30. | PLLC1 PLLDIV Ratio Change Status Register (DCHANGE) .....     | 167 |
| 8-31. | PLLC0 Clock Enable Control Register (CKEN) .....              | 168 |
| 8-32. | PLLC1 Clock Enable Control Register (CKEN) .....              | 168 |
| 8-33. | PLLC0 Clock Status Register (CKSTAT) .....                    | 169 |
| 8-34. | PLLC1 Clock Status Register (CKSTAT) .....                    | 170 |
| 8-35. | PLLC0 SYSCLK Status Register (SYSTAT) .....                   | 171 |
| 8-36. | PLLC1 SYSCLK Status Register (SYSTAT) .....                   | 172 |
| 8-37. | Emulation Performance Counter 0 Register (EMUCNT0) .....      | 173 |
| 8-38. | Emulation Performance Counter 1 Register (EMUCNT1) .....      | 173 |
| 9-1.  | Revision Identification Register (REVID) .....                | 185 |
| 9-2.  | Interrupt Evaluation Register (INTEVAL) .....                 | 185 |
| 9-3.  | PSC0 Module Error Pending Register 0 (MERRPR0) .....          | 186 |
| 9-4.  | PSC1 Module Error Pending Register 0 (MERRPR0) .....          | 186 |
| 9-5.  | PSC0 Module Error Clear Register 0 (MERRCR0) .....            | 187 |
| 9-6.  | PSC1 Module Error Clear Register 0 (MERRCR0) .....            | 187 |
| 9-7.  | Power Error Pending Register (PERRPR) .....                   | 188 |
| 9-8.  | Power Error Clear Register (PERRCR) .....                     | 188 |
| 9-9.  | Power Domain Transition Command Register (PTCMD) .....        | 189 |
| 9-10. | Power Domain Transition Status Register (PTSTAT) .....        | 190 |
| 9-11. | Power Domain 0 Status Register (PDSTAT0) .....                | 191 |
| 9-12. | Power Domain 1 Status Register (PDSTAT1) .....                | 192 |
| 9-13. | Power Domain 0 Control Register (PDCTL0) .....                | 193 |
| 9-14. | Power Domain 1 Control Register (PDCTL1) .....                | 194 |
| 9-15. | Power Domain 0 Configuration Register (PDCFG0) .....          | 195 |
| 9-16. | Power Domain 1 Configuration Register (PDCFG1) .....          | 196 |
| 9-17. | Module Status <i>n</i> Register (MDSTAT <i>n</i> ) .....      | 197 |
| 9-18. | PSC0 Module Control <i>n</i> Register (MDCTL <i>n</i> ) ..... | 198 |
| 9-19. | PSC1 Module Control <i>n</i> Register (MDCTL <i>n</i> ) ..... | 199 |
| 10-1. | Deep Sleep Mode Sequence .....                                | 214 |
| 11-1. | Revision Identification Register (REVID) .....                | 223 |
| 11-2. | Device Identification Register 0 (DEVIDR0) .....              | 223 |
| 11-3. | Boot Configuration Register (BOOTCFG) .....                   | 224 |
| 11-4. | Chip Revision Identification Register (CHIPREVIDR) .....      | 224 |
| 11-5. | Kick 0 Register (KICK0R) .....                                | 225 |
| 11-6. | Kick 1 Register (KICK1R) .....                                | 225 |
| 11-7. | Host 0 Configuration Register (HOST0CFG) .....                | 226 |
| 11-8. | Host 1 Configuration Register (HOST1CFG) .....                | 227 |
| 11-9. | Interrupt Raw Status/Set Register (IRAWSTAT) .....            | 228 |

|                                                              |     |

| 15-1. Data Paths to DDR2/mDDR Memory Controller.....                       | 385 |
| 15-2. DDR2/mDDR Memory Controller Clock Block Diagram .....                | 386 |
| 15-3. DDR2/mDDR Memory Controller Signals .....                            | 387 |
| 15-4. Refresh Command.....                                                 | 390 |
| 15-5. DCAB Command.....                                                    | 391 |
| 15-6. DEAC Command.....                                                    | 392 |
| 15-7. ACTV Command.....                                                    | 393 |
| 15-8. DDR2/mDDR READ Command.....                                          | 394 |
| 15-9. DDR2/mDDR WRT Command.....                                           | 395 |
| 15-10. DDR2/mDDR MRS and EMRS Command .....                                | 396 |
| 15-11. Byte Alignment .....                                                | 396 |
| 15-12. DDR2/mDDR SDRAM Column, Row, and Bank Access .....                  | 400 |
| 15-13. Address Mapping Diagram (IBANKPOS = 1) .....                        | 401 |
| 15-14. SDRAM Column, Row, Bank Access (IBANKPOS = 1) .....                 | 402 |
| 15-15. DDR2/mDDR Memory Controller FIFO Block Diagram.....                 | 403 |
| 15-16. DDR2/mDDR Memory Controller Reset Block Diagram.....                | 407 |
| 15-17. DDR2/mDDR Memory Controller Power Sleep Controller Diagram .....    | 412 |
| 15-18. Connecting DDR2/mDDR Memory Controller to a 16-Bit DDR2 Memory..... | 414 |
| 15-19. Revision ID Register (REVID).....                                   | 419 |
| 15-20. SDRAM Status Register (SDRSTAT) .....                               | 420 |
| 15-21. SDRAM Configuration Register (SDCR) .....                           | 421 |
| 15-22. SDRAM Refresh Control Register (SDRCR) .....                        | 424 |
| 15-23. SDRAM Timing Register 1 (SDTIMR1) .....                             | 425 |
| 15-24. SDRAM Timing Register 2 (SDTIMR2) .....                             | 426 |
| 15-25. SDRAM Configuration Register 2 (SDCR2) .....                        | 427 |
| 15-26. Peripheral Bus Burst Priority Register (PBBPR).....                 | 428 |
| 15-27. Performance Counter 1 Register (PC1) .....                          | 429 |
| 15-28. Performance Counter 2 Register (PC2) .....                          | 429 |
| 15-29. Performance Counter Configuration Register (PCC) .....              | 430 |

|                                                                                                      |     |
|------------------------------------------------------------------------------------------------------|-----|
| 15-30. Performance Counter Master Region Select Register (PCMRS) .....                               | 432 |
| 15-31. Performance Counter Time Register (PCT) .....                                                 | 433 |
| 15-32. DDR PHY Reset Control Register (DRPYRCR) .....                                                | 433 |
| 15-33. Interrupt Raw Register (IRR) .....                                                            | 434 |
| 15-34. Interrupt Masked Register (IMR).....                                                          | 434 |
| 15-35. Interrupt Mask Set Register (IMSR) .....                                                      | 435 |
| 15-36. Interrupt Mask Clear Register (IMCR) .....                                                    | 436 |
| 15-37. DDR PHY Control Register 1 (DRPYC1R) .....                                                    | 437 |
| 16-1. Multiple eCAP Modules .....                                                                    | 440 |
| 16-2. Capture and APWM Modes of Operation.....                                                       | 441 |
| 16-3. Capture Function Diagram.....                                                                  | 442 |
| 16-4. Event Prescale Control.....                                                                    | 443 |
| 16-5. Prescale Function Waveforms .....                                                              | 443 |
| 16-6. Continuous/One-shot Block Diagram .....                                                        | 444 |
| 16-7. Counter and Synchronization Block Diagram .....                                                | 445 |
| 16-8. Interrupts in eCAP Module .....                                                                | 447 |
| 16-9. PWM Waveform Details Of APWM Mode Operation .....                                              | 448 |
| 16-10. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect .....                            | 450 |
| 16-11. Capture Sequence for Absolute Time-Stamp, Rising and Falling Edge Detect .....                | 452 |
| 16-12. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect.....                           | 454 |
| 16-13. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect.....               | 456 |
| 16-14. PWM Waveform Details of APWM Mode Operation .....                                             | 458 |
| 16-15. Multichannel PWM Example Using 4 eCAP Modules.....                                            | 460 |
| 16-16. Multiphase (channel) Interleaved PWM Example Using 3 eCAP Modules .....                       | 463 |
| 16-17. Time-Stamp Counter Register (TSCTR).....                                                      | 465 |
| 16-18. Counter Phase Control Register (CTRPHS) .....                                                 | 466 |
| 16-19. Capture 1 Register (CAP1) .....                                                               | 466 |
| 16-20. Capture 2 Register (CAP2).....                                                                | 467 |
| 16-21. Capture 3 Register (CAP3).....                                                                | 467 |
| 16-22. Capture 4 Register (CAP4).....                                                                | 468 |
| 16-23. ECAP Control Register 1 (ECCTL1) .....                                                        | 468 |
| 16-24. ECAP Control Register 2 (ECCTL2) .....                                                        | 470 |
| 16-25. ECAP Interrupt Enable Register (ECEINT).....                                                  | 472 |
| 16-26. ECAP Interrupt Flag Register (ECFLG).....                                                     | 473 |
| 16-27. ECAP Interrupt Clear Register (ECCLR) .....                                                   | 474 |
| 16-28. ECAP Interrupt Forcing Register (ECFRC).....                                                  | 475 |
| 16-29. Revision ID Register (REVID).....                                                             | 476 |
| 17-1. Multiple ePWM Modules .....                                                                    | 479 |
| 17-2. Submodules and Signal Connections for an ePWM Module.....                                      | 480 |
| 17-3. ePWM Submodules and Critical Internal Signal Interconnects .....                               | 481 |
| 17-4. Time-Base Submodule Block Diagram .....                                                        | 487 |
| 17-5. Time-Base Submodule Signals and Registers.....                                                 | 488 |
| 17-6. Time-Base Frequency and Period.....                                                            | 490 |
| 17-7. Time-Base Counter Synchronization Scheme 1.....                                                | 491 |
| 17-8. Time-Base Up-Count Mode Waveforms .....                                                        | 493 |
| 17-9. Time-Base Down-Count Mode Waveforms .....                                                      | 494 |
| 17-10. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down on Synchronization Event..... | 494 |
| 17-11. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up on Synchronization Event .....  | 495 |
| 17-12. Counter-Compare Submodule .....                                                               | 496 |

|                                                                                                                            |     |
|----------------------------------------------------------------------------------------------------------------------------|-----|
| 17-13. Counter-Compare Submodule Signals and Registers .....                                                               | 496 |
| 17-14. Counter-Compare Event Waveforms in Up-Count Mode.....                                                               | 499 |
| 17-15. Counter-Compare Events in Down-Count Mode .....                                                                     | 499 |
| 17-16. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down on Synchronization Event .....           | 500 |
| 17-17. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up on Synchronization Event .....             | 500 |
| 17-18. Action-Qualifier Submodule .....                                                                                    | 501 |
| 17-19. Action-Qualifier Submodule Inputs and Outputs.....                                                                  | 502 |
| 17-20. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs .....                                               | 503 |
| 17-21. Up-Down-Count Mode Symmetrical Waveform.....                                                                        | 506 |
| 17-22. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High .....             | 507 |
| 17-23. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low .....               | 509 |
| 17-24. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA.....                            | 511 |
| 17-25. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low .....    | 513 |
| 17-26. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary ..... | 515 |
| 17-27. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low .....                | 517 |
| 17-28. Dead-Band Generator Submodule .....                                                                                 | 519 |
| 17-29. Configuration Options for the Dead-Band Generator Submodule.....                                                    | 520 |
| 17-30. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%) .....                                                      | 522 |
| 17-31. PWM-Chopper Submodule .....                                                                                         | 523 |
| 17-32. PWM-Chopper Submodule Signals and Registers.....                                                                    | 524 |
| 17-33. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only .....                                           | 525 |
| 17-34. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses .....                      | 525 |
| 17-35. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses .....             | 526 |
| 17-36. Trip-Zone Submodule .....                                                                                           | 527 |
| 17-37. Trip-Zone Submodule Mode Control Logic.....                                                                         | 530 |
| 17-38. Trip-Zone Submodule Interrupt Logic .....                                                                           | 530 |
| 17-39. Event-Trigger Submodule .....                                                                                       | 531 |
| 17-40. Event-Trigger Submodule Inter-Connectivity to Interrupt Controller .....                                            | 532 |
| 17-41. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs .....                                            | 532 |
| 17-42. Event-Trigger Interrupt Generator .....                                                                             | 534 |
| 17-43. HRPWM System Interface.....                                                                                         | 535 |
| 17-44. Resolution Calculations for Conventionally Generated PWM.....                                                       | 536 |
| 17-45. Operating Logic Using MEP .....                                                                                     | 537 |
| 17-46. Required PWM Waveform for a Requested Duty = 40.5% .....                                                            | 539 |
| 17-47. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz .....                                          | 541 |
| 17-48. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz .....                                         | 541 |
| 17-49. Simplified ePWM Module .....                                                                                        | 542 |
| 17-50. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave .....                                             | 543 |
| 17-51. Control of Four Buck Stages. (Note: $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$ ) .....                    | 544 |
| 17-52. Buck Waveforms for (Note: Only three bucks shown here) .....                                                        | 545 |
| 17-53. Control of Four Buck Stages. (Note: $F_{PWM2} = N \times F_{PWM1}$ ) .....                                          | 547 |
| 17-54. Buck Waveforms for (Note: $F_{PWM2} = F_{PWM1}$ ).....                                                              | 548 |
| 17-55. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ ) .....                                        | 550 |

|                                                                                          |     |
|------------------------------------------------------------------------------------------|-----|
| 17-56. Half-H Bridge Waveforms for (Note: $F_{PWM2} = F_{PWM1}$ ) .....                  | 551 |
| 17-57. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control..... | 553 |
| 17-58. 3-Phase Inverter Waveforms for (Only One Inverter Shown) .....                    | 554 |
| 17-59. Configuring Two PWM Modules for Phase Control .....                               | 557 |
| 17-60. Timing Waveforms Associated With Phase Control Between 2 Modules .....            | 558 |
| 17-61. Control of a 3-Phase Interleaved DC/DC Converter .....                            | 559 |
| 17-62. 3-Phase Interleaved DC/DC Converter Waveforms for .....                           | 560 |
| 17-63. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ ).....                  | 563 |
| 17-64. ZVS Full-H Bridge Waveforms .....                                                 | 564 |
| 17-65. Time-Base Control Register (TBCTL).....                                           | 566 |
| 17-66. Time-Base Status Register (TBSTS).....                                            | 568 |
| 17-67. Time-Base Phase Register (TBPHS) .....                                            | 569 |
| 17-68. Time-Base Counter Register (TBCNT) .....                                          | 569 |
| 17-69. Time-Base Period Register (TBPRD) .....                                           | 570 |
| 17-70. Counter-Compare Control Register (CMPCTL).....                                    | 571 |
| 17-71. Counter-Compare A Register (CMPA) .....                                           | 572 |
| 17-72. Counter-Compare B Register (CMPB).....                                            | 573 |
| 17-73. Action-Qualifier Output A Control Register (AQCTLA).....                          | 574 |
| 17-74. Action-Qualifier Output B Control Register (AQCTLB).....                          | 575 |
| 17-75. Action-Qualifier Software Force Register (AQSFRC) .....                           | 576 |
| 17-76. Action-Qualifier Continuous Software Force Register (AQCSFRC).....                | 577 |
| 17-77. Dead-Band Generator Control Register (DBCTL).....                                 | 578 |
| 17-78. Dead-Band Generator Rising Edge Delay Register (DBRED).....                       | 579 |
| 17-79. Dead-Band Generator Falling Edge Delay Register (DBFED) .....                     | 579 |
| 17-80. PWM-Chopper Control Register (PCCTL).....                                         | 580 |
| 17-81. Trip-Zone Select Register (TZSEL) .....                                           | 581 |
| 17-82. Trip-Zone Control Register (TZCTL) .....                                          | 582 |
| 17-83. Trip-Zone Enable Interrupt Register (TZEINT).....                                 | 582 |
| 17-84. Trip-Zone Flag Register (TZFLG).....                                              | 583 |
| 17-85. Trip-Zone Clear Register (TZCLR) .....                                            | 584 |
| 17-86. Trip-Zone Force Register (TZFRC).....                                             | 584 |
| 17-87. Event-Trigger Selection Register (ETSEL) .....                                    | 585 |
| 17-88. Event-Trigger Prescale Register (ETPS) .....                                      | 586 |
| 17-89. Event-Trigger Flag Register (ETFLG).....                                          | 587 |
| 17-90. Event-Trigger Clear Register (ETCLR) .....                                        | 587 |
| 17-91. Event-Trigger Force Register (ETFRC).....                                         | 588 |
| 17-92. Time-Base Phase High-Resolution Register (TBPHSHR) .....                          | 589 |
| 17-93. Counter-Compare A High-Resolution Register (CMPAHR) .....                         | 589 |
| 17-94. HRPWM Configuration Register (HRCNFG) .....                                       | 590 |
| 18-1. EDMA3 Controller Block Diagram .....                                               | 595 |
| 18-2. EDMA3 Channel Controller (EDMA3CC) Block Diagram .....                             | 598 |
| 18-3. EDMA3 Transfer Controller (EDMA3TC) Block Diagram.....                             | 599 |
| 18-4. Definition of ACNT, BCNT, and CCNT .....                                           | 600 |
| 18-5. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3) .....                      | 601 |
| 18-6. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3) .....                     | 602 |

|                                                                                            |     |
|--------------------------------------------------------------------------------------------|-----|
| 19-48. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR).....                        | 811 |
| 19-49. MAC Input Vector Register (MACINVECTOR) .....                                       | 812 |
| 19-50. MAC End Of Interrupt Vector Register (MACEOIVECTOR) .....                           | 813 |
| 19-51. Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW) .....                   | 814 |
| 19-52. Receive Interrupt Status (Masked) Register (RXINTSTATMASKED) .....                  | 815 |
| 19-53. Receive Interrupt Mask Set Register (RXINTMASKSET) .....                            | 816 |
| 19-54. Receive Interrupt Mask Clear Register (RXINTMASKCLEAR) .....                        | 817 |
| 19-55. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW) .....                      | 818 |
| 19-56. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED).....                      | 818 |
| 19-57. MAC Interrupt Mask Set Register (MACINTMASKSET).....                                | 819 |
| 19-58. MAC Interrupt Mask Clear Register (MACINTMASKCLEAR) .....                           | 819 |
| 19-59. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) ..... | 820 |
| 19-60. Receive Unicast Enable Set Register (RXUNICASTSET) .....                            | 823 |
| 19-61. Receive Unicast Clear Register (RXUNICASTCLEAR) .....                               | 824 |
| 19-62. Receive Maximum Length Register (RXMAXLEN).....                                     | 825 |
| 19-63. Receive Buffer Offset Register (RXBUFFEROFFSET) .....                               | 825 |
| 19-64. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH).....       | 826 |
| 19-65. Receive Channel <i>n</i> Flow Control Threshold Register (RX $n$ FLOWTHRESH) .....  | 826 |
| 19-66. Receive Channel <i>n</i> Free Buffer Count Register (RX $n$ FREEBUFFER) .....       | 827 |
| 19-67. MAC Control Register (MACCONTROL) .....                                             | 828 |
| 19-68. MAC Status Register (MACSTATUS).....                                                | 830 |
| 19-69. Emulation Control Register (EMCONTROL) .....                                        | 832 |
| 19-70. FIFO Control Register (FIFOCONTROL).....                                            | 832 |
| 19-71. MAC Configuration Register (MACCONFIG) .....                                        | 833 |
| 19-72. Soft Reset Register (SOFTRESET) .....                                               | 833 |
| 19-73. MAC Source Address Low Bytes Register (MACSRCADDRLO).....                           | 834 |
| 19-74. MAC Source Address High Bytes Register (MACSRCADDRHI) .....                         | 834 |
| 19-75. MAC Hash Address Register 1 (MACHASH1).....                                         | 835 |
| 19-76. MAC Hash Address Register 2 (MACHASH2).....                                         | 835 |
| 19-77. Back Off Random Number Generator Test Register (BOFFTEST) .....                     | 836 |
| 19-78. Transmit Pacing Algorithm Test Register (TPACETEST) .....                           | 836 |
| 19-79. Receive Pause Timer Register (RXPAUSE) .....                                        | 837 |
| 19-80. Transmit Pause Timer Register (TXPAUSE).....                                        | 837 |
| 19-81. MAC Address Low Bytes Register (MACADDRLO).....                                     | 838 |
| 19-82. MAC Address High Bytes Register (MACADDRHI) .....                                   | 839 |
| 19-83. MAC Index Register (MACINDEX) .....                                                 | 839 |
| 19-84. Transmit Channel <i>n</i> DMA Head Descriptor Pointer Register (TX $n$ HDP) .....   | 840 |
| 19-85. Receive Channel <i>n</i> DMA Head Descriptor Pointer Register (RX $n$ HDP) .....    | 840 |
| 19-86. Transmit Channel <i>n</i> Completion Pointer Register (TX $n$ CP).....              | 841 |
| 19-87. Receive Channel <i>n</i> Completion Pointer Register (RX $n$ CP) .....              | 841 |
| 19-88. Statistics Register .....                                                           | 842 |
| 20-1. EMIFA Functional Block Diagram .....                                                 | 852 |
| 20-2. Timing Waveform of SDRAM PRE Command .....                                           | 856 |
| 20-3. EMIFA to 2M × 16 × 4 bank SDRAM Interface .....                                      | 857 |
| 20-4. EMIFA to 512K × 16 × 2 bank SDRAM Interface .....                                    | 857 |
| 20-5. Timing Waveform for Basic SDRAM Read Operation .....                                 | 864 |
| 20-6. Timing Waveform for Basic SDRAM Write Operation .....                                | 865 |
| 20-7. EMIFA Asynchronous Interface .....                                                   | 867 |
| 20-8. EMIFA to 8-bit/16-bit Memory Interface.....                                          | 868 |

|                                                                                   |     |
|-----------------------------------------------------------------------------------|-----|

| 23-2.  | Multiple I2C Modules Connected .....                                                                                                                                       | 1007 |
| 23-3.  | Clocking Diagram for the I2C Peripheral .....                                                                                                                              | 1008 |
| 23-4.  | Synchronization of Two I2C Clock Generators During Arbitration .....                                                                                                       | 1009 |
| 23-5.  | Bit Transfer on the I2C-Bus .....                                                                                                                                          | 1010 |
| 23-6.  | I2C Peripheral START and STOP Conditions .....                                                                                                                             | 1010 |
| 23-7.  | I2C Peripheral Data Transfer .....                                                                                                                                         | 1011 |
| 23-8.  | I2C Peripheral 7-Bit Addressing Format (FDF = 0, XA = 0 in ICMR) .....                                                                                                     | 1011 |
| 23-9.  | I2C Peripheral 10-Bit Addressing Format With Master-Transmitter Writing to Slave-Receiver (FDF = 0, XA = 1 in ICMR) .....                                                  | 1012 |
| 23-10. | I2C Peripheral Free Data Format (FDF = 1 in ICMR) .....                                                                                                                    | 1012 |
| 23-11. | I2C Peripheral 7-Bit Addressing Format With Repeated START Condition (FDF = 0, XA = 0 in ICMR) ..                                                                          | 1012 |
| 23-12. | Arbitration Procedure Between Two Master-Transmitters .....                                                                                                                | 1015 |
| 23-13. | I2C Own Address Register (ICOAR) .....                                                                                                                                     | 1020 |
| 23-14. | I2C Interrupt Mask Register (ICMR) .....                                                                                                                                   | 1021 |
| 23-15. | I2C Interrupt Status Register (ICSTR) .....                                                                                                                                | 1022 |
| 23-16. | I2C Clock Low-Time Divider Register (ICCLKL) .....                                                                                                                         | 1025 |
| 23-17. | I2C Clock High-Time Divider Register (ICCLKH) .....                                                                                                                        | 1025 |

|                                                                                                |      |
|------------------------------------------------------------------------------------------------|------|
| 23-18. I2C Data Count Register (ICCNT) .....                                                   | 1026 |
| 23-19. I2C Data Receive Register (ICDRR).....                                                  | 1027 |
| 23-20. I2C Slave Address Register (ICSAR).....                                                 | 1028 |
| 23-21. I2C Data Transmit Register (ICDXR) .....                                                | 1029 |
| 23-22. I2C Mode Register (ICMDR).....                                                          | 1030 |
| 23-23. Block Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit.....           | 1033 |
| 23-24. I2C Interrupt Vector Register (ICIVR) .....                                             | 1034 |
| 23-25. I2C Extended Mode Register (ICEMDR).....                                                | 1035 |
| 23-26. I2C Prescaler Register (ICPSC).....                                                     | 1036 |
| 23-27. I2C Revision Identification Register 1 (REVID1) .....                                   | 1037 |
| 23-28. I2C Revision Identification Register 2 (REVID2) .....                                   | 1037 |
| 23-29. I2C DMA Control Register (ICDMAC) .....                                                 | 1038 |
| 23-30. I2C Pin Function Register (ICPFUNC) .....                                               | 1039 |
| 23-31. I2C Pin Direction Register (ICPDIR) .....                                               | 1040 |
| 23-32. I2C Pin Data In Register (ICPDIN).....                                                  | 1041 |
| 23-33. I2C Pin Data Out Register (ICPDOUT).....                                                | 1042 |
| 23-34. I2C Pin Data Set Register (ICPDSET) .....                                               | 1043 |
| 23-35. I2C Pin Data Clear Register (ICPDCLR).....                                              | 1044 |
| 24-1. LCD Controller .....                                                                     | 1046 |
| 24-2. Input and Output Clocks.....                                                             | 1047 |
| 24-3. Logical Data Path for Raster Controller .....                                            | 1054 |
| 24-4. Frame Buffer Structure .....                                                             | 1055 |
| 24-5. 16-Entry Palette/Buffer Format (1, 2, 4, 12, 16 BPP).....                                | 1056 |
| 24-6. 256-Entry Palette/Buffer Format (8 BPP) .....                                            | 1057 |
| 24-7. 16-BPP Data Memory Organization (TFT Mode Only)—Little Endian .....                      | 1057 |
| 24-8. 12-BPP Data Memory Organization—Little Endian.....                                       | 1058 |
| 24-9. 8-BPP Data Memory Organization .....                                                     | 1058 |
| 24-10. 4-BPP Data Memory Organization.....                                                     | 1058 |
| 24-11. 2-BPP Data Memory Organization .....                                                    | 1059 |
| 24-12. 1-BPP Data Memory Organization .....                                                    | 1059 |
| 24-13. Monochrome and Color Output.....                                                        | 1061 |
| 24-14. Raster Mode Display Format .....                                                        | 1062 |
| 24-15. LCD Revision Identification Register (REVID).....                                       | 1063 |
| 24-16. LCD Control Register (LCD_CTRL) .....                                                   | 1064 |
| 24-17. LCD Status Register (LCD_STAT).....                                                     | 1066 |
| 24-18. LCD LIDD Control Register (LIDD_CTRL).....                                              | 1069 |
| 24-19. LCD LIDD CS <sub>n</sub> Configuration Register (LIDD_CS <sub>n</sub> _CONF) .....      | 1071 |
| 24-20. LCD LIDD CS <sub>n</sub> Address Read/Write Register (LIDD_CS <sub>n</sub> _ADDR) ..... | 1072 |
| 24-21. LCD LIDD CS <sub>n</sub> Data Read/Write Register (LIDD_CS <sub>n</sub> _DATA).....     | 1073 |
| 24-22. LCD Raster Control Register (RASTER_CTRL) .....                                         | 1074 |
| 24-23. Monochrome Passive Mode Pixel Clock and Data Pin Timing.....                            | 1077 |
| 24-24. Color Passive Mode Pixel Clock and Data Pin Timing .....                                | 1077 |
| 24-25. Active Mode Pixel Clock and Data Pin Timing .....                                       | 1078 |
| 24-26. TFT Alternate Signal Mapping Output.....                                                | 1079 |
| 24-27. 12-Bit STN Data in Frame Buffer .....                                                   | 1080 |
| 24-28. 16-Bit STN Data in Frame Buffer .....                                                   | 1080 |
| 24-29. 16-BPP STN Mode.....                                                                    | 1080 |
| 24-30. LCD Raster Timing Register 0 (RASTER_TIMING_0) .....                                    | 1081 |
| 24-31. LCD Raster Timing Register 1 (RASTER_TIMING_1) .....                                    | 1083 |

|                                                                                          |      |
|------------------------------------------------------------------------------------------|------|
| 24-32. Vertical Synchronization Pulse Width (VSW) - Active Mode .....                    | 1084 |
| 24-33. Vertical Front Porch (VFP) .....                                                  | 1085 |
| 24-34. Vertical Back Porch (VBP) .....                                                   | 1086 |
| 24-35. LCD Raster Timing Register 2 (RASTER_TIMING_2) .....                              | 1087 |
| 24-36. SYNC_CTRL = 0, IPC = 1 in TFT Mode .....                                          | 1089 |
| 24-37. SYNC_CTRL = 1, SYNC_EDGE = 0, and IPC = 1 .....                                   | 1090 |
| 24-38. LCD Raster Subpanel Display Register (RASTER_SUBPANEL) .....                      | 1091 |
| 24-39. Subpanel Display: SPEN = 1, HOLDS = 1 .....                                       | 1092 |
| 24-40. Subpanel Display: SPEN = 1, HOLDS = 0 .....                                       | 1092 |
| 24-41. LCD DMA Control Register (LCDDMA_CTRL).....                                       | 1093 |
| 24-42. LCD DMA Frame Buffer <i>n</i> Base Address Register (LCDDMA_FBN_BASE) .....       | 1094 |
| 24-43. LCD DMA Frame Buffer <i>n</i> Ceiling Address Register (LCDDMA_FBN_CEILING) ..... | 1094 |
| 25-1. McASP Block Diagram .....                                                          | 1098 |
| 25-2. McASP to Parallel 2-Channel DACs .....                                             | 1099 |
| 25-3. McASP to 6-Channel DAC and 2-Channel DAC .....                                     | 1099 |
| 25-4. McASP to Digital Amplifier .....                                                   | 1100 |
| 25-5. McASP as Digital Audio Encoder .....                                               | 1100 |
| 25-6. TDM Format–6 Channel TDM Example .....                                             | 1101 |
| 25-7. TDM Format Bit Delays from Frame Sync .....                                        | 1102 |
| 25-8. Inter-IC Sound (I2S) Format .....                                                  | 1102 |
| 25-9. Biphase-Mark Code (BMC) .....                                                      | 1103 |
| 25-10. S/PDIF Subframe Format .....                                                      | 1104 |
| 25-11. S/PDIF Frame Format .....                                                         | 1105 |
| 25-12. Definition of Bit, Word, and Slot .....                                           | 1106 |
| 25-13. Bit Order and Word Alignment Within a Slot Examples .....                         | 1107 |
| 25-14. Definition of Frame and Frame Sync Width .....                                    | 1108 |
| 25-15. Transmit Clock Generator Block Diagram .....                                      | 1110 |
| 25-16. Receive Clock Generator Block Diagram .....                                       | 1111 |
| 25-17. Frame Sync Generator Block Diagram .....                                          | 1112 |
| 25-18. Individual Serializer and Connections Within McASP .....                          | 1113 |
| 25-19. Receive Format Unit .....                                                         | 1114 |
| 25-20. Transmit Format Unit .....                                                        | 1115 |
| 25-21. McASP I/O Pin Control Block Diagram.....                                          | 1117 |
| 25-22. McASP I/O Pin to Control Register Mapping .....                                   | 1118 |
| 25-23. Burst Frame Sync Mode.....                                                        | 1123 |
| 25-24. Transmit DMA Event (AXEVT) Generation in TDM Time Slots .....                     | 1126 |
| 25-25. DSP Service Time Upon Transmit DMA Event (AXEVT) .....                            | 1131 |
| 25-26. DSP Service Time Upon Receive DMA Event (AREVT).....                              | 1133 |
| 25-27. DMA Events in an Audio Example–Two Events .....                                   | 1135 |
| 25-28. McASP Audio FIFO (AFIFO) Block Diagram .....                                      | 1136 |
| 25-29. Data Flow Through Transmit Format Unit .....                                      | 1139 |
| 25-30. Data Flow Through Receive Format Unit .....                                       | 1141 |
| 25-31. Audio Mute (AMUTE) Block Diagram.....                                             | 1143 |
| 25-32. Transmit Clock Failure Detection Circuit Block Diagram.....                       | 1147 |
| 25-33. Receive Clock Failure Detection Circuit Block Diagram .....                       | 1148 |
| 25-34. Serializers in Loopback Mode .....                                                | 1149 |
| 25-35. Revision Identification Register (REV) .....                                      | 1155 |
| 25-36. Pin Function Register (PFUNC) .....                                               | 1156 |
| 25-37. Pin Direction Register (PDIR).....                                                | 1158 |

|                                                                         |      |
|-------------------------------------------------------------------------|------|
| 25-38. Pin Data Output Register (PDOUT).....                            | 1160 |
| 25-39. Pin Data Input Register (PDIN).....                              | 1162 |
| 25-40. Pin Data Set Register (PDSET) .....                              | 1164 |
| 25-41. Pin Data Clear Register (PDCLR).....                             | 1166 |
| 25-42. Global Control Register (GBLCTL).....                            | 1168 |
| 25-43. Audio Mute Control Register (AMUTE).....                         | 1170 |
| 25-44. Digital Loopback Control Register (DLBCTL) .....                 | 1172 |
| 25-45. Digital Mode Control Register (DITCTL) .....                     | 1173 |
| 25-46. Receiver Global Control Register (RGBLCTL) .....                 | 1174 |
| 25-47. Receive Format Unit Bit Mask Register (RMASK).....               | 1175 |
| 25-48. Receive Bit Stream Format Register (RFMT) .....                  | 1176 |
| 25-49. Receive Frame Sync Control Register (AFSRCTL) .....              | 1178 |
| 25-50. Receive Clock Control Register (ACLKRCTL) .....                  | 1179 |
| 25-51. Receive High-Frequency Clock Control Register (AHCLKRCTL) .....  | 1180 |
| 25-52. Receive TDM Time Slot Register (RTDM).....                       | 1181 |
| 25-53. Receiver Interrupt Control Register (RINTCTL).....               | 1182 |

| 29-16. | Port Parameter Register (PPARAMR).....                         | 1405 |
| 29-17. | Test Register (TESTR) .....                                    | 1406 |
| 29-18. | Version Register (VERSIONR) .....                              | 1407 |
| 29-19. | ID Register (IDR) .....                                        | 1407 |
| 29-20. | Port Command List Base Address Register (POCLB) .....          | 1408 |
| 29-21. | Port FIS Base Address Register (P0FB) .....                    | 1408 |
| 29-22. | Port Interrupt Status Register (P0IS) .....                    | 1409 |
| 29-23. | Port Interrupt Enable Register (P0IE) .....                    | 1411 |
| 29-24. | Port Command Register (P0CMD).....                             | 1412 |
| 29-25. | Port Task File Data Register (P0TFD) .....                     | 1415 |
| 29-26. | Port Signature Register (P0SIG) .....                          | 1415 |
| 29-27. | Port Serial ATA Status Register (P0SSTS).....                  | 1416 |
| 29-28. | Port Serial ATA Control Register (P0SCTL) .....                | 1417 |
| 29-29. | Port Serial ATA Error Register (P0SERR) .....                  | 1418 |
| 29-30. | Port Serial ATA Active Register (P0SACT) .....                 | 1420 |

|                                                                                                       |      |
|-------------------------------------------------------------------------------------------------------|------|
| 29-31. Port Serial ATA Active (SActive) Register (P0SACT) .....                                       | 1420 |
| 29-32. Port Serial ATA Notification Register (POSNTF).....                                            | 1421 |
| 29-33. Port DMA Control Register (P0DMACR) .....                                                      | 1422 |
| 29-34. Port PHY Control Register (P0PHYCR).....                                                       | 1424 |
| 29-35. Port PHY Status Register (P0PHYSR) .....                                                       | 1428 |
| 30-1. SPI Block Diagram .....                                                                         | 1431 |
| 30-2. SPI 3-Pin Option.....                                                                           | 1437 |
| 30-3. SPI 4-Pin Option with $\overline{\text{SPIx\_SCS}}[n]$ .....                                    | 1439 |
| 30-4. SPI 4-Pin Option with $\overline{\text{SPIx\_ENA}}$ .....                                       | 1441 |
| 30-5. SPI 5-Pin Option with $\overline{\text{SPIx\_ENA}}$ and $\overline{\text{SPIx\_SCS}}[n]$ .....  | 1443 |
| 30-6. Format for Transmitting 12-Bit Word.....                                                        | 1444 |
| 30-7. Format for 10-Bit Received Word .....                                                           | 1444 |
| 30-8. Clock Mode with POLARITY = 0 and PHASE = 0 .....                                                | 1445 |
| 30-9. Clock Mode with POLARITY = 0 and PHASE = 1 .....                                                | 1446 |
| 30-10. Clock Mode with POLARITY = 1 and PHASE = 0 .....                                               | 1446 |
| 30-11. Clock Mode with POLARITY = 1 and PHASE = 1 .....                                               | 1446 |
| 30-12. Five Bits per Character (5-Pin Option) .....                                                   | 1447 |
| 30-13. SPI 3-Pin Master Mode with WDELAY .....                                                        | 1452 |
| 30-14. SPI 4-Pin with $\overline{\text{SPIx\_SCS}}[n]$ Mode with T2CDELAY, WDELAY, and C2TDELAY ..... | 1453 |
| 30-15. SPI 4-Pin with $\overline{\text{SPIx\_ENA}}$ Mode Demonstrating T2EDELAY and WDELAY .....      | 1454 |
| 30-16. SPI 5-Pin Mode Demonstrating T2CDELAY, T2EDELAY, and WDELAY .....                              | 1456 |
| 30-17. SPI 5-Pin Mode Demonstrating C2TDELAY and C2EDELAY .....                                       | 1457 |
| 30-18. SPI Global Control Register 0 (SPIGCR0).....                                                   | 1458 |
| 30-19. SPI Global Control Register 1 (SPIGCR1).....                                                   | 1459 |
| 30-20. SPI Interrupt Register (SPIINT0) .....                                                         | 1461 |
| 30-21. SPI Interrupt Level Register (SPILVL).....                                                     | 1463 |
| 30-22. SPI Flag Register (SPIFLG) .....                                                               | 1464 |
| 30-23. SPI Pin Control Register 0 (SPIPC0).....                                                       | 1466 |
| 30-24. SPI Pin Control Register 1 (SPIPC1).....                                                       | 1467 |
| 30-25. SPI Pin Control Register 2 (SPIPC2).....                                                       | 1468 |
| 30-26. SPI Pin Control Register 3 (SPIPC3).....                                                       | 1469 |
| 30-27. SPI Pin Control Register 4 (SPIPC4).....                                                       | 1470 |
| 30-28. SPI Pin Control Register 5 (SPIPC5).....                                                       | 1471 |
| 30-29. SPI Data Register 0 (SPIDAT0) .....                                                            | 1472 |
| 30-30. SPI Data Register 1 (SPIDAT1).....                                                             | 1473 |
| 30-31. SPI Buffer Register (SPIBUF) .....                                                             | 1474 |
| 30-32. SPI Emulation Register (SPIEMU) .....                                                          | 1476 |
| 30-33. SPI Delay Register (SPIDELAY) .....                                                            | 1477 |
| 30-34. Example: $t_{\text{C2TDELAY}} = 8$ SPI Module Clock Cycles .....                               | 1478 |
| 30-35. Example: $t_{\text{T2CDELAY}} = 4$ SPI Module Clock Cycles .....                               | 1479 |
| 30-36. Transmit-Data-Finished-to- $\overline{\text{SPIx\_ENA}}$ -Inactive-Timeout .....               | 1479 |
| 30-37. Chip-Select-Active-to- $\overline{\text{SPIx\_ENA}}$ -Signal-Active-Timeout.....               | 1479 |
| 30-38. SPI Default Chip Select Register (SPIDEF) .....                                                | 1480 |
| 30-39. SPI Data Format Register (SPIFMTn).....                                                        | 1481 |
| 30-40. SPI Interrupt Vector Register 1 (INTVEC1).....                                                 | 1483 |
| 31-1. Timer Block Diagram .....                                                                       | 1486 |
| 31-2. Timer Clock Source Block Diagram.....                                                           | 1487 |
| 31-3. 64-Bit Timer Mode Block Diagram .....                                                           | 1488 |
| 31-4. Dual 32-Bit Timers Chained Mode Block Diagram .....                                             | 1491 |

|                                                                       |      |
|-----------------------------------------------------------------------|------|
| 31-5. Dual 32-Bit Timers Chained Mode Example.....                    | 1491 |
| 31-6. Dual 32-Bit Timers Unchained Mode Block Diagram.....            | 1493 |
| 31-7. Dual 32-Bit Timers Unchained Mode Example.....                  | 1494 |
| 31-8. 32-Bit Timer Counter Overflow Example.....                      | 1497 |
| 31-9. Watchdog Timer Mode Block Diagram.....                          | 1499 |
| 31-10. Watchdog Timer Operation State Diagram.....                    | 1499 |
| 31-11. Timer Operation in Pulse Mode (CPn = 0).....                   | 1501 |
| 31-12. Timer Operation in Clock Mode (CPn = 1).....                   | 1501 |
| 31-13. Revision ID Register (REVID).....                              | 1505 |
| 31-14. Emulation Management Register (EMUMGT).....                    | 1505 |
| 31-15. GPIO Interrupt Control and Enable Register (GPINTGPEN).....    | 1506 |
| 31-16. GPIO Data and Direction Register (GPDATGPDIR).....             | 1507 |
| 31-17. Timer Counter Register 12 (TIM12).....                         | 1508 |
| 31-18. Timer Counter Register 34 (TIM34).....                         | 1508 |
| 31-19. Timer Period Register 12 (PRD12).....                          | 1509 |
| 31-20. Timer Period Register 34 (PRD34).....                          | 1509 |
| 31-21. Timer Control Register (TCR).....                              | 1510 |
| 31-22. Timer Global Control Register (TGCR).....                      | 1512 |
| 31-23. Watchdog Timer Control Register (WDTCR).....                   | 1513 |
| 31-24. Timer Reload Register 12 (REL12).....                          | 1514 |
| 31-25. Timer Reload Register 34 (REL34).....                          | 1514 |
| 31-26. Timer Capture Register 12 (CAP12).....                         | 1515 |
| 31-27. Timer Capture Register 34 (CAP34).....                         | 1515 |
| 31-28. Timer Interrupt Control and Status Register (INTCTLSTAT).....  | 1516 |
| 31-29. Timer Compare Register (CMPn).....                             | 1517 |
| 32-1. UART Block Diagram.....                                         | 1520 |
| 32-2. UART Clock Generation Diagram.....                              | 1521 |
| 32-3. Relationships Between Data Bit, BCLK, and UART Input Clock..... | 1522 |
| 32-4. UART Protocol Formats.....                                      | 1524 |
| 32-5. UART Interface Using Autoflow Diagram.....                      | 1527 |
| 32-6. Autoflow Functional Timing Waveforms for <u>UARTn_RTS</u> ..... | 1528 |
| 32-7. Autoflow Functional Timing Waveforms for <u>UARTn_CTS</u> ..... | 1528 |
| 32-8. UART Interrupt Request Enable Paths.....                        | 1530 |
| 32-9. Receiver Buffer Register (RBR).....                             | 1533 |
| 32-10. Transmitter Holding Register (THR).....                        | 1534 |
| 32-11. Interrupt Enable Register (IER).....                           | 1535 |
| 32-12. Interrupt Identification Register (IIR).....                   | 1536 |
| 32-13. FIFO Control Register (FCR).....                               | 1538 |
| 32-14. Line Control Register (LCR).....                               | 1539 |
| 32-15. Modem Control Register (MCR).....                              | 1541 |
| 32-16. Line Status Register (LSR).....                                | 1542 |
| 32-17. Modem Status Register (MSR).....                               | 1545 |
| 32-18. Scratch Pad Register (SCR).....                                | 1546 |

| 35-43. Generic RNDIS EP1 Size Register (GENRNDISSZ1).....                                   | 1724 |
| 35-44. Generic RNDIS EP2 Size Register (GENRNDISSZ2).....                                   | 1725 |
| 35-45. Generic RNDIS EP3 Size Register (GENRNDISSZ3).....                                   | 1725 |
| 35-46. Generic RNDIS EP4 Size Register (GENRNDISSZ4).....                                   | 1726 |
| 35-47. Function Address Register (FADDR) .....                                              | 1726 |
| 35-48. Power Management Register (POWER) .....                                              | 1727 |
| 35-49. Interrupt Register for Endpoint 0 Plus Tx Endpoints 1 to 4 (INTRTX) .....            | 1728 |
| 35-50. Interrupt Register for Receive Endpoints 1 to 4 (INTRRX) .....                       | 1729 |
| 35-51. Interrupt Enable Register for INTRTX (INTRTXE) .....                                 | 1730 |
| 35-52. Interrupt Enable Register for INTRRX (INTRRXE) .....                                 | 1730 |
| 35-53. Interrupt Register for Common USB Interrupts (INTRUSB) .....                         | 1731 |
| 35-54. Interrupt Enable Register for INTRUSB (INTRUSBE).....                                | 1732 |
| 35-55. Frame Number Register (FRAME).....                                                   | 1732 |
| 35-56. Index Register for Selecting the Endpoint Status and Control Registers (INDEX) ..... | 1733 |
| 35-57. Register to Enable the USB 2.0 Test Modes (TESTMODE) .....                           | 1733 |
| 35-58. Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP) .....             | 1734 |
| 35-59. Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0).....           | 1735 |
| 35-60. Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0) .....                | 1736 |
| 35-61. Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR) .....          | 1737 |
| 35-62. Control Status Register for Host Transmit Endpoint (HOST_TXCSR).....                 | 1738 |
| 35-63. Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP).....               | 1739 |
| 35-64. Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR).....            | 1740 |
| 35-65. Control Status Register for Host Receive Endpoint (HOST_RXCSR) .....                 | 1741 |
| 35-66. Count 0 Register (COUNT0).....                                                       | 1742 |
| 35-67. Receive Count Register (RXCOUNT) .....                                               | 1742 |
| 35-68. Type Register (Host mode only) (HOST_TYPE0) .....                                    | 1743 |
| 35-69. Transmit Type Register (Host mode only) (HOST_TXTYPE) .....                          | 1743 |
| 35-70. NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0) .....                           | 1744 |
| 35-71. Transmit Interval Register (Host mode only) (HOST_TXINTERVAL) .....                  | 1744 |
| 35-72. Receive Type Register (Host mode only) (HOST_RXTYPE) .....                           | 1745 |
| 35-73. Receive Interval Register (Host mode only) (HOST_RXINTERVAL).....                    | 1746 |
| 35-74. Configuration Data Register (CONFIGDATA) .....                                       | 1747 |
| 35-75. Transmit and Receive FIFO Register for Endpoint 0 (FIFO0).....                       | 1748 |
| 35-76. Transmit and Receive FIFO Register for Endpoint 1 (FIFO1).....                       | 1748 |
| 35-77. Transmit and Receive FIFO Register for Endpoint 2 (FIFO2).....                       | 1749 |
| 35-78. Transmit and Receive FIFO Register for Endpoint 3 (FIFO3).....                       | 1749 |
| 35-79. Transmit and Receive FIFO Register for Endpoint 4 (FIFO4).....                       | 1750 |
| 35-80. Device Control Register (DEVCTL) .....                                               | 1750 |
| 35-81. Transmit Endpoint FIFO Size (TXFIFOSZ) .....                                         | 1751 |
| 35-82. Receive Endpoint FIFO Size (RXFIFOSZ).....                                           | 1751 |

|                                                                                                   |      |
|---------------------------------------------------------------------------------------------------|------|
| 35-83. Transmit Endpoint FIFO Address (TXFIFOADDR) .....                                          | 1752 |
| 35-84. Receive Endpoint FIFO Address (RXFIFOADDR) .....                                           | 1752 |
| 35-85. Hardware Version Register (HWVERS) .....                                                   | 1753 |
| 35-86. Transmit Function Address (TXFUNCADDR) .....                                               | 1754 |
| 35-87. Transmit Hub Address (TXHUBADDR) .....                                                     | 1754 |
| 35-88. Transmit Hub Port (TXHUBPORT) .....                                                        | 1754 |
| 35-89. Receive Function Address (RXFUNCADDR) .....                                                | 1755 |
| 35-90. Receive Hub Address (RXHUBADDR) .....                                                      | 1755 |
| 35-91. Receive Hub Port (RXHUBPORT) .....                                                         | 1755 |
| 35-92. CDMA Revision Identification Register (DMAREVID) .....                                     | 1756 |
| 35-93. CDMA Teardown Free Descriptor Queue Control Register (TDFDQ) .....                         | 1756 |
| 35-94. CDMA Emulation Control Register (DMAEMU) .....                                             | 1757 |
| 35-95. CDMA Transmit Channel <i>n</i> Global Configuration Registers (TXGCR[ <i>n</i> ]) .....    | 1757 |
| 35-96. CDMA Receive Channel <i>n</i> Global Configuration Registers (RXGCR[ <i>n</i> ]) .....     | 1758 |
| 35-97. Receive Channel <i>n</i> Host Packet Configuration Registers A (RXHPCRA[ <i>n</i> ]) ..... | 1759 |
| 35-98. Receive Channel <i>n</i> Host Packet Configuration Registers B (RXHPCRB[ <i>n</i> ]) ..... | 1760 |
| 35-99. CDMA Scheduler Control Register (DMA_SCHED_CTRL) .....                                     | 1761 |
| 35-100. CDMA Scheduler Table Word <i>n</i> Registers (WORD[ <i>n</i> ]) .....                     | 1761 |
| 35-101. Queue Manager Revision Identification Register (QMGRREVID) .....                          | 1763 |
| 35-102. Queue Manager Queue Diversion Register (DIVERSION) .....                                  | 1763 |
| 35-103. Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0) .....           | 1764 |
| 35-104. Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1) .....           | 1765 |
| 35-105. Queue Manager Free Descriptor/Buffer Starvation Count Register 2 (FDBSC2) .....           | 1766 |
| 35-106. Queue Manager Free Descriptor/Buffer Starvation Count Register 3 (FDBSC3) .....           | 1767 |
| 35-107. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE) .....                | 1767 |
| 35-108. Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE) .....                        | 1768 |
| 35-109. Queue Manager Linking RAM Region 1 Base Address Register (LRAM1BASE) .....                | 1768 |
| 35-110. Queue Manager Queue Pending Register 0 (PEND0) .....                                      | 1769 |
| 35-111. Queue Manager Queue Pending Register 1 (PEND1) .....                                      | 1769 |
| 35-112. Queue Manager Memory Region <i>R</i> Base Address Registers (QMEMRBASE[ <i>R</i> ]) ..... | 1770 |
| 35-113. Queue Manager Memory Region <i>R</i> Control Registers (QMEMRCTRL[ <i>R</i> ]) .....      | 1771 |
| 35-114. Queue Manager Queue <i>N</i> Control Register D (CTRLD[ <i>N</i> ]) .....                 | 1772 |
| 35-115. Queue Manager Queue <i>N</i> Status Register A (QSTATA[ <i>N</i> ]) .....                 | 1773 |
| 35-116. Queue Manager Queue <i>N</i> Status Register B (QSTATB[ <i>N</i> ]) .....                 | 1773 |
| 35-117. Queue Manager Queue <i>N</i> Status Register C (QSTATC[ <i>N</i> ]) .....                 | 1774 |
| 36-1. Input and Output Channels of VPIF .....                                                     | 1776 |
| 36-2. Video Port Interface (VPIF) Block Diagram .....                                             | 1777 |
| 36-3. VPIF Architecture Block Diagram .....                                                       | 1778 |
| 36-4. Interlaced Video .....                                                                      | 1781 |
| 36-5. Progressive Video .....                                                                     | 1782 |
| 36-6. Memory Storage Modes for Interlaced Video .....                                             | 1783 |
| 36-7. Functional Image of Raw Data Capturing Mode .....                                           | 1786 |
| 36-8. Raw Capture Progressive Mode .....                                                          | 1787 |
| 36-9. Raw Capture Interlaced Mode .....                                                           | 1788 |
| 36-10. Stuffing Manner in Storage Memory .....                                                    | 1788 |
| 36-11. VBI Result Data Transmit Image for Interlaced Image .....                                  | 1789 |
| 36-12. Module Performance with Emulation Suspend Signal .....                                     | 1794 |
| 36-13. Emulation Suspend Function on Channels 2 and 3 (Transmit) .....                            | 1795 |
| 36-14. Method for Turning off Module Channel .....                                                | 1796 |

|                                                                                                           |      |
|-----------------------------------------------------------------------------------------------------------|------|
| 36-15. Clock Control on Video Input and Output with SDTV Encoding .....                                   | 1797 |
| 36-16. Clock Control on Video Input and Output with HDTV Encoding .....                                   | 1799 |
| 36-17. Clock Control on Video Input and Output with HDTV Encoding .....                                   | 1800 |
| 36-18. VPIF Revision ID Register (REVID) .....                                                            | 1804 |
| 36-19. Channel 0 Control Register (C0CTRL) .....                                                          | 1804 |
| 36-20. Channel 1 Control Register (C1CTRL) .....                                                          | 1806 |
| 36-21. Channel 2 Control Register (C2CTRL) .....                                                          | 1807 |
| 36-22. Channel 3 Control Register (C3CTRL) .....                                                          | 1809 |
| 36-23. Interrupt Enable Register (INTEN) .....                                                            | 1811 |
| 36-24. Interrupt Enable Set Register (INTSET).....                                                        | 1812 |
| 36-25. Interrupt Enable Clear Register (INTCLR) .....                                                     | 1813 |
| 36-26. Interrupt Status Register (INTSTAT).....                                                           | 1814 |
| 36-27. Interrupt Status Clear Register (INTSTATCLR) .....                                                 | 1815 |
| 36-28. Emulation Suspend Control Register (EMUCTRL) .....                                                 | 1816 |
| 36-29. DMA Size Control Register (REQSIZE) .....                                                          | 1816 |
| 36-30. Channel <i>n</i> Top Field Luminance Address Register (CnTLUMA).....                               | 1817 |
| 36-31. Channel <i>n</i> Bottom Field Luminance Address Register (CnBLUMA) .....                           | 1817 |
| 36-32. Channel <i>n</i> Top Field Chrominance Address Register (CnTCHROMA) .....                          | 1818 |
| 36-33. Channel <i>n</i> Bottom Field Chrominance Address Register (CnBCHROMA) .....                       | 1818 |
| 36-34. Channel <i>n</i> Top Field Horizontal Ancillary Address Register (CnTHANC) .....                   | 1819 |
| 36-35. Channel <i>n</i> Bottom Field Horizontal Ancillary Address Register (CnBHANC) .....                | 1819 |
| 36-36. Channel <i>n</i> Top Field Vertical Ancillary Address Register (CnTVANC).....                      | 1820 |
| 36-37. Channel <i>n</i> Bottom Field Vertical Ancillary Data Buffer Start Address Register (CnBVANC)..... | 1820 |
| 36-38. Channel <i>n</i> Image Address Offset Register (CnIMGOFFSET).....                                  | 1821 |
| 36-39. Channel <i>n</i> Horizontal Ancillary Address Offset Register (CnHANCOFFSET).....                  | 1821 |
| 36-40. Channel <i>n</i> Horizontal Size Configuration Register (CnHCFG) .....                             | 1822 |
| 36-41. Channel <i>n</i> Vertical Size Configuration 0 Register (CnVCFG0) .....                            | 1823 |
| 36-42. Channel <i>n</i> Vertical Data Size Configuration 1 Register (CnVCFG1) .....                       | 1823 |
| 36-43. Channel <i>n</i> Vertical Size Configuration 2 Register (CnVCFG2) .....                            | 1824 |
| 36-44. Channel <i>n</i> Vertical Image Size Register (CnVSIZE).....                                       | 1824 |
| 36-45. Channel <i>n</i> Horizontal Size Configuration Register (CnHCFG) .....                             | 1825 |
| 36-46. Channel <i>n</i> Vertical Size Configuration 0 Register (CnVCFG0) .....                            | 1826 |
| 36-47. Channel <i>n</i> Vertical Size Configuration 1 Register (CnVCFG1) .....                            | 1826 |
| 36-48. Channel <i>n</i> Vertical Size Configuration 2 Register (CnVCFG2) .....                            | 1827 |
| 36-49. Channel <i>n</i> Vertical Image Size Register (CnVSIZE).....                                       | 1827 |
| 36-50. Channel <i>n</i> Top Field Horizontal Ancillary Position Register (CnTHANCPOS) .....               | 1828 |
| 36-51. Channel <i>n</i> Top Field Horizontal Ancillary Size Register (CnTHANCSize) .....                  | 1829 |
| 36-52. Channel <i>n</i> Bottom Field Horizontal Ancillary Position Register (CnBHANCPOS) .....            | 1830 |
| 36-53. Channel <i>n</i> Bottom Field Horizontal Ancillary Size Register (CnBHANCSize) .....               | 1831 |
| 36-54. Channel <i>n</i> Top Field Vertical Ancillary Position Register (CnTVANCPOS) .....                 | 1832 |
| 36-55. Channel <i>n</i> Top Field Vertical Ancillary Size Register (CnTVANCSize) .....                    | 1833 |
| 36-56. Channel <i>n</i> Bottom Field Vertical Ancillary Position Register (CnBVANCPOS) .....              | 1834 |
| 36-57. Channel <i>n</i> Bottom Field Vertical Ancillary Size Register (CnBVANCSize) .....                 | 1835 |

## List of Tables

|       |                                                                                                                      |     |
|-------|----------------------------------------------------------------------------------------------------------------------|-----|
| 2-1.  | Exception Vector Table for ARM .....                                                                                 | 88  |
| 2-2.  | Different Address Types in ARM System .....                                                                          | 90  |
| 3-1.  | DSP Interrupt Map .....                                                                                              | 94  |
| 4-1.  | OMAP-L138 Applications Processor System Interconnect Matrix.....                                                     | 101 |
| 6-1.  | MPU Memory Regions .....                                                                                             | 108 |
| 6-2.  | MPU Default Configuration .....                                                                                      | 108 |
| 6-3.  | Device Master Settings .....                                                                                         | 108 |
| 6-4.  | Request Type Access Controls .....                                                                                   | 110 |
| 6-5.  | MPU_BOOTCFG_ERR Interrupt Sources.....                                                                               | 112 |
| 6-6.  | Memory Protection Unit 1 (MPU1) Registers .....                                                                      | 113 |
| 6-7.  | Memory Protection Unit 2 (MPU2) Registers .....                                                                      | 113 |
| 6-8.  | Revision ID Register (REVID) Field Descriptions .....                                                                | 115 |
| 6-9.  | Configuration Register (CONFIG) Field Descriptions .....                                                             | 115 |
| 6-10. | Interrupt Raw Status/Set Register (IRAWSTAT) Field Descriptions .....                                                | 116 |
| 6-11. | Interrupt Enable Status/Clear Register (IENSTAT) Field Descriptions .....                                            | 117 |
| 6-12. | Interrupt Enable Set Register (IENSET) Field Descriptions.....                                                       | 118 |
| 6-13. | Interrupt Enable Clear Register (IENCLR) Field Descriptions .....                                                    | 118 |
| 6-14. | Fixed Range Memory Protection Page Attributes Register (FXD_MPPA) Field Descriptions.....                            | 120 |
| 6-15. | MPU1 Programmable Range <i>n</i> Start Address Register (PROG <sub><i>n</i></sub> _MPSAR) Field Descriptions.....    | 121 |
| 6-16. | MPU2 Programmable Range <i>n</i> Start Address Register (PROG <sub><i>n</i></sub> _MPSAR) Field Descriptions.....    | 121 |
| 6-17. | MPU1 Programmable Range <i>n</i> End Address Register (PROG <sub><i>n</i></sub> _MPEAR) Field Descriptions.....      | 122 |
| 6-18. | MPU2 Programmable Range <i>n</i> End Address Register (PROG <sub><i>n</i></sub> _MPEAR) Field Descriptions.....      | 122 |
| 6-19. | Programmable Range Memory Protection Page Attributes Register (PROG <sub><i>n</i></sub> _MPPA) Field Descriptions... | 123 |
| 6-20. | Fault Address Register (FLTADDRR) Field Descriptions .....                                                           | 124 |
| 6-21. | Fault Status Register (FLTSTAT) Field Descriptions .....                                                             | 125 |
| 6-22. | Fault Clear Register (FLTCLR) Field Descriptions .....                                                               | 126 |
| 7-1.  | Device Clock Inputs .....                                                                                            | 128 |
| 7-2.  | System Clock Domains .....                                                                                           | 128 |
| 7-3.  | Example PLL Frequencies .....                                                                                        | 131 |
| 7-4.  | USB Clock Multiplexing Options .....                                                                                 | 132 |
| 7-5.  | DDR2/mDDR Memory Controller MCLK Frequencies .....                                                                   | 134 |
| 7-6.  | EMIFA Frequencies .....                                                                                              | 135 |
| 7-7.  | EMAC Reference Clock Frequencies .....                                                                               | 137 |
| 7-8.  | uPP Transmit Clock Selection .....                                                                                   | 138 |
| 7-9.  | Peripherals.....                                                                                                     | 140 |
| 8-1.  | System PLLC Output Clocks .....                                                                                      | 144 |
| 8-2.  | PLL Controller 0 (PLLC0) Registers.....                                                                              | 147 |
| 8-3.  | PLL Controller 1 (PLLC1) Registers.....                                                                              | 148 |
| 8-4.  | PLLC0 Revision Identification Register (REVID) Field Descriptions .....                                              | 148 |
| 8-5.  | PLLC1 Revision Identification Register (REVID) Field Descriptions .....                                              | 149 |
| 8-6.  | Reset Type Status Register (RSTYPE) Field Descriptions .....                                                         | 149 |
| 8-7.  | Reset Control Register (RSCTRL) Field Descriptions .....                                                             | 150 |
| 8-8.  | PLLC0 Control Register (PLLCTL) Field Descriptions.....                                                              | 151 |
| 8-9.  | PLLC1 Control Register (PLLCTL) Field Descriptions.....                                                              | 152 |
| 8-10. | PLLC0 OBSCLK Select Register (OCSEL) Field Descriptions .....                                                        | 153 |
| 8-11. | PLLC1 OBSCLK Select Register (OCSEL) Field Descriptions .....                                                        | 154 |
| 8-12. | PLL Multiplier Control Register (PLLM) Field Descriptions.....                                                       | 155 |

|       |                                                                              |     |
|-------|------------------------------------------------------------------------------|-----|
| 8-13. | PLLC0 Pre-Divider Control Register (PREDIV) Field Descriptions .....         | 155 |
| 8-14. | PLLC0 Divider 1 Register (PLLDIV1) Field Descriptions .....                  | 156 |
| 8-15. | PLLC1 Divider 1 Register (PLLDIV1) Field Descriptions .....                  | 156 |
| 8-16. | PLLC0 Divider 2 Register (PLLDIV2) Field Descriptions .....                  | 157 |
| 8-17. | PLLC1 Divider 2 Register (PLLDIV2) Field Descriptions .....                  | 157 |
| 8-18. | PLLC0 Divider 3 Register (PLLDIV3) Field Descriptions .....                  | 158 |
| 8-19. | PLLC1 Divider 3 Register (PLLDIV3) Field Descriptions .....                  | 158 |
| 8-20. | PLLC0 Divider 4 Register (PLLDIV4) Field Descriptions .....                  | 159 |
| 8-21. | PLLC0 Divider 5 Register (PLLDIV5) Field Descriptions .....                  | 159 |
| 8-22. | PLLC0 Divider 6 Register (PLLDIV6) Field Descriptions .....                  | 160 |
| 8-23. | PLLC0 Divider 7 Register (PLLDIV7) Field Descriptions .....                  | 160 |
| 8-24. | PLLC0 Oscillator Divider 1 Register (OSCDIV) Field Descriptions .....        | 161 |
| 8-25. | PLLC1 Oscillator Divider 1 Register (OSCDIV) Field Descriptions .....        | 161 |
| 8-26. | PLL Post-Divider Control Register (POSTDIV) Field Descriptions .....         | 162 |
| 8-27. | PLL Controller Command Register (PLLCMD) Field Descriptions .....            | 162 |
| 8-28. | PLL Controller Status Register (PLLSTAT) Field Descriptions .....            | 163 |
| 8-29. | PLLC0 Clock Align Control Register (ALNCTL) Field Descriptions .....         | 164 |
| 8-30. | PLLC1 Clock Align Control Register (ALNCTL) Field Descriptions .....         | 165 |
| 8-31. | PLLC0 PLLDIV Ratio Change Status Register (DCHANGE) Field Descriptions ..... | 166 |
| 8-32. | PLLC1 PLLDIV Ratio Change Status Register (DCHANGE) Field Descriptions ..... | 167 |
| 8-33. | PLLC0 Clock Enable Control Register (CKEN) Field Descriptions .....          | 168 |
| 8-34. | PLLC1 Clock Enable Control Register (CKEN) Field Descriptions .....          | 168 |
| 8-35. | PLLC0 Clock Status Register (CKSTAT) Field Descriptions.....                 | 169 |
| 8-36. | PLLC1 Clock Status Register (CKSTAT) Field Descriptions.....                 | 170 |
| 8-37. | PLLC0 SYSCLK Status Register (SYSTAT) Field Descriptions.....                | 171 |
| 8-38. | PLLC1 SYSCLK Status Register (SYSTAT) Field Descriptions.....                | 172 |
| 8-39. | Emulation Performance Counter 0 Register (EMUCNT0) Field Descriptions .....  | 173 |
| 8-40. | Emulation Performance Counter 1 Register (EMUCNT1) Field Descriptions .....  | 173 |
| 9-1.  | PSC0 Default Module Configuration .....                                      | 176 |
| 9-2.  | PSC1 Default Module Configuration .....                                      | 176 |
| 9-3.  | Module States .....                                                          | 179 |
| 9-4.  | IcePick Emulation Commands .....                                             | 181 |
| 9-5.  | PSC Interrupt Events .....                                                   | 181 |
| 9-6.  | Power and Sleep Controller 0 (PSC0) Registers .....                          | 184 |
| 9-7.  | Power and Sleep Controller 1 (PSC1) Registers .....                          | 184 |
| 9-8.  | Revision Identification Register (REVID) Field Descriptions .....            | 185 |
| 9-9.  | Interrupt Evaluation Register (INTEVAL) Field Descriptions .....             | 185 |
| 9-10. | PSC0 Module Error Pending Register 0 (MERRPR0) Field Descriptions.....       | 186 |
| 9-11. | PSC0 Module Error Clear Register 0 (MERRCR0) Field Descriptions .....        | 187 |
| 9-12. | Power Error Pending Register (PERRPR) Field Descriptions .....               | 188 |
| 9-13. | Power Error Clear Register (PERRCR) Field Descriptions .....                 | 188 |
| 9-14. | Power Domain Transition Command Register (PTCMD) Field Descriptions .....    | 189 |
| 9-15. | Power Domain Transition Status Register (PTSTAT) Field Descriptions .....    | 190 |
| 9-16. | Power Domain 0 Status Register (PDSTAT0) Field Descriptions.....             | 191 |
| 9-17. | Power Domain 1 Status Register (PDSTAT1) Field Descriptions.....             | 192 |
| 9-18. | Power Domain 0 Control Register (PDCTL0) Field Descriptions.....             | 193 |
| 9-19. | Power Domain 1 Control Register (PDCTL1) Field Descriptions.....             | 194 |
| 9-20. | Power Domain 0 Configuration Register (PDCFG0) Field Descriptions.....       | 195 |
| 9-21. | Power Domain 1 Configuration Register (PDCFG1) Field Descriptions.....       | 196 |

|                                                                                   |     |
|-----------------------------------------------------------------------------------|-----|
| 9-22. Module Status $n$ Register (MDSTAT $n$ ) Field Descriptions .....           | 197 |
| 9-23. PSC0 Module Control $n$ Register (MDCTL $n$ ) Field Descriptions .....      | 198 |
| 9-24. PSC1 Module Control $n$ Register (MDCTL $n$ ) Field Descriptions .....      | 199 |
| 10-1. Power Management Features.....                                              | 202 |
| 11-1. Master IDs .....                                                            | 219 |
| 11-2. Default Master Priority .....                                               | 220 |
| 11-3. System Configuration Module 0 (SYSCFG0) Registers .....                     | 221 |
| 11-4. System Configuration Module 1 (SYSCFG1) Registers .....                     | 223 |
| 11-5. Revision Identification Register (REVID) Field Descriptions .....           | 223 |
| 11-6. Device Identification Register 0 (DEVIDR0) Field Descriptions .....         | 223 |
| 11-7. Boot Configuration Register (BOOTCFG) Field Descriptions .....              | 224 |
| 11-8. Chip Revision Identification Register (CHIPREVIDR) Field Descriptions ..... | 224 |
| 11-9. Kick 0 Register (KICK0R) Field Descriptions .....                           | 225 |
| 11-10. Kick 1 Register (KICK1R) Field Descriptions .....                          | 225 |
| 11-11. Host 0 Configuration Register (HOST0CFG) Field Descriptions .....          | 226 |
| 11-12. Host 1 Configuration Register (HOST1CFG) Field Descriptions .....          | 227 |
| 11-13. Interrupt Raw Status/Set Register (IRAWSTAT) Field Descriptions .....      | 228 |
| 11-14. Interrupt Enable Status/Clear Register (IENSTAT) Field Descriptions .....  | 229 |
| 11-15. Interrupt Enable Register (IENSET) Field Descriptions.....                 | 230 |
| 11-16. Interrupt Enable Clear Register (IENCLR) Field Descriptions .....          | 230 |
| 11-17. End of Interrupt Register (EOI) Field Descriptions .....                   | 231 |
| 11-18. Fault Address Register (FLTADDRR) Field Descriptions .....                 | 231 |
| 11-19. Fault Status Register (FLTSTAT) Field Descriptions .....                   | 232 |
| 11-20. Master Priority 0 Register (MSTPRI0) Field Descriptions .....              | 233 |
| 11-21. Master Priority 1 Register (MSTPRI1) Field Descriptions .....              | 234 |
| 11-22. Master Priority 2 Register (MSTPRI2) Field Descriptions .....              | 235 |
| 11-23. Pin Multiplexing Control 0 Register (PINMUX0) Field Descriptions.....      | 236 |
| 11-24. Pin Multiplexing Control 1 Register (PINMUX1) Field Descriptions.....      | 238 |
| 11-25. Pin Multiplexing Control 2 Register (PINMUX2) Field Descriptions.....      | 240 |
| 11-26. Pin Multiplexing Control 3 Register (PINMUX3) Field Descriptions.....      | 242 |
| 11-27. Pin Multiplexing Control 4 Register (PINMUX4) Field Descriptions.....      | 244 |
| 11-28. Pin Multiplexing Control 5 Register (PINMUX5) Field Descriptions.....      | 246 |
| 11-29. Pin Multiplexing Control 6 Register (PINMUX6) Field Descriptions.....      | 248 |
| 11-30. Pin Multiplexing Control 7 Register (PINMUX7) Field Descriptions.....      | 250 |
| 11-31. Pin Multiplexing Control 8 Register (PINMUX8) Field Descriptions.....      | 252 |
| 11-32. Pin Multiplexing Control 9 Register (PINMUX9) Field Descriptions.....      | 254 |
| 11-33. Pin Multiplexing Control 10 Register (PINMUX10) Field Descriptions.....    | 256 |
| 11-34. Pin Multiplexing Control 11 Register (PINMUX11) Field Descriptions.....    | 258 |
| 11-35. Pin Multiplexing Control 12 Register (PINMUX12) Field Descriptions.....    | 260 |
| 11-36. Pin Multiplexing Control 13 Register (PINMUX13) Field Descriptions.....    | 262 |
| 11-37. Pin Multiplexing Control 14 Register (PINMUX14) Field Descriptions.....    | 264 |
| 11-38. Pin Multiplexing Control 15 Register (PINMUX15) Field Descriptions.....    | 266 |
| 11-39. Pin Multiplexing Control 16 Register (PINMUX16) Field Descriptions.....    | 269 |
| 11-40. Pin Multiplexing Control 17 Register (PINMUX17) Field Descriptions.....    | 271 |
| 11-41. Pin Multiplexing Control 18 Register (PINMUX18) Field Descriptions.....    | 273 |
| 11-42. Pin Multiplexing Control 19 Register (PINMUX19) Field Descriptions.....    | 275 |
| 11-43. Suspend Source Register (SUSPSRC) Field Descriptions .....                 | 277 |
| 11-44. Chip Signal Register (CHIPSIG) Field Descriptions.....                     | 280 |
| 11-45. Chip Signal Clear Register (CHIPSIG_CLR) Field Descriptions .....          | 281 |

|                                                                                          |     |
|------------------------------------------------------------------------------------------|-----|

| 11-47. Chip Configuration 1 Register (CFGCHIP1) Field Descriptions .....                 | 284 |
| 11-48. Chip Configuration 2 Register (CFGCHIP2) Field Descriptions .....                 | 286 |
| 11-49. Chip Configuration 3 Register (CFGCHIP3) Field Descriptions .....                 | 288 |
| 11-50. Chip Configuration 4 Register (CFGCHIP4) Field Descriptions .....                 | 289 |
| 11-51. VTP I/O Control Register (VTPIO_CTL) Field Descriptions.....                      | 290 |
| 11-52. DDR Slew Register (DDR_SLEW) Field Descriptions .....                             | 292 |
| 11-53. Deep Sleep Register (DEEPSLEEP) Field Descriptions .....                          | 293 |
| 11-54. Pullup/Pulldown Enable Register (PUPD_ENA) Field Descriptions.....                | 294 |
| 11-55. Pullup/Pulldown Select Register (PUPD_SEL) Field Descriptions .....               | 294 |
| 11-56. Pullup/Pulldown Select Register (PUPD_SEL) Default Values .....                   | 295 |
| 11-57. RXACTIVE Control Register (RXACTIVE) Field Descriptions .....                     | 296 |
| 11-58. Power Down Control Register (PWRDN) Field Descriptions .....                      | 296 |
| 12-1. AINTC System Interrupt Assignments .....                                           | 299 |
| 12-2. ARM Interrupt Controller (AINTC) Registers .....                                   | 305 |
| 12-3. Revision Identification Register (REVID) Field Descriptions .....                  | 306 |
| 12-4. Control Register (CR) Field Descriptions .....                                     | 307 |
| 12-5. Global Enable Register (GER) Field Descriptions.....                               | 308 |
| 12-6. Global Nesting Level Register (GNLR) Field Descriptions .....                      | 308 |
| 12-7. System Interrupt Status Indexed Set Register (SISR) Field Descriptions.....        | 309 |
| 12-8. System Interrupt Status Indexed Clear Register (SICR) Field Descriptions .....     | 309 |
| 12-9. System Interrupt Enable Indexed Set Register (EISR) Field Descriptions .....       | 310 |
| 12-10. System Interrupt Enable Indexed Clear Register (EICR) Field Descriptions .....    | 310 |
| 12-11. Host Interrupt Enable Indexed Set Register (HEISR) Field Descriptions .....       | 311 |
| 12-12. Host Interrupt Enable Indexed Clear Register (HIEICR) Field Descriptions .....    | 311 |
| 12-13. Vector Base Register (VBR) Field Descriptions .....                               | 312 |
| 12-14. Vector Size Register (VSR) Field Descriptions .....                               | 312 |
| 12-15. Vector Null Register (VNR) Field Descriptions.....                                | 313 |
| 12-16. Global Prioritized Index Register (GPIR) Field Descriptions .....                 | 313 |
| 12-17. Global Prioritized Vector Register (GPVR) Field Descriptions.....                 | 314 |
| 12-18. System Interrupt Status Raw/Set Register 1 (SRSR1) Field Descriptions .....       | 314 |
| 12-19. System Interrupt Status Raw/Set Register 2 (SRSR2) Field Descriptions .....       | 315 |
| 12-20. System Interrupt Status Raw/Set Register 3 (SRSR3) Field Descriptions .....       | 315 |
| 12-21. System Interrupt Status Raw/Set Register 4 (SRSR4) Field Descriptions .....       | 316 |
| 12-22. System Interrupt Status Enabled/Clear Register 1 (SECR1) Field Descriptions ..... | 316 |
| 12-23. System Interrupt Status Enabled/Clear Register 2 (SECR2) Field Descriptions ..... | 317 |
| 12-24. System Interrupt Status Enabled/Clear Register 3 (SECR3) Field Descriptions ..... | 317 |
| 12-25. System Interrupt Status Enabled/Clear Register 4 (SECR4) Field Descriptions ..... | 318 |
| 12-26. System Interrupt Enable Set Register 1 (ESR1) Field Descriptions .....            | 318 |
| 12-27. System Interrupt Enable Set Register 2 (ESR2) Field Descriptions .....            | 319 |
| 12-28. System Interrupt Enable Set Register 3 (ESR3) Field Descriptions .....            | 319 |
| 12-29. System Interrupt Enable Set Register 4 (ESR4) Field Descriptions .....            | 320 |
| 12-30. System Interrupt Enable Clear Register 1 (ECR1) Field Descriptions.....           | 320 |
| 12-31. System Interrupt Enable Clear Register 2 (ECR2) Field Descriptions.....           | 321 |
| 12-32. System Interrupt Enable Clear Register 3 (ECR3) Field Descriptions.....           | 321 |
| 12-33. System Interrupt Enable Clear Register 4 (ECR4) Field Descriptions.....           | 322 |
| 12-34. Channel Map Registers (CMR <sub>n</sub> ) Field Descriptions .....                | 322 |
| 12-35. Host Interrupt Prioritized Index Register 1 (HIPIR1) Field Descriptions .....     | 323 |
| 12-36. Host Interrupt Prioritized Index Register 2 (HIPIR2) Field Descriptions .....     | 323 |

|                                                                                      |     |
|--------------------------------------------------------------------------------------|-----|
| 12-37. Host Interrupt Nesting Level Register 1 (HINLR1) Field Descriptions .....     | 324 |
| 12-38. Host Interrupt Nesting Level Register 2 (HINLR2) Field Descriptions .....     | 324 |
| 12-39. Host Interrupt Enable Register (HIER) Field Descriptions .....                | 325 |
| 12-40. Host Interrupt Prioritized Vector Register 1 (HIPVR1) Field Descriptions..... | 326 |
| 12-41. Host Interrupt Prioritized Vector Register 2 (HIPVR2) Field Descriptions..... | 326 |
| 14-1. Constants Table.....                                                           | 334 |
| 14-2. Abbreviations for Instruction Descriptions .....                               | 336 |
| 14-3. Load/Store Instructions .....                                                  | 336 |
| 14-4. Arithmetic Instructions.....                                                   | 336 |
| 14-5. Logical Instructions .....                                                     | 337 |
| 14-6. Program Flow Control Instructions .....                                        | 338 |
| 14-7. Format 1a: (All Arithmetic and Logical Functions – Register Op2).....          | 339 |
| 14-8. Format 1b: (All Arithmetic and Logical Functions – Immediate Op2) .....        | 341 |
| 14-9. Format 2 .....                                                                 | 342 |
| 14-10. Format 2a: (JMP,JAL – Register Op2).....                                      | 343 |
| 14-11. Format 2b: (JMP, JAL – Immediate Op2) .....                                   | 344 |
| 14-12. Format 2c: (LDI).....                                                         | 345 |
| 14-13. Format 2d: (LMBD - Leftmost Bit Detect - Register Op2) .....                  | 346 |
| 14-14. Format 2e: (LMBD - Immediate Op2) .....                                       | 347 |
| 14-15. Format 2f: (SCAN - Register Op2) .....                                        | 348 |
| 14-16. Format 2g: (SCAN - Immediate Op2) .....                                       | 349 |
| 14-17. Format 2h: (HALT).....                                                        | 349 |
| 14-18. Format 2i: (SLP) .....                                                        | 349 |
| 14-19. Format 4a: (Quick Arithmetic Test and Branch – Register Op2) .....            | 350 |
| 14-20. Format 4b: (Quick Arithmetic Test and Branch – Immediate Op2).....            | 351 |
| 14-21. Format 5a: (Quick Bit Test and Branch – Register Op2) .....                   | 352 |
| 14-22. Format 5b: (Quick Bit Test and Branch – Immediate Op2) .....                  | 353 |
| 14-23. Format 6a: (LBBO/SBBO - Register Offset).....                                 | 354 |
| 14-24. Format 6b: (LBBO/SBBO - Immediate Offset) .....                               | 355 |
| 14-25. Format 6c: (LBCO/SBCO - Register Offset) .....                                | 356 |
| 14-26. Format 6d: (LBCO/SBCO - Immediate Offset).....                                | 357 |
| 14-27. PRUSS System Events [0:31] Assignments .....                                  | 359 |
| 14-28. ARM Interrupt Controller Mapping.....                                         | 360 |
| 14-29. DSP Interrupt Controller Mapping .....                                        | 360 |
| 14-30. Local Instruction Space Memory Map .....                                      | 365 |
| 14-31. Local Data Space Memory Map .....                                             | 365 |
| 14-32. Subsystem Global Memory Map.....                                              | 365 |
| 14-33. PRU Control/Status Register Memory Map .....                                  | 366 |
| 14-34. CONTROL Register Field Descriptions .....                                     | 366 |
| 14-35. STATUS Register Field Descriptions .....                                      | 368 |
| 14-36. WAKEUP Register Field Descriptions .....                                      | 368 |
| 14-37. CYCLECNT Register Field Descriptions.....                                     | 369 |
| 14-38. STALLCNT Register Field Descriptions .....                                    | 369 |
| 14-39. CONTABBLKIDX0 Register Field Descriptions.....                                | 370 |
| 14-40. CONTABPROPTR0 Register Field Descriptions .....                               | 370 |
| 14-41. CONTABPROPTR1 Register Field Descriptions .....                               | 370 |
| 14-42. INTGPR0 to INTGPR31 Register Field Descriptions .....                         | 371 |
| 14-43. INTCTER0 to INTCTER31 Register Field Descriptions .....                       | 371 |
| 14-44. Instruction RAM Memory Region .....                                           | 372 |

|                                                                          |     |

| 17-46. EPWM2 Initialization for .....                                                         | 561 |
| 17-47. EPWM3 Initialization for .....                                                         | 562 |
| 17-48. EPWM1 Initialization for .....                                                         | 565 |
| 17-49. EPWM2 Initialization for .....                                                         | 565 |
| 17-50. Submodule Registers .....                                                              | 566 |
| 17-51. Time-Base Submodule Registers.....                                                     | 566 |
| 17-52. Time-Base Control Register (TBCTL) Field Descriptions .....                            | 567 |
| 17-53. Time-Base Status Register (TBSTS) Field Descriptions .....                             | 568 |
| 17-54. Time-Base Phase Register (TBPHS) Field Descriptions .....                              | 569 |
| 17-55. Time-Base Counter Register (TBCNT) Field Descriptions .....                            | 569 |
| 17-56. Time-Base Period Register (TBPRD) Field Descriptions.....                              | 570 |
| 17-57. Counter-Compare Submodule Registers .....                                              | 570 |
| 17-58. Counter-Compare Control Register (CMPCTL) Field Descriptions .....                     | 571 |
| 17-59. Counter-Compare A Register (CMPA) Field Descriptions.....                              | 572 |
| 17-60. Counter-Compare B Register (CMPB) Field Descriptions.....                              | 573 |
| 17-61. Action-Qualifier Submodule Registers .....                                             | 573 |
| 17-62. Action-Qualifier Output A Control Register (AQCTLA) Field Descriptions .....           | 574 |
| 17-63. Action-Qualifier Output B Control Register (AQCTLB) Field Descriptions .....           | 575 |
| 17-64. Action-Qualifier Software Force Register (AQSFRC) Field Descriptions.....              | 576 |
| 17-65. Action-Qualifier Continuous Software Force Register (AQCSFRC) Field Descriptions ..... | 577 |
| 17-66. Dead-Band Generator Submodule Registers .....                                          | 577 |
| 17-67. Dead-Band Generator Control Register (DBCTL) Field Descriptions.....                   | 578 |
| 17-68. Dead-Band Generator Rising Edge Delay Register (DBRED) Field Descriptions .....        | 579 |
| 17-69. Dead-Band Generator Falling Edge Delay Register (DBFED) Field Descriptions .....       | 579 |
| 17-70. PWM-Chopper Control Register (PCCTL) Bit Descriptions .....                            | 580 |
| 17-71. Trip-Zone Submodule Registers .....                                                    | 581 |
| 17-72. Trip-Zone Submodule Select Register (TZSEL) Field Descriptions .....                   | 581 |

|                                                                                                |     |
|------------------------------------------------------------------------------------------------|-----|
| 17-73. Trip-Zone Control Register (TZCTL) Field Descriptions .....                             | 582 |
| 17-74. Trip-Zone Enable Interrupt Register (TZEINT) Field Descriptions .....                   | 582 |
| 17-75. Trip-Zone Flag Register (TZFLG) Field Descriptions .....                                | 583 |
| 17-76. Trip-Zone Clear Register (TZCLR) Field Descriptions .....                               | 584 |
| 17-77. Trip-Zone Force Register (TZFRC) Field Descriptions .....                               | 584 |
| 17-78. Event-Trigger Submodule Registers .....                                                 | 585 |
| 17-79. Event-Trigger Selection Register (ETSEL) Field Descriptions .....                       | 585 |
| 17-80. Event-Trigger Prescale Register (ETPS) Field Descriptions .....                         | 586 |
| 17-81. Event-Trigger Flag Register (ETFLG) Field Descriptions .....                            | 587 |
| 17-82. Event-Trigger Clear Register (ETCLR) Field Descriptions .....                           | 587 |
| 17-83. Event-Trigger Force Register (ETFRC) Field Descriptions .....                           | 588 |
| 17-84. High-Resolution PWM Submodule Registers .....                                           | 588 |
| 17-85. Time-Base Phase High-Resolution Register (TBPHSHR) Field Descriptions .....             | 589 |
| 17-86. Counter-Compare A High-Resolution Register (CMPAHR) Field Descriptions.....             | 589 |
| 17-87. HRPWM Configuration Register (HRCNFG) Field Descriptions.....                           | 590 |
| 18-1. EDMA3 Channel Parameter Description .....                                                | 604 |
| 18-2. Dummy and Null Transfer Request .....                                                    | 607 |
| 18-3. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaPARAM Set) .....                 | 608 |
| 18-4. Expected Number of Transfers for Non-Null Transfer .....                                 | 616 |
| 18-5. EDMA3 DMA Channel to PaPARAM Mapping .....                                               | 618 |
| 18-6. Shadow Region Registers .....                                                            | 620 |
| 18-7. Chain Event Triggers.....                                                                | 623 |
| 18-8. EDMA3 Transfer Completion Interrupts .....                                               | 623 |
| 18-9. EDMA3 Error Interrupts .....                                                             | 624 |
| 18-10. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping .....                         | 624 |
| 18-11. Number of Interrupts .....                                                              | 625 |
| 18-12. EDMA3 Transfer Controller Configurations .....                                          | 632 |
| 18-13. Read/Write Command Optimization Rules .....                                             | 638 |
| 18-14. EDMA3 Channel Controller (EDMA3CC) Parameter RAM (PaPARAM) Entries.....                 | 657 |
| 18-15. Channel Options Parameters (OPT) Field Descriptions.....                                | 658 |
| 18-16. Channel Source Address Parameter (SRC) Field Descriptions .....                         | 660 |
| 18-17. A Count/B Count Parameter (A_B_CNT) Field Descriptions .....                            | 660 |
| 18-18. Channel Destination Address Parameter (DST) Field Descriptions .....                    | 661 |
| 18-19. Source B Index/Destination B Index Parameter (SRC_DST_BIDX) Field Descriptions.....     | 661 |
| 18-20. Link Address/B Count Reload Parameter (LINK_BCNTRLD) Field Descriptions .....           | 662 |
| 18-21. Source C Index/Destination C Index Parameter (SRC_DST_CIDX) Field Descriptions .....    | 663 |
| 18-22. C Count Parameter (CCNT) Field Descriptions.....                                        | 663 |
| 18-23. EDMA3 Channel Controller (EDMA3CC) Registers.....                                       | 664 |
| 18-24. Revision ID Register (REVID) Field Descriptions .....                                   | 667 |
| 18-25. EDMA3CC Configuration Register (CCCFG) Field Descriptions .....                         | 668 |
| 18-26. QDMA Channel <i>n</i> Mapping Register (QCHMAP <i>n</i> ) Field Descriptions.....       | 669 |
| 18-27. DMA Channel Queue Number Register <i>n</i> (DMAQNUM <i>n</i> ) Field Descriptions ..... | 670 |
| 18-28. Bits in DMAQNUM <i>n</i> .....                                                          | 670 |
| 18-29. QDMA Channel Queue Number Register (QDMAQNUM) Field Descriptions.....                   | 671 |
| 18-30. Event Missed Register (EMR) Field Descriptions .....                                    | 672 |
| 18-31. Event Missed Clear Register (EMCR) Field Descriptions .....                             | 673 |
| 18-32. QDMA Event Missed Register (QEMR) Field Descriptions .....                              | 674 |
| 18-33. QDMA Event Missed Clear Register (QEMCR) Field Descriptions .....                       | 675 |
| 18-34. EDMA3CC Error Register (CCERR) Field Descriptions .....                                 | 676 |

|                                                                                                   |     |
|---------------------------------------------------------------------------------------------------|-----|
| 18-35. EDMA3CC Error Clear Register (CCERRCLR) Field Descriptions .....                           | 677 |
| 18-36. Error Evaluate Register (EEVAL) Field Descriptions.....                                    | 678 |
| 18-37. DMA Region Access Enable Register for Region <i>m</i> (DRAEm) Field Descriptions .....     | 679 |
| 18-38. QDMA Region Access Enable for Region <i>m</i> (QRAEm) Field Descriptions .....             | 680 |
| 18-39. Event Queue Entry Registers (QxEy) Field Descriptions.....                                 | 681 |
| 18-40. Queue <i>n</i> Status Register (QSTAT <sub><i>n</i></sub> ) Field Descriptions .....       | 682 |
| 18-41. Queue Watermark Threshold A Register (QWMTHRA) Field Descriptions.....                     | 683 |
| 18-42. EDMA3CC Status Register (CCSTAT) Field Descriptions .....                                  | 684 |
| 18-43. Event Register (ER) Field Descriptions.....                                                | 686 |
| 18-44. Event Clear Register (ECR) Field Descriptions.....                                         | 687 |
| 18-45. Event Set Register (ESR) Field Descriptions .....                                          | 688 |
| 18-46. Chained Event Register (CER) Field Descriptions .....                                      | 689 |
| 18-47. Event Enable Register (EER) Field Descriptions.....                                        | 690 |
| 18-48. Event Enable Clear Register (EECR) Field Descriptions.....                                 | 691 |
| 18-49. Event Enable Set Register (EESR) Field Descriptions .....                                  | 691 |
| 18-50. Secondary Event Register (SER) Field Descriptions .....                                    | 692 |
| 18-51. Secondary Event Clear Register (SECR) Field Descriptions .....                             | 692 |
| 18-52. Interrupt Enable Register (IER) Field Descriptions.....                                    | 693 |
| 18-53. Interrupt Enable Clear Register (IECR) Field Descriptions.....                             | 694 |
| 18-54. Interrupt Enable Set Register (IESR) Field Descriptions .....                              | 694 |
| 18-55. Interrupt Pending Register (IPR) Field Descriptions .....                                  | 695 |
| 18-56. Interrupt Clear Register (ICR) Field Descriptions.....                                     | 696 |
| 18-57. Interrupt Evaluate Register (IEVAL) Field Descriptions .....                               | 697 |
| 18-58. QDMA Event Register (QER) Field Descriptions.....                                          | 698 |
| 18-59. QDMA Event Enable Register (QEER) Field Descriptions .....                                 | 699 |
| 18-60. QDMA Event Enable Clear Register (QEECR) Field Descriptions.....                           | 700 |
| 18-61. QDMA Event Enable Set Register (QEESR) Field Descriptions .....                            | 700 |
| 18-62. QDMA Secondary Event Register (QSER) Field Descriptions .....                              | 701 |
| 18-63. QDMA Secondary Event Clear Register (QSECR) Field Descriptions .....                       | 702 |
| 18-64. EDMA3 Transfer Controller (EDMA3TC) Registers .....                                        | 703 |
| 18-65. Revision ID Register (REVID) Field Descriptions .....                                      | 704 |
| 18-66. EDMA3TC Configuration Register (TCCFG) Field Descriptions .....                            | 705 |
| 18-67. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions.....                           | 706 |
| 18-68. Error Status Register (ERRSTAT) Field Descriptions .....                                   | 707 |
| 18-69. Error Enable Register (ERREN) Field Descriptions.....                                      | 708 |
| 18-70. Error Clear Register (ERRCLR) Field Descriptions .....                                     | 709 |
| 18-71. Error Details Register (ERRDET) Field Descriptions .....                                   | 710 |
| 18-72. Error Interrupt Command Register (ERRCMD) Field Descriptions.....                          | 711 |

| 19-40. Transmit Teardown Register (TXTEARDOWN) Field Descriptions .....                                     | 805 |
| 19-41. Receive Revision ID Register (RXREVID) Field Descriptions .....                                      | 806 |
| 19-42. Receive Control Register (RXCONTROL) Field Descriptions .....                                        | 806 |
| 19-43. Receive Teardown Register (RXTEARDOWN) Field Descriptions .....                                      | 807 |
| 19-44. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW) Field Descriptions .....                | 808 |
| 19-45. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED) Field Descriptions.....                | 809 |
| 19-46. Transmit Interrupt Mask Set Register (TXINTMASKSET) Field Descriptions .....                         | 810 |
| 19-47. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR) Field Descriptions .....                     | 811 |
| 19-48. MAC Input Vector Register (MACINVECTOR) Field Descriptions .....                                     | 812 |
| 19-49. MAC End Of Interrupt Vector Register (MACEOIVECTOR) Field Descriptions.....                          | 813 |
| 19-50. Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW) Field Descriptions.....                  | 814 |
| 19-51. Receive Interrupt Status (Masked) Register (RXINTSTATMASKED) Field Descriptions .....                | 815 |
| 19-52. Receive Interrupt Mask Set Register (RXINTMASKSET) Field Descriptions.....                           | 816 |
| 19-53. Receive Interrupt Mask Clear Register (RXINTMASKCLEAR) Field Descriptions.....                       | 817 |
| 19-54. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW) Field Descriptions .....                    | 818 |
| 19-55. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED) Field Descriptions.....                    | 818 |
| 19-56. MAC Interrupt Mask Set Register (MACINTMASKSET) Field Descriptions .....                             | 819 |
| 19-57. MAC Interrupt Mask Clear Register (MACINTMASKCLEAR) Field Descriptions .....                         | 819 |
| 19-58. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions     | 820 |
| 19-59. Receive Unicast Enable Set Register (RXUNICASTSET) Field Descriptions .....                          | 823 |
| 19-60. Receive Unicast Clear Register (RXUNICASTCLEAR) Field Descriptions .....                             | 824 |
| 19-61. Receive Maximum Length Register (RXMAXLEN) Field Descriptions .....                                  | 825 |
| 19-62. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions.....                              | 825 |
| 19-63. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) Field Descriptions .....    | 826 |
| 19-64. Receive Channel <i>n</i> Flow Control Threshold Register (RX $n$ FLOWTHRESH) Field Descriptions..... | 826 |
| 19-65. Receive Channel <i>n</i> Free Buffer Count Register (RX $n$ FREEBUFFER) Field Descriptions .....     | 827 |
| 19-66. MAC Control Register (MACCONTROL) Field Descriptions.....                                            | 828 |
| 19-67. MAC Status Register (MACSTATUS) Field Descriptions .....                                             | 830 |
| 19-68. Emulation Control Register (EMCONTROL) Field Descriptions.....                                       | 832 |
| 19-69. FIFO Control Register (FIFOCONTROL) Field Descriptions.....                                          | 832 |
| 19-70. MAC Configuration Register (MACCONFIG) Field Descriptions .....                                      | 833 |
| 19-71. Soft Reset Register (SOFTRESET) Field Descriptions.....                                              | 833 |
| 19-72. MAC Source Address Low Bytes Register (MACSRCADDRLO) Field Descriptions .....                        | 834 |
| 19-73. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions.....                        | 834 |
| 19-74. MAC Hash Address Register 1 (MACHASH1) Field Descriptions .....                                      | 835 |
| 19-75. MAC Hash Address Register 2 (MACHASH2) Field Descriptions .....                                      | 835 |
| 19-76. Back Off Test Register (BOFFTEST) Field Descriptions .....                                           | 836 |
| 19-77. Transmit Pacing Algorithm Test Register (TPACETEST) Field Descriptions.....                          | 836 |
| 19-78. Receive Pause Timer Register (RXPAUSE) Field Descriptions.....                                       | 837 |
| 19-79. Transmit Pause Timer Register (TXPAUSE) Field Descriptions .....                                     | 837 |
| 19-80. MAC Address Low Bytes Register (MACADDRLO) Field Descriptions .....                                  | 838 |
| 19-81. MAC Address High Bytes Register (MACADDRHI) Field Descriptions.....                                  | 839 |
| 19-82. MAC Index Register (MACINDEX) Field Descriptions.....                                                | 839 |
| 19-83. Transmit Channel <i>n</i> DMA Head Descriptor Pointer Register (TX $n$ HDP) Field Descriptions.....  | 840 |
| 19-84. Receive Channel <i>n</i> DMA Head Descriptor Pointer Register (RX $n$ HDP) Field Descriptions .....  | 840 |
| 19-85. Transmit Channel <i>n</i> Completion Pointer Register (TX $n$ CP) Field Descriptions .....           | 841 |
| 19-86. Receive Channel <i>n</i> Completion Pointer Register (RX $n$ CP) Field Descriptions.....             | 841 |
| 20-1. EMIFA Pins Used to Access Both SDRAM and Asynchronous Memories.....                                   | 853 |

|        |                                                                                 |     |

| 20-56. EMIFA Interrupt Raw Register (INTRAW) Field Descriptions .....                                                | 925  |
| 20-57. EMIFA Interrupt Mask Register (INTMSK) Field Descriptions .....                                               | 926  |
| 20-58. EMIFA Interrupt Mask Set Register (INTMSKSET) Field Descriptions .....                                        | 927  |
| 20-59. EMIFA Interrupt Mask Clear Register (INTMSKCLR) Field Descriptions .....                                      | 928  |
| 20-60. NAND Flash Control Register (NANDFCR) Field Descriptions .....                                                | 929  |
| 20-61. NAND Flash Status Register (NANDFSR) Field Descriptions .....                                                 | 931  |
| 20-62. NAND Flash <i>n</i> ECC Register (NANDFnECC) Field Descriptions .....                                         | 932  |
| 20-63. NAND Flash 4-Bit ECC LOAD Register (NAND4BITECCLOAD) Field Descriptions .....                                 | 933  |
| 20-64. NAND Flash 4-Bit ECC Register 1 (NAND4BITECC1) Field Descriptions .....                                       | 934  |
| 20-65. NAND Flash 4-Bit ECC Register 2 (NAND4BITECC2) Field Descriptions .....                                       | 934  |
| 20-66. NAND Flash 4-Bit ECC Register 3 (NAND4BITECC3) Field Descriptions .....                                       | 935  |
| 20-67. NAND Flash 4-Bit ECC Register 4 (NAND4BITECC4) Field Descriptions .....                                       | 935  |
| 20-68. NAND Flash 4-Bit ECC Error Address Register 1 (NANDERRADD1) Field Descriptions .....                          | 936  |
| 20-69. NAND Flash 4-Bit ECC Error Address Register 2 (NANDERRADD2) Field Descriptions .....                          | 936  |
| 20-70. NAND Flash 4-Bit ECC Error Value Register 1 (NANDERRVAL1) Field Descriptions .....                            | 937  |
| 20-71. NAND Flash 4-Bit ECC Error Value Register 2 (NANDERRVAL2) Field Descriptions .....                            | 937  |
| 21-1. GPIO Register Bits and Banks Associated With GPIO Signals .....                                                | 941  |
| 21-2. GPIO Registers .....                                                                                           | 948  |
| 21-3. Revision ID Register (REVID) Field Descriptions .....                                                          | 949  |
| 21-4. GPIO Interrupt Per-Bank Enable Register (BINTEN) Field Descriptions .....                                      | 950  |
| 21-5. GPIO Direction Register (DIR <sub><i>n</i></sub> ) Field Descriptions .....                                    | 952  |
| 21-6. GPIO Output Data Register (OUT_DAT <sub><i>n</i></sub> ) Field Descriptions .....                              | 954  |
| 21-7. GPIO Set Data Register (SET_DAT <sub><i>n</i></sub> ) Field Descriptions .....                                 | 956  |
| 21-8. GPIO Clear Data Register (CLR_DAT <sub><i>n</i></sub> ) Field Descriptions .....                               | 958  |
| 21-9. GPIO Input Data Register (IN_DAT <sub><i>n</i></sub> ) Field Descriptions .....                                | 960  |
| 21-10. GPIO Set Rising Edge Trigger Interrupt Register (SET_RIS_TRIG <sub><i>n</i></sub> ) Field Descriptions .....  | 962  |
| 21-11. GPIO Clear Rising Edge Interrupt Register (CLR_RIS_TRIG <sub><i>n</i></sub> ) Field Descriptions .....        | 964  |
| 21-12. GPIO Set Falling Edge Trigger Interrupt Register (SET_FAL_TRIG <sub><i>n</i></sub> ) Field Descriptions ..... | 966  |
| 21-13. GPIO Clear Falling Edge Interrupt Register (CLR_FAL_TRIG <sub><i>n</i></sub> ) Field Descriptions .....       | 968  |
| 21-14. GPIO Interrupt Status Register (INTSTAT <sub><i>n</i></sub> ) Field Descriptions .....                        | 970  |
| 22-1. HPI Pins .....                                                                                                 | 975  |
| 22-2. Value on Optional Pins when Configured as General-Purpose I/O .....                                            | 976  |
| 22-3. Options for Connecting Host and HPI Data Strobe Pins .....                                                     | 980  |
| 22-4. Access Types Selectable With the UHPI_HCNTL Signals .....                                                      | 981  |
| 22-5. Cycle Types Selectable With the UHPI_HCNTL and UHPI_HR/W Signals .....                                         | 981  |
| 22-6. HPI Registers .....                                                                                            | 995  |
| 22-7. Revision Identification Register (REVID) Field Descriptions .....                                              | 996  |
| 22-8. Power and Emulation Management Register (PWREMU_MGMT) Field Descriptions .....                                 | 996  |
| 22-9. GPIO Enable Register (GPIO_EN) Field Descriptions .....                                                        | 997  |
| 22-10. GPIO Direction 1 Register (GPIO_DIR1) Field Descriptions .....                                                | 998  |
| 22-11. GPIO Data 1 Register (GPIO_DAT1) Field Descriptions .....                                                     | 998  |
| 22-12. GPIO Direction 2 Register (GPIO_DIR2) Field Descriptions .....                                                | 999  |
| 22-13. GPIO Data 2 Register (GPIO_DAT2) Field Descriptions .....                                                     | 1000 |
| 22-14. Host Port Interface Control Register (HPIC) Field Descriptions .....                                          | 1002 |

|                                                                                                                   |      |
|-------------------------------------------------------------------------------------------------------------------|------|
| 22-15. Host Port Interface Write Address Register (HPIAW) Field Descriptions .....                                | 1003 |
| 22-16. Host Port Interface Read Address Register (HPIAR) Field Descriptions .....                                 | 1003 |
| 23-1. Operating Modes of the I2C Peripheral .....                                                                 | 1013 |
| 23-2. Ways to Generate a NACK Bit .....                                                                           | 1014 |
| 23-3. Descriptions of the I2C Interrupt Events .....                                                              | 1018 |
| 23-4. Inter-Integrated Circuit (I2C) Registers .....                                                              | 1019 |
| 23-5. I2C Own Address Register (ICOAR) Field Descriptions .....                                                   | 1020 |
| 23-6. I2C Interrupt Mask Register (ICIMR) Field Descriptions .....                                                | 1021 |
| 23-7. I2C Interrupt Status Register (ICSTR) Field Descriptions .....                                              | 1022 |
| 23-8. I2C Clock Low-Time Divider Register (ICCLKL) Field Descriptions .....                                       | 1025 |
| 23-9. I2C Clock High-Time Divider Register (ICCLKH) Field Descriptions .....                                      | 1025 |
| 23-10. I2C Data Count Register (ICCNT) Field Descriptions .....                                                   | 1026 |
| 23-11. I2C Data Receive Register (ICDRR) Field Descriptions .....                                                 | 1027 |
| 23-12. I2C Slave Address Register (ICSAR) Field Descriptions .....                                                | 1028 |
| 23-13. I2C Data Transmit Register (ICDXR) Field Descriptions .....                                                | 1029 |
| 23-14. I2C Mode Register (ICMDR) Field Descriptions .....                                                         | 1030 |
| 23-15. Master-Transmitter/Receiver Bus Activity Defined by RM, STT, and STP Bits .....                            | 1032 |
| 23-16. How the MST and FDF Bits Affect the Role of TRX Bit .....                                                  | 1032 |
| 23-17. I2C Interrupt Vector Register (ICIVR) Field Descriptions .....                                             | 1034 |
| 23-18. I2C Extended Mode Register (ICEMDR) Field Descriptions .....                                               | 1035 |
| 23-19. I2C Prescaler Register (ICPSC) Field Descriptions .....                                                    | 1036 |
| 23-20. I2C Revision Identification Register 1 (REVID1) Field Descriptions .....                                   | 1037 |
| 23-21. I2C Revision Identification Register 2 (REVID2) Field Descriptions .....                                   | 1037 |
| 23-22. I2C DMA Control Register (ICDMAC) Field Descriptions .....                                                 | 1038 |
| 23-23. I2C Pin Function Register (ICPFUNC) Field Descriptions .....                                               | 1039 |
| 23-24. I2C Pin Direction Register (ICPDIR) Field Descriptions .....                                               | 1040 |
| 23-25. I2C Pin Data In Register (ICPDIN) Field Descriptions .....                                                 | 1041 |
| 23-26. I2C Pin Data Out Register (ICPDOUT) Field Descriptions .....                                               | 1042 |
| 23-27. I2C Pin Data Set Register (ICPDSET) Field Descriptions .....                                               | 1043 |
| 23-28. I2C Pin Data Clear Register (ICPDCLR) Field Descriptions .....                                             | 1044 |
| 24-1. LCD External I/O Signals .....                                                                              | 1049 |
| 24-2. Register Configuration for DMA Engine Programming .....                                                     | 1050 |
| 24-3. LIDD I/O Name Map .....                                                                                     | 1052 |
| 24-4. Operation Modes Supported by Raster Controller .....                                                        | 1053 |
| 24-5. Bits-Per-Pixel Encoding for Palette Entry 0 Buffer .....                                                    | 1055 |
| 24-6. Frame Buffer Size According to BPP .....                                                                    | 1056 |
| 24-7. Color/Grayscale Intensities and Modulation Rates .....                                                      | 1060 |
| 24-8. Number of Colors/Shades of Gray Available on Screen .....                                                   | 1060 |
| 24-9. LCD Controller (LCDC) Registers .....                                                                       | 1063 |
| 24-10. LCD Revision Identification Register (REVID) Field Descriptions .....                                      | 1063 |
| 24-11. LCD Control Register (LCD_CTRL) Field Descriptions .....                                                   | 1064 |
| 24-12. Pixel Clock Frequency Programming Limitations .....                                                        | 1065 |
| 24-13. LCD Status Register (LCD_STAT) Field Descriptions .....                                                    | 1066 |
| 24-14. LCD LIDD Control Register (LIDD_CTRL) Field Descriptions .....                                             | 1069 |
| 24-15. LCD LIDD CS <sub>n</sub> Configuration Register (LIDD_CS <sub>n</sub> _CONF) Field Descriptions .....      | 1071 |
| 24-16. LCD LIDD CS <sub>n</sub> Address Read/Write Register (LIDD_CS <sub>n</sub> _ADDR) Field Descriptions ..... | 1072 |
| 24-17. LCD LIDD CS <sub>n</sub> Data Read/Write Register (LIDD_CS <sub>n</sub> _DATA) Field Descriptions .....    | 1073 |
| 24-18. LCD Raster Control Register (RASTER_CTRL) Field Descriptions .....                                         | 1074 |
| 24-19. LCD Controller Data Pin Utilization for Mono/Color Passive/Active Panels .....                             | 1076 |

|                                                                                                                      |      |
|----------------------------------------------------------------------------------------------------------------------|------|
| 24-20. LCD Raster Timing Register 0 (RASTER_TIMING_0) Field Descriptions .....                                       | 1081 |
| 24-21. LCD Raster Timing Register 1 (RASTER_TIMING_1) Field Descriptions .....                                       | 1083 |
| 24-22. LCD Raster Timing Register 2 (RASTER_TIMING_2) Field Descriptions .....                                       | 1087 |
| 24-23. LCD Raster Subpanel Display Register (RASTER_SUBPANEL) Field Descriptions .....                               | 1091 |
| 24-24. LCD DMA Control Register (LCDDMA_CTRL) Field Descriptions .....                                               | 1093 |
| 24-25. LCD DMA Frame Buffer <i>n</i> Base Address Register (LCDDMA_FB <i>n</i> _BASE) Field Descriptions .....       | 1094 |
| 24-26. LCD DMA Frame Buffer <i>n</i> Ceiling Address Register (LCDDMA_FB <i>n</i> _CEILING) Field Descriptions ..... | 1094 |
| 25-1. Biphase-Mark Encoder .....                                                                                     | 1103 |
| 25-2. Preamble Codes .....                                                                                           | 1104 |
| 25-3. Channel Status and User Data for Each DIT Block .....                                                          | 1130 |
| 25-4. Transmit Bitstream Data Alignment .....                                                                        | 1138 |
| 25-5. Receive Bitstream Data Alignment .....                                                                         | 1140 |
| 25-6. EDMA Events - McASP .....                                                                                      | 1150 |
| 25-7. McASP Registers Accessed by CPU/EDMA Through Peripheral Configuration Port .....                               | 1151 |
| 25-8. McASP Registers Accessed by CPU/EDMA Through DMA Port .....                                                    | 1154 |
| 25-9. McASP AFIFO Registers Accessed Through Peripheral Configuration Port .....                                     | 1154 |
| 25-10. Revision Identification Register (REV) Field Descriptions .....                                               | 1155 |
| 25-11. Pin Function Register (PFUNC) Field Descriptions .....                                                        | 1157 |
| 25-12. Pin Direction Register (PDIR) Field Descriptions .....                                                        | 1159 |
| 25-13. Pin Data Output Register (PDOUT) Field Descriptions .....                                                     | 1161 |
| 25-14. Pin Data Input Register (PDIN) Field Descriptions .....                                                       | 1163 |
| 25-15. Pin Data Set Register (PDSET) Field Descriptions .....                                                        | 1165 |
| 25-16. Pin Data Clear Register (PDCLR) Field Descriptions .....                                                      | 1167 |
| 25-17. Global Control Register (GBLCTL) Field Descriptions .....                                                     | 1168 |
| 25-18. Audio Mute Control Register (AMUTE) Field Descriptions .....                                                  | 1170 |
| 25-19. Digital Loopback Control Register (DLBCTL) Field Descriptions .....                                           | 1172 |
| 25-20. Digital Mode Control Register (DITCTL) Field Descriptions .....                                               | 1173 |
| 25-21. Receiver Global Control Register (RGBLCTL) Field Descriptions .....                                           | 1174 |
| 25-22. Receive Format Unit Bit Mask Register (RMASK) Field Descriptions .....                                        | 1175 |
| 25-23. Receive Bit Stream Format Register (RFMT) Field Descriptions .....                                            | 1176 |
| 25-24. Receive Frame Sync Control Register (AFSRCTL) Field Descriptions .....                                        | 1178 |
| 25-25. Receive Clock Control Register (ACLKRCTL) Field Descriptions .....                                            | 1179 |
| 25-26. Receive High-Frequency Clock Control Register (AHCLKRCTL) Field Descriptions .....                            | 1180 |
| 25-27. Receive TDM Time Slot Register (RTDM) Field Descriptions .....                                                | 1181 |
| 25-28. Receiver Interrupt Control Register (RINTCTL) Field Descriptions .....                                        | 1182 |
| 25-29. Receiver Status Register (RSTAT) Field Descriptions .....                                                     | 1183 |
| 25-30. Current Receive TDM Time Slot Registers (RSLOT) Field Descriptions .....                                      | 1184 |
| 25-31. Receive Clock Check Control Register (RCLKCHK) Field Descriptions .....                                       | 1185 |
| 25-32. Receiver DMA Event Control Register (REVTCTL) Field Descriptions .....                                        | 1186 |
| 25-33. Transmitter Global Control Register (XGBLCTL) Field Descriptions .....                                        | 1187 |
| 25-34. Transmit Format Unit Bit Mask Register (XMASK) Field Descriptions .....                                       | 1188 |
| 25-35. Transmit Bit Stream Format Register (XFMT) Field Descriptions .....                                           | 1189 |
| 25-36. Transmit Frame Sync Control Register (AFSXCTL) Field Descriptions .....                                       | 1191 |
| 25-37. Transmit Clock Control Register (ACLKXCTL) Field Descriptions .....                                           | 1192 |
| 25-38. Transmit High-Frequency Clock Control Register (AHCLKXCTL) Field Descriptions .....                           | 1193 |
| 25-39. Transmit TDM Time Slot Register (XTDM) Field Descriptions .....                                               | 1194 |
| 25-40. Transmitter Interrupt Control Register (XINTCTL) Field Descriptions .....                                     | 1195 |
| 25-41. Transmitter Status Register (XSTAT) Field Descriptions .....                                                  | 1196 |
| 25-42. Current Transmit TDM Time Slot Register (XSLOT) Field Descriptions .....                                      | 1197 |

|                                                                                                  |      |
|--------------------------------------------------------------------------------------------------|------|
| 25-43. Transmit Clock Check Control Register (XCLKCHK) Field Descriptions .....                  | 1198 |
| 25-44. Transmitter DMA Event Control Register (XEVTCTL) Field Descriptions .....                 | 1199 |
| 25-45. Serializer Control Registers (SRCTL <sub>n</sub> ) Field Descriptions .....               | 1200 |
| 25-46. AFIFO Revision Identification Register (AFIFOREV) Field Descriptions .....                | 1204 |
| 25-47. Write FIFO Control Register (WFIFOCTL) Field Descriptions .....                           | 1205 |
| 25-48. Write FIFO Status Register (WFIFOSTS) Field Descriptions .....                            | 1206 |
| 25-49. Read FIFO Control Register (RFIFOCTL) Field Descriptions .....                            | 1207 |
| 25-50. Read FIFO Status Register (RFIFOSTS) Field Descriptions .....                             | 1208 |
| 26-1. McBSP Interface Signals .....                                                              | 1212 |
| 26-2. Choosing an Input Clock for the Sample Rate Generator With the SCLKME and CLKSM Bits ..... | 1216 |
| 26-3. Receive Clock Selection .....                                                              | 1219 |
| 26-4. Transmit Clock Selection .....                                                             | 1220 |
| 26-5. Receive Frame Synchronization Selection .....                                              | 1221 |
| 26-6. Transmit Frame Synchronization Selection .....                                             | 1222 |
| 26-7. RCR/XCR Fields Controlling Elements per Frame and Bits per Element .....                   | 1223 |
| 26-8. Receive/Transmit Frame Length Configuration .....                                          | 1223 |
| 26-9. Receive/Transmit Element Length Configuration .....                                        | 1224 |
| 26-10. Effect of RJUST Bit Values With 12-Bit Example Data ABCh .....                            | 1226 |
| 26-11. Effect of RJUST Bit Values With 20-Bit Example Data ABCDEh .....                          | 1226 |
| 26-12. Justification of Expanded Data in DRR .....                                               | 1242 |
| 26-13. Receive Channel Assignment and Control When Two Receive Partitions are Used .....         | 1245 |
| 26-14. Transmit Channel Assignment and Control When Two Transmit Partitions are Used .....       | 1245 |
| 26-15. Receive Channel Assignment and Control When Eight Receive Partitions are Used .....       | 1247 |
| 26-16. Transmit Channel Assignment and Control When Eight Transmit Partitions are Used .....     | 1247 |
| 26-17. Selecting a Transmit Multichannel Selection Mode With the XMCM Bits .....                 | 1248 |
| 26-18. Reset State of McBSP Pins .....                                                           | 1251 |
| 26-19. Receiver Clock and Frame Configurations .....                                             | 1252 |
| 26-20. Transmitter Clock and Frame Configurations .....                                          | 1252 |
| 26-21. McBSP Emulation Modes Selectable With the FREE and SOFT Bits of SPCR .....                | 1258 |
| 26-22. McBSP Registers .....                                                                     | 1259 |
| 26-23. Data Receive Register (DRR) Field Descriptions .....                                      | 1260 |
| 26-24. Data Transmit Register (DXR) Field Descriptions .....                                     | 1260 |
| 26-25. Serial Port Control Register (SPCR) Field Descriptions .....                              | 1261 |
| 26-26. Receive Control Register (RCR) Field Descriptions .....                                   | 1263 |
| 26-27. Transmit Control Register (XCR) Field Descriptions .....                                  | 1265 |
| 26-28. Sample Rate Generator Register (SRGR) Field Descriptions .....                            | 1267 |
| 26-29. Multichannel Control Register (MCR) Field Descriptions .....                              | 1268 |
| 26-30. Enhanced Receive Channel Enable Register <i>n</i> (RCEREn) Field Descriptions .....       | 1272 |
| 26-31. Use of the Receive Channel Enable Registers .....                                         | 1273 |
| 26-32. Enhanced Transmit Channel Enable Register <i>n</i> (XCEREn) Field Descriptions .....      | 1274 |
| 26-33. Use of the Transmit Channel Enable Registers .....                                        | 1275 |
| 26-34. Pin Control Register (PCR) Field Descriptions .....                                       | 1276 |
| 26-35. BFIFO Revision Identification Register (BFIFOREV) Field Descriptions .....                | 1278 |
| 26-36. Write FIFO Control Register (WFIFOCTL) Field Descriptions .....                           | 1279 |
| 26-37. Write FIFO Status Register (WFIFOSTS) Field Descriptions .....                            | 1280 |
| 26-38. Read FIFO Control Register (RFIFOCTL) Field Descriptions .....                            | 1281 |
| 26-39. Read FIFO Status Register (RFIFOSTS) Field Descriptions .....                             | 1282 |
| 27-1. MMC/SD Controller Pins Used in Each Mode .....                                             | 1287 |
| 27-2. MMC/SD Mode Write Sequence .....                                                           | 1288 |

|                                                                                 |      |
|---------------------------------------------------------------------------------|------|
| 27-3. MMC/SD Mode Read Sequence .....                                           | 1289 |
| 27-4. Description of MMC/SD Interrupt Requests .....                            | 1299 |
| 27-5. Multimedia Card/Secure Digital (MMC/SD) Card Controller Registers.....    | 1313 |
| 27-6. MMC Control Register (MMCCTL) Field Descriptions.....                     | 1314 |
| 27-7. MMC Memory Clock Control Register (MMCCLK) Field Descriptions .....       | 1315 |
| 27-8. MMC Status Register 0 (MMCST0) Field Descriptions .....                   | 1316 |
| 27-9. MMC Status Register 1 (MMCST1) Field Descriptions .....                   | 1318 |
| 27-10. MMC Interrupt Mask Register (MMCIM) Field Descriptions .....             | 1319 |
| 27-11. MMC Response Time-Out Register (MMCTOR) Field Descriptions .....         | 1321 |
| 27-12. MMC Data Read Time-Out Register (MMCTOD) Field Descriptions.....         | 1322 |
| 27-13. MMC Block Length Register (MMCBLEN) Field Descriptions.....              | 1323 |
| 27-14. MMC Number of Blocks Register (MMCNBLK) Field Descriptions.....          | 1324 |
| 27-15. MMC Number of Blocks Counter Register (MMCNBLC) Field Descriptions ..... | 1324 |
| 27-16. MMC Data Receive Register (MMCDRR) Field Descriptions .....              | 1325 |
| 27-17. MMC Data Transmit Register (MMCDXR) Field Descriptions.....              | 1325 |
| 27-18. MMC Command Register (MMCCMD) Field Descriptions.....                    | 1326 |
| 27-19. Command Format .....                                                     | 1327 |
| 27-20. MMC Argument Register (MMCARGHL) Field Descriptions .....                | 1328 |
| 27-21. R1, R3, R4, R5, or R6 Response (48 Bits) .....                           | 1330 |
| 27-22. R2 Response (136 Bits) .....                                             | 1330 |
| 27-23. MMC Data Response Register (MMCDRSP) Field Descriptions .....            | 1331 |
| 27-24. MMC Command Index Register (MMCCIDX) Field Descriptions .....            | 1331 |
| 27-25. SDIO Control Register (SDIOCTL) Field Descriptions .....                 | 1332 |
| 27-26. SDIO Status Register 0 (SDIOST0) Field Descriptions .....                | 1333 |
| 27-27. SDIO Interrupt Enable Register (SDIOIEN) Field Descriptions .....        | 1334 |
| 27-28. SDIO Interrupt Status Register (SDIOIST) Field Descriptions .....        | 1334 |
| 27-29. MMC FIFO Control Register (MMCFIFOCTL) Field Descriptions .....          | 1335 |
| 28-1. Real-Time Clock Signals .....                                             | 1338 |
| 28-2. Real-Time Clock (RTC) Registers .....                                     | 1344 |
| 28-3. Second Register (SECOND) Field Descriptions .....                         | 1345 |
| 28-4. Minute Register (MINUTE) Field Descriptions.....                          | 1345 |
| 28-5. Hour Register (HOUR) Field Descriptions .....                             | 1346 |
| 28-6. Day Register (DAY) Field Descriptions.....                                | 1347 |
| 28-7. Month Register (MONTH) Field Descriptions.....                            | 1347 |
| 28-8. Year Register (YEAR) Field Descriptions .....                             | 1348 |
| 28-9. Day of the Week Register (DOTW) Field Descriptions.....                   | 1348 |
| 28-10. Alarm Second Register (ALARMSECOND) Field Descriptions .....             | 1349 |
| 28-11. Alarm Minute Register (ALARMMINUTE) Field Descriptions .....             | 1349 |
| 28-12. Alarm Hour Register (ALARMHOUR) Field Descriptions .....                 | 1350 |
| 28-13. Alarm Day Register (ALARMDAY) Field Descriptions.....                    | 1351 |
| 28-14. Alarm Month Register (ALARMMONTH) Field Descriptions .....               | 1352 |
| 28-15. Alarm Years Register (ALARMYEARS) Field Descriptions.....                | 1352 |
| 28-16. Control Register (CTRL) Field Descriptions .....                         | 1353 |
| 28-17. Status Register (STATUS) Field Descriptions.....                         | 1354 |
| 28-18. Interrupt Register (INTERRUPT) Field Descriptions.....                   | 1355 |
| 28-19. Compensations Register (COMPLSB) Field Descriptions .....                | 1356 |
| 28-20. Compensations Register (COMPMSB) Field Descriptions .....                | 1357 |
| 28-21. Oscillator Register (OSC) Field Descriptions.....                        | 1358 |
| 28-22. Scratch Registers (SCRATCH <sub>n</sub> ) Field Descriptions .....       | 1359 |

|                                                                                          |      |
|------------------------------------------------------------------------------------------|------|
| 28-23. Kick Registers (KICK <sub>n</sub> R) Field Descriptions .....                     | 1359 |
| 29-1. MPY Bit Field of P0PHYCR.....                                                      | 1365 |
| 29-2. Signal Descriptions.....                                                           | 1366 |
| 29-3. SATASS Memory Summary .....                                                        | 1390 |
| 29-4. SATA Controller Registers .....                                                    | 1391 |
| 29-5. HBA Capabilities Register (CAP) Field Descriptions .....                           | 1392 |
| 29-6. Global HBA Control Register (GHC) Field Descriptions .....                         | 1393 |
| 29-7. Interrupt Status Register (IS) Field Descriptions .....                            | 1394 |
| 29-8. Ports Implemented Register (PI) Field Descriptions.....                            | 1395 |
| 29-9. AHCI Version Register (VS) Field Descriptions .....                                | 1395 |
| 29-10. Command Completion Coalescing Control Register (CCC_CTL) Field Descriptions ..... | 1396 |
| 29-11. Command Completion Coalescing Ports Register (CCC_PORTS) Field Description.....   | 1397 |
| 29-12. BIST Active FIS Register (BISTAFR) Field Descriptions .....                       | 1398 |
| 29-13. BIST Control Register (BISTCR) Field Descriptions.....                            | 1399 |
| 29-14. BIST FIS Count Register (BISTFCTR) Field Description .....                        | 1401 |
| 29-15. BIST Status Register (BISTSR) Field Description .....                             | 1401 |
| 29-16. BIST DWORD Error Count Register (BISTDECR) Field Description.....                 | 1402 |
| 29-17. BIST DWORD Error Count Register (TIMER1MS) Field Description .....                | 1402 |
| 29-18. Global Parameter 1 Register (GPARAM1R) Field Descriptions .....                   | 1403 |
| 29-19. Global Parameter 2 Register (GPARAM2R) Field Descriptions .....                   | 1404 |
| 29-20. Port Parameter Register (PPARAMR) Field Descriptions .....                        | 1405 |
| 29-21. Test Register (TESTR) Field Descriptions .....                                    | 1406 |
| 29-22. Version Register (VERSIONR) Field Description .....                               | 1407 |
| 29-23. ID Register (IDR) Field Description .....                                         | 1407 |
| 29-24. Port Command List Base Address Register (P0CLB) Field Description .....           | 1408 |
| 29-25. Port FIS Base Address Register (P0FB) Field Description .....                     | 1408 |
| 29-26. Port Interrupt Status Register (P0IS) Field Descriptions .....                    | 1409 |
| 29-27. Port Interrupt Enable Register (P0IE) Field Descriptions .....                    | 1411 |
| 29-28. Port Command Register (P0CMD) Field Descriptions .....                            | 1412 |
| 29-29. Port Task File Data Register (P0TFD) Field Descriptions .....                     | 1415 |
| 29-30. Port Signature Register (P0SIG) Field Description .....                           | 1415 |
| 29-31. Port Serial ATA Status Register (P0SSTS) Field Descriptions .....                 | 1416 |
| 29-32. Port Serial ATA Control Register (P0SCTL) Field Descriptions.....                 | 1417 |
| 29-33. Port Serial ATA Error Register (P0SERR) Field Descriptions.....                   | 1418 |
| 29-34. Port Serial ATA Active Register (P0SACT) Field Description .....                  | 1420 |
| 29-35. Port Serial ATA Active (SActive) Register (P0SACT) Field Description .....        | 1420 |
| 29-36. Port Serial ATA Notification Register (POSNTF) Field Description.....             | 1421 |
| 29-37. Port DMA Control Register (P0DMACR) Field Description .....                       | 1422 |
| 29-38. Port PHY Control Register (P0PHYCR) Field Descriptions .....                      | 1424 |
| 29-39. Port PHY Status Register (P0PHYSR) Field Description .....                        | 1428 |
| 30-1. SPI Pins .....                                                                     | 1432 |
| 30-2. SPI Registers .....                                                                | 1433 |
| 30-3. SPI Register Settings Defining Master Modes .....                                  | 1434 |
| 30-4. Allowed SPI Register Settings in Master Modes .....                                | 1434 |
| 30-5. SPI Register Settings Defining Slave Modes.....                                    | 1436 |
| 30-6. Allowed SPI Register Settings in Slave Modes .....                                 | 1436 |
| 30-7. Clocking Modes.....                                                                | 1445 |
| 30-8. SPI Registers .....                                                                | 1458 |
| 30-9. SPI Global Control Register 0 (SPIGCR0) Field Descriptions .....                   | 1458 |

|                                                                                         |      |
|-----------------------------------------------------------------------------------------|------|
| 30-10. SPI Global Control Register 1 (SPIGCR1) Field Descriptions .....                 | 1459 |
| 30-11. SPI Interrupt Register (SPIINT0) Field Descriptions.....                         | 1461 |
| 30-12. SPI Interrupt Level Register (SPILVL) Field Descriptions .....                   | 1463 |
| 30-13. SPI Flag Register (SPIFLG) Field Descriptions .....                              | 1464 |
| 30-14. SPI Pin Control Register 0 (SPIPC0) Field Descriptions.....                      | 1466 |
| 30-15. SPI Pin Control Register 1 (SPIPC1) Field Descriptions.....                      | 1467 |
| 30-16. SPI Pin Control Register 2 (SPIPC2) Field Descriptions.....                      | 1468 |
| 30-17. SPI Pin Control Register 3 (SPIPC3) Field Descriptions.....                      | 1469 |
| 30-18. SPI Pin Control Register 4 (SPIPC4) Field Descriptions.....                      | 1470 |
| 30-19. SPI Pin Control Register 5 (SPIPC5) Field Descriptions.....                      | 1471 |
| 30-20. SPI Data Register 0 (SPIDAT0) Field Descriptions.....                            | 1472 |
| 30-21. SPI Data Register 1 (SPIDAT1) Field Descriptions.....                            | 1473 |
| 30-22. SPI Buffer Register (SPIBUF) Field Descriptions .....                            | 1474 |
| 30-23. SPI Emulation Register (SPIEMU) Field Descriptions.....                          | 1476 |
| 30-24. SPI Delay Register (SPIDELAY) Field Descriptions .....                           | 1477 |
| 30-25. SPI Default Chip Select Register (SPIDEF) Field Descriptions .....               | 1480 |
| 30-26. SPI Data Format Register (SPIFMTn) Field Descriptions .....                      | 1481 |
| 30-27. SPI Interrupt Vector Register 1 (INTVEC1) Field Descriptions .....               | 1483 |
| 31-1. Timer Clock Source Selection .....                                                | 1487 |
| 31-2. 64-Bit Timer Configurations .....                                                 | 1489 |
| 31-3. 32-Bit Timer Chained Mode Configurations .....                                    | 1492 |
| 31-4. 32-Bit Timer Unchained Mode Configurations.....                                   | 1495 |
| 31-5. Counter and Period Registers Used in GP Timer Modes.....                          | 1497 |
| 31-6. TSTAT Parameters in Pulse and Clock Modes .....                                   | 1501 |
| 31-7. Timer Emulation Modes Selection .....                                             | 1503 |
| 31-8. Timer Registers.....                                                              | 1503 |
| 31-9. Revision ID Register (REVID) Field Descriptions .....                             | 1505 |
| 31-10. Emulation Management Register (EMUMGT) Field Descriptions .....                  | 1505 |
| 31-11. GPIO Interrupt Control and Enable Register (GPINTGPEN) Field Descriptions .....  | 1506 |
| 31-12. GPIO Data and Direction Register (GPDATGPDIR) Field Descriptions .....           | 1507 |
| 31-13. Timer Counter Register 12 (TIM12) Field Descriptions .....                       | 1508 |
| 31-14. Timer Counter Register 34 (TIM34) Field Descriptions .....                       | 1508 |
| 31-15. Timer Period Register (PRD12) Field Descriptions.....                            | 1509 |
| 31-16. Timer Period Register (PRD34) Field Descriptions.....                            | 1509 |
| 31-17. Timer Control Register (TCR) Field Descriptions .....                            | 1510 |
| 31-18. Timer Global Control Register (TGCR) Field Descriptions .....                    | 1512 |
| 31-19. Watchdog Timer Control Register (WDTCR) Field Descriptions.....                  | 1513 |
| 31-20. Timer Reload Register 12 (REL12) Field Descriptions.....                         | 1514 |
| 31-21. Timer Reload Register 34 (REL34) Field Descriptions.....                         | 1514 |
| 31-22. Timer Capture Register 12 (CAP12) Field Descriptions .....                       | 1515 |
| 31-23. Timer Capture Register 34 (CAP34) Field Descriptions .....                       | 1515 |
| 31-24. Timer Interrupt Control and Status Register (INTCTLSTAT) Field Descriptions..... | 1516 |
| 31-25. Timer Compare Register (CMPn) Field Descriptions.....                            | 1517 |
| 32-1. Baud Rate Examples for 150-MHZ UART Input Clock and 16× Over-sampling Mode .....  | 1522 |
| 32-2. Baud Rate Examples for 150-MHZ UART Input Clock and 13× Over-sampling Mode .....  | 1522 |
| 32-3. UART Signal Descriptions .....                                                    | 1523 |
| 32-4. Character Time for Word Lengths .....                                             | 1526 |
| 32-5. UART Interrupt Requests Descriptions.....                                         | 1530 |
| 32-6. UART Registers .....                                                              | 1532 |

|                                                                                           |      |
|-------------------------------------------------------------------------------------------|------|
| 32-7. Receiver Buffer Register (RBR) Field Descriptions .....                             | 1533 |
| 32-8. Transmitter Holding Register (THR) Field Descriptions .....                         | 1534 |
| 32-9. Interrupt Enable Register (IER) Field Descriptions .....                            | 1535 |
| 32-10. Interrupt Identification Register (IIR) Field Descriptions.....                    | 1536 |
| 32-11. Interrupt Identification and Interrupt Clearing Information .....                  | 1537 |
| 32-12. FIFO Control Register (FCR) Field Descriptions .....                               | 1538 |
| 32-13. Line Control Register (LCR) Field Descriptions .....                               | 1539 |
| 32-14. Relationship Between ST, EPS, and PEN Bits in LCR.....                             | 1540 |
| 32-15. Number of STOP Bits Generated .....                                                | 1540 |
| 32-16. Modem Control Register (MCR) Field Descriptions .....                              | 1541 |
| 32-17. Line Status Register (LSR) Field Descriptions .....                                | 1542 |
| 32-18. Modem Status Register (MSR) Field Descriptions.....                                | 1545 |
| 32-19. Scratch Pad Register (MSR) Field Descriptions .....                                | 1546 |
| 32-20. Divisor LSB Latch (DLL) Field Descriptions .....                                   | 1547 |
| 32-21. Divisor MSB Latch (DLH) Field Descriptions .....                                   | 1547 |
| 32-22. Revision Identification Register 1 (REVID1) Field Descriptions.....                | 1548 |
| 32-23. Revision Identification Register 2 (REVID2) Field Descriptions.....                | 1548 |
| 32-24. Power and Emulation Management Register (PWREMU_MGMT) Field Descriptions.....      | 1549 |
| 32-25. Mode Definition Register (MDR) Field Descriptions .....                            | 1550 |
| 33-1. I/O Clock Speeds for Channel in Transmit Mode Given 150 MHz Transmit Clock.....     | 1556 |
| 33-2. uPP Signal Descriptions.....                                                        | 1556 |
| 33-3. DATA and XDATA Pin Assignments to Channels A and B According to Operating Mode..... | 1557 |
| 33-4. Interface and DMA Channel Mapping for Various Operating Modes.....                  | 1559 |
| 33-5. Required Signals for Various Modes .....                                            | 1560 |
| 33-6. Data Packing Examples for 12-Bit Data Words .....                                   | 1564 |
| 33-7. Basic Operating Mode Selection .....                                                | 1566 |
| 33-8. Sample uPP Parameters for Duplex Mode 0 .....                                       | 1567 |
| 33-9. uPP Parameters Useful for System Tuning .....                                       | 1568 |
| 33-10. uPP Registers .....                                                                | 1572 |
| 33-11. uPP Peripheral Identification Register (UPPID) Field Descriptions.....             | 1572 |
| 33-12. uPP Peripheral Control Register (UPPCR) Field Descriptions .....                   | 1573 |
| 33-13. uPP Digital Loopback Register (UPDLB) Field Descriptions .....                     | 1574 |
| 33-14. uPP Channel Control Register (UPCTL) Field Descriptions.....                       | 1575 |
| 33-15. uPP Interface Configuration Register (UPICR) Field Descriptions .....              | 1577 |
| 33-16. uPP Interface Idle Value Register (UPIVR) Field Descriptions .....                 | 1579 |
| 33-17. uPP Threshold Configuration Register (UPTCR) Field Descriptions .....              | 1580 |
| 33-18. uPP Interrupt Raw Status Register (UPISR) Field Descriptions .....                 | 1581 |
| 33-19. uPP Interrupt Enabled Status Register (UPIER) Field Descriptions.....              | 1583 |
| 33-20. uPP Interrupt Enable Set Register (UPIES) Field Descriptions .....                 | 1585 |
| 33-21. uPP Interrupt Enable Clear Register (UPIEC) Field Descriptions .....               | 1587 |
| 33-22. uPP End of Interrupt Register (UPEOI) Field Descriptions .....                     | 1589 |
| 33-23. uPP DMA Channel I Descriptor 0 Register (UPID0) Field Descriptions .....           | 1589 |
| 33-24. uPP DMA Channel I Descriptor 1 Register (UPID1) Field Descriptions .....           | 1590 |
| 33-25. uPP DMA Channel I Descriptor 2 Register (UPID2) Field Descriptions .....           | 1590 |
| 33-26. uPP DMA Channel I Status 0 Register (UPIS0) Field Descriptions .....               | 1591 |
| 33-27. uPP DMA Channel I Status 1 Register (UPIS1) Field Descriptions .....               | 1591 |
| 33-28. uPP DMA Channel I Status 2 Register (UPIS2) Field Descriptions .....               | 1592 |
| 33-29. uPP DMA Channel Q Descriptor 0 Register (UPQD0) Field Descriptions.....            | 1593 |
| 33-30. uPP DMA Channel Q Descriptor 1 Register (UPQD1) Field Descriptions.....            | 1593 |

|                                                                                         |      |

| 33-32. uPP DMA Channel Q Status 0 Register (UPQS0) Field Descriptions .....             | 1595 |
| 33-33. uPP DMA Channel Q Status 1 Register (UPQS1) Field Descriptions .....             | 1595 |
| 33-34. uPP DMA Channel Q Status 2 Register (UPQS2) Field Descriptions .....             | 1596 |
| 34-1. USB1.1 Host Controller Registers .....                                            | 1603 |
| 34-2. OHCI Revision Number Register (HCREVISION) Field Descriptions .....               | 1604 |
| 34-3. HC Operating Mode Register (HCCONTROL) Field Descriptions .....                   | 1605 |
| 34-4. HC Command and Status Register (HCCOMMANDSTATUS) Field Descriptions .....         | 1606 |
| 34-5. HC Interrupt and Status Register (HCINTERRUPTSTATUS) Field Descriptions.....      | 1607 |
| 34-6. HC Interrupt Enable Register (HCINTERRUPTENABLE) Field Descriptions .....         | 1608 |
| 34-7. HC Interrupt Disable Register (HCINTERRUPTDISABLE) Field Descriptions.....        | 1609 |
| 34-8. HC HCAA Address Register (HCHCCA) Field Descriptions.....                         | 1610 |
| 34-9. HC Current Periodic Register (HCPERIODCURRENTED) Field Descriptions.....          | 1610 |
| 34-10. HC Head Control Register (HCCONTROLHEADED) Field Descriptions .....              | 1611 |
| 34-11. HC Current Control Register (HCCONTROLCURRENTED) Field Descriptions .....        | 1611 |
| 34-12. HC Head Bulk Register (HCBULKHEADED) Field Descriptions.....                     | 1612 |
| 34-13. HC Current Bulk Register (HCBULKCURRENTED) Field Descriptions .....              | 1612 |
| 34-14. HC Head Done Register (HCDONEHEAD) Field Descriptions .....                      | 1613 |
| 34-15. HC Frame Interval Register (HCFMINTERVAL) Field Descriptions .....               | 1613 |
| 34-16. HC Frame Remaining Register (HCFMREMAINING) Field Descriptions.....              | 1614 |
| 34-17. HC Frame Number Register (HCFMNUMBER) Field Descriptions.....                    | 1614 |
| 34-18. HC Periodic Start Register (HCPERIODICSTART) Field Descriptions .....            | 1615 |
| 34-19. HC Low-Speed Threshold Register (HCLSTHRESHOLD) Field Descriptions .....         | 1615 |
| 34-20. HC Root Hub A Register (HCRHDESCRIPTORA) Field Descriptions .....                | 1616 |
| 34-21. HC Root Hub B Register (HCRHDESCRIPTORB) Field Descriptions .....                | 1617 |
| 34-22. HC Root Hub Status Register (HCRHSTATUS) Field Descriptions .....                | 1618 |
| 34-23. HC Port 1 Status and Control Register (HCRHPORTSTATUS1) Field Descriptions ..... | 1619 |
| 34-24. HC Port 2 Status and Control Register (HCRHPORTSTATUS2) Field Descriptions ..... | 1621 |
| 35-1. USB Clock Multiplexing Options.....                                               | 1626 |
| 35-2. PHY PLL Clock Frequencies Supported .....                                         | 1626 |
| 35-3. USB Terminal Functions .....                                                      | 1627 |
| 35-4. PERI_TXCSR Register Bit Configuration for Bulk IN Transactions .....              | 1642 |
| 35-5. PERI_RXCSR Register Bit Configuration for Bulk OUT Transactions .....             | 1643 |
| 35-6. PERI_TXCSR Register Bit Configuration for Isochronous IN Transactions .....       | 1645 |
| 35-7. PERI_RXCSR Register Bit Configuration for Isochronous OUT Transactions.....       | 1647 |
| 35-8. Host Packet Descriptor Word 0 (HPD Word 0).....                                   | 1668 |
| 35-9. Host Packet Descriptor Word 1 (HPD Word 1).....                                   | 1668 |
| 35-10. Host Packet Descriptor Word 2 (HPD Word 2).....                                  | 1669 |
| 35-11. Host Packet Descriptor Word 3 (HPD Word 3).....                                  | 1669 |
| 35-12. Host Packet Descriptor Word 4 (HPD Word 4).....                                  | 1669 |
| 35-13. Host Packet Descriptor Word 5 (HPD Word 5).....                                  | 1669 |
| 35-14. Host Packet Descriptor Word 6 (HPD Word 6).....                                  | 1670 |
| 35-15. Host Packet Descriptor Word 7 (HPD Word 7).....                                  | 1670 |
| 35-16. Host Buffer Descriptor Word 0 (HBD Word 0).....                                  | 1671 |
| 35-17. Host Buffer Descriptor Word 1 (HBD Word 1).....                                  | 1671 |
| 35-18. Host Buffer Descriptor Word 2 (HBD Word 2).....                                  | 1671 |
| 35-19. Host Buffer Descriptor Word 3 (HBD Word 3).....                                  | 1671 |
| 35-20. Host Buffer Descriptor Word 4 (HBD Word 4).....                                  | 1672 |
| 35-21. Host Buffer Descriptor Word 5 (HBD Word 5).....                                  | 1672 |

|                                                                                                               |      |
|---------------------------------------------------------------------------------------------------------------|------|
| 35-22. Host Buffer Descriptor Word 6 (HBD Word 6) .....                                                       | 1672 |
| 35-23. Host Buffer Descriptor Word 7 (HBD Word 7) .....                                                       | 1672 |
| 35-24. Teardown Descriptor Word 0 .....                                                                       | 1673 |
| 35-25. Teardown Descriptor Words 1-7 .....                                                                    | 1673 |
| 35-26. Allocation of Queues .....                                                                             | 1674 |
| 35-27. Interrupts Generated by the USB Controller .....                                                       | 1688 |
| 35-28. USB Interrupt Conditions .....                                                                         | 1688 |
| 35-29. USB Interrupts .....                                                                                   | 1691 |
| 35-30. Universal Serial Bus OTG (USB0) Registers .....                                                        | 1704 |
| 35-31. Revision Identification Register (REVID) Field Descriptions .....                                      | 1711 |
| 35-32. Control Register (CTRLR) Field Descriptions .....                                                      | 1711 |
| 35-33. Status Register (STATR) Field Descriptions .....                                                       | 1712 |
| 35-34. Emulation Register (EMUR) Field Descriptions .....                                                     | 1712 |
| 35-35. Mode Register (MODE) Field Descriptions .....                                                          | 1713 |
| 35-36. Auto Request Register (AUTOREQ) Field Descriptions .....                                               | 1715 |
| 35-37. SRP Fix Time Register (SRPFIXTIME) Field Descriptions .....                                            | 1716 |
| 35-38. Teardown Register (TEARDOWN) Field Descriptions .....                                                  | 1716 |
| 35-39. USB Interrupt Source Register (INTSRCR) Field Descriptions .....                                       | 1717 |
| 35-40. USB Interrupt Source Set Register (INTSETR) Field Descriptions .....                                   | 1718 |
| 35-41. USB Interrupt Source Clear Register (INTCLRR) Field Descriptions .....                                 | 1719 |
| 35-42. USB Interrupt Mask Register (INTMSKR) Field Descriptions .....                                         | 1720 |
| 35-43. USB Interrupt Mask Set Register (INTMSKSETR) Field Descriptions .....                                  | 1721 |
| 35-44. USB Interrupt Mask Clear Register (INTMSKCLRR) Field Descriptions .....                                | 1722 |
| 35-45. USB Interrupt Source Masked Register (INTMASKEDR) Field Descriptions .....                             | 1723 |
| 35-46. USB End of Interrupt Register (EOIR) Field Descriptions .....                                          | 1724 |
| 35-47. Generic RNDIS EP1 Size Register (GENRNDISSZ1) Field Descriptions .....                                 | 1724 |
| 35-48. Generic RNDIS EP2 Size Register (GENRNDISSZ2) Field Descriptions .....                                 | 1725 |
| 35-49. Generic RNDIS EP3 Size Register (GENRNDISSZ3) Field Descriptions .....                                 | 1725 |
| 35-50. Generic RNDIS EP4 Size Register (GENRNDISSZ4) Field Descriptions .....                                 | 1726 |
| 35-51. Function Address Register (FADDR) Field Descriptions .....                                             | 1726 |
| 35-52. Power Management Register (POWER) Field Descriptions .....                                             | 1727 |
| 35-53. Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 4 (INTRTX)Field Descriptions .....      | 1728 |
| 35-54. Interrupt Register for Receive Endpoints 1 to 4 (INTRRX) Field Descriptions .....                      | 1729 |
| 35-55. Interrupt Enable Register for INTRTX (INTRTXE) Field Descriptions .....                                | 1730 |
| 35-56. Interrupt Enable Register for INTRRX (INTRRXE) Field Descriptions .....                                | 1730 |
| 35-57. Interrupt Register for Common USB Interrupts (INTRUSB) Field Descriptions .....                        | 1731 |
| 35-58. Interrupt Enable Register for INTRUSB (INTRUSBE) Field Descriptions .....                              | 1732 |
| 35-59. Frame Number Register (FRAME) Field Descriptions .....                                                 | 1732 |
| 35-60. Index Register for Selecting the Endpoint Status and Control Registers (INDEX)Field Descriptions ..... | 1733 |
| 35-61. Register to Enable the USB 2.0 Test Modes (TESTMODE) Field Descriptions .....                          | 1733 |
| 35-62. Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP) Field Descriptions .....            | 1734 |
| 35-63. Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0) Field Descriptions .....         | 1735 |
| 35-64. Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0) Field Descriptions .....               | 1736 |
| 35-65. Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR) Field Descriptions .....         | 1737 |
| 35-66. Control Status Register for Host Transmit Endpoint (HOST_TXCSR) Field Descriptions .....               | 1738 |
| 35-67. Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP) Field Descriptions .....             | 1739 |
| 35-68. Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR) Field Descriptions .....          | 1740 |
| 35-69. Control Status Register for Host Receive Endpoint (HOST_RXCSR) Field Descriptions .....                | 1741 |
| 35-70. Count 0 Register (COUNT0) Field Descriptions .....                                                     | 1742 |

|                                                                                                                       |      |
|-----------------------------------------------------------------------------------------------------------------------|------|
| 35-71. Receive Count Register (RXCOUNT) Field Descriptions .....                                                      | 1742 |
| 35-72. Type Register (Host mode only) (HOST_TYPE0) Field Descriptions .....                                           | 1743 |
| 35-73. Transmit Type Register (Host mode only) (HOST_TXTYPE) Field Descriptions .....                                 | 1743 |
| 35-74. NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0) Field Descriptions .....                                  | 1744 |
| 35-75. Transmit Interval Register (Host mode only) (HOST_TXINTERVAL) Field Descriptions .....                         | 1744 |

### About This Manual

This Technical Reference Manual (TRM) describes the System-on-Chip (SoC) and each peripheral in the device. The SoC consists of the following primary components

- ARM subsystem and associated memories
- DSP subsystem and associated memories
- A set of I/O peripherals

### Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers are shown with the suffix h. For example, the following number is 40 hexadecimal (decimal 64): 40h.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure designate a bit that is used for future device expansion.

### Related Documentation From Texas Instruments

Copies of these documents are available on the Internet at [www.ti.com](http://www.ti.com). *Tip:* Enter the literature number in the search box provided at [www.ti.com](http://www.ti.com).

The current documentation that describes related peripherals and other technical collateral, is available in the C6000 DSP product folder at: [www.ti.com/c6000](http://www.ti.com/c6000).

**SPRUFK5— TMS320C674x DSP Megamodule Reference Guide.** Describes the TMS320C674x digital signal processor (DSP) megamodule. Included is a discussion on the internal direct memory access (IDMA) controller, the interrupt controller, the power-down controller, memory protection, bandwidth management, and the memory and cache.

**SPRUF8— TMS320C674x DSP CPU and Instruction Set Reference Guide.** Describes the CPU architecture, pipeline, instruction set, and interrupts for the TMS320C674x digital signal processors (DSPs). The C674x DSP is an enhancement of the C64x+ and C67x+ DSPs with added functionality and an expanded instruction set.

**SPRUG82— TMS320C674x DSP Cache User's Guide.** Explains the fundamentals of memory caches and describes how the two-level cache-based internal memory architecture in the TMS320C674x digital signal processor (DSP) can be efficiently used in DSP applications. Shows how to maintain coherence with external memory, how to use DMA to reduce memory latencies, and how to optimize your code to improve cache efficiency. The internal memory architecture in the C674x DSP is organized in a two-level hierarchy consisting of a dedicated program cache (L1P) and a dedicated data cache (L1D) on the first level. Accesses by the CPU to the these first level caches can complete without CPU pipeline stalls. If the data requested by the CPU is not contained in cache, it is fetched from the next lower memory level, L2 or external memory.

## Overview

| Topic                   | Page |
|-------------------------|------|
| 1.1 Introduction .....  | 83   |
| 1.2 DSP Subsystem ..... | 83   |
| 1.3 ARM Subsystem.....  | 83   |

## 1.1 Introduction

The OMAP-L138 Applications Processor contains two primary CPU cores: an ARM RISC CPU for general-purpose processing and systems control; and a powerful DSP to efficiently handle communication and audio processing tasks. The OMAP-L138 Applications Processor consists of the following primary components:

- ARM subsystem and associated memories
- DSP subsystem and associated memories
- A set of I/O peripherals
- A powerful DMA subsystem and SDRAM EMIF interface

## Block Diagram

A block diagram for the OMAP-L138 Applications Processor is shown in [Figure 1-1](#).

## 1.2 DSP Subsystem

The DSP subsystem (DSPSS) includes TI's standard TMS320C674x megamodule and several blocks of internal memory (L1P, L1D, and L2). The *DSP Subsystem* chapter describes the DSPSS components.

## 1.3 ARM Subsystem

The ARM926EJ-S™ 32-bit RISC CPU in the ARM subsystem (ARMSS) acts as the overall system controller. The ARM CPU performs general system control tasks, such as system initialization, configuration, power management, user interface, and user command implementation. The *ARM Subsystem* chapter describes the ARMSS components and system control functions that the ARM core performs.

**Figure 1-1. OMAP-L138 Applications Processor Block Diagram**

Note: Not all peripherals are available at the same time due to multiplexing.

## DMA Subsystem

The DMA subsystem includes two instances of the enhanced DMA controller (EDMA3). For more information, see the *Enhanced Direct Memory Access (EDMA3) Controller* chapter.

## 2.1 Introduction

This chapter describes the ARM subsystem and its associated memories. The ARM subsystem consists of the following components:

- ARM926EJ-S™ 32-bit RISC CPU
- 16-KB Instruction cache
- 16-KB Data cache
- Memory Management Unit (MMU)
- Co-Processor 15 (CP15) to control MMU, cache, etc.
- Jazelle™ Java Accelerator
- ARM Internal Memory
  - 8 KB RAM
  - 64 KB built-in ROM
- Embedded Trace Module and Embedded Trace Buffer (ETM/ETB)
- Features:
  - The main write buffer has a 16-word data buffer and a 4-address buffer
  - Support for 32-bit ARM/16-bit THUMB instruction sets
  - Fixed little-endian memory format
  - Enhanced DSP instructions

The ARM926EJ-S processor is a member of the ARM9 family of general-purpose microprocessors. The ARM926EJ-S processor targets multi-tasking applications where full memory management, high performance, low die size, and low power are all important.

The ARM926EJ-S processor supports the 32-bit ARM and the 16-bit THUMB instruction sets, enabling you to trade off between high performance and high code density. This includes features for efficient execution of Java byte codes and providing Java performance similar to Just in Time (JIT) Java interpreter without associated code overhead.

The ARM926EJ-S processor supports the ARM debug architecture and includes logic to assist in both hardware and software debugging. The ARM926EJ-S processor has a Harvard architecture and provides a complete high performance subsystem, including the following:

- An ARM926EJ-S integer core
- A Memory Management Unit (MMU)
- Separate instruction and data Advanced Microcontroller Bus Architecture (AHBA) Advanced High Performance Bus (AHB) bus interfaces

---

**NOTE:** There is no TCM memory and interface on this device.

---

The ARM926EJ-S processor implements ARM architecture version 5TEJ.

The ARM core also has 8 KB RAM (typically used for vector table) and 64 KB ROM (for boot images) associated with it. The RAM/ROM locations are not accessible by the DSP or any other master peripherals. Furthermore, the ARM has DMA and CFG bus master ports via the AHB interface.

## 2.2 Operating States/Modes

The ARM can operate in two states: ARM (32-bit) mode and THUMB (16-bit) mode. You can switch the ARM926EJ-S processor between ARM mode and THUMB mode using the BX instruction.

The ARM can operate in the following modes:

- User mode (USR): Non-privileged mode, usually for the execution of most application programs.
- Fast interrupt mode (FIQ): Fast interrupt processing
- Interrupt mode (IRQ): Normal interrupt processing
- Supervisor mode (SVC): Protected mode of execution for operating systems
- Abort mode (ABT): Mode of execution after a data abort or a pre-fetch abort
- System mode (SYS): Privileged mode of execution for operating systems
- Undefined mode (UND): Executing an undefined instruction causes the ARM to enter undefined mode.

You can only enter privileged modes (system or supervisor) from other privileged modes.

To enter supervisor mode from user mode, generate a software interrupt (SWI). An IRQ interrupt causes the processor to enter the IRQ mode. An FIQ interrupt causes the processor to enter the FIQ mode.

Different stacks must be set up for different modes. The stack pointer (SP) automatically changes to the SP of the mode that was entered.

## 2.3 Processor Status Registers

The processor status register (PSR) controls the enabling and disabling of interrupts and setting the mode of operation of the processor. The 8 least-significant bits PSR[7:0] are the control bits of the processor. PSR[27:8] are reserved bits and PSR[31:28] are status registers. The details of the control bits are:

- Bit 7 - I bit: Disable IRQ (I = 1) or enable IRQ (I = 0)
- Bit 6 - F bit: Disable FIQ (F = 1) or enable FIQ (F = 0)
- Bit 5 - T bit: Controls whether the processor is in thumb mode (T = 1) or ARM mode (T = 0)
- Bits 4:0 Mode: Controls the mode of operation of the processor
  - PSR [4:0] = 10000 : User mode
  - PSR [4:0] = 10001 : FIQ mode
  - PSR [4:0] = 10010 : IRQ mode
  - PSR [4:0] = 10011 : Supervisor mode
  - PSR [4:0] = 10111 : Abort mode
  - PSR [4:0] = 11011 : Undefined mode
  - PSR [4:0] = 11111 : System mode

Status bits show the result of the most recent ALU operation. The details of status bits are:

- Bit 31 - N bit: Negative or less than
- Bit 30 - Z bit: Zero
- Bit 29 - C bit: Carry or borrow
- Bit 28 - V bit: Overflow or underflow

---

**NOTE:** See the Programmer's Model of the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp> for more detailed information.

---

## 2.4 Exceptions and Exception Vectors

Exceptions arise when the normal flow of the program must be temporarily halted. The exceptions that occur in an ARM system are given below:

- Reset exception: processor reset
- FIQ interrupt: fast interrupt
- IRQ interrupt: normal interrupt
- Abort exception: abort indicates that the current memory access could not be completed. The abort could be a pre-fetch abort or a data abort.
- SWI interrupt: use software interrupt to enter supervisor mode.
- Undefined exception: occurs when the processor executes an undefined instruction

The exceptions in the order of highest priority to lowest priority are: reset, data abort, FIQ, IRQ, pre-fetch abort, undefined instruction, and SWI. SWI and undefined instruction have the same priority. The ARM is configured with the VINITHI signal set high (VINITHI = 1), such that the vector table is located at address FFFF 0000h. This address maps to the beginning of the ARM local RAM (8 KB).

**NOTE:** The VINITHI signal is configurable by way of the register setting in CP15. However, it is not recommended to set VINITHI = 0, as the device has no physical memory in the 0000 0000h address region.

The default vector table is shown in [Table 2-1](#).

**Table 2-1. Exception Vector Table for ARM**

| Vector Offset Address | Exception             | Mode on entry | I Bit State on Entry | F Bit State on Entry |
|-----------------------|-----------------------|---------------|----------------------|----------------------|
| 0h                    | Reset                 | Supervisor    | Set                  | Set                  |
| 4h                    | Undefined instruction | Undefined     | Set                  | Unchanged            |
| 8h                    | Software interrupt    | Supervisor    | Set                  | Unchanged            |
| Ch                    | Pre-fetch abort       | Abort         | Set                  | Unchanged            |
| 10h                   | Data abort            | Abort         | Set                  | Unchanged            |
| 14h                   | Reserved              | —             | —                    | —                    |
| 18h                   | IRQ                   | IRQ           | Set                  | Unchanged            |
| 1Ch                   | FIQ                   | FIQ           | Set                  | Set                  |

## 2.5 The 16-BIS/32-BIS Concept

The key idea behind 16-BIS is that of a super-reduced instruction set. Essentially, the ARM926EJ processor has two instruction sets:

- ARM mode or 32-BIS: the standard 32-bit instruction set
- THUMB mode or 16-BIS: a 16-bit instruction set

The 16-bit instruction length (16-BIS) allows the 16-BIS to approach twice the density of standard 32-BIS code while retaining most of the 32-BIS's performance advantage over a traditional 16-bit processor using 16-bit registers. This is possible because 16-BIS code operates on the same 32-bit register set as 32-BIS code. 16-bit code can provide up to 65% of the code size of the 32-bit code and 160% of the performance of an equivalent 32-BIS processor connected to a 16-bit memory system.

## 2.6 16-BIS/32-BIS Advantages

16-bit instructions operate with the standard 32-bit register configuration, allowing excellent interoperability between 32-BIS and 16-BIS states. Each 16-bit instruction has a corresponding 32-bit instruction with the same effect on the processor model. The major advantage of a 32-bit architecture over a 16-bit architecture is its ability to manipulate 32-bit integers with single instructions, and to address a large address space efficiently. When processing 32-bit data, a 16-bit architecture takes at least two instructions to perform the same task as a single 32-bit instruction. However, not all of the code in a program processes 32-bit data (for example, code that performs character string handling), and some instructions (like branches) do not process any data at all. If a 16-bit architecture only has 16-bit instructions, and a 32-bit architecture only has 32-bit instructions, then the 16-bit architecture has better code density overall, and has better than one half of the performance of the 32-bit architecture. Clearly, 32-bit performance comes at the cost of code density. The 16-bit instruction breaks this constraint by implementing a 16-bit instruction length on a 32-bit architecture, making the processing of 32-bit data efficient with compact instruction coding. This provides far better performance than a 16-bit architecture, with better code density than a 32-bit architecture. The 16-BIS also has a major advantage over other 32-bit architectures with 16-bit instructions. The advantage is the ability to switch back to full 32-bit code and execute at full speed. Thus, critical loops for applications such as fast interrupts and DSP algorithms can be coded using the full 32-BIS and linked with 16-BIS code. The overhead of switching from 16-bit code to 32-bit code is folded into sub-routine entry time. Various portions of a system can be optimized for speed or for code density by switching between 16-BIS and 32-BIS execution, as appropriate.

## 2.7 Co-Processor 15 (CP15)

The system control coprocessor (CP15) is used to configure and control instruction and data caches, Tightly-Coupled Memories (TCMs), Memory Management Units (MMUs), and many system functions. The CP15 registers are only accessible with MRC and MCR instructions by the ARM in a privileged mode like supervisor mode or system mode.

### 2.7.1 Addresses in an ARM926EJ-S System

Three different types of addresses exist in an ARM926EJ-S system. They are listed in [Table 2-2](#).

**Table 2-2. Different Address Types in ARM System**

| Domain       | ARM9EJ-S             | Caches and MMU                 | TCM and AMBA Bus      |
|--------------|----------------------|--------------------------------|-----------------------|
| Address type | Virtual Address (VA) | Modified Virtual Address (MVA) | Physical Address (PA) |

An example of the address manipulation that occurs when the ARM9EJ-S core requests an instruction is shown in [Example 2-1](#)

#### Example 2-1. Address Manipulation

The VA of the instruction is issued by the ARM9EJ-S core.

The VA is translated to the MVA. The Instruction Cache (Icache) and Memory Management Unit (MMU) detect the MVA.

If the protection check carried out by the MMU on the MVA does not abort and the MVA tag is in the Icache, the instruction data is returned to the ARM9EJ-S core.

If the protection check carried out by the MMU on the MVA does not abort, and the MVA tag is not in the cache, then the MMU translates the MVA to produce the PA.

**NOTE:** See the Programmers Model of the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp> for more detailed information.

### 2.7.2 Memory Management Unit (MMU)

The ARM926EJ-S MMU provides virtual memory features required by operating systems such as SymbianOS, WindowsCE, and Linux. A single set of two level page tables stored in main memory controls the address translation, permission checks, and memory region attributes for both data and instruction accesses. The MMU uses a single unified Translation Lookaside Buffer (TLB) to cache the information held in the page tables.

The MMU features are as follows:

- Standard ARM architecture v4 and v5 MMU mapping sizes, domains, and access protection scheme.
- Mapping sizes are 1 MB (sections), 64 KB (large pages), 4 KB (small pages) and 1 KB (tiny pages)
- Access permissions for large pages and small pages can be specified separately for each quarter of the page (subpage permissions)
- Hardware page table walks
- Invalidate entire TLB, using CP15 register 8
- Invalidate TLB entry, selected by MVA, using CP15 register 8
- Lockdown of TLB entries, using CP15 register 10

**NOTE:** See the Memory Management Unit of the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp> for more detailed information.

### 2.7.3 Caches and Write Buffer

The ARM926EJ-S processor includes:

- An Instruction cache (Icache)
- A Data cache (Dcache)
- A write buffer

The size of the data cache is 16 KB, instruction cache is 16 KB, and write buffer is 17 bytes.

The caches have the following features:

- Virtual index, virtual tag, addressed using the Modified Virtual Address (MVA)
- Four-way set associative, with a cache line length of eight words per line (32 bytes per line), and two dirty bits in the Dcache
- Dcache supports write-through and write-back (or copy back) cache operation, selected by memory region using the C and B bits in the MMU translation tables
- Perform critical-word first cache refilling
- Cache lockdown registers enable control over which cache ways are used for allocation on a line fill, providing a mechanism for both lockdown and controlling cache pollution.
- Dcache stores the Physical Address TAG (PA TAG) corresponding to each Dcache entry in the TAGRAM for use during the cache line write-backs, in addition to the Virtual Address TAG stored in the TAG RAM. This means that the MMU is not involved in Dcache write-back operations, removing the possibility of TLB misses related to the write-back address.
- Cache maintenance operations to provide efficient invalidation of the following:
  - The entire Dcache or Icache
  - Regions of the Dcache or Icache
  - The entire Dcache
  - Regions of virtual memory
- They also provide operations for efficient cleaning and invalidation of the following:
  - The entire Dcache
  - Regions of the Dcache
  - Regions of virtual memory

The write buffer is used for all writes to a non-cachable bufferable region, write-through region, and write misses to a write-back region. A separate buffer is incorporated in the Dcache for holding write-back for cache line evictions or cleaning of dirty cache lines.

The main write buffer has a 16-word data buffer and a four-address buffer.

The Dcache write-back has eight data word entries and a single address entry.

The MCR drain write buffer enables both write buffers to be drained under software control.

The MCR wait for interrupt causes both write buffers to be drained and the ARM926EJ-S processor to be put into a low power state until an interrupt occurs.

---

**NOTE:** See the Caches and Write Buffer of the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp> for more detailed information.

## **DSP Subsystem**

| Topic                                            | Page      |
|--------------------------------------------------|-----------|
| <b>3.1 Introduction .....</b>                    | <b>93</b> |
| <b>3.2 TMS320C674x Megamodule .....</b>          | <b>94</b> |
| <b>3.3 Memory Map .....</b>                      | <b>99</b> |
| <b>3.4 Advanced Event Triggering (AET) .....</b> | <b>99</b> |

### 3.1 Introduction

The DSP subsystem ([Figure 3-1](#)) includes TI's standard TMS320C674x megamodule and several blocks of internal memory (L1P, L1D, and L2). This chapter provides an overview of the DSP subsystem and the following considerations associated with it:

- Memory mapping
- Interrupts
- Power management

For more information on the TMS320C674x megamodule, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)), the *TMS320C674x DSP CPU and Instruction Set Reference Guide* ([SPRUF8](#)), and the *TMS320C674x DSP Cache User's Guide* ([SPRUG82](#)).

**Figure 3-1. TMS320C674x Megamodule Block Diagram**

## 3.2 TMS320C674x Megamodule

The C674x megamodule ([Figure 3-1](#)) consists of the following components:

- TMS320C674x CPU
- Internal memory controllers:
  - Level 1 program memory controller (PMC)
  - Level 1 data memory controller (DMC)
  - Level 2 unified memory controller (UMC)
  - Extended memory controller (EMC)
  - Internal direct memory access (IDMA) controller
- Internal peripherals:
  - Interrupt controller (INTC)
  - Power-down controller (PDC)
  - Bandwidth manager (BWM)
- Advanced event triggering (AET)

For more information about each of these controllers, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 3.2.1 Internal Memory Controllers

The C674x megamodule implements a two-level internal cache-based memory architecture with external memory support. Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). L1 memory is accessible to the CPU without stalls. Level 2 memory (L2) can also be split into L2 RAM (normal addressable on-chip memory) and L2 cache for caching external memory locations. The internal direct memory access controller (IDMA) manages DMA among the L1P, L1D, and L2 memories.

### 3.2.2 Internal Peripherals

The C674x megamodule includes the following internal peripherals:

- DSP interrupt controller (INTC)
- DSP power-down controller (PDC)
- Bandwidth manager (BWM)
- Internal DMA (IDMA) controller

This section briefly describes the INTC, PDC, BWM, and IDMA controller. For more information on these internal peripherals, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

#### 3.2.2.1 Interrupt Controller (INTC)

The C674x megamodule includes an interrupt controller (INTC) to manage CPU interrupts. The INTC maps DSP device events to 12 CPU interrupts. All DSP device events are listed in [Table 3-1](#). The INTC is fully described in the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

The interrupt events listed in [Table 3-1](#) are for the DSP interrupt controller (INTC) only. For the ARM interrupt controller (AINTC) event mappings, see the *ARM Interrupt Controller (AINTC)* chapter.

**Table 3-1. DSP Interrupt Map**

| Event | Interrupt Name | Source                    |
|-------|----------------|---------------------------|
| 0     | EVT0           | C674x Interrupt Control 0 |
| 1     | EVT1           | C674x Interrupt Control 1 |
| 2     | EVT2           | C674x Interrupt Control 2 |
| 3     | EVT3           | C674x Interrupt Control 3 |

**Table 3-1. DSP Interrupt Map (continued)**

| Event | Interrupt Name   | Source                                                                     |
|-------|------------------|----------------------------------------------------------------------------|
| 4     | T64P0_TINT12     | Timer64P0 Interrupt (TINT12)                                               |
| 5     | SYSCFG_CHIPINT2  | SYSCFG CHIPSIG Register                                                    |
| 6     | PRU_EVTOUT0      | PRUSS Interrupt                                                            |
| 7     | EHRPWM0          | HiResTimer/PWM0 Interrupt                                                  |
| 8     | EDMA3_0_CC0_INT1 | EDMA3_0 Channel Controller 0 Shadow Region 1 Transfer Completion Interrupt |
| 9     | EMU-DTDMA        | C674x-ECM                                                                  |
| 10    | EHRPWM0TZ        | HiResTimer/PWM0 Trip Zone Interrupt                                        |
| 11    | EMU-RTDXRX       | C674x-RTDX                                                                 |
| 12    | EMU-RTDXTX       | C674x-RTDX                                                                 |
| 13    | IDMAINT0         | C674x-EMC                                                                  |
| 14    | IDMAINT1         | C674x-EMC                                                                  |
| 15    | MMCSDB0_INT0     | MMCSDB0 MMC/SD Interrupt                                                   |
| 16    | MMCSDB0_INT1     | MMCSDB0 SDIO Interrupt                                                     |
| 17    | PRU_EVTOUT1      | PRUSS Interrupt                                                            |
| 18    | EHRPWM1          | HiResTimer/PWM1 Interrupt                                                  |
| 19    | USB0_INT         | USB0 (USB2.0) Interrupt                                                    |
| 20    | USB1_HCINT       | USB1 (USB1.1) OHCI Host Controller Interrupt                               |
| 21    | USB1_R/WAKEUP    | USB1 (USB1.1) Remote Wakeup Interrupt                                      |
| 22    | PRU_EVTOUT2      | PRUSS Interrupt                                                            |
| 23    | EHRPWM1TZ        | HiResTimer/PWM1 Trip Zone Interrupt                                        |
| 24    | SATA_INT         | SATA Controller Interrupt                                                  |
| 25    | T64P2_TINTALL    | Timer64P2 Combined Interrupt (TINT12 and TINT34)                           |
| 26    | EMAC_C0RXTHRESH  | EMAC - Core 0 Receive Threshold Interrupt                                  |
| 27    | EMAC_C0RX        | EMAC - Core 0 Receive Interrupt                                            |
| 28    | EMAC_C0TX        | EMAC - Core 0 Transmit Interrupt                                           |
| 29    | EMAC_C0MISC      | EMAC - Core 0 Miscellaneous Interrupt                                      |
| 30    | EMAC_C1RXTHRESH  | EMAC - Core 1 Receive Threshold Interrupt                                  |
| 31    | EMAC_C1RX        | EMAC - Core 1 Receive Interrupt                                            |
| 32    | EMAC_C1TX        | EMAC - Core 1 Transmit Interrupt                                           |
| 33    | EMAC_C1MISC      | EMAC - Core 1 Miscellaneous Interrupt                                      |
| 34    | UHPI_DSPINT      | HPI DSP Interrupt                                                          |

### 3.2.2.1.1 Interrupt Controller Registers

For more information on the DSP interrupt controller (INTC) registers, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 3.2.2.1.2 NMI Interrupt

In addition to the interrupts listed in [Table 3-1](#), the DSP also supports a special interrupt that behaves more like an exception, non-maskable interrupt (NMI). The NMI interrupt is controlled by two registers in the System Configuration Module, the chip signal register (CHIPSIG) and the chip signal clear register (CHIPSIG\_CLR).

The NMI interrupt is asserted by writing a 1 to the CHIPSIG4 bit in CHIPSIG. The NMI interrupt is cleared by writing a 1 to the CHIPSIG4 bit in CHIPSIG\_CLR. For more information on CHIPSIG and CHIPSIG\_CLR, see the *System Configuration (SYSCFG) Module* chapter.

### 3.2.2.2 Power-Down Controller (PDC)

The C674x megamodule includes a power-down controller (PDC). The PDC can power-down all of the following components of the C674x megamodule and internal memories of the DSP subsystem:

- C674x CPU
- Level 1 program memory controller (PMC)
- Level 1 data memory controller (DMC)
- Level 2 unified memory controller (UMC)
- Extended memory controller (EMC)
- Internal direct memory access (IDMA) controller
- L1P memory
- L1D memory
- L2 memory

This device supports the static power-down feature from the C674x megamodule. The *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)) describes the power-down control in more detail.

- Static power-down: The PDC initiates power-down (clock gating) of the entire C674x megamodule and all internal memories immediately upon command from software.

Static power-down (clock gating) affects all components of the C674x megamodule and all internal memories. Software can initiate static power-down by way of a register bit in the power-down controller command register (PDCCMD) of the PDC. For more information on the PDC, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 3.2.2.3 Bandwidth Manager (BWM)

The bandwidth manager (BWM) provides a programmable interface for optimizing bandwidth among the requesters for resources, which include the following:

- EDMA3-initiated DMA transfers (and resulting coherency operations)
- DSP subsystem IDMA-initiated transfers (and resulting coherency operations)
- Programmable cache coherency operations
  - Block based coherency operations
  - Global coherency operations
- CPU direct-initiated transfers
  - Data access (load/store)
  - Program access

The resources include the following:

- L1P memory
- L1D memory
- L2 memory
- Resources outside of the C674x megamodule: external memory, on-chip peripherals, registers

Since any given requestor could potentially block a resource for extended periods of time, the bandwidth manager is implemented to assure fairness for all requesters.

The bandwidth manager implements a weighted-priority-driven bandwidth allocation. Each requestor (EDMA3, DSP subsystem IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system. There are a total of nine priority levels, where priority zero is the highest priority and priority eight is the lowest priority. When requests for a single resource contend, access is granted to the highest-priority requestor. When the contention occurs for multiple successive cycles, a contention counter assures that the lower-priority requestor gets access to the resource every 1 out of  $n$  arbitration cycles, where  $n$  is programmable. A priority level of -1 represents a transfer whose priority has been increased due to expiration of the contention counter or a transfer that is fixed as the highest-priority transfer to a given resource.

### 3.2.2.4 Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the C674x megamodule. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port. The IDMA cannot transfer data to or from the internal DSP memory-mapped register space. The IDMA is fully described in the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 3.3 Memory Map

Refer to your device-specific data manual for the addresses of the memory-map registers.

#### 3.3.1 DSP Internal Memory

See the *System Memory* chapter for a description of the DSP internal memory.

#### 3.3.2 External Memory

See the *System Interconnect* chapter and the *System Memory* chapter for a description of the additional memory and peripherals that the DSP has access to.

### 3.4 Advanced Event Triggering (AET)

The C674x megamodule supports advanced event triggering (AET). This capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- Hardware Program Breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data Watchpoints: specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- Counters: count the occurrence of an event or cycles for performance monitoring.
- State Sequencing: allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

## System Interconnect

| Topic                                       | Page |
|---------------------------------------------|------|
| 4.1 Introduction .....                      | 101  |
| 4.2 System Interconnect Block Diagram ..... | 102  |

## 4.1 Introduction

The DSP, the ARM, the Programmable Real-Time Unit (PRU) subsystem, the EDMA3 transfer controllers, and the device peripherals are interconnected through a switch fabric architecture (see [Section 4.2](#)). The switch fabric is composed of multiple switched central resources (SCRs) and multiple bridges. The SCRs establish low-latency connectivity between master peripherals and slave peripherals.

Additionally, the SCRs provide priority-based arbitration and facilitate concurrent data movement between master and slave peripherals. Through the SCRs, the DSP can send data to the EMIF without affecting a data transfer between a device peripheral and internal shared memory. Bridges are mainly used to perform bus-width conversion as well as bus operating frequency conversion.

The DSP, the ARM, the PRU subsystem, the EDMA3 transfer controllers, and the various device peripherals can be classified into two categories: master peripherals and slave peripherals.

Master peripherals are typically capable of initiating read and write transfers in the system and do not rely on the EDMA3 or on a CPU to perform transfers to and from them. The system master peripherals include the DSP, the ARM, the EDMA3 transfer controllers, EMAC, HPI, LCD, uPP, SATA, VPIF, PRU subsystem, and USB DMAs. Not all master peripherals may connect to all slave peripherals. The supported connections are designated by an X in [Table 4-1](#).

**Table 4-1. OMAP-L138 Applications Processor System Interconnect Matrix**

| Masters     |                  | Slaves         |         |          |       |            |          |                  |              |                                 |
|-------------|------------------|----------------|---------|----------|-------|------------|----------|------------------|--------------|---------------------------------|
| Master      | Default Priority | ARM ROM, AINTC | ARM RAM | DSP SDMA | EMIFA | DDR2/ mDDR | 128K RAM | EDMA3_0_ TC0/TC1 | EDMA3_1_ TC0 | Peripheral Group <sup>(1)</sup> |

## System Memory

| Topic                  | Page |
|------------------------|------|
| 5.1 Introduction ..... | 104  |
| 5.2 ARM Memories ..... | 104  |
| 5.3 DSP Memories.....  | 104  |
| 5.4 Peripherals .....  | 105  |

## 5.1 Introduction

This device has multiple on-chip/off-chip memories and several external device interfaces associated with its two CPUs and various subsystems. To help simplify software development, a unified memory-map is used wherever possible to maintain a consistent view of device resources across all masters.

For details on the memory addresses, actual memory supported and accessibility by various bus masters, see the detailed memory-map information in the device-specific data manual.

## 5.2 ARM Memories

The configuration for the ARM internal memory is:

- 8 KB ARM local RAM
- 64 KB ARM local ROM
- 16 KB Instruction Cache and 16 KB Data cache

The ARM RAM/ROM are only accessible by ARM and PRU0.

## 5.3 DSP Memories

The DSP internal memories are accessible by the ARM and other master peripherals (as dictated by the connectivity matrix) via the system interconnect through the DSP SDMA port.

The DSP internal memory consists of L1P, L1D, and L2. The DSP internal memory configuration is:

- L1P memory includes 32 KB of RAM. The DSP program memory controller (PMC) allows you to configure part or all of the L1P RAM as normal program RAM or as cache. You can configure cache sizes of 0 KB, 4 KB, 8 KB, 16 KB, or 32 KB of the 32 KB of RAM. The default configuration is 32 KB cache.
- L1D memory includes 32 KB of RAM. The DSP data memory controller (DMC) allows you to configure part of the L1D RAM as normal data RAM or as cache. You can configure cache sizes of 0 KB, 4 KB, 8 KB, 16 KB, or 32 KB of the 32 KB of RAM. The default configuration is 32 KB cache.
- L2 memory includes 256 KB of RAM. The DSP unified memory controller (UMC) allows you to configure part or all of the L2 RAM as normal RAM or as cache. You can configure cache sizes of 0 KB, 4 KB, 8 KB, 16 KB, 32 KB, 64 KB, 128 KB, or 256 KB of the 256 KB of RAM. The default configuration is 256 KB normal RAM.
- L2 memory also includes 1024 KB of ROM.

## Shared RAM Memory

This device also offers an on-chip 128-KB shared single-port RAM, apart from the ARM and the DSP internal memories. This shared RAM is accessible by both the ARM and the DSP, and is also accessible by several master peripherals. Writes to this RAM by all masters is atomic.

## External Memories

This device has two external memory interfaces that provide multiple external memory options accessible by the CPU and master peripherals:

- EMIF:
  - 8/16-bit wide asynchronous EMIF module that supports asynchronous devices such as ASRAM, NAND Flash, and NOR Flash (up to 4 devices)
  - 8/16-bit wide NAND Flash with 4-bit ECC (up to 4 devices)
  - 16-bit SDRAM with 128-MB address space
- DDR2/mDDR memory controller:
  - 16-bit DDR2 with up to 256-MB memory address space
  - 16-bit mDDR with up to 256-MB memory address space

## Internal Peripherals

The following peripherals are internal to the DSP subsystem and are only accessible to the DSP:

- DSP interrupt controller (INTC)
- DSP power down controller (PDC)
- Bandwidth manager (BWM)
- Internal DMA (IDMA)

For more information on the internal peripherals, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFG5](#)).

The peripheral only accessible by the ARM is the ARM interrupt controller (AINTC). For more information on the AINTC, see the *ARM Interrupt Controller (AINTC)* chapter.

## 5.4 Peripherals

The ARM and the DSP have access to all peripherals. This also includes system modules like the PLL controller (PLLCC), the power and sleep controller (PSC), and the system configuration module (SYSCFG). See the device-specific data manual for the complete list of peripherals supported on your device.

## Memory Protection Unit (MPU)

---

---

---

| Topic                   | Page |
|-------------------------|------|
| 6.1 Introduction .....  | 107  |
| 6.2 Architecture .....  | 108  |
| 6.3 MPU Registers ..... | 113  |

## 6.1 Introduction

This device supports two memory protection units (MPU1 and MPU2). MPU1 supports the 128KB shared RAM and MPU2 supports the DDR2/mDDR SDRAM.

### 6.1.1 Purpose of the MPU

The memory protection unit (MPU) is provided to manage access to memory. The MPU allows you to define multiple ranges and limit access to system masters based on their privilege ID. The MPU can record a detected fault, or invalid access, and notify the system through an interrupt.

### 6.1.2 Features

The MPU supports the following features:

- Supports multiple programmable address ranges
- Supports 0 or 1 fixed range
- Supports read, write, and execute access privileges
- Supports privilege ID associations with ranges
- Generates an interrupt when there is a protection violation, and saves violating transfer parameters
- Supports L1/L2 cache accesses
- Supports protection of its own registers

### 6.1.3 Block Diagram

Figure 6-1 shows a block diagram of the MPU. An access to a protected memory must pass through the MPU. During an access, the MPU checks the memory address on the input data bus against fixed and programmable ranges. If allowed, the transfer is passed unmodified to the output data bus. If the transfer fails the protection check then the MPU does not pass the transfer to the output bus but rather services the transfer internally back to the input bus (to prevent a hang) returning the fault status to the requestor as well as generating an interrupt about the fault. The MPU generates two interrupts: an address error interrupt (MPU\_ADDR\_ERR\_INT) and a protection interrupt (MPU\_PROT\_ERR\_INT).

**Figure 6-1. MPU Block Diagram**

### 6.1.4 MPU Default Configuration

Two MPUs are supported on the device, one for the 128KB shared RAM and one for the DDR2/mDDR SDRAM. [Table 6-1](#) shows the memory regions protected by each MPU. [Table 6-2](#) shows the configuration of each MPU.

**Table 6-1. MPU Memory Regions**

| Unit | Memory Protection | Memory Region |             |
|------|-------------------|---------------|-------------|
|      |                   | Start Address | End Address |
| MPU1 | 128KB Shared RAM  | 8000 0000h    | 8001 FFFFh  |
| MPU2 | DDR2/mDDR SDRAM   | C000 0000h    | DFFF FFFFh  |

**Table 6-2. MPU Default Configuration**

| Setting                                 | MPU1             | MPU2              |
|-----------------------------------------|------------------|-------------------|
| Default permission                      | Assume allowed   | Assume allowed    |
| Number of allowed IDs supported         | 12               | 12                |
| Number of fixed ranges supported        | 1                | 0                 |
| Number of programmable ranges supported | 6                | 12                |
| Compare width                           | 1 KB granularity | 64 KB granularity |

## 6.2 Architecture

### 6.2.1 Privilege Levels

The privilege level of a memory access determines what level of permissions the originator of the memory access might have. Two privilege levels are supported: supervisor and user.

Supervisor level is generally granted access to peripheral registers and the memory protection configuration. User level is generally confined to the memory spaces that the OS specifically designates for its use.

ARM and DSP CPU instruction and data accesses have a privilege level associated with them. The privilege level is inherited from the code running on the CPU. See the *TMS320C674x DSP CPU and Instruction Set Reference Guide* ([SPRUFE8](#)) and the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp> for more details on privilege levels of the DSP and ARM CPU.

Although master peripherals like the HPI do not execute code, they still have a privilege level associated with them. Unlike the ARM and DSP CPU, the privilege level of this peripheral is fixed.

[Table 6-3](#) shows the privilege ID of the CPU and every mastering peripheral. [Table 6-3](#) also shows the privilege level (supervisor vs. user) and access type (instruction read vs. data/DMA read or write) of each master on the device. In some cases, a particular setting depends on software being executed at the time of the access or the configuration of the master peripheral.

**Table 6-3. Device Master Settings**

| Master                      | Privilege ID | Privilege Level    | Access Type |
|-----------------------------|--------------|--------------------|-------------|
| EDMA3_0_CC0                 | Inherited    | Inherited          | DMA         |
| EDMA3_0_TC0 and EDMA3_0_TC1 | Inherited    | Inherited          | DMA         |
| EDMA3_1_CC0                 | Inherited    | Inherited          | DMA         |
| EDMA3_1_TC0                 | Inherited    | Inherited          | DMA         |
| ARM (instruction access)    | 0            | Software dependant | Instruction |

**Table 6-3. Device Master Settings (continued)**

| Master            | Privilege ID | Privilege Level    | Access Type        |
|-------------------|--------------|--------------------|--------------------|
| ARM (data access) | 0            | Software dependant | Data               |
| DSP               | 1            | Software dependant | Software dependant |
| PRU0/PRU1         | 2            | Supervisor         | DMA                |
| HPI               | 3            | User               | DMA                |
| EMAC              | 4            | Supervisor         | Data/DMA           |
| USB1.1            | 5            | Supervisor         | DMA                |
| USB2.0            | 6            | Supervisor         | DMA                |
| LCD Controller    | 7            | Supervisor         | DMA                |
| uPP               | 8            | Supervisor         | DMA                |
| SATA              | 9            | Supervisor         | DMA                |
| VPIF DMA0         | 10           | Supervisor         | DMA                |
| VPIF DMA1         | 11           | Supervisor         | DMA                |

## 6.2.2 Memory Protection Ranges

**NOTE:** In some cases the amount of physical memory in actual use may be less than the maximum amount of memory supported by the device. For example, the device may support a total of 512 Mbytes of SDRAM memory, but your design may only populate 128 Mbytes. In such cases, the unpopulated memory range must be protected in order to prevent unintended/disallowed aliased access to protected memory. One of the programmable address ranges could be used to detect accesses to this unpopulated memory.

The MPU divides its assigned memory into address ranges. Each MPU can support one fixed address range and multiple programmable address ranges. The fixed address range is configured to an exact address. The programmable address range allows software to program the start and end addresses.

Each address range has the following set of registers:

- Range start and end address registers (MPSAR and MPEAR): Specifies the starting and ending address of the address range.
- Memory protection page attribute register (MPPA): Use to program the permission settings of the address range.

It is allowed to configure ranges such that they overlap each other. In this case, all the overlapped ranges must allow the access, otherwise the access is not allowed. The final permissions given to the access are the lowest of each type of permission from any hit range.

Addresses not covered by a range are either allowed or disallowed based on the configuration of the MPU. The MPU can be configured for assumed allowed or assumed disallowed mode as dictated by the ASSUME\_ALLOWED bit in the configuration register (CONFIG).

### 6.2.3 Permission Structures

The MPU defines a per-range permission structure with three permission fields in a 32-bit permission entry. [Figure 6-2](#) shows the structure of a permission entry.

### Figure 6-2. Permission Fields

|             |      |      |      |      |      |     |          |             |              |      |      |      |      |    |
|-------------|------|------|------|------|------|-----|----------|-------------|--------------|------|------|------|------|----|
| 31          |      |      |      |      |      |     |          | 22          | 21           | 20   | 19   | 18   | 17   | 16 |
| Reserved    |      |      |      |      |      |     |          | Allowed IDs |              |      |      |      |      |    |
|             |      |      |      |      |      |     |          | AID11       | AID10        | AID9 | AID8 | AID7 | AID6 |    |
| 15          | 14   | 13   | 12   | 11   | 10   | 9   | 8        | 6           | 5            | 4    | 3    | 2    | 1    | 0  |
| Allowed IDs |      |      |      |      |      |     | Reserved |             | Access Types |      |      |      |      |    |
| AID5        | AID4 | AID3 | AID2 | AID1 | AID0 | AIX |          |             | SR           | SW   | SX   | UR   | UW   | UX |

### 6.2.3.1 Requestor-ID Based Access Controls

Each master on the device has an N-bit code associated with it that identifies it for privilege purposes. This privilege ID accompanies all memory accesses made on behalf of that master. That is, when a master triggers a memory access command, the privilege ID will be carried alongside the command.

Each memory protection range has an allowed ID (AID) field associated with it that indicates which requestors may access the given address range. The MPU maps the privilege IDs of all the possible requestors to bits in the allowed IDs field in the memory protection page attribute registers (MPPA).

- AID0 through AID11 are used to specify the allowed privilege IDs.
- An additional allowed ID bit, AIDX, captures access made by all privilege IDs not covered by AID0 through AID11.

When set to 1, the AID bit grants access to the corresponding ID. When cleared to 0, the AID bit denies access to the corresponding requestor.

### 6.2.3.2 Request-Type Based Permissions

The memory protection model defines three fundamental functional access types: read, write, and execute. Read and write refer to data accesses -- accesses originating via the load/store units on the CPU or via a master peripheral. Execute refers to accesses associated with an instruction fetch.

The memory protection model allows controlling read, write, and execute permissions independently for both user and supervisor mode. This results in six permission bits, listed in [Table 6-4](#). For each bit, a 1 permits the access type and a 0 denies access. For example, UX = 1 means that User Mode may execute from the given page. The memory protection unit allows you to specify all six of these bits separately; 64 different encodings are permitted altogether, although programs might not use all of them.

### Table 6-4. Request Type Access Controls

| Bit | Field | Description            |
|-----|-------|------------------------|
| 5   | SR    | Supervisor may read    |
| 4   | SW    | Supervisor may write   |
| 3   | SX    | Supervisor may execute |
| 2   | UR    | User may read          |
| 1   | UW    | User may write         |
| 0   | UX    | User may execute       |

## 6.2.4 Protection Check

During a memory access, the MPU checks if the address range of the input transfer overlaps one of the address ranges. When the input transfer address is within a range the transfer parameters are checked against the address range permissions.

The MPU first checks the transfers privilege ID against the AID settings. If the AID bit is 0, then the range will not be checked; if the AID bit is 1, then the transfer parameters are checked against the memory protection page attribute register (MPPA) values to detect an allowed access.

For non-debug accesses, the read, write, and execute permissions are also checked. There is a set of permissions for supervisor mode and a set for user mode. For supervisor mode accesses, the SR, SW, and SX bits are checked. For user mode accesses, the UR, UW, and UX bits are checked.

If the transfer address range does not match any address range then the transfer is either allowed or disallowed based on the configuration of the MPU. The MPU can be configured for assumed allowed or assumed disallowed mode as dictated by the ASSUME\_ALLOWED bit in the configuration register (CONFIG).

In the case that a transfer spans multiple address ranges, all the overlapped ranges must allow the access, otherwise the access is not allowed. The final permissions given to the access are the lowest of each type of permission from any hit range. Therefore, if a transfer matches 2 ranges, one that is RW and one that is RX, then the final permission is just R.

The MPU has a special mechanism for handling DSP L1/L2 cache controller read accesses, see [Section 6.2.5](#) for more details.

## 6.2.5 DSP L1/L2 Cache Controller Accesses

A memory read access that originates from the DSP L1/L2 cache is treated differently to allow memory protection to be enforced by the DSP level. This is because a subsequent memory access that hits in the cache does not pass through the MPU. Instead the memory access is serviced directly by the L1/L2 memory controllers.

During a cache memory read, the permission settings stored in the memory protection page attribute registers (MPPA) are passed to the L1/L2 memory controllers along with the read data. The permissions settings returned by the MPU are taken from MPPA that covers the address range of the original request—only the SR, SW, SX, UR, UW, and UX bits are passed. If the request address is covered by multiple address ranges, then the returned value is the logical-AND of all MPPA permissions. If the transfer address range is not covered by an address range then the transfer is either allowed or disallowed based on the configuration of the MPU.

## 6.2.6 MPU Register Protection

Access to the range start and end address registers (MPSAR and MPEAR) and memory protection page attribute registers (MPPA) is also protected. All non-debug writes must be by a supervisor entity. A protection fault can occur from a register write with invalid permissions and this triggers an interrupt just like a memory access.

Faults are not recorded (nor interrupts generated) for debug accesses.

## 6.2.7 Invalid Accesses and Exceptions

When a transfer fails the protection check, the MPU does not pass the transfer to the output bus. The MPU instead services the transfer locally to prevent a hang and returns a protection error to the requestor. The behavior of the MPU depends on whether the access was a read or a write:

- For a read: The MPU returns 0s, a permission value is 0 (no access allowed), a protection error status.
- For a write: The MPU receives all the write data and returns a protection error status.

The MPU captures system faults due to addressing or protection violations in its registers. The MPU can store the fault information for only one fault, so the first detected fault is recorded into the fault registers and an interrupt is generated. Software must use the fault clear register (FLTCLR) to clear the fault status so that another fault can be recorded. The MPU will not record another fault nor generate another interrupt until the existing fault has been cleared. Also, additional faults will be ignored. Faults are not recorded (no interrupts generated) for debug accesses.

## 6.2.8 Reset Considerations

After reset, the memory protection page attribute registers (MPPA) default to 0. This disables all protection features.

## 6.2.9 Interrupt Support

### 6.2.9.1 Interrupt Events and Requests

The MPU generates two interrupts: an address error interrupt (MPU\_ADDR\_ERR\_INT) and a protection interrupt (MPU\_PROT\_ERR\_INT). The MPU\_ADDR\_ERR\_INT is generated when there is an addressing violation due to an access to a non-existent location in the MPU register space. The MPU\_PROT\_ERR\_INT interrupt is generated when there is a protection violation of either in the defined ranges or to the MPU registers.

The transfer parameters that caused the violation are saved in the MPU registers.

### 6.2.9.2 Interrupt Multiplexing

The interrupts from both MPUs are combined with the boot configuration module into a single interrupt called MPU\_BOOTCFG\_ERR. The combined interrupt is routed to the ARM and DSP interrupt controllers. [Table 6-5](#) shows the interrupt sources that are combined to make MPU\_BOOTCFG\_ERR.

**Table 6-5. MPU\_BOOTCFG\_ERR Interrupt Sources**

| Interrupt         | Source                              |
|-------------------|-------------------------------------|
| MPU1_ADDR_ERR_INT | MPU1 address error interrupt        |
| MPU1_PROT_ERR_INT | MPU1 protection interrupt           |
| MPU2_ADDR_ERR_INT | MPU2 address error interrupt        |
| MPU2_PROT_ERR_INT | MPU2 protection interrupt           |
| BOOTCFG_ADDR_ERR  | Boot configuration address error    |
| BOOTCFG_PROT_ERR  | Boot configuration protection error |

## 6.2.10 Emulation Considerations

Memory and MPU registers are not protected against emulation accesses.

## 6.3 MPU Registers

There are two MPUs on the device. Each MPU contains a set of memory-mapped registers.

[Table 6-6](#) lists the memory-mapped registers for the MPU1. [Table 6-7](#) lists the memory-mapped registers for the MPU2.

**Table 6-6. Memory Protection Unit 1 (MPU1) Registers**

### 6.3.1 Revision Identification Register (REVID)

The revision ID register (REVID) contains the MPU revision. The REVID is shown in [Figure 6-3](#) and described in [Table 6-8](#).

### Figure 6-3. Revision ID Register (REVID)

LEGEND: R = Read only; -n = value after reset

### Table 6-8. Revision ID Register (REVID) Field Descriptions

| Bit  | Field | Value      | Description             |
|------|-------|------------|-------------------------|
| 31-0 | REV   | 4E81 0101h | Revision ID of the MPU. |

### 6.3.2 Configuration Register (CONFIG)

The configuration register (CONFIG) contains the configuration value of the MPU. The CONFIG is shown in [Figure 6-4](#) and described in [Table 6-9](#).

**NOTE:** Although the NUM\_AIDS bit defaults to 12 (Ch), not all AIDs may be supported on your device. Unsupported AIDs should be cleared to 0 in the memory page protection attributes registers (MPPA). See for a list of AIDs supported on your device.

### Figure 6-4. Configuration Register (CONFIG)

LEGEND: R = Read only; -n = value after reset

(1) For MPU1,

(2) For MPU2,

| 0     | ASSUME_ALLOWED |       | Assume allowed. When an address is not covered by any MPU protection range, this bit determines whether the transfer is assumed to be allowed or not allowed. |
|       |                | 0     | Assume is disallowed.                                                                                                                                         |
|       |                | 1     | Assume is allowed.                                                                                                                                            |

### 6.3.3 Interrupt Raw Status/Set Register (IRAWSTAT)

Reading the interrupt raw status/set register (IRAWSTAT) returns the status of all interrupts. Software can write to IRAWSTAT to manually set an interrupt; however, an interrupt is generated only if the interrupt is enabled in the interrupt enable set register (IENSET). Writes of 0 have no effect. The IRAWSTAT is shown in Figure 6-5 and described in Table 6-10.

**Figure 6-5. Interrupt Raw Status/Set Register (IRAWSTAT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 6-10. Interrupt Raw Status/Set Register (IRAWSTAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                            |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                                                               |
| 1    | ADDRERR  | 0     | Address violation error. Reading this bit reflects the status of the interrupt. Writing 1 sets the status; writing 0 has no effect.    |
|      |          | 0     | Interrupt is not set.                                                                                                                  |
|      |          | 1     | Interrupt is set.                                                                                                                      |
| 0    | PROTERR  | 0     | Protection violation error. Reading this bit reflects the status of the interrupt. Writing 1 sets the status; writing 0 has no effect. |
|      |          | 0     | Interrupt is not set.                                                                                                                  |
|      |          | 1     | Interrupt is set.                                                                                                                      |

### 6.3.4 Interrupt Enable Status/Clear Register (IENSTAT)

Reading the interrupt enable status/clear register (IENSTAT) returns the status of only those interrupts that are enabled in the interrupt enable set register (IENSET). Software can write to IENSTAT to clear an interrupt; the interrupt is cleared from both IENSTAT and the interrupt raw status/set register (IRAWSTAT). Writes of 0 have no effect. The IENSTAT is shown in [Figure 6-6](#) and described in [Table 6-11](#).

**Figure 6-6. Interrupt Enable Status/Clear Register (IENSTAT)**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                   |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                                                                                                                                                      |
| 1    | ADDRERR  | 0     | Address violation error. If the interrupt is enabled, reading this bit reflects the status of the interrupt. If the interrupt is disabled, reading this bit returns 0. Writing 1 sets the status; writing 0 has no effect.    |
|      |          | 0     | Interrupt is not set.                                                                                                                                                                                                         |
|      |          | 1     | Interrupt is set.                                                                                                                                                                                                             |
| 0    | PROTERR  |       | Protection violation error. If the interrupt is enabled, reading this bit reflects the status of the interrupt. If the interrupt is disabled, reading this bit returns 0. Writing 1 sets the status; writing 0 has no effect. |
|      |          | 0     | Interrupt is not set.                                                                                                                                                                                                         |
|      |          | 1     | Interrupt is set.                                                                                                                                                                                                             |

### 6.3.5 Interrupt Enable Set Register (IENSET)

Reading the interrupt enable set register (IENSET) returns the interrupts that are enabled. Software can write to IENSET to enable an interrupt. Writes of 0 have no effect. The IENSET is shown in [Figure 6-7](#) and described in [Table 6-12](#).

**Figure 6-7. Interrupt Enable Set Register (IENSET)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 6-12. Interrupt Enable Set Register (IENSET) Field Descriptions**

| Bit  | Field      | Value | Description                                                    |
|------|------------|-------|----------------------------------------------------------------|
| 31-2 | Reserved   | 0     | Reserved                                                       |
| 1    | ADDRERR_EN | 0     | Address violation error enable.<br>Writing 0 has no effect.    |
|      |            | 1     | Interrupt is enabled.                                          |
| 0    | PROTERR_EN | 0     | Protection violation error enable.<br>Writing 0 has no effect. |
|      |            | 1     | Interrupt is enabled.                                          |

### 6.3.6 Interrupt Enable Clear Register (IENCLR)

Reading the interrupt enable clear register (IENCLR) returns the interrupts that are enabled. Software can write to IENCLR to clear/disable an interrupt. Writes of 0 have no effect. The IENCLR is shown in [Figure 6-8](#) and described in [Table 6-13](#).

**Figure 6-8. Interrupt Enable Clear Register (IENCLR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 6-13. Interrupt Enable Clear Register (IENCLR) Field Descriptions**

| Bit  | Field       | Value | Description                                                     |
|------|-------------|-------|-----------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                        |
| 1    | ADDRERR_CLR | 0     | Address violation error disable.<br>Writing 0 has no effect.    |
|      |             | 1     | Interrupt is cleared/disabled.                                  |
| 0    | PROTERR_CLR | 0     | Protection violation error disable.<br>Writing 0 has no effect. |
|      |             | 1     | Interrupt is cleared/disabled.                                  |

### 6.3.7 Fixed Range Start Address Register (FXD\_MPSAR)

The fixed range start address register (FXD\_MPSAR) holds the start address for the fixed range. The fixed address range manages access to the DDR2/mDDR SDRAM control registers (B000 0000h–B000 7FFFh). However, these addresses are *not* indicated in FXD\_MPSAR and the fixed range end address register (FXD\_MPEAR), which instead read as 0. The FXD\_MPSAR is shown in [Figure 6-9](#).

**Figure 6-9. Fixed Range Start Address Register (FXD\_MPSAR)**

|----------|--|---|
| 31       |  | 0 |
| Reserved |  |   |
| R-0      |  |   |

LEGEND: R = Read only; -n = value after reset

### 6.3.8 Fixed Range End Address Register (FXD\_MPEAR)

The fixed range end address register (FXD\_MPEAR) holds the end address for the fixed range. The fixed address range manages access to the DDR2/mDDR SDRAM control registers (B000 0000h–B000 7FFFh). However, these addresses are *not* indicated in FXD\_MPEAR and the fixed range start address register (FXD\_MPSAR), which instead read as 0. The FXD\_MPEAR is shown in [Figure 6-10](#).

**Figure 6-10. Fixed Range End Address Register (FXD\_MPEAR)**

| R-0      |  |   |

LEGEND: R = Read only; -n = value after reset

### 6.3.9 Fixed Range Memory Protection Page Attributes Register (FXD\_MPPA)

The fixed range memory protection page attributes register (FXD\_MPPA) holds the permissions for the fixed region. This register is writeable by a supervisor entity only. The FXD\_MPPA is shown in [Figure 6-11](#) and described in [Table 6-14](#).

**Figure 6-11. Fixed Range Memory Protection Page Attributes Register (FXD\_MPPA)**

|                                                                 |  |       |  |       |  |          |  |       |  |       |  |       |       |       |       |       |       |       |  |       |  |       |  |       |  |       |  |       |  |    |  |

### 6.3.10 Programmable Range *n* Start Address Registers (PROG<sub>*n*</sub>\_MPSAR)

**NOTE:** In some cases the amount of physical memory in actual use may be less than the maximum amount of memory supported by the device. For example, the device may support a total of 512 Mbytes of SDRAM memory, but your design may only populate 128 Mbytes. In such cases, the unpopulated memory range must be protected in order to prevent unintended/disallowed aliased access to protected memory, especially memory. One of the programmable address ranges could be used to detect accesses to this unpopulated memory.

The programmable range *n* start address register (PROG<sub>*n*</sub>\_MPSAR) holds the start address for the range *n*. The PROG<sub>*n*</sub>\_MPSAR is writeable by a supervisor entity only.

The start address must be aligned on a page boundary. The size of the page depends on the MPU: the page size for MPU1 is 1 KByte; the page size for MPU2 is 64 KBytes. The size of the page determines the width of the address field in PROG<sub>*n*</sub>\_MPSAR and the programmable range *n* end address register (PROG<sub>*n*</sub>\_MPEAR). For example, to protect a 64-KB page starting at byte address 8001 0000h, write 8001 0000h to PROG<sub>*n*</sub>\_MPSAR and 8001 FFFFh to PROG<sub>*n*</sub>\_MPEAR.

#### 6.3.10.1 MPU1 Programmable Range *n* Start Address Register (PROG1\_MPSAR-PROG6\_MPSAR)

The PROG<sub>*n*</sub>\_MPSAR for MPU1 is shown in [Figure 6-12](#) and described in [Table 6-15](#).

**Figure 6-12. MPU1 Programmable Range *n* Start Address Register (PROG<sub>*n*</sub>\_MPSAR)**

| R/W-20 0000h |  |    |   | R-0      |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 6-15. MPU1 Programmable Range *n* Start Address Register (PROG<sub>*n*</sub>\_MPSAR)  
Field Descriptions**

| Bit   | Field      | Value                 | Description                 |
|-------|------------|-----------------------|-----------------------------|
| 31-10 | START_ADDR | 20 0000h–<br>20 007Fh | Start address for range N . |
| 9-0   | Reserved   | 0                     | Reserved                    |

#### 6.3.10.2 MPU2 Programmable Range *n* Start Address Register (PROG1\_MPSAR-PROG12\_MPSAR)

The PROG<sub>*n*</sub>\_MPSAR for MPU2 is shown in [Figure 6-13](#) and described in [Table 6-16](#).

**Figure 6-13. MPU2 Programmable Range *n* Start Address Register (PROG<sub>*n*</sub>\_MPSAR)**

|            |  |    |    |          |
|------------|--|----|----|----------|
| 31         |  | 16 | 15 | 0        |
| START_ADDR |  |    |    | Reserved |
| R/W-C000h  |  |    |    | R-0      |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 6-16. MPU2 Programmable Range *n* Start Address Register (PROG<sub>*n*</sub>\_MPSAR)  
Field Descriptions**

| Bit   | Field      | Value       | Description                |
|-------|------------|-------------|----------------------------|
| 31-16 | START_ADDR | C000h–DFFFh | Start address for range N. |
| 15-0  | Reserved   | 0           | Reserved                   |

### 6.3.11 Programmable Range $n$ End Address Registers (PROG $n$ \_MPEAR)

The programmable range  $n$  end address register (PROG $n$ \_MPEAR) holds the end address for the range  $n$ . This register is writeable by a supervisor entity only.

The end address must be aligned on a page boundary. The size of the page depends on the MPU: the page size for MPU1 is 1 KByte; the page size for MPU2 is 64 KBytes. The size of the page determines the width of the address field in the programmable range  $n$  start address register (PROG $n$ \_MPSAR) and PROG $n$ \_MPEAR. For example, to protect a 64-KB page starting at byte address 8001 0000h, write 8001 0000h to PROG $n$ \_MPSAR and 8001 FFFFh to PROG $n$ \_MPEAR.

#### 6.3.11.1 MPU1 Programmable Range $n$ End Address Register (PROG1\_MPEAR-PROG6\_MPEAR)

The PROG $n$ \_MPEAR for MPU1 is shown in [Figure 6-14](#) and described in [Table 6-17](#).

**Figure 6-14. MPU1 Programmable Range  $n$  End Address Register (PROG $n$ \_MPEAR)**

|              |    |   |          |
|--------------|----|---|----------|

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 6-17. MPU1 Programmable Range  $n$  End Address Register (PROG $n$ \_MPEAR)  
Field Descriptions**

| Bit   | Field    | Value                 | Description              |
|-------|----------|-----------------------|--------------------------|
| 31-10 | END_ADDR | 20 0000h–<br>20 007Fh | End address for range N. |
| 9-0   | Reserved | 3FFh                  | Reserved                 |

#### 6.3.11.2 MPU2 Programmable Range $n$ End Address Register (PROG1\_MPEAR-PROG12\_MPEAR)

The PROG $n$ \_MPEAR for MPU2 is shown in [Figure 6-15](#) and described in [Table 6-18](#).

**Figure 6-15. MPU2 Programmable Range  $n$  End Address Register (PROG $n$ \_MPEAR)**

|           |    |    |          |
|-----------|----|----|----------|
| 31        | 16 | 15 | 0        |
| END_ADDR  |    |    | Reserved |
| R/W-DFFFh |    |    | R-FFFFh  |

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 6-18. MPU2 Programmable Range  $n$  End Address Register (PROG $n$ \_MPEAR)  
Field Descriptions**

| Bit   | Field    | Value       | Description                |
|-------|----------|-------------|----------------------------|
| 31-16 | END_ADDR | C000h–DFFFh | Start address for range N. |
| 15-0  | Reserved | FFFFh       | Reserved                   |

### 6.3.12 Programmable Range *n* Memory Protection Page Attributes Register (PROG<sub>*n*</sub> MPPA)

The programmable range *n* memory protection page attributes register (PROG<sub>*n*</sub>\_MPPA) holds the permissions for the region *n*. This register is writeable only by a supervisor entity. The PROG<sub>*n*</sub>\_MPPA is shown in [Figure 6-16](#) and described in [Table 6-19](#).

**Figure 6-16. Programmable Range Memory Protection Page Attributes Register (PROG<sub>n</sub>\_MPPA)**

[illegible]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 6-19. Programmable Range Memory Protection Page Attributes Register (PROG<sub>n</sub>\_MPPA)**

| Bit   | Field    | Value | Description                              |

### 6.3.13 Fault Address Register (FLTADDRR)

The fault address register (FLTADDRR) holds the address of the first protection fault transfer. The FLTADDRR is shown in [Figure 6-17](#) and described in [Table 6-20](#).

**Figure 6-17. Fault Address Register (FLTADDRR)**

LEGEND: R = Read only; -n = value after reset

**Table 6-20. Fault Address Register (FLTADDRR) Field Descriptions**

| Bit  | Field   | Value        | Description              |
|------|---------|--------------|--------------------------|
| 31-0 | FLTADDR | 0-FFFF FFFFh | Memory address of fault. |

### 6.3.14 Fault Status Register (FLTSTAT)

The fault status register (FLTSTAT) holds the status and attributes of the first protection fault transfer. The FLTSTAT is shown in [Figure 6-18](#) and described in [Table 6-21](#).

**Figure 6-18. Fault Status Register (FLTSTAT)**

LEGEND: R = Read only; -n = value after reset

**Table 6-21. Fault Status Register (FLTSTAT) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                          |
|-------|----------|---------|----------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved | 0       | Reserved                                                                                                             |
| 23-16 | MSTID    | 0-FFh   | Master ID of fault transfer.                                                                                         |
| 15-13 | Reserved | 0       | Reserved                                                                                                             |
| 12-9  | PRIVID   | 0-Fh    | Privilege ID of fault transfer.                                                                                      |
| 8-6   | Reserved | 0       | Reserved                                                                                                             |
| 5-0   | TYPE     | 0-3Fh   | Fault type. The TYPE bit field is cleared when a 1 is written to the CLEAR bit in the fault clear register (FLTCLR). |
|       |          | 0       | No fault.                                                                                                            |
|       |          | 1h      | User execute fault.                                                                                                  |
|       |          | 2h      | User write fault.                                                                                                    |

### 6.3.15 Fault Clear Register (FLTCLR)

The fault clear register (FLTCLR) allows software to clear the current fault so that another can be captured in the fault status register (FLTSTAT) as well as produce an interrupt. Only the TYPE bit field in FLTSTAT is cleared when a 1 is written to the CLEAR bit. The FLTCLR is shown in [Figure 6-19](#) and described in [Table 6-22](#).

**Figure 6-19. Fault Clear Register (FLTCLR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 6-22. Fault Clear Register (FLTCLR) Field Descriptions**

| Bit  | Field    | Value | Description                                                  |
|------|----------|-------|--------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                     |
| 0    | CLEAR    |       | Command to clear the current fault. Writing 0 has no effect. |
|      |          | 0     | No effect.                                                   |
|      |          | 1     | Clear the current fault.                                     |

## Device Clocking

| 7.2 Frequency Flexibility..... | 130  |
| 7.3 Peripheral Clocking .....  | 131  |

## 7.1 Overview

This device requires two primary reference clocks:

- One reference clock is required for the phase-locked loop controllers (PLLs)
- One reference clock is required for the real-time clock (RTC) module.

These reference clocks may be sourced from either the on-board oscillator via an externally supplied crystal or by a direct external oscillator input. For detailed specifications on clock frequency and voltage requirements, see the electrical specifications in your device-specific data manual.

In addition to the reference clocks required for the PLLs and RTC module, some peripherals, such as the USB, may also require an input reference clock to be supplied. All possible input clocks are described in [Table 7-1](#). The CPU and the majority of the device peripherals operate at fixed ratios of the primary system/CPU clock frequency, as listed in [Table 7-2](#). However, there are two system clock domains that do not require a fixed ratio to the CPU, these are PLL0\_SYSCLK3 and PLL0\_SYSCLK7. [Figure 7-1](#) shows the clocking architecture.

**Table 7-1. Device Clock Inputs**

| Peripheral        | Input Clock Signal Name      |
|-------------------|------------------------------|
| Oscillator/PLL    | OSCIN                        |
| RTC               | RTC_XI                       |
| JTAG              | TCK, RTCK                    |
| EMAC RMII         | RMII_MHZ_50_CLK              |
| EMAC MII          | MII_TXCLK, MII_RXCLK         |
| USB2.0 and USB1.1 | USB_REFCLKIN                 |
| I2Cs              | I2Cn_SCL                     |
| Timers            | TM64Pn_IN12                  |
| SATA              | SATA_REFCLKP, SATA_REFCLKN   |
| SPIs              | SPIn_CLK                     |
| uPP               | UPP_CHn_CLK                  |

## 7.2 Frequency Flexibility

There are two PLLs on the device with similar architecture and behavior. Each PLL has two clocking modes:

- PLL Bypass
- PLL Active

When the PLL is in Bypass mode, the reference clock supplied on OSCIN serves as the clock source from which all of the system clocks (SYSCLK1 to SYSCLK7) are derived. This means that when the PLL is in Bypass mode, the reference clock supplied on OSCIN passes directly to the system of PLLDIV blocks that creates each of the system clocks. For PLL0 only, the EXTCLKSRC bit in PLLCTL can be configured to use PLL1\_SYSCLK3 as the Bypass mode reference clock.

When the PLL operates in Active mode, the PLL is enabled and the PLL multiplier setting is used to multiply the input clock frequency supplied on the OSCIN pin up to the desired frequency. It is this multiplied frequency that all system clocks are derived from in PLL Active mode.

The output of the PLL multiplier passes through a post divider (POSTDIV) block and then is applied to the system of PLLDIV blocks that creates each of the system clock domains (SYSCLK1 to SYSCLK7). Each SYSCLK $n$  has a PLLDIV $n$  block associated with it. See the *Phase-Locked Loop Controller (PLLC)* chapter for more details on the PLL.

The combination of the PLL multiplier, POSTDIV, and PLLDIV blocks provides flexibility in the frequencies that the system clock domains support. This flexibility does have limitations, as follows:

- OSCIN input frequency is limited to a supported range.
- The output of the PLL Multiplier must be within the range specified in the device-specific data manual.
- The output of each PLLDIV block must be less than or equal to the maximum device frequency specified in the device-specific data manual.

---

**NOTE:** The above limitations are provided here as an example and are used to illustrate the recommended configuration of the PLL controller. These limitations may vary based on core voltage and between devices. See the device-specific data manual for more details.

---

[Table 7-3](#) shows examples of possible PLL multiplier settings, along with the available PLL post-divider modes. The PLL post-divider modes are defined by the value programmed in the RATIO field of the PLL post-divider control register (POSTDIV). For Div1, Div2, Div3, and Div4 modes, the RATIO field would be programmed to 0, 1, 2, and 3, respectively. The Div1, Div2, Div3, and Div4 modes are shown here as an example. Additional post-divider modes are supported and are documented in the *Phase-Locked Loop Controller (PLLC)* chapter.

---

**NOTE:** PLL power consumption increases as the output frequency of the PLL multiplier increases. To decrease PLL power consumption, the lowest PLL multiplier (PLLM) setting should be chosen that achieves the desired frequency. For example, if 200 MHz is the desired CPU operating frequency and the OSCIN frequency is 25 MHz; lower power consumption is achieved by choosing a PLLM setting of  $\times 16$  and a post-divider (POSTDIV) setting of /2 instead of a PLLM setting of  $\times 24$  and a POSTDIV setting of /3, even though both of these modes would result in a CPU frequency of 200 MHz.

---

**Table 7-3. Example PLL Frequencies**

| OSCIN Frequency | PLL Multiplier | Multiplier Frequency | Div1 | Div2 | Div3 | Div4  |
|-----------------|----------------|----------------------|------|------|------|-------|
| 20              | 30             | 600 MHz              | 600  | 300  | 200  | 150   |
| 24              | 25             | 600 MHz              | 600  | 300  | 200  | 150   |
| 25              | 24             | 600 MHz              | 600  | 300  | 200  | 150   |

## 7.3 Peripheral Clocking

### 7.3.1 USB Clocking

Figure 7-2 shows the clock connections for the USB2.0 module. The USB2.0 subsystem requires a reference clock for its internal PLL. This reference clock can be sourced from either the USB\_REFCLKIN pin or from the AUXCLK of the system PLL. The reference clock input to the USB2.0 subsystem is selected by programming the USB0PHYCLKMUX bit in the chip configuration 2 register (CFGCHIP2) of the System Configuration Module. The USB\_REFCLKIN source should be selected when it is not possible (such as when specific audio rates are required) to operate the device at one of the allowed input frequencies to the USB2.0 subsystem. The USB2.0 subsystem peripheral bus clock is sourced from PLL0\_SYSCLK2.

The USB1.1 subsystem requires both a 48 MHz (CLK48) and a 12 MHz (CLK12) clock input. The 12 MHz clock is derived from the 48 MHz clock. The 48 MHz clock required by the USB1.1 subsystem can be sourced from either the USB\_REFCLKIN or from the 48 MHz clock provided by the USB2.0 PHY. The CLK48 source is selected by programming the USB1PHYCLKMUX bit in CFGCHIP2 of the System Configuration Module. The USB1.1 subsystem peripheral bus clock is sourced from PLL0\_SYSCLK4. See Table 7-4.

---

**NOTE:** If the USB1.1 subsystem is used and the 48 MHz clock input is sourced from the USB2.0 PHY, then the USB2.0 must be configured to always generate the 48 MHz clock. The USB0PHY\_PLLON bit in CFGCHIP2 controls the USB2.0 PHY, allowing or preventing it from stopping the 48 MHz clock during USB SUSPEND. When the USB0PHY\_PLLON bit is set to 1, the USB2.0 PHY is prevented from stopping the 48 MHz clock during USB SUSPEND; when the USB0PHY\_PLLON bit is cleared to 0, the USB2.0 PHY is allowed to stop the 48 MHz clock during USB SUSPEND.

---

| 0                                 | 0                                 | USB_REFCLKIN              | CLK48MHz output<br>from USB2.0 PHY | USB_REFCLKIN must be 12, 24, 48, 19.2, 38.4, 13, 26, 20, or 40 MHz. The PLL inside the USB2.0 PHY can be configured to accept any of these input clock frequencies.                             |
| 0                                 | 1                                 | USB_REFCLKIN              | USB_REFCLKIN                       | USB_REFCLKIN must be 48 MHz. The PLL inside the USB2.0 PHY can be configured to accept this input clock frequency.                                                                              |
| 1                                 | 0                                 | PLL0_AUXCLK               | CLK48MHz output<br>from USB2.0 PHY | PLL0_AUXCLK must be 12, 24, 48, 19.2, 38.4, 13, 26, 20, or 40 MHz. The PLL inside the USB2.0 PHY can be configured to accept any of these input clock frequencies.                              |
| 1                                 | 1                                 | PLL0_AUXCLK               | USB_REFCLKIN                       | PLL0_AUXCLK must be 12, 24, 48, 19.2, 38.4, 13, 26, 20, or 40 MHz. The PLL inside the USB2.0 PHY can be configured to accept any of these input clock frequencies. USB_REFCLKIN must be 48 MHz. |

### 7.3.2 DDR2/mDDR Memory Controller Clocking

The DDR2/mDDR memory controller requires two input clocks to source VCLK and 2X\_CLK (see [Figure 7-3](#)):

- VCLK is sourced from PLL0\_SYSCLK2/2 that clocks the command FIFO, write FIFO, and read FIFO of the DDR2/mDDR memory controller. From this, VCLK drives the interface to the peripheral bus.
- 2X\_CLK is sourced from PLL1\_SYSCLK1.

2X\_CLK clock is again divided down by 2 in the DDR PHY controller to generate a clock called MCLK. The MCLK domain consists of the DDR2/mDDR memory controller state machine and memory-mapped registers. This clock domain is clocked at the rate of the external DDR2/mDDR memory, 2X\_CLK/2.

[Table 7-5](#) shows example PLL register settings based on the OSCIN reference clock frequency of 25 MHz. From these example configurations, the following observations are made:

- To achieve the maximum frequency (150 MHz) supported by the DDR2/mDDR memory controller and the typical CPU frequency of 300 MHz, the output of the PLL multiplier should be set to be 300 MHz and the DDR\_CLK source should be set to PLL1\_SYSCLK1.
- The frequency of the PLL1 direct output clock is fixed at the output frequency of the PLL1 multiplier block.
- The PLLDIV1 block that sets the divider ratio for SYSCLK1 can be changed to achieve various clock frequencies.
- For certain PLL1 multiplier and PLL1 post-divider control register (POSTDIV) settings, a higher clock frequency can be achieved by selecting SYSCLK1 as the clock source for 2X\_CLK.

If the DDR2/mDDR memory controller is not in use and the DDR\_CLK and  $\overline{\text{DDR\_CLK}}$  are used in the application as a free running clock that could be used by an FPGA or for some other purpose, then 2X\_CLK should be used as the source for DDR\_CLK and  $\overline{\text{DDR\_CLK}}$  and VCLK should be gated off. This allows clock gating of the majority of the logic in the DDR2/mDDR memory controller via the LPSC while still providing a clock on the DDR\_CLK and  $\overline{\text{DDR\_CLK}}$ .

---

**NOTE:** DDR\_CLK and  $\overline{\text{DDR\_CLK}}$  are output clock signals.

---

<sup>(1)</sup> See [Section 7.2](#) for explanation of POSTDIV divider modes.

### 7.3.3 EMIFA Clocking

EMIFA requires a single input clock source. The EMIFA clock can be sourced from either PLL0\_SYSCLK3 or DIV4P5 (see [Figure 7-4](#)). The EMA\_CLKSRC bit in the chip configuration 3 register (CFGCHIP3) of the System Configuration Module controls whether PLL0\_SYSCLK3 or DIV4P5 is selected as the clock source for EMIFA.

Selecting the appropriate clock source for EMIFA is determined by the desired clock rate. [Table 7-6](#) shows example PLL register settings and the resulting DIV4P5 and PLL0\_SYSCLK3 frequencies based on the OSCIN reference clock frequency of 25 MHz. From these example configurations, the following observations can be made:

- To achieve a typical frequency of 100 MHz supported by EMIFA and the typical CPU frequency of 300 MHz, the output of the PLL multiplier should be set to 600 MHz and the EMA\_CLK source should be set to PLL0\_SYSCLK3 with the PLLDIV3 register set to 3.
- The frequency of the DIV4P5 clock is fixed at the output frequency of the PLL multiplier block divided by 4.5.
- The PLLDIV3 block that sets the divider ratio for PLL0\_SYSCLK3 can be changed to achieve various clock frequencies.

**Figure 7-4. EMIFA Clocking Diagram**

**Table 7-6. EMIFA Frequencies**

| OSCIN Frequency | PLL Multiplier Register Setting | Multiplier Frequency | Post Divider Mode <sup>(1)</sup> | POSTDIV Output Frequency | DIV4P5  | PLLDIV3 Register Setting | PLL0_SYSCLK3 |
|-----------------|---------------------------------|----------------------|----------------------------------|--------------------------|---------|--------------------------|--------------|

<sup>(1)</sup> See [Section 7.2](#) for explanation of POSTDIV divider modes.

### 7.3.4 EMAC Clocking

The EMAC module sources its peripheral bus interface reference clock from PLL0\_SYSCLK4 that is at a fixed ratio of the CPU clock. The external clock requirement for EMAC varies with the interface used. When the MII interface is active, the MII\_TXCLK and MII\_RXCLK signals must be provided from an external source. When the RMII interface is active, the RMII 50 MHz reference clock is sourced either from an external clock on the RMII\_MHZ\_50\_CLK pin or from PLL0\_SYSCLK7 (as shown in [Figure 7-5](#)). The PINMUX15\_3\_0 bits in the pin multiplexing control 15 register (PINMUX15) of the System Configuration Module control this clock selection:

- PINMUX15\_3\_0 = 0: enables sourcing of the 50 MHz reference clock from an external source on the RMII\_MHZ\_50\_CLK pin.
- PINMUX15\_3\_0 = 8h: enables sourcing of the 50 MHz reference clock from PLL0\_SYSCLK7. Also, PLL0\_SYSCLK7 is driven out on the RMII\_MHZ\_50\_CLK pin.

[Table 7-7](#) shows example PLL register settings and the resulting PLL0\_SYSCLK7 frequencies based on the OSCIN reference clock frequency of 25 MHz.

**Figure 7-5. EMAC Clocking Diagram**

**NOTE:** The SYSCLK7 output clock does not meet the RMII reference clock specification of 50 MHz +/-50 ppm.

**Table 7-7. EMAC Reference Clock Frequencies**

| OSCIN Frequency | PLL Multiplier Register Setting | Multiplier Frequency | Post Divider Mode <sup>(1)</sup> | POSTDIV Output Frequency | PLLDIV7 Register Setting | PLL0_SYSCLK7                  |
|-----------------|---------------------------------|----------------------|----------------------------------|--------------------------|--------------------------|-------------------------------|
| 25              | 24                              | 600 MHz              | Div2                             | 300 MHz                  | 5                        | 50 MHz                        |
|                 |                                 |                      | Div3                             | 200 MHz                  | 3                        | 50 MHz                        |
|                 |                                 |                      | Div4                             | 150 MHz                  | 2                        | 50 MHz                        |
| 25              | 18                              | 450 MHz              | Div2                             | 225 MHz                  |                          | Not Applicable <sup>(2)</sup> |
|                 |                                 |                      | Div3                             | 150 MHz                  | 2                        | 50 MHz                        |
|                 |                                 |                      | Div4                             | 112.5 MHz                |                          | Not Applicable <sup>(2)</sup> |

<sup>(1)</sup> See [Section 7.2](#) for explanation of POSTDIV divider modes.

<sup>(2)</sup> Certain PLL configurations do not support a 50 MHz clock on PLL0\_SYSCLK7.

### 7.3.5 uPP Clocking

Figure 7-6 displays the clock connections for the uPP module. The uPP subsystem requires a module clock to drive its internal logic and a transmit clock to drive I/O signals in transmit mode. The module clock is always sourced by PLL0\_SYSCLK2. The transmit clock is sourced by three different clocks: PLL0\_SYSCLK2 (default), PLL1\_SYSCLK2, or the externally driven UPP\_2xTXCLK pin. The transmit clock source is selected by the UPP\_TX\_CLKSRC and ASYNC3\_CLKSRC bits in the chip configuration 3 register (CFGCHIP3) of the System Configuration Module. Table 7-8 lists the register values that select each of the three possible clock sources.

Regardless of the source, the uPP transmit clock speed cannot exceed the uPP module clock speed. The module clock speed must be greater than or equal to the transmit clock speed.

**Figure 7-6. uPP Clocking Diagram**

**Table 7-8. uPP Transmit Clock Selection**

| CFGCHIP3.UPP_TX_CLKSRC bit | CFGCHIP3.ASYNC3_CLKSRC bit | uPP Transmit Clock Source |
|----------------------------|----------------------------|---------------------------|
| 0                          | 0                          | PLL0_SYSCLK2              |
| 0                          | 1                          | PLL1_SYSCLK2              |
| 1                          | x                          | UPP_2xTXCLK pin           |

### 7.3.6 McASP Clocking

As shown in Figure 7-7, the McASP peripheral requires multiple clock sources. Internally, the module clock is selected to be either PLL0\_SYSCLK2 or PLL1\_SYSCLK2 by configuring the ASYNC3\_CLKSRC bit in the chip configuration 3 register (CFGCHIP3) of the System Configuration Module.

The transmit and receive clocks are sourced internally or externally by configuring the McASP clock control registers ACLKCTL, AHCLKCTL, ACLKXCTL, and AHCLKXCTL. If an external clock is driven into a high-frequency master clock (AHCLKX or AHCLKR), the McASP module allows for a mixed clock mode where the associated lower frequency clock (ACLKX or ACLKR) can be derived from the high-frequency master clock through a programmable divider.

When the internal clock source option is selected, the transmit and receive clocks are derived from the PLL0\_AUXCLK clock through programmable dividers.

Figure 7-7. McASP Clocking Diagram

### 7.3.7 I/O Domains

The I/O domains refer to the frequencies of the peripherals that communicate through device pins. In many cases, there are frequency requirements for a peripheral pin interface that are set by an outside standard and must be met. It is not necessarily possible to obtain these frequencies from the on-chip clock generation circuitry, so the frequencies must be obtained from external sources and are asynchronous to the CPU frequency by definition.

The peripherals can be divided into the following groups, depending upon their clock requirements, as shown in [Table 7-9](#).

**Table 7-9. Peripherals**

| Peripheral Group                     | Peripheral Group Definition                                                                                                                                                                                                                                                               | Peripherals Contained within Group | Source of Peripheral Clock               |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|------------------------------------------|
| RTC                                  | Operates off of a dedicated 32 kHz crystal oscillator.                                                                                                                                                                                                                                    | RTC                                | —                                        |
| Fixed-Frequency Peripherals          | As the name suggests, fixed-frequency peripherals have a fixed-frequency. They are fed the AUXCLK directly from the oscillator input.                                                                                                                                                     | Timer64P0/P1                       | —                                        |
|                                      |                                                                                                                                                                                                                                                                                           | I2C0                               | —                                        |
| Synchronous Peripherals              | Synchronous peripherals have their frequencies derived from the CPU clock frequency. The peripheral system clock frequency changes accordingly, if the PLL0 frequency changes. Most synchronous peripherals have internal dividers so they can generate their required clock frequencies. | MMC/SDs                            | PLL0_SYSCCLK2                            |
|                                      |                                                                                                                                                                                                                                                                                           | HPI                                | PLL0_SYSCCLK2                            |
|                                      |                                                                                                                                                                                                                                                                                           | UART0                              | PLL0_SYSCCLK2                            |

## 8.1 Introduction

This device has two phase-locked loop (PLL) controllers, PLLC0 and PLLC1. These PLL controllers provide clock signals to most of the components of the device through various clock dividers.

Both PLL0 and PLL1 provide the following:

- Glitch-free transitions when clock settings are changed
- Domain clock alignment
- Clock gating
- PLL power-down

The clock outputs generated by the PLL controllers are:

- Domain clocks: PLL0\_SYSCLK[1-7] and PLL1\_SYSCLK[1-3]
- Auxiliary clock (PLL0\_AUXCLK) from the PLLC0 reference clock source

Dividers that can be used for the PLL controllers are:

- Pre-PLL divider: PREDIV
- Post-PLL divider: POSTDIV
- SYSCLK divider: D1, ..., Dn

Various other control signals supported are:

- PLL multiplier: PLLM
- Software-programmable PLL bypass: PLEN

## 8.2 PLL Controllers

PLL0 and PLL1 share the same internal architecture so they also share the same approach for mode configuration.

PLL0 provides the primary system clock to the device. PLL0 operations are software programmable through the PLL controller 0 (PLLC0) registers.

PLL1 provides the reference clocks to various peripherals (including DDR2/mDDR) and may generate clocks that are asynchronous to the PLL0 clocks. PLL1 operations are software programmable through the PLL controller 1 (PLLC1) registers.

[Figure 8-1](#) shows the PLLC0 and PLLC1 architecture.

The PLL0 and PLL1 multipliers are controlled by their respective PLL multiplier control register (PLLM). The PLLM defaults to a multiplier value of 13h at power-up, which results in a PLL multiplier of 20×. The PLL0 and PLL1 output clocks may be divided-down for slower device operation using the PLL post-divider control register (POSTDIV). The POSTDIV has a default value of /2, but may be modified through software (using the RATIO field in POSTDIV) to achieve lower device operation frequencies. The default PLLM and POSTDIV settings produce a 300-MHz PLL output clock when given a 30-MHz clock source.

At power-up, PLL0 and PLL1 are powered-down/disabled and must be powered-up by software through the PLLPWRDN bit in their respective PLL control register (PLLCTL). Before each PLL completes the power-up and frequency-lock sequence, the system operates in bypass mode by default and the system clock (OSCIN) is provided directly from an input reference clock (square wave or internal oscillator) selected by the CLKMODE bit in PLLCTL. After the power-up and frequency-lock sequences are complete, software can switch the device to PLL mode operation (set the PLEN bit in PLLCTL to 1).

The PLL controller registers are listed in [Section 8.3](#).

Figure 8-1. PLLC Structure

## 8.2.1 Device Clock Generation

The PLL controllers (PLL0 and PLL1) manage the clock ratios, alignment, and gating for the device system clocks. Various PLL mode attributes such as pre-division, multiplier, and post-division are software programmable through the PLL controller registers. Additionally, the reset controller in PLL0 manages reset propagation through the device, clock alignment, and test points.

The PLL0 stage in PLL0 and PLL1 is capable of providing frequencies greater than what the SYSCLK dividers can handle. The POSTDIV stage should be programmed to keep the input to the SYSCLK dividers within operating limits. See the device datasheet for the maximum operating frequencies.

PLL0 and PLL1 generate several clocks for use by the various processors and modules. These reference clocks are summarized in [Table 8-1](#). Some output clock dividers require fixed values so that clock ratios between various device components are maintained regardless of PLL or bypass frequency.

**Table 8-1. System PLLC Output Clocks**

| Output Clock                | Used by                                                                                                                       | Default Ratio<br>(relative to PLL <sub>n</sub> _SYSCLK1) | Fixed Clock<br>Ratio |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|----------------------|
| <b>PLL0<sup>(1)</sup></b>   |                                                                                                                               |                                                          |                      |
| PLL0_SYSCLK1                | DSP                                                                                                                           | /1                                                       | Yes                  |
| PLL0_SYSCLK2                | ARM RAM/ROM, DSP ports, Shared RAM, UART0, EDMA, SPI0, MMC/SDs, VPIF, LCD, SATA, uPP, DDR2/mDDR (bus ports), USB2.0, HPI, PRU | /2                                                       | Yes                  |
| PLL0_SYSCLK3 <sup>(2)</sup> | EMIFA                                                                                                                         | /3                                                       | No                   |
| PLL0_SYSCLK4                | System configuration (SYSCFG), GPIO, PLLCs, PSCs, I2C1, EMAC/MDIO, USB1.1, ARM INT                                            | /4                                                       | Yes                  |
| PLL0_SYSCLK5                | Not used                                                                                                                      | /3                                                       | No                   |
| PLL0_SYSCLK6                | ARM                                                                                                                           | /1                                                       | Yes                  |
| PLL0_SYSCLK7                | EMAC RMII clock                                                                                                               | /6                                                       | No                   |
| PLL0_AUXCLK                 | I2C0, Timer64P0/P1, RTC, USB2.0 PHY, McASP0 serial clock                                                                      | PLL bypass clock                                         | No                   |
| PLL0_OBCLK                  | Observation clock (OBCLK) source                                                                                              | Pin configurable                                         | No                   |
| <b>PLL1</b>                 |                                                                                                                               |                                                          |                      |
| PLL1_SYSCLK1                | DDR2/mDDR PHY                                                                                                                 | /1 or disabled                                           | No                   |
| PLL1_SYSCLK2 <sup>(3)</sup> | ECAPs, UART1/2, Timer64P2/3, eHRPWMs, McBSPs, McASP0, SPI1 (all these modules use PLL0_SYSCLK2 by default)                    | /2 or disabled                                           | No                   |
| PLL1_SYSCLK3 <sup>(4)</sup> | PLL0 input reference clock (not configured by default)                                                                        | /3 or disabled                                           | No                   |

- (1) The divide values in PLL0 for PLL0\_SYSCLK1/PLL0\_SYSCLK6, PLL0\_SYSCLK2, and PLL0\_SYSCLK4 can be changed for power savings, but the device must maintain the 1:2:4 clock ratios between the clock domains.
- (2) PLL0 supports an additional post-divider value of /4.5 that can be used for EMIFA clock generation. When this /4.5 value is used, the resulting clock will not have a 50% duty cycle. Instead, the duty cycle will be 44.4%. The EMIFA uses PLL0\_SYSCLK3 by default, but can be configured to use a /4.5 divide-down of PLL0\_PLLOUT instead of PLL0\_SYSCLK3 by programming the EMA\_CLKSRC and DIV45PENA bits in the chip configuration 3 register (CFGCHIP3) of the system configuration (SYSCFG) module.
- (3) The ASYNC3 modules use PLL0\_SYSCLK2 by default, but all these modules can be configured as a group to use PLL1\_SYSCLK2 by programming the ASYNC3\_CLKSRC bit in the chip configuration 3 register (CFGCHIP3) of the system configuration (SYSCFG) module.
- (4) The PLL0 input clock source can be configured to use PLL1\_SYSCLK3 instead of OSCIN by programming the EXTCLKSRC bit in the PLL0 PLL control register (PLLCTL). The PLL1 input clock source will also be OSCIN.

## 8.2.2 Steps for Programming the PLLs

Note that there is a lock mechanism implemented to protect the PLL controller registers. See [Section 8.2.2.1](#) for information on unlocking the PLL controller registers.

Refer to the appropriate subsection on how to program the PLL clocks:

- If the PLL is powered down (PLLWDRN bit in PLLCTL is set to 1), follow the full PLL initialization procedure in [Section 8.2.2.2](#).
- If the PLL is not powered down (PLLWDRN bit in PLLCTL is cleared to 0), follow the sequence in [Section 8.2.2.3](#) to change the PLL multiplier.
- If the PLL is already running at a desired multiplier and only the SYSCLK dividers will be updated, follow the sequence in [Section 8.2.2.4](#).

Note that the PLLs are powered down after a Power-on Reset (POR). The PLLs are not powered down after a Warm Reset (RESET), but the PLEN bit in PLLCTL is cleared to 0 (bypass mode) and the PLLDIVx registers are reset to default values.

### 8.2.2.1 Locking/Unlocking PLL Register Access

A lock mechanism is implemented on the device to prevent inadvertent writes to the PLL controller registers. This provides protection from stopping modules when the module clocks are disabled. For example, the watchdog timer that runs on the PLL0\_AUXCLK will stop if this PLL clock is unintentionally disabled.

The PLL lock bits are located within the system configuration (SYSCFG) module:

- When set, the PLL\_MASTER\_LOCK bit in the chip configuration 0 register (CFGCHIP0) locks PLLC0.
- When set, the PLL1\_MASTER\_LOCK bit in the chip configuration 3 register (CFGCHIP3) locks PLLC1.

Because the SYSCFG module has its own lock mechanism, the SYSCFG module must be unlocked first by writing to the KICK0R and KICK1R registers before the PLL lock bits can be cleared. Like the KICK registers, the PLL lock bits can only be modified while in a privileged mode. See the *System Configuration (SYSCFG) Module* chapter for information on privilege type and the KICK0R and KICK1R registers.

---

**NOTE:** The PLL\_MASTER\_LOCK bit in CFGCHIP0 and the PLL1\_MASTER\_LOCK bit in CFGCHIP3 default to unlocked after reset, so the following procedure is only required if the PLLs have been locked (set to 1).

---

To modify the PLL controller registers, use the following sequence:

1. Write the correct key values to KICK0R and KICK1R registers.
2. Clear the PLL\_MASTER\_LOCK bit in CFGCHIP0 and/or the PLL1\_MASTER\_LOCK bit in CFGCHIP3, as required.
3. Configure the desired PLL controller register values.
4. Set the PLL\_MASTER\_LOCK bit in CFGCHIP0 and/or the PLL1\_MASTER\_LOCK bit in CFGCHIP3, as required.
5. Write an incorrect key value to the KICK0R and KICK1R registers.

### 8.2.2.2 Initializing PLL Mode from PLL Power Down

If the PLL is powered down (PLLPWDN bit in PLLCTL is set to 1), perform the following procedure to initialize the PLL:

1. Program the CLKMODE bit in PLLC0 PLLCTL.
2. Switch the PLL to bypass mode:
  - (a) Clear the PLENSRC bit in PLLCTL to 0 (allows PLEN bit to take effect).
  - (b) For PLL0 only, select the clock source by programming the EXTCLKSRC bit in PLLCTL.
  - (c) Clear the PLEN bit in PLLCTL to 0 (PLL in bypass mode).
  - (d) Wait for 4 OSCIN cycles to ensure that the PLLC has switched to bypass mode.
3. Clear the PLLRST bit in PLLCTL to 0 (resets PLL).
4. Clear the PLLPWDN bit in PLLCTL to 0 (brings PLL out of power-down mode).
5. Program the desired multiplier value in PLLM. Program the POSTDIV, as needed.
6. If desired, program PLLDIV<sub>n</sub> registers to change the SYSCLK<sub>n</sub> divide values:
  - (a) Wait for the GOSTAT bit in PLLSTAT to clear to 0 (indicates that no operation is currently in progress).
  - (b) Program the RATIO field in PLLDIV<sub>n</sub>.
  - (c) Set the GOSET bit in PLLCMD to 1 (initiates a new divider transition).
  - (d) Wait for the GOSTAT bit in PLLSTAT to clear to 0 (completion of divider change).
7. Set the PLLRST bit in PLLCTL to 1 (brings PLL out of reset).
8. Wait for the PLL to lock. See the device-specific data manual for PLL lock time.
9. Set the PLEN bit in PLLCTL to 1 (removes PLL from bypass mode).

### 8.2.2.3 Changing PLL Multiplier

If the PLL is not powered down (PLLPWDN bit in PLLCTL is cleared to 0), perform the following procedure to change the PLL multiplier:

1. Switch the PLL to bypass mode:
  - (a) Clear the PLENSRC bit in PLLCTL to 0 (allows PLEN bit to take effect).
  - (b) For PLL0 only, select the clock source by programming the EXTCLKSRC bit in PLLCTL.
  - (c) Clear the PLEN bit in PLLCTL to 0 (PLL in bypass mode).
  - (d) Wait for 4 OSCIN cycles to ensure that the PLLC has switched to bypass mode.
2. Clear the PLLRST bit in PLLCTL to 0 (resets PLL).
3. Program the desired multiplier value in PLLM. Program the POSTDIV, as needed.
4. If desired, program PLLDIV<sub>n</sub> registers to change the SYSCLK<sub>n</sub> divide values:
  - (a) Wait for the GOSTAT bit in PLLSTAT to clear to 0 (indicates that no operation is currently in progress).
  - (b) Program the RATIO field in PLLDIV<sub>n</sub>.
  - (c) Set the GOSET bit in PLLCMD to 1 (initiates a new divider transition).
  - (d) Wait for the GOSTAT bit in PLLSTAT to clear to 0 (completion of divider change).
5. Set the PLLRST bit in PLLCTL to 1 (brings PLL out of reset).
6. Wait for the PLL to lock. See the device-specific data manual for PLL lock time.
7. Set the PLEN bit in PLLCTL to 1 (removes PLL from bypass mode).

### 8.2.2.4 Changing SYSCLK Dividers

If the PLL is already operating at the desired multiplier mode, perform the following procedure to change the SYSCLK divider values:

1. Wait for the GOSTAT bit in PLLSTAT to clear to 0 (indicates that no operation is currently in progress).
2. Program the RATIO field in PLLDIV $n$ .
3. Set the GOSET bit in PLLCMD to 1 (initiates a new divider transition).
4. Wait for the GOSTAT bit in PLLSTAT to clear to 0 (completion of divider change).

## 8.3 PLLC Registers

[Table 8-2](#) lists the memory-mapped registers for the PLLC0 and [Table 8-3](#) lists the memory-mapped registers for the PLLC1.

### 8.3.1 PLLC0 Revision Identification Register (REVID)

The PLLC0 revision identification register (REVID) is shown in [Figure 8-2](#) and described in [Table 8-4](#).

**Figure 8-2. PLLC0 Revision Identification Register (REVID)**

LEGEND: R = Read only; -n = value after reset

**Table 8-4. PLLC0 Revision Identification Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description                       |
|------|-------|------------|-----------------------------------|
| 31-0 | REV   | 4481 3C00h | Peripheral revision ID for PLLC0. |

### 8.3.2 PLLC1 Revision Identification Register (REVID)

The PLLC1 revision identification register (REVID) is shown in [Figure 8-3](#) and described in [Table 8-5](#).

### Figure 8-3. PLLC1 Revision Identification Register (REVID)

LEGEND: R = Read only; -n = value after reset

### Table 8-5. PLLC1 Revision Identification Register (REVID) Field Descriptions

| Bit  | Field | Value      | Description                       |
|------|-------|------------|-----------------------------------|
| 31-0 | REV   | 4481 4400h | Peripheral revision ID for PLLC1. |

### 8.3.3 Reset Type Status Register (RSTYPE)

The reset type status register (RSTYPE) latches the cause of the last reset. If multiple reset sources are asserted simultaneously, RSTYPE records the reset source that deasserts last. If multiple reset sources are asserted and deasserted simultaneously, RSTYPE latches the highest priority reset source. RSTYPE is shown in [Figure 8-4](#) and described in [Table 8-6](#).

### Figure 8-4. Reset Type Status Register (RSTYPE)

LEGEND: R = Read only; -n = value after reset

### Table 8-6. Reset Type Status Register (RSTYPE) Field Descriptions

| Bit  | Field    | Value | Description                                           |
|------|----------|-------|-------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                              |
| 2    | PLLSWRST | 0     | PLL software reset.                                   |
|      |          | 0     | PLL soft reset was not the last reset to occur.       |
|      |          | 1     | PLL soft was the last reset to occur.                 |
| 1    | XWRST    |       | External warm reset.                                  |
|      |          | 0     | External warm reset was not the last reset to occur.  |
|      |          | 1     | External warm reset was the last reset to occur.      |
| 0    | POR      |       | Power on reset.                                       |
|      |          | 0     | Power On Reset (POR) was not the last reset to occur. |
|      |          | 1     | Power On Reset (POR) was the last reset to occur.     |

### 8.3.4 PLLC0 Reset Control Register (RSCTRL)

The reset control register (RSCTRL) allows the device to perform a software-initiated reset. Before writing to the SWRST bit, the register must be unlocked by writing the key value of 5A69h to the KEY bit field. The KEY bit field reads back as Ch when the register is unlocked; any other key value is invalid and indicates that the register is locked. Any write to the register following a successful unlock relocks the register. RSCTRL is shown in [Figure 8-5](#) and described in [Table 8-7](#).

**Figure 8-5. Reset Control Register (RSCTRL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-7. Reset Control Register (RSCTRL) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                         |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------|
| 31-17 | Reserved | 0       | Reserved                                                                                                                            |
| 16    | SWRST    | 0       | PLL software reset. Register must be unlocked before writing to this bit. Writes are possible only when qualified with a valid key. |
|       |          | 1       | In software reset                                                                                                                   |
|       |          |         | Not in software reset                                                                                                               |
| 15-0  | KEY      | 0-FFFFh | RSCTRL unlock key. Key used to enable writes to RSCTRL.                                                                             |
|       |          | 3h      | Register is locked when read value is 3h.                                                                                           |
|       |          | Ch      | Register is unlocked when read value is Ch.                                                                                         |
|       |          | 5A69h   | RSCTRL unlock key                                                                                                                   |

### 8.3.5 PLLC0 Control Register (PLLCTL)

The PLLC0 control register (PLLCTL) is shown in [Figure 8-6](#) and described in [Table 8-8](#).

**Figure 8-6. PLLC0 Control Register (PLLCTL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### 8.3.6 PLLC1 Control Register (PLLCTL)

The PLLC1 control register (PLLCTL) is shown in [Figure 8-7](#) and described in [Table 8-9](#).

**Figure 8-7. PLLC1 Control Register (PLLCTL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-9. PLLC1 Control Register (PLLCTL) Field Descriptions**

| Bit  | Field    | Value | Description                                                        |
|------|----------|-------|--------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                           |
| 7-6  | Reserved | 1     | Reserved                                                           |
| 5    | PLENSRC  | 0     | This bit must be cleared before the PLEN bit will have any effect. |
| 4    | Reserved | 1     | Reserved. Write the default value when modifying this register.    |
| 3    | PLLRST   | 0     | PLL1 reset.                                                        |
|      |          | 0     | PLL1 reset is asserted.                                            |
|      |          | 1     | PLL1 reset is not asserted.                                        |
| 2    | Reserved | 0     | Reserved                                                           |
| 1    | PLLPWRDN | 0     | PLL1 power-down.                                                   |
|      |          | 0     | PLL1 is operating.                                                 |
|      |          | 1     | PLL1 is powered-down.                                              |
| 0    | PLEN     | 0     | PLL1 mode enables.                                                 |
|      |          | 0     | PLL1 is in bypass mode.                                            |
|      |          | 1     | PLL1 mode is enabled, not bypassed.                                |

### 8.3.7 PLLC0 OBSCLK Select Register (OCSEL)

The PLLC0 OBSCLK select register (OCSEL) controls which clock is output on the CLKOUT pin so that it may be used for test and debug purposes (in addition to its normal function of being a direct input clock divider). The OCSEL is shown in [Figure 8-8](#) and described in [Table 8-10](#).

**Figure 8-8. PLLC0 OBSCLK Select Register (OCSEL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-10. PLLC0 OBSCLK Select Register (OCSEL) Field Descriptions**

| Bit  | Field    | Value   | Description                                |
|------|----------|---------|--------------------------------------------|
| 31-5 | Reserved | 0       | Reserved                                   |

| 4-0   | RATIO    | 0-1Fh  | Divider ratio. Divider Value = RATIO + 1. RATIO defaults to 1 (PLL post-divide by 2). |

### 8.3.24 PLL Controller Command Register (PLLCMD)

The PLL controller command register (PLLCMD) contains the command bit for phase alignment. A write of 1 initiates the command; a write of 0 clears the bit, but has no effect. PLLCMD is shown in [Figure 8-25](#) and described in [Table 8-27](#).

**Figure 8-25. PLL Controller Command Register (PLLCMD)**

LEGEND: R/W = Read/Write; R = Read only; W0C = Write 0 to clear bit; -n = value after reset

**Table 8-27. PLL Controller Command Register (PLLCMD) Field Descriptions**

| Bit  | Field    | Value  | Description                                                             |
|------|----------|--------|-------------------------------------------------------------------------|
| 31-1 | Reserved | 0      | Reserved                                                                |
| 0    | GOSET    | 0<br>1 | GO bit for phase alignment.<br>Clear bit (no effect)<br>Phase alignment |

### 8.3.25 PLL Controller Status Register (PLLSTAT)

The PLL controller status register (PLLSTAT) is shown in [Figure 8-26](#) and described in [Table 8-28](#).

**Figure 8-26. PLL Controller Status Register (PLLSTAT)**

LEGEND: R = Read only; -n = value after reset

**Table 8-28. PLL Controller Status Register (PLLSTAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                             |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                |
| 2    | STABLE   | 0     | OSC counter done, oscillator assumed to be stable. By the time the device comes out of reset, this bit should become 1. |
|      |          | 1     | No                                                                                                                      |
|      |          | 1     | Yes                                                                                                                     |

### 8.3.28 PLLC0 PLLDIV Ratio Change Status Register (DCHANGE)

The PLLC0 PLLDIV ratio change status register (DCHANGE) indicates if the PLL0\_SYSCCLK $n$  divide ratio has been modified. DCHANGE is shown in [Figure 8-29](#) and described in [Table 8-31](#).

**Figure 8-29. PLLC0 PLLDIV Ratio Change Status Register (DCHANGE)**

|          |  |  |  |  |  |  |      |      |      |      |      |      |      |   |  |    |

### 8.3.36 Emulation Performance Counter 0 Register (EMUCNT0)

The emulation performance counter 0 register (EMUCNT0) is shown in [Figure 8-37](#) and described in [Table 8-39](#). EMUCNT0 is for emulation performance profiling. It counts in a divide-by-4 of the system clock. To start the counter, a write must be made to EMUCNT0. This register is not writable, but only used to start the register. After the register is started, it can not be stopped except for power on reset. When EMUCNT0 is read, it snapshots EMUCNT0 and EMUCNT1. The snapshot version is what is read. It is important to read the EMUCNT0 followed by EMUCNT1 or else the snapshot version may not get updated correctly.

**Figure 8-37. Emulation Performance Counter 0 Register (EMUCNT0)**

LEGEND: R = Read only; -n = value after reset

**Table 8-39. Emulation Performance Counter 0 Register (EMUCNT0) Field Descriptions**

| Bit  | Field | Value        | Description                      |
|------|-------|--------------|----------------------------------|
| 31-0 | COUNT | 0-FFFF FFFFh | Counter value for lower 64-bits. |

### 8.3.37 Emulation Performance Counter 1 Register (EMUCNT1)

The emulation performance counter 1 register (EMUCNT1) is shown in [Figure 8-38](#) and described in [Table 8-40](#). EMUCNT1 is for emulation performance profiling. To start the counter, a write must be made to EMUCNT0. This register is not writable, but only used to start the register. After the register is started, it can not be stopped except for power on reset. When EMUCNT0 is read, it snapshots EMUCNT0 and EMUCNT1. The snapshot version is what is read. It is important to read the EMUCNT0 followed by EMUCNT1 or else the snapshot version may not get updated correctly.

## 9.1 Introduction

The Power and Sleep Controllers (PSC) are responsible for managing transitions of system power on/off, clock on/off, resets (device level and module level). It is used primarily to provide granular power control for on chip modules (peripherals and CPU). A PSC module consists of a Global PSC (GPSC) and a set of Local PSCs (LPSCs).

The GPSC contains memory mapped registers, PSC interrupts, a state machine for each peripheral/module it controls. An LPSC is associated with every module that is controlled by the PSC and provides clock and reset control. Many of the operations of the PSC are transparent to user (software), such as power on and reset control. However, the PSC module(s) also provide you with interface to control several important power, clock and reset operations. The module level power, clock and reset operations managed and controlled by the PSC are the focus of this chapter.

The PSC includes the following features:

- Manages chip power-on/off
- Provides a software interface to:
  - Control module clock enable/disable
  - Control module reset
  - Control CPU local reset
- Manages on-chip RAM sleep modes (for DSP memories and L3 RAM)
- Supports IcePick emulation features: power, clock and reset

## 9.2 Power Domain and Module Topology

This device includes two PSC modules. Each PSC module consists of:

- an Always On power domain
- an additional pseudo/internal power domain that manages the sleep modes for the RAMs present in the DSP subsystem and the L3 RAM, respectively

Each PSC module controls clock states for several on the on chip modules, controllers and interconnect components. [Table 9-1](#) and [Table 9-2](#) lists the set of peripherals/modules that are controlled by the PSC, the power domain they are associated with, the LPSC assignment and the default (power-on reset) module states. See the device-specific data manual for the peripherals available on a given device. The module states and terminology are defined in [Section 9.2.2](#).

Even though there are 2 PSC modules with 2 power domains each on the device, both PSC modules and all the power domains are powered by the CVDD pins of the device. All power domains are on when the chip is powered on. There is no provision to remove power externally for the non Always On domains, that is, the pseudo/internal power domains.

There are a few modules/peripherals on the device that do not have an LPSC assigned to them. These modules do not have their module reset/clocks controlled by the PSC module. The decision to assign an LPSC to a module on a device is primarily based on whether or not disabling the clocks to a module will result in significant power savings. This typically depends on the size and the frequency of operation of the module.

---

**NOTE:** There are no LPSCs for peripherals in the Async2 clock domain (this includes RTC, Timer64P0/P1, and I2C0); from a power savings stand point, clock-gating these peripherals does not result in significant power savings.

---

**Table 9-1. PSC0 Default Module Configuration**

| LPSC Number | Module Name                   | Power Domain   | Default Module State | Auto Sleep/Wake Only |
|-------------|-------------------------------|----------------|----------------------|----------------------|
| 0           | EDMA3_0 Channel Controller 0  | AlwaysON (PD0) | SwRstDisable         | —                    |
| 1           | EDMA3_0 Transfer Controller 0 | AlwaysON (PD0) | SwRstDisable         | —                    |
| 2           | EDMA3_0 Transfer Controller 1 | AlwaysON (PD0) | SwRstDisable         | —                    |

| 21          | EDMA3_1 Transfer Controller 0 | AlwaysON (PD0) | SwRstDisable         | —                    |
| 22-23       | Not Used                      | —              | —                    | —                    |

<sup>(1)</sup> Note that the SATA module requires forced state transitions.

**Table 9-2. PSC1 Default Module Configuration (continued)**

| LPSC Number | Module Name | Power Domain   | Default Module State | Auto Sleep/Wake Only |
|-------------|-------------|----------------|----------------------|----------------------|
| 24          | SCR F0      | AlwaysON (PD0) | Enable               | Yes                  |
| 25          | SCR F1      | AlwaysON (PD0) | Enable               | Yes                  |
| 26          | SCR F2      | AlwaysON (PD0) | Enable               | Yes                  |
| 27          | SCR F6      | AlwaysON (PD0) | Enable               | Yes                  |
| 28          | SCR F7      | AlwaysON (PD0) | Enable               | Yes                  |
| 29          | SCR F8      | AlwaysON (PD0) | Enable               | Yes                  |
| 30          | BR F7       | AlwaysON (PD0) | Enable               | Yes                  |
| 31          | Shared RAM  | PD_SHRAM       | Enable               | —                    |

### 9.2.1 Power Domain States

A power domain can only be in one of the two states: ON or OFF, defined as follows:

- ON: power to the domain is on
- OFF: power to the domain is off

In this device, for both PSC0 and PSC1, the Always ON domain (or PD0 power domain), is always in the ON state when the chip is powered-on. This domain is not programmable to OFF state (See details on PDCTL register).

Additionally, for both PSC0 and PSC1, the PD1 power domains, the internal/pseudo power domain can either be in the ON state or OFF state. Furthermore, for these power domains the transition from ON to OFF state is further qualified by the PSC0/1.PDCTL1.PDMODE settings. The PDCTL1.PDMODE settings determines the various sleep mode for the on-chip RAM associated with module in the PD1 domain.

- On PSC0 PD1/PD\_DSP Domain: Controls the sleep state for DSP L1 and L2 Memories
- On PSC1 PD1/PD\_SHRAM Domain: Controls the sleep state for the 128KB Shared RAM

**NOTE:** Currently programming the PD1 power domain state to OFF is not supported. You should leave both the PDCTL1.NEXT and PDCTL1.PDMODE values at default/power on reset values.

Both PD0 and PD1 power domains in PSC0 and PSC1 are powered by the CVDD pins of the device. There is no capability to individually remove voltage/power from the DSP or Shared RAM power domains .

## 9.2.2 Module States

The PSC defines several possible states for a module. These various states are essentially a combination of the module reset asserted or de-asserted and module clock on/enabled or off/disabled. The various module states are defined in [Table 9-3](#).

The key difference between the Auto Sleep and Auto Wake states is that once the module is configured in Auto Sleep mode, it will transition back to the clock disabled state (automatically sleep) after servicing the internal read/write access request where as in Auto Wake mode, on receiving the first internal read/write access request, the module will permanently transition from the clock disabled to clock enabled state (automatically wake).

When the module state is programmed to Disable, SwRstDisable, Auto Sleep or Auto Wake modes, where in the module clocks are off/disabled, an external event or I/O request cannot enable the clocks. For the module to appropriately respond to such external request, it would need to be reconfigured to the Enable state.

### 9.2.2.1 Auto Sleep/Wake Only Configurations and Limitation

---

**NOTE:** Currently no modules should be configured in Auto Sleep or Auto Wake modes. If the module clocks need to be gated/disabled for power savings, you should program the module state to Disable. For Auto Sleep/Auto Wake Only modules, disabling the clock is not supported and they should be kept in their default "Enable" state.

---

[Table 9-1](#) and [Table 9-2](#) each have a column to indicate whether or not the LPSC configuration for a module is Auto Sleep/Wake Only. Modules that have a "Yes" marked for the Auto Sleep/Wake Only column can be programmed in software to be in Enable, Auto Sleep and Auto Wake states only; that is, if the software tries to program these modules to Disable, SyncReset, or SwRstDisable state the power sleep controller ignores these transition requests and transitions the module state to Enable.

### 9.2.2.2 Local Reset

In addition to module reset, the following modules can be reset using a special local reset that is also a part of the PSC module control for resets.

- **DSP:** When the DSP local reset is asserted the DSP internal memories (L1P, L1D and L2) are still accessible. The local reset only resets the DSP CPU core, not the rest of the DSP subsystem, as the DSP module reset would. Local Reset is useful in cases where the DSP is in enable or disable state; since when the module is in SyncReset or SwRstDisable state the module reset is asserted, and the module reset takes precedence over the local reset.
- **ARM:** When the ARM local reset is asserted the entire ARM processor is reset, including cache etc. This does not include the ARM RAM/ROM or ARM interrupt controller module as these exist outside the ARM core. The local reset for ARM additionally ensures that any outstanding requests are completed before ARM is reset, therefore for scenarios where it is needed to just reset the ARM locally but not change the state of clocks, user can use ARM local reset feature.

The procedures for asserting and de-asserting the local reset are as follows (where *n* corresponds to the module that supports local reset):

1. Clear the LRST bit in the module control register (MDCTL<sub>*n*</sub>) to 0 to assert the module's local reset.
2. Set the LRST bit in the module control register (MDCTL<sub>*n*</sub>) to 1 to de-assert module's local reset.

If the CPU is in the enable state, it immediately executes program instructions after reset is de-asserted.

**Table 9-3. Module States**

| Module State | Module Reset | Module Clock | Module State Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|--------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable       | De-asserted  | On           | A module in the enable state has its module reset de-asserted and it has its clock on. This is the normal operational state for a given module                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Disable      | De-asserted  | Off          | A module in the disabled state has its module reset de-asserted and it has its module clock off. This state is typically used for disabling a module clock to save power. This device is designed in full static CMOS, so when you stop a module clock, it retains the module's state. When the clock is restarted, the module resumes operating from the stopping point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| SyncReset    | Asserted     | On           | A module state in the SyncReset state has its module reset asserted and it has its clock on. Generally, software is not expected to initiate this state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SwRstDisable | Asserted     | Off          | A module in the SwResetDisable state has its module reset asserted and it has its clock disabled. After initial power-on, several modules come up in the SwRstDisable state. Generally, software is not expected to initiate this state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Auto Sleep   | De-asserted  | Off          | A module in the Auto Sleep state also has its module reset de-asserted and its module clock disabled, similar to the Disable state. However this is a special state, once a module is configured in this state by software, it can "automatically" transition to "Enable" state whenever there is an internal read/write request made to it, and after servicing the request it will "automatically" transition into the sleep state (with module reset re de-asserted and module clock disabled), without any software intervention. The transition from sleep to enabled and back to sleep state has some cycle latency associated with it. It is not envisioned to use this mode when peripherals are fully operational and moving data. See <a href="#">Section 9.2.2.1</a> for additional considerations, constraints, limitations around this mode. |
| Auto Wake    | De-asserted  | Off          | A module in the Auto Wake state also has its module reset de-asserted and its module clock disabled, similar to the Disable state. However this is a special state, once a module is configured in this state by software, it will "automatically" transition to "Enable" state whenever there is an internal read/write request made to it, and will remain in the "Enabled" state from then on (with module reset re de-asserted and module clock on), without any software intervention. The transition from sleep to enabled state has some cycle latency associated with it. It is not envisioned to use this mode when peripherals are fully operational and moving data. See <a href="#">Section 9.2.2.1</a> for additional considerations, constraints, limitations around this mode.                                                             |

## 9.3 Executing State Transitions

This section describes how to execute the state transitions modules.

### 9.3.1 Power Domain State Transitions

This device consists of two types of domain (in each PSC controller):

- Always On domain(s)
- pseudo/RAM power domain(s)

The Always On power domains are always in the ON state when the chip is powered on. You are not allowed to change the power domain state to OFF.

The pseudo/RAM power domains allow internally powering down the state of the RAMs associated with these domains (L1/L2 for PD\_DSP in PSC0 and Shared RAM for PD\_SHRAM in PSC1) so that these RAMs can run in lower power sleep modes via the power sleep controller.

---

**NOTE:** Currently powering down the RAMs via the pseudo/RAM power domain is not supported; therefore, these domains and the RAM should be left in their default power on state.

As mentioned in [Section 9.2](#), the pseudo/RAM power domains are powered down internally, and in this context powering down does not imply removing the core voltage from pins externally.

---

### 9.3.2 Module State Transitions

This section describes the procedure for transitioning the module state (clock and reset control). Note that some peripherals have special programming requirements and additional recommended steps you must take before you can invoke the PSC module state transition. See the individual peripheral user guides for more details. For example, the external memory controller requires that you first place the SDRAM memory in self-refresh mode before you invoke the PSC module state transitions, if you want to maintain the memory contents.

The following procedure is directly applicable for all modules that are controlled via the PSC (shown in [Table 9-1](#) and [Table 9-2](#)), except for the core(s). To transition the DSP or ARM module state, there are additional system considerations and constraints that you should be aware of. These system considerations and the procedure for transitioning the DSP or ARM module state are described in details in the *Power Management* chapter.

---

**NOTE:** In the following procedure, x is 0 for modules in PD0 (Power Domain 0 or Always On domain) and x is 1 for modules in PD1 (Power Domain 1). See [Table 9-1](#) and [Table 9-2](#) for power domain associations.

---

The procedure for module state transitions is:

1. Wait for the GOSTAT[x] bit in PTSTAT to clear to 0. You must wait for any previously initiated transitions to finish before initiating a new transition.
2. Set the NEXT bit in MDCTLn to SwRstDisable (0), SyncReset (1), Disable (2h), Enable (3h), Auto Sleep (4h) or Auto Wake (5h).

---

**NOTE:** You may set transitions in multiple NEXT bits in MDCTLn in this step. Transitions do not actually take place until you set the GO[x] bit in PTCMD in a later step.

---

3. Set the GO[x] bit in PTCMD to 1 to initiate the transition(s).
4. Wait for the GOSTAT[x] bit in PTSTAT to clear to 0. The modules are safely in the new states only after the GOSTAT[x] bit in PTSTAT is cleared to 0.

## 9.4 IcePick Emulation Support in the PSC

The PSC supports IcePick commands that allow IcePick emulation tools to have some control over the state of power domains and modules. This IcePick support only applies to the following modules:

- DSP [MDCTL15]
- ARM [MDCTL14]

In particular, [Table 9-4](#) shows IcePick emulation commands recognized by the PSC.

**Table 9-4. IcePick Emulation Commands**

| Power On and Enable Features | Power On and Enable Descriptions                                                                                   | Reset Features | Reset Descriptions                                                                                                           |
|------------------------------|--------------------------------------------------------------------------------------------------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------|
| Inhibit Sleep                | Allows emulation to prevent software from transitioning the module out of the enable state.                        | Assert Reset   | Allows emulation to assert the module's local reset.                                                                         |
| Force Power                  | Allows emulation to force the power domain into an on state. Not applicable as AlwaysOn power domain is always on. | Wait Reset     | Allows emulation to keep local reset asserted for an extended period of time after software initiates local reset de-assert. |
| Force Active                 | Allows emulation to force the module into the enable state.                                                        | Block Reset    | Allows emulation to block software initiated local and module resets.                                                        |

**NOTE:** When emulation tools remove the above commands, the PSC immediately executes a state transition based on the current values in the NEXT bit in PDCTL0 and the NEXT bit in MDCTLn, as set by software.

## 9.5 PSC Interrupts

The PSC has an interrupt that is tied to the core interrupt controller. This interrupt is named PSCINT in the interrupt map. The PSC interrupt is generated when certain IcePick emulation events occur.

### 9.5.1 Interrupt Events

The PSC interrupt is generated when any of the following events occur:

- Power Domain Emulation Event (applies to pseudo/RAM power domain only)
- Module State Emulation event
- Module Local Reset Emulation event

These interrupt events are summarized in [Table 9-5](#) and described in more detail in this section.

**Table 9-5. PSC Interrupt Events**

| Interrupt Enable Bits |            |                                                                             |
|-----------------------|------------|-----------------------------------------------------------------------------|
| Control Register      | Enable Bit | Interrupt Condition                                                         |
| PDCTLn                | EMUIHBIE   | Interrupt occurs when the emulation alters the power domain state           |
| MDCTLn                | EMUIHBIE   | Interrupt occurs when the emulation alters the module state                 |
| MDCTLn                | EMURSTIE   | Interrupt occurs when the emulation tries to alter the module's local reset |

The PSC interrupt events only apply when IcePick emulation alters the state of the module from the user-programmed state in the NEXT bit in the MDCTL/PDCTL registers. IcePick support only applies to the modules listed in [Section 9.4](#); therefore, the PSC interrupt conditions only apply to those modules listed.

### 9.5.1.1 Power Domain Emulation Events

A power domain emulation event occurs when emulation alters the state of a power domain (does not apply to the Always On domain). Status is reflected in the EMUIHB bit in PDSTAT $n$ . In particular, a power domain emulation event occurs under the following conditions:

- When inhibit sleep is asserted by emulation and software attempts to transition the module out of the on state
- When force power is asserted by emulation and power domain is not already in the on state
- When force active is asserted by emulation and power domain is not already in the on state

---

**NOTE:** Putting the pseudo/RAM power domain associated with the DSP (PD\_DSP) to the off state currently is **not** supported.

---

### 9.5.1.2 Module State Emulation Events

A module state emulation event occurs when emulation alters the state of a module. Status is reflected in the EMUIHB bit in the module status register (MDSTAT $n$ ). In particular, a module state emulation event occurs under the following conditions:

- When inhibit sleep is asserted by emulation and software attempts to transition the module out of the enable state
- When force active is asserted by emulation and module is not already in the enable state

### 9.5.1.3 Local Reset Emulation Events

A local reset emulation event occurs when emulation alters the local reset of a module. Status is reflected in the EMURST bit in the module status register (MDSTAT $n$ ). In particular, a module local reset emulation event occurs under the following conditions:

- When assert reset is asserted by emulation although software de-asserted the local reset
- When wait reset is asserted by emulation
- When block reset is asserted by emulation and software attempts to change the state of local reset

## 9.5.2 Interrupt Registers

The PSC interrupt enable bits are: the EMUIHBIE bit in PDCTL1 (PSC0), the EMUIHBIE and the EMURSTIE bits in MDCTL $n$  (where  $n$  is the modules that have IcePick emulation support, as specified in [Section 9.4](#)).

---

**NOTE:** To interrupt the CPU, the power sleep controller interrupt (PSC0\_ALLINT and PSC1\_ALLINT) must also be enabled appropriately in the ARM interrupt controller. For details on the ARM interrupt controller, see the *ARM Interrupt Controller (AINTC)* chapter.

---

The PSC interrupt status bits are:

- For DSP:
  - The M[15] bit in the module error pending register 0 (MERRPR0) in PSC0 module.
  - The EMUIHB and the EMURST bits in the module status register for DSP (MDSTAT15).
  - The P[1] bit in the power error pending register (PERRPR) for the pseudo/RAM power domain associated with DSP memories.
- For ARM:
  - The M[14] bit in the module error pending register 0 (MERRPR0) in PSC0 module.
  - The EMUIHB and the EMURST bits in the module status register for ARM (MDSTAT14).

The status bit in MERRPR0 and PERRPR registers is read by software to determine which module or power domain has generated an emulation interrupt and then software can read the corresponding status bits in MDSTAT register or the PDSTATn (PDCTL1 for pseudo/RAM power domain in PSC0) to determine which event caused the interrupt.

The PSC interrupt can be cleared by writing to bit corresponding to the module number in the module error clear register (MERRCR0), or the bit corresponding to the power domain number in the power error clear register (PERRCR) in PSC0 module.

The PSC interrupt evaluation bit is the ALLEV bit in the INTEVAL register. When set, this bit forces the PSC interrupt logic to re-evaluate event status. If any events are still active (if any status bits are set) when the ALLEV bit in the INTEVAL is set to 1, the PSC interrupt is re-asserted to the interrupt controller. Set the ALLEV bit in the INTEVAL before exiting your PSC interrupt service routine to ensure that you do not miss any PSC interrupts.

See [Section 9.6](#) for a description of the PSC registers.

### 9.5.3 Interrupt Handling

Handle the PSC interrupts as described in the following procedure:

First, enable the interrupt:

1. Set the EMUIHBIE bit in PDCTLn, the EMUIHBIE and the EMURSTIE bits in MDCTLn to enable the interrupt events that you want.

---

**NOTE:** The PSC interrupt is sent to the device interrupt controller when at least one enabled event becomes active.

---

2. Enable the power sleep controller interrupt (PSCn\_ALLINT) in the device interrupt controller. To interrupt the CPU, PSCn\_ALLINT must be enabled in the device interrupt controller. See the *ARM Interrupt Controller (AINTC)* chapter for more information on interrupts.

The CPU enters the interrupt service routine (ISR) when it receives the interrupt.

1. Read the P[n] bit in PERRPR, and/or the M[n] bit in MERRPR0, the M[n] bit in MERRPR1, to determine the source of the interrupt(s).
2. For each active event that you want to service:
  - (a) Read the event status bits in PDSTATn and MDSTATn, depending on the status bits read in the previous step to determine the event that caused the interrupt.
  - (b) Service the interrupt as required by your application.
  - (c) Write the M[n] bit in MERRCRn and the P[n] bit in PERRCR to clear corresponding status.
  - (d) Set the ALLEV bit in INTEVAL. Setting this bit reasserts the PSC interrupt to the device interrupt controller, if there are still any active interrupt events.

## 9.6 PSC Registers

Table 9-6 lists the memory-mapped registers for the PSC0 and Table 9-7 lists the memory-mapped registers for the PSC1.

**Table 9-6. Power and Sleep Controller 0 (PSC0) Registers**

### 9.6.1 Revision Identification Register (REVID)

The revision identification register (REVID) is shown in [Figure 9-1](#) and described in [Table 9-8](#).

**Figure 9-1. Revision Identification Register (REVID)**

LEGEND: R = Read only; -n = value after reset

**Table 9-8. Revision Identification Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description             |
|------|-------|------------|-------------------------|
| 31-0 | REV   | 4482 5A00h | Peripheral revision ID. |

### 9.6.2 Interrupt Evaluation Register (INTEVAL)

The interrupt evaluation register (INTEVAL) is shown in [Figure 9-2](#) and described in [Table 9-9](#).

**Figure 9-2. Interrupt Evaluation Register (INTEVAL)**

LEGEND: R = Read only; W= Write only; -n = value after reset

**Table 9-9. Interrupt Evaluation Register (INTEVAL) Field Descriptions**

| Bit  | Field    | Value | Description                                        |
|------|----------|-------|----------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                           |
| 0    | ALLEV    |       | Evaluate PSC interrupt (PSCn_ALLINT).              |
|      |          | 0     | A write of 0 has no effect.                        |
|      |          | 1     | A write of 1 re-evaluates the interrupt condition. |

### 9.6.3 PSC0 Module Error Pending Register 0 (modules 0-15) (MERRPR0)

The PSC0 module error pending register 0 (MERRPR0) is shown in [Figure 9-3](#) and described in [Table 9-10](#).

**Figure 9-3. PSC0 Module Error Pending Register 0 (MERRPR0)**

LEGEND: R = Read only; -n = value after reset

**Table 9-10. PSC0 Module Error Pending Register 0 (MERRPR0) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                |

| 31-16 | Reserved | 0      | Reserved                                                                                                                                                                                                   |
| 15    | M[15]    | 0<br>1 | Module interrupt status bit for module 15 (DSP).<br>Module 15 does not have an error condition.<br>Module 15 has an error condition. See the module status 15 register (MDSTAT15) for the error condition. |
| 14    | M[14]    | 0<br>1 | Module interrupt status bit for module 14 (ARM).<br>Module 14 does not have an error condition.<br>Module 14 has an error condition. See the module status 14 register (MDSTAT14) for the error condition. |
| 13-0  | Reserved | 0      | Reserved                                                                                                                                                                                                   |

### 9.6.4 PSC1 Module Error Pending Register 0 (modules 0-31) (MERRPR0)

The PSC1 module error pending register 0 (MERRPR0) is shown in [Figure 9-4](#).

**Figure 9-4. PSC1 Module Error Pending Register 0 (MERRPR0)**

LEGEND: R = Read only; -n = value after reset

### 9.6.5 PSC0 Module Error Clear Register 0 (modules 0-15) (MERRCR0)

The PSC0 module error clear register 0 (MERRCR0) is shown in [Figure 9-5](#) and described in [Table 9-11](#).

**Figure 9-5. PSC0 Module Error Clear Register 0 (MERRCR0)**

LEGEND: R = Read only; W = Write only; -n = value after reset

### Table 9-11. PSC0 Module Error Clear Register 0 (MERRCR0) Field Descriptions

| Bit   | Field    | Value | Description                                                                                                                                                                      |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Reserved                                                                                                                                                                         |
| 15    | M[15]    |       | Clears the interrupt status bit (M[15]) set in the PSC0 module error pending register 0 (MERRPR0) and the interrupt status bits set in the module status 15 register (MDSTAT15). |
|       |          | 0     | A write of 0 has no effect.                                                                                                                                                      |
|       |          | 1     | A write of 1 clears the M[15] bit in MERRPR0 and the EMUIHB and EMURST bits in MDSTAT15.                                                                                         |
| 14    | M[14]    |       | Clears the interrupt status bit (M[14]) set in the PSC0 module error pending register 0 (MERRPR0) and the interrupt status bits set in the module status 14 register (MDSTAT14). |
|       |          | 0     | A write of 0 has no effect.                                                                                                                                                      |
|       |          | 1     | A write of 1 clears the M[14] bit in MERRPR0 and the EMUIHB and EMURST bits in MDSTAT14.                                                                                         |

## 10.1 Introduction

Power management is an important aspect for most embedded applications. For several applications and target markets, there may be a specific power budget and requirements to minimize power consumption for both power supply sizing and battery life considerations. Additionally, lower power consumption results in more optimal and efficient designs from cost, design, and energy perspectives. This device has several means of managing the power consumption. This chapter discusses the various power management features.

## 10.2 Power Consumption Overview

Power consumed by semiconductor devices has two components: dynamic and static. This can be shown as:

$$P_{total} = P_{dynamic} + P_{static}$$

The dynamic power is the power consumed to perform work when the device is in active modes (clocks applied, busses, and I/O switching), that is, analog circuits changing states. The dynamic power is defined by:

$$P_{dynamic} = Capacitance \times Voltage^2 \times Frequency$$

From the above formula, the dynamic power scales with the clock frequency (device/module frequency for core operations and switching frequency for I/O). Dynamic power can be reduced by controlling the clocks in such a way as to either operate at a clock setting just high enough to complete the required operation in the required timeline or to run at a clock setting until the work is complete and then drastically reduce the clock frequency or cut off the clocks until additional work must be performed.

In the formula, the dynamic power varies with the voltage squared, so the voltage of operations has significant impact on overall power consumption and, thus, on the battery life. Dynamic power can be reduced by scaling the operating voltage, when the performance requirements are not that high and the device can be operated at a corresponding lower frequency.

The capacitance is the capacitance of the switching nodes, or the load capacitances on the switching I/O pins.

The static power, as the name suggests, is independent of the switching frequency of the logic. It can be shown as:

$$P_{static} = I_{(leakage\ current)}$$

It is essentially a function of the "leakage", or the power consumed by the logic when it is not switching or is not performing any work. Leakage current is dependent mostly on the manufacturing process used, the size of the die, etc. Leakage current is unavoidable while power is applied and scales roughly with the operating junction temperatures. Leakage power can only be avoided by removing power completely from a device or subsystem. The static power consumption plays a significant role in the Standby Modes (when the application is not running and in a dormant state) and plays an important role in the battery life for portable applications, etc.

## 10.3 PSC and PLLC Overview

The power and sleep controller (PSC) module plays an important role in managing the enabling/disabling of the clocks to the core and various peripheral modules. The PSC provides a granular support to turn on/off clocks on a module by module basis. Similarly, the two PLL controllers (PLLC0 and PLLC1) play an important role in device and module clock generation, and manage the frequency scaling operations for the device. Together these modules play a significant role in managing the clocks from a power management feature standpoint. For detailed information on the PSC, see the *Power and Sleep Controller (PSC)* chapter. For detailed information on the PLLC0 and PLLC1, see the *Device Clocking* chapter and the *Phase-Locked Loop Controller (PLLC)* chapter.

## 10.4 Features

This device has several means of managing power consumption, as detailed in the subsequent sections. This device uses the state-of-the-art 65 nm process, which provides a good balance on power and performance, providing high-performance transistors with relatively less leakage current and, thereby, low standby-power consumption modes.

There are several features in design as well as user driven software control to reduce dynamic power consumption. The design features (not under user control) include a power optimized clock tree design to reduce overall clock tree power consumption and automatic clock gating in several modules when the logic in the modules is not active.

The on-chip power and sleep controller (PSC) module provides granular software controlled module level clock gating, which reduces both clock tree and module power by basically disabling the clocks when the modules are not being used. Clock management also allows you to slow down the clocks, to reduce the dynamic power.

Table 10-1 describes the power management features.

**Table 10-1. Power Management Features**

| Power Management                                | Description                                                                                                                                                                                       | Features                                                                                                                                                  |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Clock Management</b>                         |                                                                                                                                                                                                   |                                                                                                                                                           |
| PLL bypass and power-down                       | Both PLLs can be powered-down and run in bypass mode when not in use.                                                                                                                             | Reduces the dynamic power consumption of the core.                                                                                                        |
| Module clock ON                                 | Module clocks can be turned on/off without requiring reconfiguring the registers.                                                                                                                 | Reduces the dynamic power consumption of the core and I/O (if any free running I/O clocks).                                                               |
| <b>Core Sleep Management</b>                    |                                                                                                                                                                                                   |                                                                                                                                                           |
| ARM subsystem sleep modes                       | The ARM CPU can be put in sleep mode. Additionally, the ARM subsystem clock can be completely gated when not in use.                                                                              | Reduces the dynamic power consumption.                                                                                                                    |
| DSP subsystem sleep mode                        | The DSP CPU can be put in sleep (IDLE) mode. Additionally, the DSP subsystem clock can be completely gated when not in use.                                                                       | Reduces the dynamic power consumption.                                                                                                                    |
| <b>Voltage Management</b>                       |                                                                                                                                                                                                   |                                                                                                                                                           |
| RTC-only mode                                   | Allows removing power from all core and I/O supply and just have the real-time clock (RTC) running.                                                                                               | Reduces the dynamic and static power for standby modes that require only the RTC to be functional.                                                        |
| <b>Dynamic Voltage and Frequency Scaling</b>    |                                                                                                                                                                                                   |                                                                                                                                                           |
| Dynamic Voltage and Frequency Scaling (DVFS)    | The operating voltage and frequency of the device can be dynamically scaled to meet the requirements of the application.                                                                          | Reduces the dynamic power consumption of the core and I/O as well as standby power                                                                        |
| <b>System/Device Sleep Management</b>           |                                                                                                                                                                                                   |                                                                                                                                                           |
| Deep Sleep Mode                                 | All internal clocks of the device can be turned on/off at the OSCIN level. The deep sleep function can be controlled externally through the DEESLEEP pin or internally through the RTC_ALARM pin. | Reduces the dynamic power consumption of the core and I/O.                                                                                                |
| <b>Peripheral I/O Power Management</b>          |                                                                                                                                                                                                   |                                                                                                                                                           |
| USB PHY power-down                              | The USB2.0 PHY can be powered-down.                                                                                                                                                               | Minimizes the USB2.0 I/O power consumption when not in use.                                                                                               |
| DDR2/mDDR self-refresh mode                     | Allows memory to retain its contents while the rest of the system is powered down.                                                                                                                | mDDR and DDR2 can be clock gated to reduce the dynamic power consumption or the entire device can be powered down to reduce the static power consumption. |
| SATA PHY power-down                             | The SATA PHY can be placed in standby mode.                                                                                                                                                       | Minimizes the SATA I/O power consumption when not in use.                                                                                                 |
| LVC MOS I/O buffer receiver disable             | LVC MOS I/O buffer receivers are disabled.                                                                                                                                                        | Minimizes the I/O power consumption.                                                                                                                      |
| Internal pull-up and pull-down resistor control | The internal pull-ups and pull-downs are enabled/disabled by groups.                                                                                                                              | Reduces the I/O leakage power.                                                                                                                            |

## 10.5 Clock Management

### 10.5.1 Module Clock ON/OFF

The module clock on/off feature allows software to disable clocks to module individually, in order to reduce the module's dynamic/switching power consumption down to zero. This device is designed in full static CMOS; thus, when a module clock stops, the module's state is preserved and retained. When the clock is restarted, the module resumes operating from the stopping point.

---

**NOTE:** Stopping clocks to a module only affects dynamic power consumption, it does not affect static power consumption of the module or the device.

---

The power and sleep controller (PSC) module controls module clock gating. If a module's clock(s) is stopped while being accessed, the access may not occur, and it can potentially result in unexpected behavior. The PSC provides some protection against such erroneous conditions by monitoring the internal bus activity to ensure there are no accesses to the module from the internal bus, before allowing module's internal clock to be gated. However, it is still recommended that software must ensure that all of the transactions to the module are finished prior to disabling the clocks.

The procedure to turn module clocks on/off using the PSC is described in the *Power and Sleep Controller (PSC)* chapter.

---

**NOTE:** To preserve the state of the module, the module state in the PSC must be set to Disable. In this state, the module reset is not asserted and only the module clock is turned off.

---

Furthermore, special consideration must be given to DSP/ARM clock on/off. The procedure to turn the core clock on/off is further described in [Section 10.7.4](#).

Additionally some peripherals implement additional power saving features by automatically shutting of clock to components within the module, when the logic is not active. This is transparent to you, but reduces overall dynamic power consumption when modules are not active.

### 10.5.2 Module Clock Frequency Scaling

Module clock frequency is scalable by programming the PLL multiply and divide parameters. Additionally, some modules might also have internal clock dividers. Reducing the clock frequency reduces the dynamic/switching power consumption, which scales linearly with frequency.

The *Device Clocking* chapter details the clocking structure of the device. The *Phase-Locked Loop Controller (PLL)* chapter describes how to program the PLL0 and PLL1 frequency and the frequency constraints.

### 10.5.3 PLL Bypass and Power Down

You can bypass each PLL in this device. Bypassing the PLL sends a bypass clock instead of the PLL VCO output (PLLOUT) to the system clocks of the PLLC. For PLLC0, the bypass clock is selected from either the PLL reference clock (OSCIN) or PLL1\_SYSCCLK3. For PLLC1, the bypass clock is always OSCIN. The OSCIN frequency is typically, at most, up to 50 MHz.

You can use the OSCIN bypass mode to reduce the core and module clock frequencies to very low maintenance levels without using the PLL during periods of very low system activity. This can lower the overall dynamic power consumption, which is linearly proportional to the frequency.

When the PLL controller is placed in bypass mode, the PLL retains its frequency lock. This allows you to switch between bypass mode and PLL mode without having to wait for the PLL to relock. However, keeping the PLL locked consumes power. You can also power-down the PLL when bypassing it to minimize the overall power consumed by the PLL module. The advantage of bypassing the PLL without powering it down is that you do not have to incur the PLL lock time when switching back to a normal operating level.

The *Device Clocking* chapter and the *Phase-Locked Loop Controller (PLLC)* chapter describe PLL bypass and PLL power down.

## 10.6 ARM Sleep Mode Management

### 10.6.1 ARM Wait-For-Interrupt Sleep Mode

The ARM module can be put into a low-power state using a special sleep mode called wait-for-interrupt (WFI). When the wait-for-interrupt mode is enabled, all internal clocks within the ARM9 module are shut off, the core is completely inactive and only resumes operation after receiving an interrupt. This is a feature for dynamic power management of the ARM processor itself, it does not impact the static power.

---

**NOTE:** To enable the WFI mode, the ARM needs to be in supervisor mode.

---

You can enable the WFI mode via the CP15 register #7 using the following instruction:

- MCR p15, #0, <Rd>, c7, c0, #4

Once the ARM module transitions into the WFI mode, it will remain in this state until an interrupt request (IRQ/FIQ) occurs.

The following sequence exemplifies how to enter the WFI mode:

- Enable any interrupt (for example, an external interrupt) that you plan to use as the wake-up interrupt to exit from the WFI mode.
- Enable the WFI mode using the following CP15 instruction:
  - MCR p15, #0, r3, c7, c0, #4

The following sequence describes the procedure to wake-up from the WFI mode:

- To wake-up from the WFI mode, trigger any enabled interrupt (for example, an external interrupt).
- The ARM's PC jumps to the IRQ/FIQ vector and you must handle the interrupt in an interrupt service routine (ISR).

Exit the ISR and continue normal program execution starting from the instruction immediately following the instruction that enabled the WFI mode.

---

**NOTE:** The ARM interrupt controller (AINTC) and the module sourcing the wake-up interrupt (for example, GPIO or watchdog timer) must not be disabled, or the device will never wake up.

---

For more information on this sleep mode, see the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp>.

---

### 10.6.2 ARM Clock OFF

The software must be structured such that no peripheral is allowed to access the ARM resources before disabling the clocks to the ARM subsystem. The ARM must check for the completion of all its master peripheral initiated requests (that is, CFG and DMA port operations, etc.). The DSP must check for the completion of all transactions initiated by it and the peripherals controls by the DSP to the ARM resources.

ARM module clock off sequence:

1. The DSP stops all masters from accessing the ARM and ARM memory.
2. The DSP polls all masters for write-completion status (or wait  $n$  number of cycles, if the transfer completion status is not implemented).
3. The ARM must have the ARM Clock Stop Request interrupt (ARMCLKSTOPREQ, ARM interrupt # 90) enabled and the associated interrupt service routine (ISR) set up before the DSP initiates the following ARM clock shutdown procedure.
  - (a) Initiate the ARM clock off sequence by issuing the ARM clock stop command (PSC DISABLE Command) to the ARM subsystem by writing a 2h to the NEXT bit field in the ARM local power sleep controller (LPSC) module control register (PSC0.MDCTL14).
  - (b) Write a 1 to the GO[0] bit (ARM subsystem is part of the PD\_ALWAYS ON domain) in the power domain transition command register (PSC0.PTCMD) to start the state transition sequence for the ARM module. This generates the ARMCLKSTOPREQ interrupt to the ARM.
  - (c) Check (poll for 0) the GOSTAT[0] bit in the power domain transition status register (PSC0.PTSTAT) for power transition sequence completion. The GOSTAT[0] bit transitions to 0 when the ARM executes the wait-for-interrupt instruction from inside its interrupt service routine (ISR).
  - (d) Check (poll for 2h) the STATE bit field in the ARM LPSC module status register (PSC0.MDSTAT14) indicating the ARM clock stop sequence completion (STATE: Disable).

The following sequence should be executed by the ARM within the ARM Clock Stop Request interrupt ISR:

1. Check for completion of all ARM master requests (the ARM polls transfer completion statuses of all Master peripherals).
2. Enable the interrupt to be used as the “wake-up” interrupt (for example, one of the CHIPSIG interrupts controlled by the chip signal register (CHIPSIG) in the *System Configuration (SYSCFG) Module* chapter—CHIPSIG[0], CHIPSIG[1], etc.) that will be used to wake-up the ARM during the ARM clock-on sequence.
3. Execute the wait-for-interrupt (WFI) ARM instruction.

### 10.6.3 ARM Subsystem Clock ON

The ARM module defaults to the SwRstDisable state; therefore, the DSP side software is responsible for enabling the clock and releasing the reset to the ARM at power-on reset. If the DSP has put the ARM in the clock off/Disable state, the following clock on sequence is applicable only when it is required to wake-up the ARM. Perform the following sequence for the DSP to enable clocks to the ARM:

1. Wait for the GOSTAT[0] bit in the power domain transition status register (PSC0.PTSTAT) to clear to 0. You must wait for the power domain to finish any previously initiated transitions before initiating a new transition.
2. Write a 3h to the NEXT bit in the ARM local power sleep controller (LPSC) module control register (PSC0.MDCTL14) to prepare the ARM module for an enable transition.
3. Write a 1 to the GO[0] bit (ARM subsystem is part of the PD\_ALWAYS\_ON domain) in the power domain transition command register (PSC0.PTCMD) to start the state transition sequence for the ARM module.
4. Check (poll for 0) the GOSTAT[0] bit in PSC0.PTSTAT for power transition sequence completion. The domain is only safely in the new state after the GOSTAT[0] bit is cleared to 0.
5. Wait for the STATE bit field in the ARM LPSC module status register (PSC0.MDSTAT14) to change to 3h. The module is only safely in the new state after the STATE bit field changes to reflect the new state.

---

**NOTE:** This only applies if you are transitioning from the Disable state. If previously in the Disable state, a wake-up interrupt must be triggered in order to wake the ARM (to exit the wait-for-interrupt mode). This example assumes that the ARM enabled this interrupt before entering its wait-for-interrupt sleep mode state.

---

For the DSP to wake the ARM if transitioning from the Disable state, trigger an ARM interrupt that has previously been configured as a wake-up interrupt.

## 10.7 DSP Sleep Mode Management

### 10.7.1 DSP Sleep Modes

The C674x megamodule has an internal power down controller (PDC) module that provides additional power management features in addition to clock management control provided by the device-level power and sleep controller (PSC) module. For information on the PDC module, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 10.7.2 C674x DSP CPU Sleep Mode

The DSP CPU can be put in a low-power state by executing the IDLE instruction. For information on the IDLE instruction, see the *TMS320C674x DSP CPU and Instruction Set Reference Guide* ([SPRUFE8](#)).

### 10.7.3 C674x Megamodule Sleep Mode

The IDLE instruction is used as part of the procedure for shutting down the entire C674x megamodule, by the power-down controller (PDC) module. In shutting down the entire C674x megamodule, the PDC can internally clock gate off the following components of the megamodule and internal memories of the DSP subsystem:

- C674x CPU
- Level 1 Program Memory Controller (PMC)
- Level 1 Data Memory Controller (DMC)
- Level 2 Unified Memory Controller (UMC)
- Extended Memory Controller (EMC)
- L1P Memory
- L1D Memory
- L2 Memory

Putting the entire C674x megamodule into the low-power sleep mode is typically more useful and saves a lot more power, as compared to just executing the IDLE instruction to put only the CPU in idle mode.

For information on putting the C674x megamodule in the low-power mode using the PDC, see the *TMS320C674x DSP Megamodule Reference Guide* ([SPRUFK5](#)).

### 10.7.4 C674x Megamodule Clock ON/OFF

The C674x megamodule can clock gate its own components to save power. Additional power saving can be achieved by stopping the clock sourced (PLL output) to the C674x megamodule by programming the power and sleep controller (PSC) module to place the megamodule in the Disable state. The DSP cannot perform this programming task on its own, because the DSP will not be able to complete the PSC programming sequence if its clock source is gated in the middle of the process.

If additional power saving is desired (more than just power savings obtained by using the power down controller), then you can choose to disable the clock to the DSP using the PSC. The ARM is responsible for programming the PSC to disable the clock going to the C674x megamodule at the root level (stopping PLL0\_SYSCLK1 at the PLL output). By clock gating the megamodule at the root, this enables saving additional clock tree power (for the path from the PLL to the megamodule boundary). The ARM is also responsible for programming the PSC to enable the C674x megamodule.

#### 10.7.4.1 C674x Megamodule Clock OFF

The software must be structured such that no peripheral is allowed to access the DSP resources before disabling the DSP clocks. The DSP must check for the completion of all its master peripheral initiated requests (that is, IDMA, MDMA, EDMA, cache operations, etc.). The ARM must check for the completion of all transactions initiated by it and the peripherals controls by it to the DSP resources.

1. The ARM stops all masters from accessing the DSP and DSP memory.
2. The ARM polls all masters for write-completion status (or wait *n* number of cycles, if the transfer completion status is not implemented).
3. The DSP must have the power-down controller interrupt PDC\_INT (DSP interrupt #118) enabled and the PDC interrupt service routine (ISR) set up before the ARM initiates the following DSP clock shutdown procedure.
  - (a) Initiate the DSP clock off sequence by issuing the DSP clock stop command (PSC DISABLE Command) to the DSP subsystem by writing a 2h to the NEXT bit field in the DSP local power sleep controller (LPSC) module control register (PSC0.MDCTL15).
  - (b) Write a 1 to the GO[1] bit (DSP subsystem is part of the PD\_DSP domain) in the power domain transition command register (PSC0.PTCMD) to start the state transition sequence for the DSP module. This generates the PDC\_INT interrupt to the DSP.
  - (c) Check (poll for 0) the GOSTAT[1] bit in the power domain transition status register (PSC0.PTSTAT) for power transition sequence completion. The GOSTAT[1] bit transitions to 0 when the DSP executes the IDLE instruction from inside its interrupt service routine (ISR).
  - (d) Check (poll for 2h) the STATE bit field in the DSP LPSC module status register (PSC0.MDSTAT15) indicating the DSP clock stop sequence completion (STATE: Disable).

The following sequence should be executed by the DSP within the PDC interrupt ISR:

1. Check for completion of all DSP master requests (the DSP polls transfer completion statuses of all Master peripherals).
2. Enable the interrupt to be used as “wake-up” interrupt (for example, one of the CHIPSIG interrupts controlled by the chip signal register (CHIPSIG) in the *System Configuration (SYSCFG) Module* chapter—CHIPSIG[2], CHIPSIG[3], or CHIPSIG[4]/NMI interrupt) that will be used to wake-up the DSP during the DSP clock-on sequence.

---

**NOTE:** The power-down command register (PDCCMD) in the power-down controller (PDC) can only be written while the DSP is in Supervisor mode.

---

3. Write a 0001 5555h to PDCCMD.
4. Execute the IDLE instruction.

#### 10.7.4.2 C674x Megamodule Clock ON

The C674x megamodule defaults to the Enable state; therefore, the DSP subsystem clock is on, and the following sequence is typically not needed. This clock on sequence is only required to wake-up the DSP, if the ARM put the DSP in a clock off state. Perform the following sequence for the ARM to enable clocks to the DSP:

1. Wait for the GOSTAT[1] bit in the power domain transition status register (PSC0.PTSTAT) to clear to 0. You must wait for the power domain to finish any previously initiated transitions before initiating a new transition.
2. Write a 3h to the NEXT bit field in the DSP local power sleep controller (LPSC) module control register (PSC0.MDCTL15) to prepare the DSP module for an enable transition.
3. Write a 1 to the GO[1] bit (DSP subsystem is part of the PD\_DSP domain) in the power domain transition command register (PSC0.PTCMD) to start the state transition sequence for the DSP module.
4. Check (poll for 0) the GOSTAT[1] bit in PSC0.PTSTAT for power transition sequence completion. The domain is only safely in the new state after the GOSTAT[1] bit is cleared to 0.
5. Wait for the STATE bit field in the DSP LPSC module status register (PSC0.MDSTAT15) to change to 3h. The module is only safely in the new state after the STATE bit field changes to reflect the new state.

---

**NOTE:** This only applies if you are transitioning from the Disable state. If previously in the Disable state, a wake-up interrupt must be triggered in order to wake the DSP. This example assumes that the DSP enabled this interrupt before entering its IDLE state. See the *DSP Subsystem* chapter for more information on DSP interrupts.

---

For the ARM to wake the DSP if transitioning from the Disable state, trigger a DSP interrupt that has previously been configured as a wake-up interrupt.

### 10.8 RTC-Only Mode

In real-time clock (RTC)-only mode, the RTC is powered on and the rest of the device is completely powered off (all supplies except the RTC supply are removed). In this mode, the RTC is fully functional and keeps track of date, hours, minutes, and seconds. In this mode, the overall power consumption would be significantly lower, as voltage from the rest of the core and I/O logic can be completely removed, eliminating most of the active and static power of the device, except for what is consumed by the RTC module, running at 32 kHz.

---

**NOTE:** To put the device in RTC-only mode, there is no software control sequence. You can put the device in the RTC-only mode by removing the power supply from all core and I/O logic, except for the RTC core logic supply (RTC\_CVDD). During wake up, all power sequencing requirements described in the device-specific data manual must be followed.

---

Some limitations apply in the RTC-only mode. First, the RTC\_ALARM pin is not available as an option for use as a control to signal an external power supply to reapply power to the rest of the device. This is because the RTC\_ALARM pin is powered by the I/O supply that is powered down in RTC-only mode. Second, in RTC-only mode, only the RTC register contents are preserved, all other internal memory and register contents are lost. Mobile DDR and DDR2 contents can be preserved through the use of self-refresh (see [Section 10.10.2](#)). However, software must be in place to restore the context of the device, for example, reinitialize internal registers, setup cache memory configurations, interrupt vectors, etc.

## 10.9 Dynamic Voltage and Frequency Scaling (DVFS)

Dynamic voltage and frequency scaling (DVFS) consists of minimizing the idle time of the system. The DVFS technique uses dynamic selection of the optimal frequency and voltage to allow a task to be performed in the required amount of time. This reduces the total power consumption of the device while still meeting task requirements. DVFS requires control over the clock frequency and the operating voltage of the device elements. By intelligently switching these elements to their optimal operating points, it is possible to minimize the power consumption of the device for a given task.

For reasons related to the device (clock architecture, process, etc.), DVFS is used only for a few discrete steps, not over a continuum of voltage and frequency values. Each step, or operating performance point (OPP), is composed of a voltage and frequency pair. For an OPP, the frequency corresponds to the maximum frequency allowed at a voltage, or reciprocally; the voltage corresponds to the minimum voltage allowed for a frequency. See your device data manual for a list of the OPPs supported by the device.

When applying DVFS, a processor or system always runs at the lowest OPP that meets the performance requirement at a given time. You determine the optimal OPP for a given task and then switch to that OPP to save power.

### 10.9.1 Frequency Scaling Considerations

The operating frequency of the device is controlled through its two PLL controllers (PLLC0 and PLLC1). Through a series of multipliers and dividers you can change the frequencies of various clocks throughout the device. See the *Device Clocking* chapter for information on the clock architecture of the device and see the *Phase-Locked Loop Controller (PLLC)* chapter for information on the PLL controllers. A few things must be noted when changing the various internal frequencies of the device:

- Changing the SYSCLK frequency

The PLL\_VCO (PLLOUT) frequency can be programmed through a PLL multiplier. A series of dividers divide PLLOUT to generate the various device SYSCLKs.

To change the SYSCLK frequency you can change the PLL multiplier or you can change the SYSCLK divider ratio. When changing the PLL multiplier, you must put the PLL controller in bypass mode while the PLL multiplier value is modified and a lock on the new frequency is reached. The lock time is given in the device data manual. When changing the divider ratios it is not required to put the PLL controller in bypass mode.

Changing the SYSCLK frequency through the dividers is faster as there is no need to reprogram the PLL. However, the SYSCLK frequency will depend solely on the divider ratios used.

- SYSCLK domain fixed ratios

Certain SYSCLK domains need to operate at a fixed ratio with respect to the CPU clock. Care should be taken to ensure that these fixed ratios are maintained. For additional details, see the *Device Clocking* chapter.

- PLLC0 bypass clock

When switching the PLL multiplier, the PLL controller must be placed in bypass mode. Bypassing the PLL sends a bypass clock instead of the PLL VCO output (PLLOUT) to the system clock dividers of the PLL controller.

For PLLC0 the bypass clock is selected from either the PLL reference clock (OSCIN) or PLL1\_SYSCLK3. For PLLC1, the bypass clock is always OSCIN. The OSCIN frequency is typically, at most, up to 50 MHz.

You can use the OSCIN bypass mode to reduce the core and module clock frequencies to very low maintenance levels without using the PLL during periods of very low system activity.

It may be desirable for the bypass clock to not revert to OSCIN in some situations to preserved bandwidth during frequency scaling transitions. For this reason, the PLLC0 bypass clock can be set to PLL1\_SYSCLK3. This selection is made through the EXTCLKSRC bit in the PLLCTL register of PLLC0.

- Peripheral immunity from CPU clock frequency changes

Peripherals that are clocked by the PLL0\_AUXCLK are immune to changes in the PLL0 frequency. The PLL0\_AUXCLK is derived from OSCIN.

Peripherals in the ASYNC3 domain are clocked off from either PLL1\_SYSCLK2 or PLL0\_SYSCLK2.

Furthermore, PLL0\_SYSCLK2 must always be /2 of the CPU clock frequency. To keep these peripherals immune from changes in PLL0 frequency (such as when the CPU frequency is modified), you can configure the ASYNC3 domain to be clocked from PLL1\_SYSCLK2. PLL1 is mainly used to clock the DDR2/mDDR memory controller.

When peripherals are immune to changes in the CPU clock frequency, their internal clock dividers do not have to be adjusted for changes in their input clock frequencies.

### 10.9.2 Voltage Scaling Considerations

The operating voltage of the device must be totally controlled through mechanisms outside the device. I2C ports on the device can be used to communicate with external power management chips. A few things must be noted when changing the operating voltage of the device:

- Voltage ramp rate: The ramp rate of the operating voltage must be observed during operating performance point (OPP) transitions. See the device data manual for ramp rate specifications.
- Switching to a lower voltage: When switching to a lower voltage, the maximum operating frequency changes. Care must be taken such that the maximum operating frequency supported at the new voltage is not violated. For this reason, it is recommended to change the operating frequency before switching the operating voltage.

### 10.10 Deep Sleep Mode

This device supports a Deep Sleep mode where all device clocks are stopped and the on-chip oscillator is shut down to save power. Registers and memory contents are preserved, thus, upon recovery, the program may continue from where it left off with minimal overhead involved.

The Deep Sleep mode is initiated when the `DEEPSLEEP` pin is driven low. The device wakes up from Deep Sleep mode when the `DEEPSLEEP` pin is driven high. The `DEEPSLEEP` pin can be driven by an external controller or it can be driven internally by the real-time clock (RTC). The RTC method allows for automatic wake-up at a programmed time.

---

**NOTE:** Due to pin multiplexing, the `DEEPSLEEP` pin can only be driven by an external controller or its internal real-time clock (RTC). The `DEEPSLEEP` pin cannot be driven by both an external controller and its internal real-time clock at the same time.

---

#### 10.10.1 Entering/Exiting Deep Sleep Mode Using Externally Controlled Wake-Up

##### 10.10.1.1 Entering Deep Sleep Mode

Use the following procedure to enter the Deep Sleep mode if an external signal is used to wake-up the device:

1. To preserve DDR2/mDDR memory contents, activate the self-refresh mode and gate the clocks to the DDR2/mDDR memory controller. You can use partial array self-refresh (PASR) for additional power savings for mDDR memory.
2. The SATA PHY should be disabled (see [Section 10.11.3](#)).
3. The USB2.0 (USB0) PHY should be disabled, if this interface is used and internal clocks are selected (see [Section 10.11.1](#)).
4. The USB1.1 (USB1) PHY should be disabled, if this interface is used and internal clocks are selected (see [Section 10.11.1](#)).
5. PLL/PLLC0 and PLL/PLLC1 should be placed in bypass mode (clear the PLLEN bit in the PLL control register (PLLCTL) of each PLLC to 0).
6. PLL/PLLC0 and PLL/PLLC1 should be powered down (set the PLLPWRDN bit in PLLCTL of each PLLC to 1).
7. Configure the `DEEPSLEEP` pin as input-only using the PINMUX0\_31\_28 bits in the PINMUX0 register in the *System Configuration (SYSCFG) Module* chapter.
8. The external controller should drive the `DEEPSLEEP` pin high (not in Deep Sleep).

9. Configure the desired delay in the SLEEP\_COUNT bit field in the deep sleep register (DEEPSLEEP) in the *System Configuration (SYSCFG) Module* chapter. This count determines the delay before the Deep Sleep logic releases the clocks to the device during wake up (allowing the oscillator to stabilize).
10. Set the SLEEPENABLE bit in DEEPSLEEP to 1. This automatically clears the SLEEPCOMPLETE bit.
11. Begin polling the SLEEPCOMPLETE bit until it is set to 1. This bit is set once the device is woken up from Deep Sleep mode.
12. The external controller drives the  $\overline{\text{DEEPSLEEP}}$  pin low to initiate Deep Sleep mode.

For more details on the clock stop procedure of the DDR2/mDDR memory controller, see the *DDR2/mDDR Memory Controller* chapter.

### 10.10.1.2 Exiting Deep Sleep Mode

Use the following procedure to exit the Deep Sleep state if an external signal is used to wake-up the device:

1. The external controller drives the  $\overline{\text{DEEPSLEEP}}$  pin high.
2. When the SLEEP\_COUNT delay is complete, the Deep Sleep logic releases the clock to the device and sets the SLEEPCOMPLETE bit in the deep sleep register (DEEPSLEEP) in the *System Configuration (SYSCFG) Module* chapter.
3. Clear the SLEEPENABLE bit in DEEPSLEEP to 0. This automatically clears the SLEEPCOMPLETE bit.
4. Initialize the PLL controllers as described in [Section 8.2.2.2](#). Note that the state of the PLL controller registers is preserved during Deep Sleep mode. Therefore, it is not necessary to reprogram all the PLL controller registers unless a new setting is desired. At minimum, steps 3, 4, and 7-10 of the PLL initialization procedure must be followed.
5. Enable the clocks to the DDR2/mDDR memory controller, reset the DDR PHY, and then take the DDR2/mDDR out of self-refresh mode.
6. Configure the desired states to the peripherals and enable as required.

For more details on the clock enable procedure of the DDR2/mDDR memory controller, see the *DDR2/mDDR Memory Controller* chapter.

## 10.10.2 Entering/Exiting Deep Sleep Mode Using RTC Controlled Wake-Up

### 10.10.2.1 Entering Deep Sleep Mode

Use the following procedure to enter the Deep Sleep state if the RTC is used to wake-up the device:

1. To preserve DDR2/mDDR memory contents, activate the self-refresh mode and gate the clocks to the DDR2/mDDR memory controller. You can use partial array self-refresh (PASR) for additional power savings for mDDR memory.
2. The SATA PHY should be disabled (see [Section 10.11.3](#)).
3. The USB2.0 (USB0) PHY should be disabled, if this interface is used and internal clocks are selected (see [Section 10.11.1](#)).
4. The USB1.1 (USB1) PHY should be disabled, if this interface is used and internal clocks are selected (see [Section 10.11.1](#)).
5. PLL/PLLC0 and PLL/PLLC1 should be placed in bypass mode (clear the PLEN bit in the PLL control register (PLLCTL) of each PLLC to 0).
6. PLL/PLLC0 and PLL/PLLC1 should be powered down (set the PLLPWRDN bit in PLLCTL of each PLLC to 1).
7. Configure the desired wake-up time as an alarm in the RTC.
8. Configure the  $\overline{\text{DEEPSLEEP}}/\text{RTC\_ALARM}$  pin to output RTC\_ALARM using the PINMUX0\_31\_28 bits in the PINMUX0 register in the *System Configuration (SYSCFG) Module* chapter. The pin is driven low since the alarm has not yet occurred.

9. Configure the desired delay in the SLEEP\_COUNT bit field in the deep sleep register (DEEPSLEEP) in the *System Configuration (SYSCFG) Module* chapter. This count determines the delay before the Deep Sleep logic releases the clocks to the device during wake up (allowing the oscillator to stabilize).
10. Set the SLEEPENABLE bit in DEEPSLEEP to 1. This automatically clears the SLEEPCOMPLETE bit. Also, the device now enters the Deep Sleep mode since the  $\overline{\text{DEEPSLEEP}}$  pin is low.

For more details on the clock stop procedure of the DDR2/mDDR memory controller, see the *DDR2/mDDR Memory Controller* chapter.

#### 10.10.2.2 Exiting Deep Sleep Mode

Use the following procedure to exit the Deep Sleep state if the RTC is used to wake-up the device:

1. The RTC alarm occurs and the RTC\_ALARM pin is driven high (which is internally connected to the  $\overline{\text{DEEPSLEEP}}$  pin). This causes the Deep Sleep logic to exit the Deep Sleep mode.
2. When the SLEEP\_COUNT delay is complete, the Deep Sleep logic releases the clock to the device and sets the SLEEPCOMPLETE bit in the deep sleep register (DEEPSLEEP) in the *System Configuration (SYSCFG) Module* chapter.
3. Clear the SLEEPENABLE bit in DEEPSLEEP to 0. This automatically clears the SLEEPCOMPLETE bit.
4. Initialize the PLL controllers as described in [Section 8.2.2.2](#). Note that the state of the PLL controller registers is preserved during Deep Sleep mode. Therefore, it is not necessary to reprogram all the PLL controller registers unless a new setting is desired. At minimum, steps 3, 4, and 7-10 of the PLL initialization procedure must be followed.
5. Enable the clocks to the DDR2/mDDR memory controller, reset the DDR PHY, and then take the DDR2/mDDR out of self-refresh mode.
6. Configure the desired states to the peripherals and enable as required.

For more details on the clock enable procedure of the DDR2/mDDR memory controller, see the *DDR2/mDDR Memory Controller* chapter.

#### 10.10.3 Deep Sleep Sequence

[Figure 10-1](#) illustrates the Deep Sleep sequence:

1. Software sets the SLEEPENABLE bit in the deep sleep register (DEEPSLEEP) in the *System Configuration (SYSCFG) Module* chapter.
2. The  $\overline{\text{DEEPSLEEP}}$  pin is driven low by either an external device or the RTC\_ALARM pin. The Deep Sleep mode begins.
3. The PLL controller reference clock is gated.
4. The on-chip oscillator is disabled. If the device is being clocked by an external source, this clock may stay enabled; the power savings from turning off this clock is minimal.
5. The  $\overline{\text{DEEPSLEEP}}$  pin is driven high and the on-chip oscillator is enabled.
6. The Deep Sleep counter begins counting valid clock cycles.
7. The count has reached the number specified in the SLEEP\_COUNT bit field and the SLEEPCOMPLETE bit is set. The PLL reference clock is enabled and the Deep Sleep mode ends.
8. Software clears the SLEEPENABLE bit. The SLEEPCOMPLETE bit is automatically cleared.

**Figure 10-1. Deep Sleep Mode Sequence**

#### 10.10.4 Entering/Exiting Deep Sleep Mode Using Software Handshaking

Entering the Deep Sleep mode stops all of the clocks to the device so it is the responsibility of the software to ensure that all peripheral accesses have been completed and peripheral interfaces appropriately configured for clocks to stop. Therefore, before an external controller drives the **DEEPSLEEP** pin, a handshaking mechanism must be in place to give software time to prepare the device for Deep Sleep mode. The implementation of the handshake mechanism is up to the system designer.

##### 10.10.4.1 Entering Deep Sleep Mode

The following example sequence can be used to activate the Deep Sleep mode using a handshaking mechanism between your device and an external device:

1. Clear the **SLEEPENABLE** bit in the deep sleep register (**DEEPSLEEP**) in the *System Configuration (SYSCFG) Module* chapter to 0. The **DEEPSLEEP** pin has no effect until software running on the device sets this bit.
2. Configure the **GP0[8]/DEEPSLEEP/RTC\_ALARM** pin to output GP0[8] using the **PINMUX0\_31\_28** bits in the **PINMUX0** register in the *System Configuration (SYSCFG) Module* chapter. When the pin is configured for GPIO functionality, the internal **DEEPSLEEP** signal is still driven by the value on the pin.
3. Configure the **GP0[8]** pin to generate interrupts on the falling edge of the GPIO signal.
4. An external device drives the **GP0[8]** pin low.
5. Software prepares the device for Deep Sleep mode.
6. Set the **SLEEPENABLE** bit in **DEEPSLEEP** to 1. The Deep Sleep mode is immediately started and all device clocks are stopped. Also, the **SLEEPCOMPLETE** bit is automatically cleared.

#### 10.10.4.2 Exiting Deep Sleep Mode

To exit the Deep Sleep mode, follow this sequence:

1. An external device drives the GP0[8] pin high.
2. The device exits the Deep Sleep mode. When the SLEEPDELAY delay is complete, the Deep Sleep logic releases the clock to the device and sets the SLEEPCOMPLETE bit in the deep sleep register (DEEPSLEEP) in the *System Configuration (SYSCFG) Module* chapter.
3. Clear the SLEEPENABLE bit in DEEPSLEEP to 0.

### 10.11 Additional Peripheral Power Management Considerations

This section lists additional power management features and considerations that might be part of other chip-level or peripheral logic, apart from the features supported by the core, PLL controller (PLL), and power and sleep controller (PSC).

#### 10.11.1 USB PHY Power Down Control

The USB modules can be clock gated using the PSC; however, this does not power down/clock gate the PHY logic. You can put the USB2.0 PHY and OTG module in the lowest power state, when not in use, by writing to the USB0PHYPWDN and the USB0OTGPWRDN bits in the Chip Configuration 2 Register (CFGCHIP2) in the *System Configuration (SYSCFG) Module* chapter.

---

**NOTE:** If the USB1.1 subsystem is used and the 48 MHz clock input is sourced from the USB2.0 PHY, then the USB2.0 PHY should not be powered down.

---

#### 10.11.2 DDR2/mDDR Memory Controller Clock Gating and Self-Refresh Mode

The DDR2/mDDR memory controller supports different methods for reducing its power consumption including self-refresh mode, power-down mode, and clock gating. Additionally, the DDR2/mDDR memory controller DLL, PHY, and the receivers at the I/O pins can be disabled. Even if the PHY is active, the receivers can be configured to disable whenever writes are in progress and the receivers are not needed.

Self-refresh mode can be used to preserve the contents of DDR2/mDDR memory when the DDR2/mDDR memory controller is clock gated or when the device is placed in RTC-only mode. However, in the RTC-only mode, care must be taken to correctly take the DDR2/mDDR out of self-refresh mode.

---

**NOTE:** To preserve the contents of the external memory while the DDR2/mDDR memory controller is clock gated, its self-refresh mode must be enabled before the DDR2/mDDR memory controller clock is turned off.

---

In RTC-only mode, all portions of the device except for the RTC are powered down, including the DDR2/mDDR memory controller. During power-up, the DDR2/mDDR memory controller defaults to its reset state. When the DDR2/mDDR memory controller is taken out of reset, it automatically runs its memory initialization routine; the self-refresh state of the memory is ignored. This hardware sequence cannot be stopped by software running on the device.

To correctly take the memory out of self-refresh after coming back from RTC-only mode, follow these steps:

1. Before going into RTC-only mode, disconnect the DDR2/mDDR memory controller CKE output pin from the memory; ensure the memory's CKE input pin continues to be driven low.
2. After coming back from RTC-only mode, configure the device to the desired operating state.
3. Program the DDR2/mDDR memory controller following the normal sequence.
4. Enable the self-refresh mode of the DDR2/mDDR memory controller.
5. Connect the DDR2/mDDR memory controller CKE output pin to the memory.
6. Disable the self-refresh mode of the DDR2/mDDR memory controller.

After this sequence, the DDR2/mDDR memory controller is ready for use. Note that hardware logic is needed to disconnect the CKE output pin from the memory and to drive the memory's CKE input pin low.

For more details on the power management features of the DDR2/mDDR memory controller, see the *DDR2/mDDR Memory Controller* chapter.

### **10.11.3 SATA PHY Power Down**

The SATA PHY supports a standby power mode that yields significant power reduction during periods in which the PHY is not used. In applications in which the SATA is not used at all, the power supply to the SATA PHY can be left unconnected.

### **10.11.4 LVC MOS I/O Buffer Receiver Disable**

This device supports two types of LVC MOS I/Os: 1.8V I/Os and low-static current dual-voltage I/Os that operate at either 1.8V or 3.3V. The receivers on the LVC MOS I/Os are enabled and disabled by software (see the RXACTIVE Control Register (RXACTIVE) in the *System Configuration (SYSCFG) Module* chapter). In the event that certain receivers are not used (such as in a low-power state), they can be disabled to conserve power.

### **10.11.5 Pull-Up/Pull-Down Disable**

In general, you must ensure that all input pins are always pulled to a logic-high or a logic-low voltage level. A floating input pin can consume a small amount of I/O leakage current. The I/O leakage current can be greatly multiplied in the case of several floating inputs pins.

This device includes internal pull-up and pull-down resistors that prevent floating input pins. These internal resistors are generally very weak and their use is intended for pins that are not connected on the board design. For pins that are connected, external pull-up and pull-down resistors are recommended.

When an input pin is externally driven to a valid logic level, through an external pull-up resistor or by an external device for example, it is recommended to disable the internal resistor. Opposing an internal pull-up or pull-down resistor can consume a small amount of current. Internal resistors are disabled through the pullup/pulldown enable register (PUPD\_ENA) in the *System Configuration (SYSCFG) Module* chapter.

## System Configuration (SYSCFG) Module

| <b>11.2 Protection .....</b>              | <b>218</b> |
| <b>11.3 Master Priority Control .....</b> | <b>219</b> |
| <b>11.4 Interrupt Support .....</b>       | <b>221</b> |
| <b>11.5 SYSCFG Registers .....</b>        | <b>221</b> |

## 11.1 Introduction

The system configuration (SYSCFG) module is a system-level module containing status and top level control logic required by the device. The system configuration module consists of a set of memory-mapped status and control registers, accessible by the CPU, supporting all of the following system features, and miscellaneous functions and operations.

- Device Identification
- Device Configuration
  - Pin multiplexing control
  - Device Boot Configuration Status
- Master Priority Control
  - Controls the system priority for all master peripherals (including EDMA3TC)
- Emulation Control
  - Emulation suspend control for peripherals that support the feature
- Special Peripheral Status and Control
  - Locking of PLL control settings
  - Default burst size configuration for EDMA3 transfer controllers
  - Event source selection for the eCAP peripheral input capture
  - McASP0 AMUTEIN selection and clearing of AMUTE
  - USB PHY Control
  - Clock source selection for EMIFA and DDR2/mDDR
  - HPI Control
- ARM-DSP Integration
  - On-chip inter-processor interrupts and status for signaling between ARM and DSP

The system configuration module controls several global operations of the device; therefore, the module supports protection against erroneous and illegal accesses to the registers in its memory-map. The protection mechanisms that are present in the module are:

- A special key sequence that needs to be written into a set of registers in the system configuration module, to allow write ability to the rest of registers in the system configuration module.
- Several registers in the module are only accessible when the CPU requesting read/write access is in privileged mode.

## 11.2 Protection

The SYSCFG module controls several global operations of the device; therefore, it has a protection mechanism that prevents spurious and illegal accesses to the registers in its memory map. The protection mechanism enables accesses to these registers only if certain conditions are met.

### 11.2.1 Privilege Mode Protection

The CPU supports two privilege levels: Supervisor and User. Several registers in the SYSCFG memory-map can only be accessed when the accessing host (CPU or master peripheral) is operating in privileged mode, that is, in Supervisor mode. The registers that can only be accessed in privileged mode are listed in [Section 11.5](#). See the *TMS320C674x DSP CPU and Instruction Set Reference Guide* ([SPRUFE8](#)) and the ARM926EJ-S Technical Reference Manual (TRM), downloadable from <http://infocenter.arm.com/help/index.jsp> for details on privilege levels.

### 11.2.2 Kicker Mechanism Protection

**NOTE:** The Kick registers are disabled in silicon revision 2 and later. The SYSCFG registers are always unlocked and writes to the Kick registers have no functional effect.

The Kick registers (KICK0R and KICK1R) can only be accessed in privileged mode (the host needs to be in Supervisor mode). Any number of accesses may be performed to the SYSCFG module, while the module is unlocked.

The SYSCFG module remains unlocked after the unlock sequence, until locked again. Locking the module is accomplished by writing any value other than the key values to either KICK0R or KICK1R.

To access any registers in the SYSCFG module, it is required to follow a special sequence of writes to the Kick registers (KICK0R and KICK1R) with correct key values. Writing the correct key value to the kick registers unlocks the registers in the SYSCFG memory-map. In order to access the SYSCFG registers, the following unlock sequence needs to be executed in software:

1. Write the key value of 83E7 0B13h to KICK0R.
2. Write the key value of 95A4 F1E0h to KICK1R.

After steps 1 and 2, the SYSCFG module registers are accessible and can be configured as per the application requirements.

### 11.3 Master Priority Control

The on-chip peripherals/modules are essentially divided into two broad categories, masters and slaves. The master peripherals are typically capable of initiating their own read/write data access requests, this includes the ARM, DSP, EDMA3 transfer controllers, and peripherals that do not rely on the CPU or EDMA3 for initiating the data transfer to/from them. In order to determine allowed connection between masters and slave, each master request source must have a unique master ID (mstid) associated with it. The master ID is shown in [Table 11-1](#). See the device-specific data manual to determine the masters present on your device.

Each switched central resource (SCR) performs prioritization based on priority level of the master that sends the read/write requests. For all peripherals/ports classified as masters on the device, the priority is programmed in the master priority registers (MSTPRI0-3) in the SYSCFG modules. The default priority levels for each bus master is shown in [Table 11-2](#). Application software is expected to modify these values to obtain the desired performance.

**Table 11-1. Master IDs**

| Master ID | Peripheral          |
|-----------|---------------------|
| 0         | ARM - Instruction   |
| 1         | ARM - Data          |
| 2         | DSP MDMA            |
| 3         | DSP CFG             |
| 4-7       | Reserved            |
| 8         | PRU0                |
| 9         | PRU1                |
| 10        | EDMA3_0_CC0         |
| 11        | EDMA3_1_CC0         |
| 12-15     | Reserved            |
| 16        | EDMA3_0_TC0 - read  |
| 17        | EDMA3_0_TC0 - write |
| 18        | EDMA3_0_TC1 - read  |
| 19        | EDMA3_0_TC1 - write |
| 20        | EDMA3_1_TC0 - read  |

**Table 11-1. Master IDs (continued)**

| Master ID | Peripheral          |
|-----------|---------------------|
| 21        | EDMA3_1_TC0 – write |
| 22-33     | Reserved            |
| 34        | USB2.0 CFG          |
| 35        | USB2.0 DMA          |
| 36        | Reserved            |
| 37        | HPI                 |
| 38        | EMAC                |
| 39        | USB1.1              |

| LCDC <sup>(4)</sup>        | 5                               | MSTPRI2                  |
| HPI                        | 6                               | MSTPRI2                  |

<sup>(1)</sup> The default priority settings might not be optimal for all applications. The master priority should be changed from default based on application specific requirement, in order to get optimal performance and prioritization for masters moving data that is real time sensitive.

<sup>(2)</sup> The priority for EDMA3\_0\_TC0, EDMA3\_0\_TC1, and EDMA3\_1\_TC0 is configurable through fields in the master priority 1 register (MSTPRI1), not the EDMA3CC\_QUEPRI register.

<sup>(3)</sup> The priority for DSP MDMA and DSP CFG is controlled by fields in the master priority 0 register (MSTPRI0) and not DSP.MDMAARBE.PRI (DSP Bandwidth manager module).

<sup>(4)</sup> LCDC traffic is typically real-time sensitive, therefore, the default priority of 5, which is lower as compared to the default priority of several masters, is not recommended. You should reconfigure the LCDC priority to the highest or equal to other high-priority masters in an application to ensure that the throughput/latency requirements for the LCDC are met.

## 11.4 Interrupt Support

### 11.4.1 Interrupt Events and Requests

The SYSCFG module generates two interrupts: an address error interrupt (BOOTCFG\_ADDR\_ERR) and a protection interrupt (BOOTCFG\_PROT\_ERR). The BOOTCFG\_ADDR\_ERR is generated when there is an addressing violation due to an access to a non-existent location in the SYSCFG register space. The BOOTCFG\_PROT\_ERR interrupt is generated when there is a protection violation of either in the defined ranges or to the SYSCFG registers. It is required to write a value of 0 to the end of interrupt register (EOI) after the software has processed the SYSCFG interrupt, this acts as an acknowledgement of completion of the SYSCFG interrupt so that the module can reliably generate subsequent interrupts.

The transfer parameters that caused the violation are saved in the fault address register (FLTADDR) and the fault status register (FLTSTAT).

### 11.4.2 Interrupt Multiplexing

The interrupts from the SYSCFG module are combined with the interrupts from the MPU module into a single interrupt called MPU\_BOOTCFG\_ERR. The combined interrupt is routed to the ARM and DSP interrupt controllers.

### 11.4.3 ARM-DSP Communication Interrupts

The SYSCFG module also has a set of registers, the chip signal register (CHIPSIG) and the chip signal clear register (CHIPSIG\_CLR), to facilitate interprocessor communication. This is generally used to allow the ARM and the DSP to coordinate. For example, the ARM may interrupt the DSP when it is ready to have the DSP process some data buffer in shared memory. A typical sequence, often referred to as ARM-DSP communication, is as follows:

1. ARM writes command in shared memory.
2. ARM interrupts DSP.
3. DSP responds to interrupt and reads command in shared memory.
4. DSP executes a task based on the command.
5. DSP interrupts ARM upon completion of the task.

Either of the processors can set specific bits in this SYSCFG register, which in turn can interrupt the other processor, if the interrupts have been appropriately enabled in the processor's interrupt controller.

## 11.5 SYSCFG Registers

[Table 11-3](#) lists the memory-mapped registers for the system configuration module 0 (SYSCFG0) and [Table 11-4](#) lists the memory-mapped registers for the system configuration module 1 (SYSCFG1). These tables also indicate whether a particular register can be accessed only when the CPU is in privileged mode.

### 11.5.1 Revision Identification Register (REVID)

The revision identification register (REVID) provides the revision information for the SYSCFG module. The REVID is shown in [Figure 11-1](#) and described in [Table 11-5](#).

**Figure 11-1. Revision Identification Register (REVID)**

|              |   |
|--------------|---|
| 31           | 0 |
| REV          |   |
| R-4E84 0102h |   |

LEGEND: R = Read only; -n = value after reset

**Table 11-5. Revision Identification Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description                                                     |
|------|-------|------------|-----------------------------------------------------------------|
| 31-0 | REV   | 4E84 0102h | <b>Revision ID.</b> Revision information for the SYSCFG module. |

### 11.5.2 Device Identification Register 0 (DEVIDR0)

The device identification register 0 (DEVIDR0) contains a software readable version of the JTAG ID device. Software can use this register to determine the version of the device on which it is executing. The DEVIDR0 is shown in [Figure 11-2](#) and described in [Table 11-6](#).

**Figure 11-2. Device Identification Register 0 (DEVIDR0)**

|              |   |
|--------------|---|
| 31           | 0 |
| DEVID0       |   |
| R-1B7D 102Fh |   |

LEGEND: R = Read only; -n = value after reset

**Table 11-6. Device Identification Register 0 (DEVIDR0) Field Descriptions**

| Bit  | Field  | Value      | Description            |
|------|--------|------------|------------------------|
| 31-0 | DEVID0 | 1B7D 102Fh | Device identification. |

### 11.5.3 Boot Configuration Register (BOOTCFG)

The device boot and configuration settings are latched at device reset, and captured in the boot configuration register (BOOTCFG). See your device-specific data manual and the *Boot Considerations* chapter for details on boot and configuration settings. The BOOTCFG is shown in [Figure 11-3](#) and described in [Table 11-7](#).

**Figure 11-3. Boot Configuration Register (BOOTCFG)**

|     |          |    |
|-----|----------|----|
| 31  | Reserved | 16 |
| R-0 |          |    |
| 15  | BOOTMODE | 0  |
| R-0 |          |    |

LEGEND: R = Read only; -n = value after reset

**Table 11-7. Boot Configuration Register (BOOTCFG) Field Descriptions**

| Bit   | Field    | Value   | Description                                                      |
|-------|----------|---------|------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                         |
| 15-0  | BOOTMODE | 0-FFFFh | <b>Boot Mode.</b> This reflects the state of the boot mode pins. |

### 11.5.4 Chip Revision Identification Register (CHIPREVIDR)

The chip revision identification register (CHIPREVIDR) provides the software-readable silicon revision information for the device. The CHIPREVID is shown in [Figure 11-4](#) and described in [Table 11-8](#).

**Figure 11-4. Chip Revision Identification Register (CHIPREVIDR)**

|     |          |      |

## 11.5.5 Kick Registers (KICK0R-KICK1R)

**NOTE:** The kick registers are disabled in silicon revision 2 and later. The SYSCFG registers are always unlocked and writes to the kick registers have no functional effect.

The SYSCFG module has a protection mechanism to prevent any spurious writes from changing any of the modules memory-mapped registers. At power-on reset, none of the SYSCFG module registers are writeable (they are readable). To allow writing to the registers in the module, it is required to “unlock” the registers by writing to two memory-mapped registers in the SYSCFG module, Kick0 and Kick1, with exact data values. Once these values are written, then all the registers in the SYSCFG module that are writeable can be written to. See [Section 11.2.2](#) for the exact key values and sequence of steps. Writing any other data value to either of these kick registers will cause the memory mapped registers to be “locked” again and block out any write accesses to registers in the SYSCFG module.

### 11.5.5.1 Kick 0 Register (KICK0R)

The KICK0R is shown in [Figure 11-5](#) and described in [Table 11-9](#).

**Figure 11-5. Kick 0 Register (KICK0R)**

|       |  |   |
|-------|--|---|
| 31    |  | 0 |
| KICK1 |  |   |
| R/W-0 |  |   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 11-9. Kick 0 Register (KICK0R) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                    |
|------|-------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | KICK0 | 0-FFFF FFFFh | <b>KICK0R allows writing to unlock the kick0 data.</b> The written data must be 83E7 0B13h to unlock this register. It must be written before writing to the kick1 register. Writing any other value will lock the other MMRs. |

### 11.5.5.2 Kick 1 Register (KICK1R)

The KICK1R is shown in [Figure 11-6](#) and described in [Table 11-10](#).

**Figure 11-6. Kick 1 Register (KICK1R)**

|       |  |   |
|-------|--|---|
| 31    |  | 0 |
| KICK0 |  |   |
| R/W-0 |  |   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 11-10. Kick 1 Register (KICK1R) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                        |
|------|-------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | KICK1 | 0-FFFF FFFFh | <b>KICK1R allows writing to unlock the kick1 data and the kicker mechanism to write to other MMRs.</b> The written data must be 95A4 F1E0h to unlock this register. KICK0R must be written before writing to the kick1 register. Writing any other value will lock the other MMRs. |

### 11.5.6 Host 0 Configuration Register (HOST0CFG)

The ARM subsystem is held in reset when 0 is written to the BOOTRDY bit in the host 0 configuration register (HOST0CFG). In a typical application, the BOOTRDY bit should not be cleared.

The HOST0CFG is shown in [Figure 11-7](#) and described in [Table 11-11](#).

**NOTE:** In addition to writing to HOST0CFG, the ARM subsystem must be enabled via the power and sleep controller (PSC) module. By default, the ARM subsystem is in a SwRstDisable state (see the *Power and Sleep Controller (PSC)* chapter for additional details).

**Figure 11-7. Host 0 Configuration Register (HOST0CFG)**

|     |          |  |  |  |  |  |  |  |  |  |         |   |  |  |    |

|      |          | 1     | ARM released from wait in reset mode.                                      |

### 11.5.7 Host 1 Configuration Register (HOST1CFG)

The host 1 configuration register (HOST1CFG) provides information on the DSP boot address value at power-on reset. The boot address defaults to 0070 0000h (DSP ROM) on power-up. The address field is read/writeable after reset and can be modified to allow execution from an alternate location after a module level or local reset on the DSP. The HOST1CFG is shown in [Figure 11-8](#) and described in [Table 11-12](#).

**Figure 11-8. Host 1 Configuration Register (HOST1CFG)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-12. Host 1 Configuration Register (HOST1CFG) Field Descriptions**

| Bit   | Field            | Value      | Description              |
|-------|------------------|------------|--------------------------|
| 31-10 | DSP_ISTP_RST_VAL | 0-3F FFFFh | DSP boot address vector. |
| 9-0   | Reserved         | 0          | Reserved                 |

## 11.5.8 Interrupt Registers

The interrupt registers are a set of registers that provide control for the address and protection violation error interrupt generated by the SYSCFG module when there is an address or protection violation to the module's memory-mapped register address space. This includes enable control, interrupt set and clear control, and end of interrupt (EOI) control.

### 11.5.8.1 Interrupt Raw Status/Set Register (IRAWSTAT)

The interrupt raw status/set register (IRAWSTAT) shows the interrupt status before enabling the interrupt and allows setting of the interrupt status. The IRAWSTAT is shown in [Figure 11-9](#) and described in [Table 11-13](#).

**Figure 11-9. Interrupt Raw Status/Set Register (IRAWSTAT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-13. Interrupt Raw Status/Set Register (IRAWSTAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                         |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved. Always read 0.                                                                                                                                                            |
| 1    | ADDRERR  | 0     | <b>Addressing violation error.</b> Reading this bit field reflects the raw status of the interrupt before enabling.<br>Indicates the interrupt is not set. Writing 0 has no effect. |
|      |          | 1     | Indicates the interrupt is set. Writing 1 sets the status.                                                                                                                          |
| 0    | PROTERR  | 0     | <b>Protection violation error.</b> Reading this bit field reflects the raw status of the interrupt before enabling.<br>Indicates the interrupt is not set. Writing 0 has no effect. |
|      |          | 1     | Indicates the interrupt is set. Writing 1 sets the status.                                                                                                                          |

### 11.5.8.2 Interrupt Enable Status/Clear Register (IENSTAT)

The interrupt enable status/clear register (IENSTAT) shows the status of enabled interrupt and allows clearing of the interrupt status. The IENSTAT is shown in [Figure 11-10](#) and described in [Table 11-14](#).

**Figure 11-10. Interrupt Enable Status/Clear Register (IENSTAT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-14. Interrupt Enable Status/Clear Register (IENSTAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                      |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved. Always read 0.                                                                                                                                         |
| 1    | ADDRERR  | 0     | <b>Addressing violation error.</b> Reading this bit field reflects the interrupt enabled status.<br>Indicates the interrupt is not set. Writing 0 has no effect. |
|      |          | 1     | Indicates the interrupt is set. Writing 1 clears the status.                                                                                                     |
| 0    | PROTERR  | 0     | <b>Protection violation error.</b> Reading this bit field reflects the interrupt enabled status.<br>Indicates the interrupt is not set. Writing 0 has no effect. |
|      |          | 1     | Indicates the interrupt is set. Writing 1 clears the status.                                                                                                     |

### 11.5.8.3 Interrupt Enable Register (IENSET)

The interrupt enable register (IENSET) allows setting/enabling the interrupt for address and/or protection violation condition. It also shows the value of the register (whether or not interrupt is enabled). The IENSET is shown in [Figure 11-11](#) and described in [Table 11-15](#).

**Figure 11-11. Interrupt Enable Register (IENSET)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-15. Interrupt Enable Register (IENSET) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                              |
|------|------------|--------|----------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved   | 0      | Reserved. Always read 0.                                                                                 |
| 1    | ADDRERR_EN | 0<br>1 | <b>Addressing violation error.</b><br>Writing a 0 has not effect.<br>Writing a 1 enables this interrupt. |
| 0    | PROTERR_EN | 0<br>1 | <b>Protection violation error.</b><br>Writing a 0 has not effect.<br>Writing a 1 enables this interrupt. |

### 11.5.8.4 Interrupt Enable Clear Register (IENCLR)

The interrupt enable clear register (IENCLR) allows clearing/disable the interrupt for address and/or protection violation condition. It also shows the value of the interrupt enable register (IENSET). The IENCLR is shown in [Figure 11-12](#) and described in [Table 11-16](#).

**Figure 11-12. Interrupt Enable Clear Register (IENCLR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-16. Interrupt Enable Clear Register (IENCLR) Field Descriptions**

| Bit  | Field       | Value  | Description                                                                                                      |
|------|-------------|--------|------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0      | Reserved. Always read 0.                                                                                         |
| 1    | ADDRERR_CLR | 0<br>1 | <b>Addressing violation error.</b><br>Writing a 0 has not effect.<br>Writing a 1 clears/disables this interrupt. |
| 0    | PROTERR_CLR | 0<br>1 | <b>Protection violation error.</b><br>Writing a 0 has not effect.<br>Writing a 1 clears/disables this interrupt. |

### 11.5.8.5 End of Interrupt Register (EOI)

The end of interrupt register (EOI) is used in software to indicate completion of the interrupt servicing of the SYSCFG interrupt (for address/protection violation). It is required to write a value of 0 to the EOI register after the software has processed the SYSCFG interrupt, this acts as an acknowledgement of completion of the SYSCFG interrupt so that the module can reliably generate the subsequent interrupts. The EOI is shown in [Figure 11-13](#) and described in [Table 11-17](#).

**Figure 11-13. End of Interrupt Register (EOI)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 11-17. End of Interrupt Register (EOI) Field Descriptions**

| Bit  | Field    | Value | Description                                                                  |
|------|----------|-------|------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved. Always read 0.                                                     |
| 7-0  | EOI ECT  | 0-FFh | <b>EOI vector value.</b> Write the interrupt distribution value of the chip. |

## 11.5.9 Fault Registers

The fault registers are a group of registers responsible for capturing the details on the faulty (address/protection violation errors) accesses, such as address and type of error.

### 11.5.9.1 Fault Address Register (FLTADDR)

The fault address register (FLTADDR) captures the address of the first transfer that causes the address or memory violation error. The FLTADDR is shown in [Figure 11-14](#) and described in [Table 11-18](#).

**Figure 11-14. Fault Address Register (FLTADDR)**

LEGEND: R = Read only; -n = value after reset

**Table 11-18. Fault Address Register (FLTADDR) Field Descriptions**

| Bit  | Field   | Value        | Description                                        |
|------|---------|--------------|----------------------------------------------------|
| 31-0 | FLTADDR | 0-FFFF FFFFh | <b>Fault address for the first fault transfer.</b> |

### 11.5.9.2 Fault Status Register (FLTSTAT)

The fault status register (FLTSTAT) holds/captures additional attributes and status of the first erroneous transaction. This includes things like the master id for the master that caused the address/memory violation error, details on whether it is a user or supervisor level read/write or execute fault. The FLTSTAT is shown in [Figure 11-15](#) and described in [Table 11-19](#).

**Figure 11-15. Fault Status Register (FLTSTAT)**

LEGEND: R = Read only; -n = value after reset

**Table 11-19. Fault Status Register (FLTSTAT) Field Descriptions**

| Bit   | Field    | Value                                                                                                                                                                                    | Description                                                                                                                                                                                                                                                                                                    |
|-------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | ID       | 0-FFh                                                                                                                                                                                    | <b>Transfer ID of the first fault transfer.</b>                                                                                                                                                                                                                                                                |
| 23-16 | MSTID    | 0-FFh                                                                                                                                                                                    | <b>Master ID of the first fault transfer.</b>                                                                                                                                                                                                                                                                  |
| 15-13 | Reserved | 0                                                                                                                                                                                        | Reserved. ### 11.5.11 Pin Multiplexing Control Registers (PINMUX0-PINMUX19)

Extensive use of pin multiplexing is used to accommodate the large number of peripheral functions in the smallest possible package. On the device, pin multiplexing can be controlled on a pin by pin basis. This is done by the pin multiplexing registers (PINMUX0-PINMUX19). Each pin that is multiplexed with several different functions has a corresponding 4-bit field in PINMUX $n$ . Pin multiplexing selects which of several peripheral pin functions control the pins I/O buffer output data and output enable values only. Note that the input from each pin is always routed to all of the peripherals that share the pin; the PINMUX registers have no effect on input from a pin. Hardware does not attempt to ensure that the proper pin multiplexing is selected for the peripherals or that interface mode is being used. Detailed information about the pin multiplexing and control is covered in the device-specific data manual. Access to the pin multiplexing utility is available in *OMAP-L132/L138, TMS320C6742/6/8 Pin Multiplexing Utility Application Report (SPRAB63)*.

#### 11.5.11.1 Pin Multiplexing Control 0 Register (PINMUX0)

**Figure 11-19. Pin Multiplexing Control 0 Register (PINMUX0)**

|               |    |    |    |               |    |    |    |
|---------------|----|----|----|---------------|----|----|----|
| 31            | 28 | 27 | 24 | 23            | 20 | 19 | 16 |
| PINMUX0_31_28 |    |    |    | PINMUX0_27_24 |    |    |    |
| R/W-0         |    |    |    | R/W-0         |    |    |    |
| 15            | 12 | 11 | 8  | 7             | 4  | 3  | 0  |
| PINMUX0_15_12 |    |    |    | PINMUX0_11_8  |    |    |    |
| R/W-0         |    |    |    | R/W-0         |    |    |    |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 11-23. Pin Multiplexing Control 0 Register (PINMUX0) Field Descriptions**

| Bit   | Field         | Value | Description                                                     | Type <sup>(1)</sup> |
|-------|---------------|-------|-----------------------------------------------------------------|---------------------|
| 31-28 | PINMUX0_31_28 |       | <b>RTC_ALARM/UART2_CTS/GP0[8]/DEEPSLEEP Control</b>             |                     |
|       |               | 0     | Selects Function DEEPSLEEP                                      | I                   |
|       |               | 1h    | Reserved                                                        | X                   |
|       |               | 2h    | Selects Function RTC_ALARM                                      | O                   |
|       |               | 3h    | Reserved                                                        | X                   |
|       |               | 4h    | Selects Function UART2_CTS                                      | I                   |
|       |               | 5h-7h | Reserved                                                        | X                   |
|       |               | 8h    | Selects Function GP0[8]                                         | I/O                 |
|       |               | 9h-Fh | Reserved                                                        | X                   |
| 27-24 | PINMUX0_27_24 |       | <b>AMUTE/PRU0_R30[16]/UART2_RTS/GP0[9]/PRU0_R31[16] Control</b> |                     |
|       |               | 0     | Selects Function PRU0_R31[16]                                   | I                   |
|       |               | 1h    | Selects Function AMUTE                                          | I/O                 |
|       |               | 2h    | Selects Function PRU0_R30[16]                                   | O                   |

### 11.5.12 Suspend Source Register (SUSPSRC)

The suspend source register (SUSPSRC) indicates the emulation suspend source for those peripherals that support emulation suspend. A value of 1 (default) for a SUSPSRC bit corresponding to the peripheral, indicates that the DSP emulator controls the peripheral's emulation suspend signal. You should maintain this register with its default values. The flexibility of the device architecture allows either the ARM or the DSP to control the various peripherals (setup registers, service interrupts, etc.). While this assignment is a matter of software convention, during an emulation halt, the device must know which peripherals are associated with the halting processor, so that only those modules receive the suspend signal. This allows peripherals associated with the other (unhalted) processor to continue normal operation.

The SUSPSRC is shown in [Figure 11-39](#) and described in [Table 11-43](#).

### 11.5.13 Chip Signal Register (CHIPSIG)

The DSP has access to 4 ARM interrupt events in the ARM interrupt map: SYSCFG\_CHIPINT0, SYSCFG\_CHIPINT1, SYSCFG\_CHIPINT2, and SYSCFG\_CHIPINT3. The ARM has access to 3 DSP interrupt events in the DSP interrupt event map: SYSCFG\_CHIPINT2, SYSCFG\_CHIPINT3, and NMI.

**NOTE:** SYSCFG\_CHIPINT2 and SYSCFG\_CHIPINT3 are essentially for the ARM to interrupt the DSP. However, these are additionally mapped to the ARM interrupt controller (AINTC), so that it can be used as debug interrupts, in case there is a need to halt both processors simultaneously.

The ARM may generate an interrupt to the DSP by setting one of the two CHIPSIG[3-2] bits or an NMI interrupt by setting the CHIPSIG[4] bit in the chip signal register (CHIPSIG). The DSP may generate an interrupt to the ARM by setting one of the four CHIPSIG[3-0] bits. Writing a 1 to these bits sets the interrupts, writing a 0 has no effect. Reads return the value of these bits and can also be used as status bits. The CHIPSIG is shown in [Figure 11-40](#) and described in [Table 11-44](#).

### 11.5.14 Chip Signal Clear Register (CHIPSIG\_CLR)

The chip signal clear register (CHIPSIG\_CLR) is used to clear the bits set in the chip signal register (CHIPSIG). Writing a 1 to a CHIPSIG[n] bit in CHIPSIG\_CLR clears the corresponding CHIPSIG[n] bit in CHIPSIG; writing a 0 has no effect. After servicing the interrupt, the interrupted processor can clear the bits set in CHIPSIG by writing 1 to the corresponding bits in CHIPSIG\_CLR. The other processor may poll the CHIPSIG[n] bit to determine when the interrupted processor has completed the interrupt service. The CHIPSIG\_CLR is shown in [Figure 11-41](#) and described in [Table 11-45](#).

For more information on ARM interrupts, see the *ARM Interrupt Controller (AINTC)* chapter. For more information on DSP interrupts, see the *DSP Subsystem* chapter.

### 11.5.15 Chip Configuration 0 Register (CFGCHIP0)

The chip configuration 0 register (CFGCHIP0) controls the following functions:

- PLL Controller 0 memory-mapped register lock: Used to lock out writes to the PLLC0 memory-mapped registers (MMRs) to prevent any erroneous writes in software to the PLLC0 register space.
- EDMA3\_0 Transfer Controller Default Burst Size (DBS) Control: This controls the maximum number of bytes issued per read/write command or the burst size for the individual transfer controllers (TCs) on the device. By default for all transfer controllers, the burst size is set to 16 bytes. However, CFGCHIP0 allows configurability of this parameter so that the TC can have a burst size of 16, 32, or 64 bytes. The burst size determines the intra packet efficiency for the EDMA3\_0 transfers. Additionally, it also facilitates preemption at a system level, as all transfer requests are internally broken down by the transfer controller up to DBS size byte chunks and on a system level, each master's priority (configured by the MSTPRI register) is evaluated at burst size boundaries. The DBS value can significantly impact the standalone throughput performance depending on the source and destination (bus width/frequency/burst support etc) and the TC FIFO size, etc. Therefore, the DBS size configuration should be carefully analyzed to meet the system's throughput/performance requirements.

The CFGCHIP0 is shown in [Figure 11-42](#) and described in [Table 11-46](#).

### 11.5.16 Chip Configuration 1 Register (CFGCHIP1)

The chip configuration 1 register (CFGCHIP1) controls the following functions:

- eCAP0/1/2 event input source: Allows using McASP0 TX/RX events or various EMAC TX/RX threshold, pulse, or miscellaneous interrupt events as eCAP event input sources.
- HPI Control: Allows HPIEN bit control that determines whether or not the HPI module has control over the HPI pins (multiplexed with other peripheral pins). It also provides configurability to select whether the host address is a word address or a byte address mode.
- EDMA3\_1 Transfer Controller Default Burst Size (DBS) Control: This controls the maximum number of bytes issued per read/write command or the burst size for the individual transfer controllers (TCs) on the device. By default for all transfer controllers, the burst size is set to 16 bytes. However, CFGCHIP1 allows configurability of this parameter so that the TC can have a burst size of 16, 32, or 64 bytes. The burst size determines the intra packet efficiency for the EDMA3\_1 transfers. Additionally, it also facilitates preemption at a system level, as all transfer requests are internally broken down by the transfer controller up to DBS size byte chunks and on a system level, each master's priority (configured by the MSTPRI register) is evaluated at burst size boundaries. The DBS value can significantly impact the standalone throughput performance depending on the source and destination (bus width/frequency/burst support etc) and the TC FIFO size, etc. Therefore, the DBS size configuration should be carefully analyzed to meet the system's throughput/performance requirements.
- eHRPWM Time Base Clock (TBCLK) Synchronization: Allows the software to globally synchronize all enabled eHRPWM modules to the time base clock (TBCLK).
- McASP0 AMUTEIN signal source control: Allows selecting GPIO interrupt from different banks as source for the McASP0 AMUTEIN signal.

The CFGCHIP1 is shown in [Figure 11-43](#) and described in [Table 11-47](#).

### 11.5.17 Chip Configuration 2 Register (CFGCHIP2)

The chip configuration 2 register (CFGCHIP2) controls the following functions:

- USB1.1 OHCI
- USB2.0 OTG PHY

The CFGCHIP2 is shown in [Figure 11-44](#) and described in [Table 11-48](#).

**Figure 11-44. Chip Configuration 2 Register (CFGCHIP2)**

### 11.5.18 Chip Configuration 3 Register (CFGCHIP3)

The chip configuration 3 register (CFGCHIP3) controls the following peripheral/module functions:

- EMAC MII/RMII Mode Select.
- uPP Clock Source Control: Allows control for the source of the uPP 2x transmit clock.
- PLL Controller 1 memory-mapped register lock: Used to lock out writes to the PLLC1 memory-mapped registers (MMRs) to prevent any erroneous writes in software to the PLLC1 register space.
- ASYNC3 Clock Source Control: Allows control for the source of the ASYNC3 clock.
- PRU Event Input Select.
- DIV4p5 Clock Enable/Disable: The DIV4p5 (/4.5) hardware clock divider is provided to generate 133 MHz from the 600 MHz PLL clock for use as clocks to the EMIFs. Allows enabling/disabling this clock divider.
- EMIFA Module Clock Source Control: Allows control for the source of the EMIFA module clock.

The CFGCHIP3 is shown in [Figure 11-45](#) and described in [Table 11-49](#).

### 11.5.19 Chip Configuration 4 Register (CFGCHIP4)

The chip configuration 4 register (CFGCHIP4) is used for clearing the AMUNTEIN signal for McASP0. Writing a 1 causes a single pulse that clears the latched GPIO interrupt for AMUTEIN of McASP0, if it was previously set; reads always return a value of 0. The CFGCHIP4 is shown in [Figure 11-46](#) and described in [Table 11-50](#).

**Figure 11-46. Chip Configuration 4 Register (CFGCHIP4)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### 11.5.20 VTP I/O Control Register (VTPIO\_CTL)

The VTP I/O control register (VTPIO\_CTL) is used to control the calibration of the DDR2/mDDR memory controller I/Os with respect to voltage, temperature, and process (VTP). The voltage, temperature, and process information is used to control the IO's output impedance. The VTPIO\_CTL is shown in Figure 11-47 and described in Table 11-51.

**Figure 11-47. VTP I/O Control Register (VTPIO\_CTL)**

### 11.5.21 DDR Slew Register (DDR\_SLEW)

The DDR slew register (DDR\_SLEW) reflects the DDR I/O timing as programmed in the device eFuse. The CMOSEN field configures the DDR I/O cells into an LVCMOS buffer (this makes it mDDR compatible). The DDR\_SLEW is shown in Figure 11-48 and described in Table 11-52.

**Figure 11-48. DDR Slew Register (DDR\_SLEW)**

| Bit  | Field      | Value | Description                                                                                                                                                                                                                                                                                                                       |
|------|------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | PUPDENA[n] |       | <b>Enables internal pull-up or pull-down functionality for pin group CP[n].</b> See your device-specific data manual for pin group information. The internal pull-up or pull-down functionality selection for bit position $n$ in PUPD_ENA is set in the same bit position $n$ of the pullup/pulldown select register (PUPD_SEL). |
|      |            | 0     | Internal pull-up or pull-down functionality for pin group $n$ is disabled.                                                                                                                                                                                                                                                        |
|      |            | 1     | Internal pull-up or pull-down functionality for pin group $n$ is enabled.                                                                                                                                                                                                                                                         |

### 11.5.24 Pullup/Pulldown Select Register (PUPD\_SEL)

The pullup/pulldown select register (PUPD\_SEL) selects between the pull-up or pull-down functionality for the pin group  $n$  defined in your device-specific data manual. The PUPD\_SEL is shown in [Figure 11-51](#) and described in [Table 11-55](#) and [Table 11-56](#).

**NOTE:** The PUPD\_SEL settings are not active until the device is out of reset. During reset, all of the CP[n] pins are pulled down. If the application requires a pull-up during reset, an external pull-up should be used.

**Figure 11-51. Pullup/Pulldown Select Register (PUPD\_SEL)**

## ***ARM Interrupt Controller (AINTC)***

---

---

| Topic                               | Page       |
|-------------------------------------|------------|
| <b>12.1 Introduction .....</b>      | <b>298</b> |
| <b>12.2 Interrupt Mapping .....</b> | <b>298</b> |
| <b>12.3 AINTC Methodology .....</b> | <b>301</b> |
| <b>12.4 AINTC Registers .....</b>   | <b>305</b> |

## 12.1 Introduction

The ARM interrupt controller (AINTC) is an interface between interrupts coming from different parts of the system (these are referred to as system interrupts in this document), and the ARM9 interrupt interface. ARM9 supports two types of interrupts: FIQ and IRQ (these are referred to as host interrupts in this document). The AINTC has the following features:

- Supports up to 101 system interrupts.
- Supports up to 32 interrupt channels.
- Channels 0 and 1 are mapped (hard-wired) to the FIQ ARM interrupt and channels 2-31 are mapped to IRQ ARM interrupt.
- Each system interrupt can be enabled and disabled.
- Each host interrupt can be enabled and disabled.
- Hardware prioritization of interrupts.
- Combining of interrupts from IPs to a single system interrupt.
- Supports two active low debug interrupts.

See the ARM926EJ Technical Reference Manual for information about the ARM's FIQ and IRQ interrupts.

## 12.2 Interrupt Mapping

The AINTC supports up to 101 system interrupts from different peripherals to be mapped to 32 channels inside the AINTC (see [Figure 12-1](#)). Interrupts from these 32 channels are further mapped to either an ARM FIQ interrupt or an ARM IRQ interrupt.

- Any of the 101 system interrupts can be mapped to any of the 32 channels.
- Multiple interrupts can be mapped to a single channel.
- An interrupt should not be mapped to more than one channel.
- Interrupts from channels 0 and 1 are mapped to FIQ ARM interrupt on host side.
- Interrupts from channels 2 to 31 are mapped to IRQ ARM interrupt on host side.
- For  $l < k$ , interrupts on channel- $l$  have higher priority than interrupts on channel- $k$ .
- For interrupts on same channel, priority is determined by the hardware interrupt number. The lower the interrupt number, the higher the priority.

[Table 12-1](#) shows the system interrupt assignments for the AINTC.

**Table 12-1. AINTC System Interrupt Assignments**

| Event | Interrupt Name     | Source                                                                     |
|-------|--------------------|----------------------------------------------------------------------------|
| 0     | COMMTX             | ARM                                                                        |
| 1     | COMMRX             | ARM                                                                        |
| 2     | NINT               | ARM                                                                        |
| 3     | PRU_EVTOUT0        | PRUSS Interrupt                                                            |
| 4     | PRU_EVTOUT1        | PRUSS Interrupt                                                            |
| 5     | PRU_EVTOUT2        | PRUSS Interrupt                                                            |
| 6     | PRU_EVTOUT3        | PRUSS Interrupt                                                            |
| 7     | PRU_EVTOUT4        | PRUSS Interrupt                                                            |
| 8     | PRU_EVTOUT5        | PRUSS Interrupt                                                            |
| 9     | PRU_EVTOUT6        | PRUSS Interrupt                                                            |
| 10    | PRU_EVTOUT7        | PRUSS Interrupt                                                            |
| 11    | EDMA3_0_CC0_INT0   | EDMA3_0 Channel Controller 0 Shadow Region 0 Transfer Completion Interrupt |
| 12    | EDMA3_0_CC0_ERRINT | EDMA3_0 Channel Controller 0 Error Interrupt                               |
| 13    | EDMA3_0_TC0_ERRINT | EDMA3_0 Transfer Controller 0 Error Interrupt                              |
| 14    | EMIFA_INT          | EMIFA Interrupt                                                            |
| 15    | IIC0_INT           | I2C0 interrupt                                                             |
| 16    | MMCSD0_INT0        | MMCSD0 MMC/SD Interrupt                                                    |
| 17    | MMCSD0_INT1        | MMCSD0 SDIO Interrupt                                                      |
| 18    | PSC0_ALLINT        | PSC0 Interrupt                                                             |
| 19    | RTC_IRQS[1:0]      | RTC Interrupt                                                              |
| 20    | SPI0_INT           | SPI0 Interrupt                                                             |
| 21    | T64P0_TINT12       | Timer64P0 Interrupt (TINT12)                                               |
| 22    | T64P0_TINT34       | Timer64P0 Interrupt (TINT34)                                               |
| 23    | T64P1_TINT12       | Timer64P1 Interrupt (TINT12)                                               |
| 24    | T64P1_TINT34       | Timer64P1 Interrupt (TINT34)                                               |
| 25    | UART0_INT          | UART0 Interrupt                                                            |
| 26    | —                  | Reserved                                                                   |
| 27    | PROTERR            | SYSCFG Protection Shared Interrupt                                         |
| 28    | SYSCFG_CHIPINT0    | SYSCFG CHIPSIG Register                                                    |
| 29    | SYSCFG_CHIPINT1    | SYSCFG CHIPSIG Register                                                    |
| 30    | SYSCFG_CHIPINT2    | SYSCFG CHIPSIG Register                                                    |
| 31    | SYSCFG_CHIPINT3    | SYSCFG CHIPSIG Register                                                    |
| 32    | EDMA3_0_TC1_ERRINT | EDMA3_0 Transfer Controller 1 Error Interrupt                              |
| 33    | EMAC_C0RXTHRESH    | EMAC - Core 0 Receive Threshold Interrupt                                  |
| 34    | EMAC_C0RX          | EMAC - Core 0 Receive Interrupt                                            |
| 35    | EMAC_C0TX          | EMAC - Core 0 Transmit Interrupt                                           |
| 36    | EMAC_C0MISC        | EMAC - Core 0 Miscellaneous Interrupt                                      |
| 37    | EMAC_C1RXTHRESH    | EMAC - Core 1 Receive Threshold Interrupt                                  |
| 38    | EMAC_C1RX          | EMAC - Core 1 Receive Interrupt                                            |
| 39    | EMAC_C1TX          | EMAC - Core 1 Transmit Interrupt                                           |
| 40    | EMAC_C1MISC        | EMAC - Core 1 Miscellaneous Interrupt                                      |
| 41    | DDR2_MEMERR        | DDR2 Controller Interrupt                                                  |
| 42    | GPIO_B0INT         | GPIO Bank 0 Interrupt                                                      |
| 43    | GPIO_B1INT         | GPIO Bank 1 Interrupt                                                      |
| 44    | GPIO_B2INT         | GPIO Bank 2 Interrupt                                                      |
| 45    | GPIO_B3INT         | GPIO Bank 3 Interrupt                                                      |
| 46    | GPIO_B4INT         | GPIO Bank 4 Interrupt                                                      |

**Table 12-1. AINTC System Interrupt Assignments (continued)**

| Event | Interrupt Name   | Source                                                                     |
|-------|------------------|----------------------------------------------------------------------------|
| 47    | GPIO_B5INT       | GPIO Bank 5 Interrupt                                                      |
| 48    | GPIO_B6INT       | GPIO Bank 6 Interrupt                                                      |
| 49    | GPIO_B7INT       | GPIO Bank 7 Interrupt                                                      |
| 50    | GPIO_B8INT       | GPIO Bank 8 Interrupt                                                      |
| 51    | IIC1_INT         | I2C1 Interrupt                                                             |
| 52    | LCDC_INT         | LCD Controller Interrupt                                                   |
| 53    | UART_INT1        | UART1 Interrupt                                                            |
| 54    | MCASP_INT        | McASP0 Combined RX/TX Interrupt                                            |
| 55    | PSC1_ALLINT      | PSC1 Interrupt                                                             |
| 56    | SPI1_INT         | SPI1 Interrupt                                                             |
| 57    | UHPI_ARMINT      | HPI ARM Interrupt                                                          |
| 58    | USB0_INT         | USB0 (USB2.0) Interrupt                                                    |
| 59    | USB1_HCINT       | USB1 (USB1.1) OHCI Host Controller Interrupt                               |
| 60    | USB1_R/WAKEUP    | USB1 (USB1.1) Remote Wakeup Interrupt                                      |
| 61    | UART2_INT        | UART2 Interrupt                                                            |
| 62    | —                | Reserved                                                                   |
| 63    | EHRPWM0          | HiResTimer / PWM0 Interrupt                                                |
| 64    | EHRPWM0TZ        | HiResTimer / PWM0 Trip Zone Interrupt                                      |
| 65    | EHRPWM1          | HiResTimer / PWM1 Interrupt                                                |
| 66    | EHRPWM1TZ        | HiResTimer / PWM1 Trip Zone Interrupt                                      |
| 67    | SATA_INT         | SATA Controller Interrupt                                                  |
| 68    | T64P2_ALL        | Timer64P2 Combined Interrupt (TINT12 and TINT34)                           |
| 69    | ECAP0            | eCAP0 Interrupt                                                            |
| 70    | ECAP1            | eCAP1 Interrupt                                                            |
| 71    | ECAP2            | eCAP2 Interrupt                                                            |
| 72    | MMCSD1_INT0      | MMCSD1 MMC/SD Interrupt                                                    |
| 73    | MMCSD1_INT1      | MMCSD1 SDIO Interrupt                                                      |
| 74    | T64P2_CMPINT0    | Timer64P2 - Compare Interrupt 0                                            |
| 75    | T64P2_CMPINT1    | Timer64P2 - Compare Interrupt 1                                            |
| 76    | T64P2_CMPINT2    | Timer64P2 - Compare Interrupt 2                                            |
| 77    | T64P2_CMPINT3    | Timer64P2 - Compare Interrupt 3                                            |
| 78    | T64P2_CMPINT4    | Timer64P2 - Compare Interrupt 4                                            |
| 79    | T64P2_CMPINT5    | Timer64P2 - Compare Interrupt 5                                            |
| 80    | T64P2_CMPINT6    | Timer64P2 - Compare Interrupt 6                                            |
| 81    | T64P2_CMPINT7    | Timer64P2 - Compare Interrupt 7                                            |
| 82    | T64P3_CMPINT0    | Timer64P3 - Compare Interrupt 0                                            |
| 83    | T64P3_CMPINT1    | Timer64P3 - Compare Interrupt 1                                            |
| 84    | T64P3_CMPINT2    | Timer64P3 - Compare Interrupt 2                                            |
| 85    | T64P3_CMPINT3    | Timer64P3 - Compare Interrupt 3                                            |
| 86    | T64P3_CMPINT4    | Timer64P3 - Compare Interrupt 4                                            |
| 87    | T64P3_CMPINT5    | Timer64P3 - Compare Interrupt 5                                            |
| 88    | T64P3_CMPINT6    | Timer64P3 - Compare Interrupt 6                                            |
| 89    | T64P3_CMPINT7    | Timer64P3 - Compare Interrupt 7                                            |
| 90    | ARMCLKSTOPREQ    | PSC0 Interrupt                                                             |
| 91    | uPP_ALLINT       | uPP Combined Interrupt                                                     |
| 92    | VPIF_ALLINT      | VPIF Combined Interrupt                                                    |
| 93    | EDMA3_1_CC0_INT0 | EDMA3_1 Channel Controller 0 Shadow Region 0 Transfer Completion Interrupt |

**Table 12-1. AINTC System Interrupt Assignments (continued)**

| Event | Interrupt Name     | Source                                           |
|-------|--------------------|--------------------------------------------------|
| 94    | EDMA3_1_CC0_ERRINT | EDMA3_1 Channel Controller 0 Error Interrupt     |
| 95    | EDMA3_1_TC0_ERRINT | EDMA3_1 Transfer Controller 0 Error Interrupt    |
| 96    | T64P3_ALL          | Timer64P3 Combined Interrupt (TINT12 and TINT34) |
| 97    | MCBSP0_RINT        | McBSP0 Receive Interrupt                         |

## 12.3 AINTC Methodology

The AINTC module controls the system interrupt mapping to the host interrupt interface. System interrupts are generated by the device peripherals. The AINTC receives the system interrupts and maps them to internal channels. The channels are used to combine and prioritize system interrupts. These channels are then mapped onto the host interface that is typically a smaller number of host interrupts or a vector input. Interrupts from system side are active high in polarity. Also, they are pulse type of interrupts.

The AINTC encompasses many functions to process the system interrupts and prepare them for the host interface. These functions are: processing, enabling, status, channel mapping, host interrupt mapping, prioritization, vectorization, debug, and host interfacing. [Figure 12-2](#) illustrates the flow of system interrupts through the functions to the host. The following subsections describe each part of the flow.

**Figure 12-2. Flow of System Interrupts to Host**

### 12.3.1 Interrupt Processing

The interrupt processing block does the following tasks:

- Synchronization of slower and asynchronous interrupts
- Conversion of polarity to active high
- Conversion of interrupt type to pulse interrupts

After the processing block, all interrupts will be active-high pulses.

### 12.3.2 Interrupt Enabling

The AINTC interrupt enable system allows individual interrupts to be enabled or disabled. Use the following sequence to enable interrupts:

1. Enable global host interrupts. All host interrupts are enabled by setting the ENABLE bit in the global enable register (GER). Individual host interrupts are enabled or disabled from their individual enables and are not overridden by the global enable.
2. Enable host interrupt lines. Host interrupt lines (FIQ and IRQ) can be enabled through one of two methods:
  - (a) Set the desired mapped bit(s) in the host interrupt enable register (HIER), or
  - (b) Write the host interrupt index (0-1) to the host interrupt enable indexed set register (HIEISR) for every interrupt line to enable.
3. Enable system interrupts. System interrupts can be individually enabled through one of two methods:
  - (a) Set the desired mapped bit(s) in the system interrupt enable set registers (ESR1-ESR4), or
  - (b) Write the system interrupt index (0-100) to the system interrupt enable indexed set register (EISR) for every system interrupt to enable.

### 12.3.3 Interrupt Status Checking

The next stage is to capture which system interrupts are pending. There are two kinds of pending status: raw status and enabled status. Raw status is the pending status of the system interrupt without regards to the enable bit for the system interrupt. Enabled status is the pending status of the system interrupts with the enable bits active. When the enable bit is inactive, the enabled status will always be inactive.

The enabled status of system interrupts is captured in system interrupt status enabled/clear registers (SECR1-SECR4). Status of system interrupt 'N' is indicated by the Nth bit of SECR1-SECR4. Since there exists 101 system interrupts, four 32-bit registers are used to capture the enabled status of interrupts.

The pending status reflects whether the system interrupt occurred since the last time the status register bit was cleared. Each bit in the status register is individually clearable.

### 12.3.4 Interrupt Channel Mapping

The AINTC has 32 internal channels to which enabled system interrupts can be mapped. Higher priority interrupts should be mapped to channels 0 and 1. Other interrupts can be mapped to any of the channels from 2 to 31. Channel 0 has highest priority and channel 31 has the lowest priority. Channels 0 and 1 are connected to FIQ ARM interrupt. Channels 2 to 31 are connected to IRQ ARM interrupt. Channels are used to group the system interrupts into a smaller number of priorities that can be given to a host interface with a very small number of interrupt inputs. When multiple system interrupts are mapped to the same channel their interrupts are ORed together so that when either is active the output is active.

The channel map registers (CMR<sub>m</sub>) define the channel for each system interrupt. There is one register per 4 system interrupts; therefore, there are 26 channel map registers (CMR0-CMR25) for a system of 101 interrupts. Channel for each system interrupt can be set using these registers.

### 12.3.5 Host Interrupt Mapping Interrupts

The Host is ARM9, which has two lines: FIQ and IRQ. The 32 channels from the AINTC are mapped to these two lines. The AINTC has a fixed host interrupt mapping scheme. Channels 0 and 1 are mapped to FIQ and channels 2-31 are mapped to IRQ. Thus, system interrupts mapped to channels 0 and 1 are propagated as FIQ to the host and system interrupts mapped to channels 2-31 are propagated as IRQ to the host. When multiple channels are mapped to the same host interrupt, then prioritization is done to select which interrupt is in the highest-priority channel and which should be sent first to the host.

### 12.3.6 Interrupt Prioritization

The next stage of the AINTC is prioritization. Since multiple interrupts feed into a single channel and multiple channels feed into a single host interrupt, it is necessary to prioritize between all the system interrupts/channels to decide on a single system interrupt to handle. The AINTC provides hardware to perform this prioritization with a given scheme so that software does not have to do this. There are two levels of prioritizations:

1. The first level of prioritization is between the active channels for a host interrupt. Channel 0 has the highest priority and channel 31 has the lowest. So the first level of prioritization picks the lowest numbered active channel.
2. The second level of prioritization is between the active system interrupts for the prioritized channel. The system interrupt in vector position 0 has the highest priority and system interrupt 100 has the lowest priority. So the second level of prioritization picks the lowest vector position active system interrupt.

The prioritized system interrupt for each host interrupt line (FIQ and IRQ) can be obtained from the host interrupt prioritized index registers (HIPIR1 and HIPIR2). The host interrupt prioritized index register values update dynamically as interrupts arrive at AINTC so care should be taken to avoid register race conditions.

The AINTC features a prioritization hold mode that is intended to prevent race conditions while servicing interrupts. This mode is enabled by setting the priority hold mode (PRHOLDMODE) bit in the control register (CR). When enabled, a read of either the host interrupt prioritized index register (HIPIR $n$ ) or the host interrupt prioritized vector register (HIPVR $n$ ) will freeze both the HIPIR $n$  and HIPVR $n$  values for the respective host interrupt  $n$ . The values are frozen until one of the following actions is taken to release the registers:

1. Write to the host interrupt prioritized index register (HIPIR $n$ )
2. Write to the host interrupt prioritized vector register (HIPVR $n$ )
3. Write-set bit  $n$  of the host interrupt enable register (HIER)
4. Write-set the active interrupt index to the host interrupt enable index set register (HIEISR)
5. Write-clear the active interrupt index to the host interrupt enable index clear register (HIEICR)

### 12.3.7 Interrupt Nesting

If interrupt service routines (ISRs) consume a large number of CPU cycles and may delay the servicing of other interrupts, the AINTC can perform a nesting function in its prioritization. Nesting is a method of disabling certain interrupts (usually lower-priority interrupts) when an interrupt is taken so that only those desired interrupts can trigger to the host while it is servicing the current interrupt. The typical usage is to nest on the current interrupt and disable all interrupts of the same or lower priority (or channel). Then the host will only be interrupted from a higher priority interrupt.

Nesting is available in 1 of 3 methods selectable by the NESTMODE bit in the control register (CR):

1. Nesting for all host interrupts, based on channel priority: When an interrupt is taken, the nesting level is set to its channel priority. From then, that channel priority and all lower priority channels will be disabled from generating host interrupts and only higher priority channels are allowed. When the interrupt is completely serviced, the nesting level is returned to its original value. When there is no interrupt being serviced, there are no channels disabled due to nesting. The global nesting level register (GNLR) allows the checking and setting of the global nesting level across all host interrupts. The nesting level is the channel (and all of lower priority channels) that are nested out because of a current interrupt.
2. Nesting for individual host interrupts, based on channel priority: Always nest based on channel priority for each host interrupt individually. When an interrupt is taken on a host interrupt, then, the nesting level is set to its channel priority for just that host interrupt, and other host interrupts do not have their nesting affected. Then for that host interrupt, equal or lower priority channels will not interrupt the host but may on other host interrupts if programmed. When the interrupt is completely serviced the nesting level for the host interrupt is returned to its original value. The host interrupt nesting level registers (HINLR1 and HINLR2) display and control the nesting level for each host interrupt. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.

3. Software manually performs the nesting of interrupts. When an interrupt is taken, the software will disable all the host interrupts, manually update the enables for any or all the system interrupts, and then re-enable all the host interrupts. This now allows only the system interrupts that are still enabled to trigger to the host. When the interrupt is completely serviced the software must reverse the changes to re-enable the nested out system interrupts. This method requires the most software interaction but gives the most flexibility if simple channel based nesting mechanisms are not adequate.

The recommended approach is the automatic host interrupt nesting method (second method). Because higher priority interrupts can preempt lower priority interrupts in this method, a software stack is used to keep track of nest priorities. The base stack value should be initialized to the default nest priority of the application. Take the following steps within the ARM hardware interrupt service routine to handle interrupts using host interrupt priority nesting:

1. Disable the ARM hardware interrupt.
2. Clear the OVERRIDE bit in the host interrupt nesting level register  $n$  (HINLR $n$ ) to expose the priority level of the active interrupt.
3. Push the active (or desired) interrupt priority value into the nest priority stack.
4. Write the active (or desired) priority level into HINLR $n$  by setting the OVERRIDE bit.
5. Calculate and store the ISR address for the active interrupt. Unfreeze the host interrupt prioritized index register  $n$  (HIPIR $n$ ) and the host interrupt prioritized vector register  $n$  (HIPVR $n$ ), if the PRHOLDMODE bit in the control register (CR) is set.
6. Clear the system interrupt status by setting the appropriate bit in the system interrupt status enabled/clear register  $n$  (SECR $n$ ) or by writing the appropriate index to the system interrupt status indexed clear register (SICR).
7. Acknowledge and enable the ARM hardware interrupt.
8. Execute the ISR at the address stored from step 5. During this step, interrupts enabled by the new nest priority level will be able to preempt the ISR.
9. Disable the ARM hardware interrupt.
10. Discard the most recent priority level in the nest priority stack and restore the previous priority level to HINLR $n$  by setting the OVERRIDE bit.
11. Enable the ARM hardware interrupt.

### 12.3.8 Interrupt Vectorization

The next stage of the AINTC is vectorization. Vectorization is an advanced feature that allows the host to receive an interrupt service routine (ISR) address in addition to just the interrupt status. Without vectorization the host would receive the interrupt and enter a general ISR that gets the prioritized system interrupt to service from the AINTC, looks up the specific ISR address for that system interrupt, and then jumps to that address. With vectorization the host can read a register that has the ISR address already calculated and jump to that address immediately.

Vectorization uses a base and universal size where all the ISR code is placed in a contiguous memory region with each ISR code a standard size. For this calculation, the vector base register (VBR) is programmed by software to hold the base address of all the ISR code and the vector size register (VSR) is programmed for the size in words between ISR code for each system interrupt. The index number of each system interrupt is used to calculate the final offset. The specific system interrupt ISR address is then calculated as:

$$\text{ISR address} = \text{base} + (\text{index} \times \text{size})$$

There is also a special case when there is no interrupt pending and then the ISR address is the ISR Null address. This is in case the vector address is executed when there is no pending interrupt so that a Null handler can be in place to just return from the interrupt. The vector null address register (VNR) holds the address of the ISR null address. When there is a pending interrupt then the ISR address is calculated as *exact base + offset* for that interrupt number.

### 12.3.9 Interrupt Status Clearing

After servicing the interrupt (after execution of the ISR), interrupt status is to be cleared. If a system interrupt status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. For clearing the status of an interrupt, whose interrupt number is N, write a 1 to the Nth bit position in the system interrupt status enabled/clear registers (SECR1-SECR4). System interrupt N can also be cleared by writing the value N into the system interrupt status indexed clear register (SICR).

### 12.3.10 Interrupt Disabling

At any time, if any interrupt is not to be propagated to the host, then that interrupt should be disabled. For disabling an interrupt whose interrupt number is N, write a 1 to the Nth bit in the system interrupt enable clear registers (ECR1-ECR4). System interrupt N can also be disabled by writing the value N in the system interrupt enable indexed clear register (EICR).

## 12.4 AINTC Registers

Table 12-2 lists the memory-mapped registers for the AINTC.

### 12.4.1 Revision Identification Register (REVID)

The revision identification register (REVID) is shown in [Figure 25-35](#) and described in [Table 12-3](#).

**Figure 12-3. Revision Identification Register (REVID)**

LEGEND: R = Read only; -n = value after reset

**Table 12-3. Revision Identification Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description               |
|------|-------|------------|---------------------------|
| 31-0 | REV   | 4E82 A900h | Revision ID of the AINTC. |

### 12.4.2 Control Register (CR)

The control register (CR) holds global control parameters. The CR is shown in [Figure 12-4](#) and described in [Table 12-4](#).

**Figure 12-4. Control Register (CR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 12-4. Control Register (CR) Field Descriptions**

| Bit  | Field      | Value | Description                                                                                                                                                        |
|------|------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved   | 0     | Reserved                                                                                                                                                           |
| 4    | PRHOLDMODE | 0     | Enables priority holding mode.                                                                                                                                     |
|      |            | 0     | No priority holding. Prioritized MMRs will continually update.                                                                                                     |
|      |            | 1     | Priority holding enabled. Prioritized Index and Vector Address MMRs will hold their value after the first is read. See <a href="#">Section 12.3.6</a> for details. |
| 3-2  | NESTMODE   | 0-3h  | Nesting mode.                                                                                                                                                      |
|      |            | 0     | No nesting                                                                                                                                                         |
|      |            | 1h    | Automatic individual nesting (per host interrupt)                                                                                                                  |
|      |            | 2h    | Automatic global nesting (over all host interrupts)                                                                                                                |
|      |            | 3h    | Manual nesting                                                                                                                                                     |
| 1-0  | Reserved   | 0     | Reserved                                                                                                                                                           |

### 12.4.3 Global Enable Register (GER)

The global enable register (GER) enables all the host interrupts. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable. The GER is shown in [Figure 12-5](#) and described in [Table 12-5](#).

**Figure 12-5. Global Enable Register (GER)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 12-5. Global Enable Register (GER) Field Descriptions**

| Bit  | Field    | Value | Description                                                              |
|------|----------|-------|--------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                                 |
| 0    | ENABLE   | 0-1   | The current global enable value when read. Writes set the global enable. |

### 12.4.4 Global Nesting Level Register (GNLR)

The global nesting level register (GNLR) allows the checking and setting of the global nesting level across all host interrupts when automatic global nesting mode is set. The nesting level is the channel (and all of lower priority) that are nested out because of a current interrupt. The GNLR is shown in [Figure 12-6](#) and described in [Table 12-6](#).

**Figure 12-6. Global Nesting Level Register (GNLR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 12-6. Global Nesting Level Register (GNLR) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                 |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | OVERRIDE | 0-1    | Always read as 0. Writes of 1 override the automatic nesting and set the NESTLVL to the written data.                                                                                       |
| 30-9 | Reserved | 0      | Reserved                                                                                                                                                                                    |
| 8-0  | NESTLVL  | 0-1FFh | The current global nesting level (highest channel that is nested). Writes set the nesting level. In autonesting mode this value is updated internally, unless the auto_override bit is set. |

### 12.4.5 System Interrupt Status Indexed Set Register (SISR)

The system interrupt status indexed set register (SISR) allows setting the status of an interrupt. The interrupt to set is the INDEX value written. This sets the Raw Status Register bit of the given INDEX. The SISR is shown in [Figure 12-7](#) and described in [Table 12-7](#).

**Figure 12-7. System Interrupt Status Indexed Set Register (SISR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-7. System Interrupt Status Indexed Set Register (SISR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                      |
|------|----------|-------|----------------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved                                                                         |
| 6-0  | INDEX    | 0-7Fh | Writes set the status of the interrupt given in the INDEX value. Reads return 0. |

### 12.4.6 System Interrupt Status Indexed Clear Register (SICR)

The system interrupt status indexed clear register (SICR) allows clearing the status of an interrupt. The interrupt to clear is the INDEX value written. This clears the Raw Status Register bit of the given INDEX. The SICR is shown in [Figure 12-8](#) and described in [Table 12-8](#).

**Figure 12-8. System Interrupt Status Indexed Clear Register (SICR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-8. System Interrupt Status Indexed Clear Register (SICR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                        |
|------|----------|-------|------------------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved                                                                           |
| 6-0  | INDEX    | 0-7Fh | Writes clear the status of the interrupt given in the INDEX value. Reads return 0. |

### 12.4.7 System Interrupt Enable Indexed Set Register (EISR)

The system interrupt enable indexed set register (EISR) allows enabling an interrupt. The interrupt to enable is the INDEX value written. This sets the Enable Register bit of the given INDEX. The EISR is shown in [Figure 12-9](#) and described in [Table 12-9](#).

**Figure 12-9. System Interrupt Enable Indexed Set Register (EISR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-9. System Interrupt Enable Indexed Set Register (EISR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                      |
|------|----------|-------|----------------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved                                                                         |
| 6-0  | INDEX    | 0-7Fh | Writes set the enable of the interrupt given in the INDEX value. Reads return 0. |

### 12.4.8 System Interrupt Enable Indexed Clear Register (EICR)

The system interrupt enable indexed clear register (EICR) allows disabling an interrupt. The interrupt to disable is the INDEX value written. This clears the Enable Register bit of the given INDEX. The EICR is shown in [Figure 12-10](#) and described in [Table 12-10](#).

**Figure 12-10. System Interrupt Enable Indexed Clear Register (EICR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-10. System Interrupt Enable Indexed Clear Register (EICR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                        |
|------|----------|-------|------------------------------------------------------------------------------------|
| 31-7 | Reserved | 0     | Reserved                                                                           |
| 6-0  | INDEX    | 0-7Fh | Writes clear the enable of the interrupt given in the INDEX value. Reads return 0. |

### 12.4.9 Host Interrupt Enable Indexed Set Register (HIEISR)

The host interrupt enable indexed set register (HIEISR) allows enabling a host interrupt output. The host interrupt to enable is the INDEX value written. This enables the host interrupt output or triggers the output again if already enabled. The HIEISR is shown in [Figure 12-11](#) and described in [Table 12-11](#).

**Figure 12-11. Host Interrupt Enable Indexed Set Register (HIEISR)**

|     |          |  |  |  |  |  |  |  |  |  |  |  |  |       |   |     |
|-----|----------|--|--|--|--|--|--|--|--|--|--|--|--|-------|---|-----|
| 31  | Reserved |  |  |  |  |  |  |  |  |  |  |  |  |       |   | 16  |
| R-0 |          |  |  |  |  |  |  |  |  |  |  |  |  |       |   |     |
| 15  | Reserved |  |  |  |  |  |  |  |  |  |  |  |  | 1     | 0 |     |
| R-0 |          |  |  |  |  |  |  |  |  |  |  |  |  | INDEX |   | W-0 |

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-11. Host Interrupt Enable Indexed Set Register (HIEISR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                           |
|------|----------|-------|---------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                                              |
| 0    | INDEX    | 0     | Writes set the enable of the host interrupt given in the INDEX value. Reads return 0. |
|      |          | 0     | Writing a 0 sets FIQ.                                                                 |
|      |          | 1     | Writing a 1 sets IRQ.                                                                 |

### 12.4.10 Host Interrupt Enable Indexed Clear Register (HIEICR)

The host interrupt enable indexed clear register (HIEICR) allows disabling a host interrupt output. The host interrupt to disable is the INDEX value written. This disables the host interrupt output. The HIEICR is shown in [Figure 12-12](#) and described in [Table 12-12](#).

**Figure 12-12. Host Interrupt Enable Indexed Clear Register (HIEICR)**

|     |          |  |  |  |  |  |  |  |  |  |  |  |  |       |   |     |
|-----|----------|--|--|--|--|--|--|--|--|--|--|--|--|-------|---|-----|
| 31  | Reserved |  |  |  |  |  |  |  |  |  |  |  |  |       |   | 16  |
| R-0 |          |  |  |  |  |  |  |  |  |  |  |  |  |       |   |     |
| 15  | Reserved |  |  |  |  |  |  |  |  |  |  |  |  | 1     | 0 |     |
| R-0 |          |  |  |  |  |  |  |  |  |  |  |  |  | INDEX |   | W-0 |

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-12. Host Interrupt Enable Indexed Clear Register (HIEICR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                             |
|------|----------|-------|-----------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                                                |
| 0    | INDEX    |       | Writes clear the enable of the host interrupt given in the INDEX value. Reads return 0. |
|      |          | 0     | Writing a 0 clears FIQ.                                                                 |
|      |          | 1     | Writing a 1 clears IRQ.                                                                 |

### 12.4.11 Vector Base Register (VBR)

The vector base register (VBR) holds the base address of the ISR vector addresses. The VBR is shown in [Figure 12-13](#) and described in [Table 12-13](#).

**Figure 12-13. Vector Base Register (VBR)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 12-13. Vector Base Register (VBR) Field Descriptions**

| Bit  | Field | Value        | Description       |
|------|-------|--------------|-------------------|
| 31-0 | BASE  | 0-FFFF FFFFh | ISR Base Address. |

### 12.4.12 Vector Size Register (VSR)

The vector size register (VSR) holds the sizes of the individual ISR routines in the vector table. This is only the sizes to space the calculated vector addresses for the initial ISR targets (the ISR targets could branch off to the full ISR routines). The VSR is shown in [Figure 12-14](#) and described in [Table 12-14](#).

**NOTE:** The VSR must be configured even if the desired value is equal to the default value.

**Figure 12-14. Vector Size Register (VSR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 12-14. Vector Size Register (VSR) Field Descriptions**

| Bit  | Field    | Value  | Description                 |
|------|----------|--------|-----------------------------|
| 31-8 | Reserved | 0      | Reserved                    |
| 7-0  | SIZE     | 0-FFh  | Size of ISR address spaces. |
|      |          | 0      | 4 bytes                     |
|      |          | 1h     | 8 bytes                     |
|      |          | 2h     | 16 bytes                    |
|      |          | 3h     | 32 bytes                    |
|      |          | 4h     | 64 bytes                    |
|      |          | 5h-FFh | ...                         |

### 12.4.13 Vector Null Register (VNR)

The vector null register (VNR) holds the address of the ISR null address that handles no pending interrupts (if accidentally branched to when no interrupts are pending). The VNR is shown in [Figure 12-15](#) and described in [Table 12-15](#).

### Figure 12-15. Vector Null Register (VNR)

LEGEND: R/W = Read/Write; -n = value after reset

### Table 12-15. Vector Null Register (VNR) Field Descriptions

| Bit  | Field | Value        | Description       |
|------|-------|--------------|-------------------|
| 31-0 | NULL  | 0-FFFF FFFFh | ISR Null Address. |

#### 12.4.14 Global Prioritized Index Register (GPIR)

The global prioritized index register (GPIR) shows the interrupt number of the highest priority interrupt pending across all the host interrupts. The GPIR is shown in [Figure 12-16](#) and described in [Table 12-16](#).

### Figure 12-16. Global Prioritized Index Register (GPIR)

LEGEND: R = Read only; -n = value after reset

### Table 12-16. Global Prioritized Index Register (GPIR) Field Descriptions

| Bit   | Field    | Value  | Description                                                                                                    |
|-------|----------|--------|----------------------------------------------------------------------------------------------------------------|
| 31    | NONE     | 0-1    | No Interrupt is pending. Can be used by host to test for a negative value to see if no interrupts are pending. |
| 30-10 | Reserved | 0      | Reserved                                                                                                       |
| 9-0   | PRI_INDx | 0-3FFh | The currently highest priority interrupt index pending across all the host interrupts.                         |

### 12.4.15 Global Prioritized Vector Register (GPVR)

The global prioritized vector register (GPVR) shows the interrupt vector address of the highest priority interrupt pending across all the host interrupts. The GPVR is shown in [Figure 12-17](#) and described in [Table 12-17](#).

**Figure 12-17. Global Prioritized Vector Register (GPVR)**

LEGEND: R = Read only; -n = value after reset

**Table 12-17. Global Prioritized Vector Register (GPVR) Field Descriptions**

| Bit  | Field | Value        | Description                                                                              |
|------|-------|--------------|------------------------------------------------------------------------------------------|
| 31-0 | ADDR  | 0-FFFF FFFFh | The currently highest priority interrupts vector address across all the host interrupts. |

### 12.4.16 System Interrupt Status Raw/Set Register 1 (SRSR1)

The system interrupt status raw/set register 1 (SRSR1) shows the pending enabled status of the system interrupts 0 to 31. Software can write to SRSR1 to set a system interrupt without a hardware trigger. There is one bit per system interrupt. The SRSR1 is shown in [Figure 12-18](#) and described in [Table 12-18](#).

**Figure 12-18. System Interrupt Status Raw/Set Register 1 (SRSR1)**

LEGEND: W = Write only; -n = value after reset

**Table 12-18. System Interrupt Status Raw/Set Register 1 (SRSR1) Field Descriptions**

| Bit  | Field         | Value | Description                                                                                            |
|------|---------------|-------|--------------------------------------------------------------------------------------------------------|
| 31-0 | RAW_STATUS[n] |       | System interrupt raw status and setting of the system interrupts 0 to 31. Reads return the raw status. |
|      |               | 0     | Writing a 0 has no effect.                                                                             |
|      |               | 1     | Write a 1 in bit position [n] to set the status of the system interrupt n.                             |

### 12.4.17 System Interrupt Status Raw/Set Register 2 (SRSR2)

The system interrupt status raw/set register 2 (SRSR2) shows the pending enabled status of the system interrupts 32 to 63. Software can write to SRSR2 to set a system interrupt without a hardware trigger. There is one bit per system interrupt. The SRSR2 is shown in [Figure 12-19](#) and described in [Table 12-19](#).

**Figure 12-19. System Interrupt Status Raw/Set Register 2 (SRSR2)**

LEGEND: W = Write only; -n = value after reset

**Table 12-19. System Interrupt Status Raw/Set Register 2 (SRSR2) Field Descriptions**

| Bit  | Field         | Value | Description                                                                                             |
|------|---------------|-------|---------------------------------------------------------------------------------------------------------|
| 31-0 | RAW_STATUS[n] | 0     | System interrupt raw status and setting of the system interrupts 32 to 63. Reads return the raw status. |
|      |               | 1     | Writing a 0 has no effect.                                                                              |
|      |               |       | Write a 1 in bit position [n] to set the status of the system interrupt n + 32.                         |

### 12.4.18 System Interrupt Status Raw/Set Register 3 (SRSR3)

The system interrupt status raw/set register 3 (SRSR3) shows the pending enabled status of the system interrupts 64 to 95. Software can write to SRSR3 to set a system interrupt without a hardware trigger. There is one bit per system interrupt. The SRSR3 is shown in [Figure 12-20](#) and described in [Table 12-20](#).

**Figure 12-20. System Interrupt Status Raw/Set Register 3 (SRSR3)**

LEGEND: W = Write only; -n = value after reset

**Table 12-20. System Interrupt Status Raw/Set Register 3 (SRSR3) Field Descriptions**

| Bit  | Field         | Value | Description                                                                                             |
|------|---------------|-------|---------------------------------------------------------------------------------------------------------|
| 31-0 | RAW_STATUS[n] | 0     | System interrupt raw status and setting of the system interrupts 64 to 95. Reads return the raw status. |
|      |               | 1     | Writing a 0 has no effect.                                                                              |
|      |               |       | Write a 1 in bit position [n] to set the status of the system interrupt n + 64.                         |

### 12.4.19 System Interrupt Status Raw/Set Register 4 (SRSR4)

The system interrupt status raw/set register 4 (SRSR4) shows the pending enabled status of the system interrupts 96 to 100. Software can write to SRSR4 to set a system interrupt without a hardware trigger. There is one bit per system interrupt. The SRSR4 is shown in [Figure 12-21](#) and described in [Table 12-21](#).

**Figure 12-21. System Interrupt Status Raw/Set Register 4 (SRSR4)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-21. System Interrupt Status Raw/Set Register 4 (SRSR4) Field Descriptions**

| Bit  | Field         | Value | Description                                                                                              |
|------|---------------|-------|----------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved      | 0     | Reserved                                                                                                 |
| 4-0  | RAW_STATUS[n] | 0     | System interrupt raw status and setting of the system interrupts 96 to 100. Reads return the raw status. |
|      |               | 0     | Writing a 0 has no effect.                                                                               |
|      |               | 1     | Write a 1 in bit position [n] to set the status of the system interrupt n + 96.                          |

### 12.4.20 System Interrupt Status Enabled/Clear Register 1 (SECR1)

The system interrupt status enabled/clear register 1 (SECR1) shows the pending enabled status of the system interrupts 0 to 31. Software can write to SECR1 to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt. The SECR1 is shown in [Figure 12-22](#) and described in [Table 12-22](#).

**Figure 12-22. System Interrupt Status Enabled/Clear Register 1 (SECR1)**

LEGEND: W = Write only; -n = value after reset

**Table 12-22. System Interrupt Status Enabled/Clear Register 1 (SECR1) Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                 |
|------|----------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENBL_STATUS[n] |       | System interrupt enabled status and clearing of the system interrupts 0 to 31. Reads return the enabled status (before enabling with the Enable Registers). |
|      |                | 0     | Writing a 0 has no effect.                                                                                                                                  |
|      |                | 1     | Write a 1 in bit position [n] to clear the status of the system interrupt n.                                                                                |

### 12.4.21 System Interrupt Status Enabled/Clear Register 2 (SECR2)

The system interrupt status enabled/clear register 2 (SECR2) shows the pending enabled status of the system interrupts 32 to 63. Software can write to SECR2 to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt. The SECR2 is shown in [Figure 12-23](#) and described in [Table 12-23](#).

**Figure 12-23. System Interrupt Status Enabled/Clear Register 2 (SECR2)**

LEGEND: W = Write only; -n = value after reset

**Table 12-23. System Interrupt Status Enabled/Clear Register 2 (SECR2) Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                  |
|------|----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENBL_STATUS[n] |       | System interrupt enabled status and clearing of the system interrupts 32 to 63. Reads return the enabled status (before enabling with the Enable Registers). |
|      |                | 0     | Writing a 0 has no effect.                                                                                                                                   |
|      |                | 1     | Write a 1 in bit position [n] to clear the status of the system interrupt n + 32.                                                                            |

### 12.4.22 System Interrupt Status Enabled/Clear Register 3 (SECR3)

The system interrupt status enabled/clear register 3 (SECR3) shows the pending enabled status of the system interrupts 64 to 95. Software can write to SECR3 to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt. The SECR3 is shown in [Figure 12-24](#) and described in [Table 12-24](#).

**Figure 12-24. System Interrupt Status Enabled/Clear Register 3 (SECR3)**

LEGEND: W = Write only; -n = value after reset

**Table 12-24. System Interrupt Status Enabled/Clear Register 3 (SECR3) Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                  |
|------|----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENBL_STATUS[n] |       | System interrupt enabled status and clearing of the system interrupts 64 to 95. Reads return the enabled status (before enabling with the Enable Registers). |
|      |                | 0     | Writing a 0 has no effect.                                                                                                                                   |
|      |                | 1     | Write a 1 in bit position [n] to clear the status of the system interrupt n + 64.                                                                            |

### 12.4.23 System Interrupt Status Enabled/Clear Register 4 (SECR4)

The system interrupt status enabled/clear register 4 (SECR4) shows the pending enabled status of the system interrupts 96 to 100. Software can write to SECR4 to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt. The SECR4 is shown in [Figure 12-25](#) and described in [Table 12-25](#).

**Figure 12-25. System Interrupt Status Enabled/Clear Register 4 (SECR4)**

|          |  |   |   |                |

|------|----------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved       | 0     | Reserved                                                                                                                                                      |
| 4-0  | ENBL_STATUS[n] | 0     | System interrupt enabled status and clearing of the system interrupts 96 to 100. Reads return the enabled status (before enabling with the Enable Registers). |
|      |                | 0     | Writing a 0 has no effect.                                                                                                                                    |
|      |                | 1     | Write a 1 in bit position [n] to clear the status of the system interrupt $n + 96$ .                                                                          |

### 12.4.24 System Interrupt Enable Set Register 1 (ESR1)

The system interrupt enable set register 1 (ESR1) enables system interrupts 0 to 31 to trigger outputs. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ESR1 is shown in [Figure 12-26](#) and described in [Table 12-26](#).

**Figure 12-26. System Interrupt Enable Set Register 1 (ESR1)**

|           |  |   |

**Table 12-26. System Interrupt Enable Set Register 1 (ESR1) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                 |
|------|-----------|-------|---------------------------------------------------------------------------------------------|
| 31-0 | ENABLE[n] | 0     | System interrupt 0 to 31 enable. Read returns the enable value (0 = disabled, 1 = enabled). |
|      |           | 0     | Writing a 0 has no effect.                                                                  |
|      |           | 1     | Write a 1 in bit position [n] to set the enable for system interrupt $n$ .                  |

### 12.4.25 System Interrupt Enable Set Register 2 (ESR2)

The system interrupt enable set register 2 (ESR2) enables system interrupts 32 to 63 to trigger outputs. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ESR2 is shown in [Figure 12-27](#) and described in [Table 12-27](#).

**Figure 12-27. System Interrupt Enable Set Register 2 (ESR2)**

LEGEND: W = Write only; -n = value after reset

**Table 12-27. System Interrupt Enable Set Register 2 (ESR2) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                |
|------|-----------|-------|----------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENABLE[n] | 0     | System interrupt 32 to 63 enable. Read returns the enable value (0 = disabled, 1 = enabled).<br>Writing a 0 has no effect. |
|      |           | 1     | Write a 1 in bit position [n] to set the enable for system interrupt $n + 32$ .                                            |

### 12.4.26 System Interrupt Enable Set Register 3 (ESR3)

The system interrupt enable set register 3 (ESR3) enables system interrupts 64 to 95 to trigger outputs. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ESR3 is shown in [Figure 12-28](#) and described in [Table 12-28](#).

**Figure 12-28. System Interrupt Enable Set Register 3 (ESR3)**

LEGEND: W = Write only; -n = value after reset

**Table 12-28. System Interrupt Enable Set Register 3 (ESR3) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                |
|------|-----------|-------|----------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENABLE[n] | 0     | System interrupt 64 to 95 enable. Read returns the enable value (0 = disabled, 1 = enabled).<br>Writing a 0 has no effect. |
|      |           | 1     | Write a 1 in bit position [n] to set the enable for system interrupt $n + 64$ .                                            |

### 12.4.27 System Interrupt Enable Set Register 4 (ESR4)

The system interrupt enable set register 4 (ESR4) enables system interrupts 96 to 100 to trigger outputs. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ESR4 is shown in [Figure 12-29](#) and described in [Table 12-29](#).

**Figure 12-29. System Interrupt Enable Set Register 4 (ESR4)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 12-29. System Interrupt Enable Set Register 4 (ESR4) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                   |
|------|-----------|-------|-----------------------------------------------------------------------------------------------|
| 31-5 | Reserved  | 0     | Reserved                                                                                      |
| 4-0  | ENABLE[n] |       | System interrupt 96 to 100 enable. Read returns the enable value (0 = disabled, 1 = enabled). |
|      |           | 0     | Writing a 0 has no effect.                                                                    |
|      |           | 1     | Write a 1 in bit position [n] to set the enable for system interrupt $n + 96$ .               |

### 12.4.28 System Interrupt Enable Clear Register 1 (ECR1)

The system interrupt enable clear register 1 (ECR1) disables system interrupts 0 to 31 to map to channels. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ECR1 is shown in [Figure 12-30](#) and described in [Table 12-30](#).

**Figure 12-30. System Interrupt Enable Clear Register 1 (ECR1)**

LEGEND: W = Write only; -n = value after reset

**Table 12-30. System Interrupt Enable Clear Register 1 (ECR1) Field Descriptions**

| Bit  | Field      | Value | Description                                                                                  |
|------|------------|-------|----------------------------------------------------------------------------------------------|
| 31-0 | DISABLE[n] |       | System interrupt 0 to 31 disable. Read returns the enable value (0 = disabled, 1 = enabled). |
|      |            | 0     | Writing a 0 has no effect.                                                                   |
|      |            | 1     | Write a 1 in bit position [n] to clear the enable for system interrupt $n$ .                 |

### 12.4.29 System Interrupt Enable Clear Register 2 (ECR2)

The system interrupt enable clear register 2 (ECR2) disables system interrupts 32 to 63 to map to channels. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ECR2 is shown in [Figure 12-31](#) and described in [Table 12-31](#).

**Figure 12-31. System Interrupt Enable Clear Register 2 (ECR2)**

LEGEND: W = Write only; -n = value after reset

**Table 12-31. System Interrupt Enable Clear Register 2 (ECR2) Field Descriptions**

| Bit  | Field      | Value | Description                                                                                                                 |
|------|------------|-------|-----------------------------------------------------------------------------------------------------------------------------|
| 31-0 | DISABLE[n] | 0     | System interrupt 32 to 63 disable. Read returns the enable value (0 = disabled, 1 = enabled).<br>Writing a 0 has no effect. |
|      |            | 1     | Write a 1 in bit position [n] to clear the enable for system interrupt $n + 32$ .                                           |

### 12.4.30 System Interrupt Enable Clear Register 3 (ECR3)

The system interrupt enable clear register 3 (ECR3) disables system interrupts 64 to 95 to map to channels. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ECR3 is shown in [Figure 12-32](#) and described in [Table 12-32](#).

**Figure 12-32. System Interrupt Enable Clear Register 3 (ECR3)**

LEGEND: W = Write only; -n = value after reset

**Table 12-32. System Interrupt Enable Clear Register 3 (ECR3) Field Descriptions**

| Bit  | Field      | Value | Description                                                                                                                 |
|------|------------|-------|-----------------------------------------------------------------------------------------------------------------------------|
| 27-0 | DISABLE[n] | 0     | System interrupt 64 to 95 disable. Read returns the enable value (0 = disabled, 1 = enabled).<br>Writing a 0 has no effect. |
|      |            | 1     | Write a 1 in bit position [n] to clear the enable for system interrupt $n + 64$ .                                           |

### 12.4.31 System Interrupt Enable Clear Register 4 (ECR4)

The system interrupt enable clear register 4 (ECR4) disables system interrupts 96 to 100 to map to channels. System interrupts that are not enabled do not interrupt the host. There is one bit per system interrupt. The ECR4 is shown in [Figure 12-33](#) and described in [Table 12-33](#).

**Figure 12-33. System Interrupt Enable Clear Register 4 (ECR4)**

|          |  |   |   |            |
|----------|--|---|---|------------|

**Table 12-33. System Interrupt Enable Clear Register 4 (ECR4) Field Descriptions**

| Bit  | Field      | Value | Description                                                                                    |
|------|------------|-------|------------------------------------------------------------------------------------------------|
| 31-5 | Reserved   | 0     | Reserved                                                                                       |
| 4-0  | DISABLE[n] | 0     | System interrupt 96 to 100 disable. Read returns the enable value (0 = disabled, 1 = enabled). |
|      |            | 0     | Writing a 0 has no effect.                                                                     |
|      |            | 1     | Write a 1 in bit position [n] to clear the enable for system interrupt n + 96.                 |

### 12.4.32 Channel Map Registers (CMR0-CMR25)

The channel map registers (CMR0-CMR25) define the channel for each system interrupt. There is one register per 4 system interrupts. The CMRn is shown in [Figure 12-34](#) and described in [Table 12-34](#).

**Figure 12-34. Channel Map Registers (CMRn)**

**Table 12-34. Channel Map Registers (CMRn) Field Descriptions**

| Bit   | Field       | Value | Description                                                            |
|-------|-------------|-------|------------------------------------------------------------------------|
| 31-24 | CHNL_NPLUS3 | 0-FFh | Sets the host interrupt for channel N + 3.                             |
| 23-16 | CHNL_NPLUS2 | 0-FFh | Sets the host interrupt for channel N + 2.                             |
| 15-8  | CHNL_NPLUS1 | 0-FFh | Sets the host interrupt for channel N + 1.                             |
| 7-0   | CHNL_N      | 0-FFh | Sets the channel for the system interrupt N. (N ranges from 0 to 100). |

### 12.4.33 Host Interrupt Prioritized Index Register 1 (HIPIR1)

The host interrupt prioritized index register 1 (HIPIR1) shows the highest priority current pending interrupt for the FIQ interrupt. The HIPIR1 is shown in [Figure 12-35](#) and described in [Table 12-35](#).

**Figure 12-35. Host Interrupt Prioritized Index Register 1 (HIPIR1)**

LEGEND: R = Read only; -n = value after reset

**Table 12-35. Host Interrupt Prioritized Index Register 1 (HIPIR1) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                        |
|-------|----------|--------|------------------------------------------------------------------------------------|
| 31    | NONE     | 0-1    | No Interrupt is pending.                                                           |
| 30-10 | Reserved | 0      | Reserved                                                                           |
| 9-0   | PRI_IND  | 0-3FFh | Interrupt number of the highest priority pending interrupt for FIQ host interrupt. |

### 12.4.34 Host Interrupt Prioritized Index Register 2 (HIPIR2)

The host interrupt prioritized index register 2 (HIPIR2) shows the highest priority current pending interrupt for the IRQ interrupt. The HIPIR2 is shown in [Figure 12-36](#) and described in [Table 12-36](#).

**Figure 12-36. Host Interrupt Prioritized Index Register 2 (HIPIR2)**

LEGEND: R = Read only; -n = value after reset

**Table 12-36. Host Interrupt Prioritized Index Register 2 (HIPIR2) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                        |
|-------|----------|--------|------------------------------------------------------------------------------------|
| 31    | NONE     | 0-1    | No Interrupt is pending.                                                           |
| 30-10 | Reserved | 0      | Reserved                                                                           |
| 9-0   | PRI_IND  | 0-3FFh | Interrupt number of the highest priority pending interrupt for IRQ host interrupt. |

### 12.4.35 Host Interrupt Nesting Level Register 1 (HINLR1)

The host interrupt nesting level register 1 (HINLR1) displays and controls the nesting level for FIQ host interrupt. The nesting level controls which channel and lower priority channels are nested. The HINLR1 is shown in [Figure 12-37](#) and described in [Table 12-37](#).

**Figure 12-37. Host Interrupt Nesting Level Register 1 (HINLR1)**

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 12-37. Host Interrupt Nesting Level Register 1 (HINLR1) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                           |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | OVERRIDE | 0-1    | Reads return 0. Writes of a 1 override the auto updating of the NEST_LVL and use the write data.                                                                                                                                      |
| 30-9 | Reserved | 0      | Reserved                                                                                                                                                                                                                              |
| 8-0  | NEST_LVL | 0-1FFh | Reads return the current nesting level for the FIQ host interrupt. Writes set the nesting level for the FIQ host interrupt. In auto mode the value is updated internally, unless the OVERRIDE is set and then the write data is used. |

### 12.4.36 Host Interrupt Nesting Level Register 2 (HINLR2)

The host interrupt nesting level register 2 (HINLR2) displays and controls the nesting level for IRQ host interrupt. The nesting level controls which channel and lower priority channels are nested. The HINLR2 is shown in [Figure 12-38](#) and described in [Table 12-38](#).

**Figure 12-38. Host Interrupt Nesting Level Register 2 (HINLR2)**

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 12-38. Host Interrupt Nesting Level Register 2 (HINLR2) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                           |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | OVERRIDE | 0-1    | Reads return 0. Writes of a 1 override the auto updating of the NEST_LVL and use the write data.                                                                                                                                      |
| 30-9 | Reserved | 0      | Reserved                                                                                                                                                                                                                              |
| 8-0  | NEST_LVL | 0-1FFh | Reads return the current nesting level for the IRQ host interrupt. Writes set the nesting level for the IRQ host interrupt. In auto mode the value is updated internally, unless the OVERRIDE is set and then the write data is used. |

### 12.4.37 Host Interrupt Enable Register (HIER)

The host interrupt enable register (HIER) enables or disables individual host interrupts (FIQ and IRQ). These work separately from the global enables. There is one bit per host interrupt. These bits are updated when writing to the host interrupt enable indexed set register (HIEISR) and the host interrupt disable indexed clear register (HIDISR). The HIER is shown in [Figure 12-39](#) and described in [Table 12-39](#).

**Figure 12-39. Host Interrupt Enable Register (HIER)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 12-39. Host Interrupt Enable Register (HIER) Field Descriptions**

| Bit  | Field    | Value | Description      |
|------|----------|-------|------------------|
| 31-2 | Reserved | 0     | Reserved         |
| 1    | IRQ      | 0     | Enable of IRQ    |
|      |          | 0     | IRQ is disabled. |
|      |          | 1     | IRQ is enabled.  |
| 0    | FIQ      | 0     | Enable of FIQ    |
|      |          | 0     | FIQ is disabled. |
|      |          | 1     | FIQ is enabled.  |

### 12.4.38 Host Interrupt Prioritized Vector Register 1 (HIPVR1)

The host interrupt prioritized vector register 1 (HIPVR1) shows the interrupt vector address of the highest priority interrupt pending for FIQ host interrupt. The HIPVR1 is shown in [Figure 12-40](#) and described in [Table 12-40](#).

**Figure 12-40. Host Interrupt Prioritized Vector Register 1 (HIPVR1)**

LEGEND: R = Read only; -n = value after reset

**Table 12-40. Host Interrupt Prioritized Vector Register 1 (HIPVR1) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                |
|------|-------|--------------|--------------------------------------------------------------------------------------------|
| 31-0 | ADDR  | 0-FFFF FFFFh | The currently highest priority interrupt vector address across for the FIQ host interrupt. |

### 12.4.39 Host Interrupt Prioritized Vector Register 2 (HIPVR2)

The host interrupt prioritized vector register 2 (HIPVR2) shows the interrupt vector address of the highest priority interrupt pending for IRQ host interrupt. The HIPVR2 is shown in [Figure 12-41](#) and described in [Table 12-41](#).

**Figure 12-41. Host Interrupt Prioritized Vector Register 2 (HIPVR2)**

LEGEND: R = Read only; -n = value after reset

**Table 12-41. Host Interrupt Prioritized Vector Register 2 (HIPVR2) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                |
|------|-------|--------------|--------------------------------------------------------------------------------------------|
| 31-0 | ADDR  | 0-FFFF FFFFh | The currently highest priority interrupt vector address across for the IRQ host interrupt. |

## ***Boot Considerations***

---

---

---

| Topic                          | Page       |
|--------------------------------|------------|
| <b>13.1</b> Introduction ..... | <b>328</b> |
| <b>13.2</b> DSP Wake Up .....  | <b>329</b> |

## 13.1 Introduction

This device supports a variety of boot modes through an internal ARM ROM bootloader. This device does not support dedicated hardware boot modes; therefore, all boot modes utilize the internal ARM ROM. The input states of the BOOT pins are sampled and latched into the BOOTCFG register, which is part of the system configuration (SYSCFG) module, when device reset is deasserted. Boot mode selection is determined by the values of the BOOT pins.

The following boot modes are supported:

- NAND Flash boot
  - 8-bit NAND
  - 16-bit NAND
- NOR Flash boot
  - NOR Direct boot (8-bit or 16-bit)
  - NOR Legacy boot (8-bit or 16-bit)
  - NOR AIS boot (8-bit or 16-bit)
- HPI boot
- I2C0/I2C1 boot
  - EEPROM (Master Mode)
  - External Host (Slave Mode)
- SPI0/SPI1 boot
  - Serial Flash (Master Mode)
  - Serial EEPROM (Master Mode)
  - External Host (Slave Mode)
- UART0/1/2 boot
  - External Host
- MMC/SD0 boot

See *Using the OMAP-L132/L138 Bootloader Application Report* ([SPRAB41](#)) for more details on the ROM Boot Loader, a list of boot pins used, and the complete list of supported boot modes.

## 13.2 DSP Wake Up

Following deassertion of device reset, the DSP initializes the ARM296 so that it can execute the ARM ROM bootloader. Upon successful wake up, the ARM places the DSP in a reset and clock gated (SwRstDisable) state that is controlled by the LPSC and the SYSCFG modules.

Perform the following steps to wake up the DSP:

1. Write a 83E7 0B13h to the KICK0R register in the SYSCFG module.
2. Write a 95A4 F1E0h to the KICK1R register in the SYSCFG module.
3. Write the truncated DSP boot address vector to the DSP\_ISTP\_RST\_VAL field in the host 1 configuration register (HOST1CFG) of the SYSCFG module. The least-significant bits of the boot address are fixed at 0.
4. Write a 3h to the NEXT bit in the DSP local power sleep controller (LPSC) module control register (PSC0.MDCTL15) to prepare the DSP module for an enable transition (to enable the clocks and all transitioning from the SwRstDisable state to Enable state).
5. Write a 1 to the GO[1] bit (DSP subsystem is part of the PD\_DSP domain) in the power domain transition command register (PSC0.PTCMD) to start the state transition sequence for the DSP module.
6. Check (poll for 0) the GOSTAT[1] bit in the power domain transition status register (PSC0.PTSTAT) for power transition sequence completion. The domain is only safely in the new state after the GOSTAT[1] bit is cleared to 0.
7. Wait for the STATE bit field in the DSP LPSC module status register (PSC0.MDSTAT15) to change to 3h. The module is only safely in the new state after the STATE bit field changes to reflect the new state.
8. Write a 1 to the LRST bit in PSC0.MDCTL15 to release the DSP local reset controlled by the PSC module.

---

**NOTE:** Step 8 can also be combined with Step 4. You can write a 103h to the PSC0.MDCTL15 in Step 4 to release the DSP local reset and transition it from a SwRstDisable to Enable state.

The steps to release the DSP reset by the SYSCFG module (Steps 1-3) are only required at device reset/system reset/warm reset. Disabling/enabling clocks to the DSP module at any other time can be independently controlled by the PSC module alone. Guidelines to enable/disable clocks for power management are provided in the *Power Management* chapter.

---

## ***Programmable Real-Time Unit Subsystem (PRUSS)***

---

---

---

| Topic                                     | Page       |
|-------------------------------------------|------------|
| <b>14.1 Overview .....</b>                | <b>331</b> |
| <b>14.2 Description .....</b>             | <b>333</b> |
| <b>14.3 Constants Table .....</b>         | <b>334</b> |
| <b>14.4 PRU Module Interface .....</b>    | <b>335</b> |
| <b>14.5 Instruction Set.....</b>          | <b>336</b> |
| <b>14.6 Instruction Formats .....</b>     | <b>339</b> |
| <b>14.7 PRU Interrupt Controller.....</b> | <b>357</b> |
| <b>14.8 Registers .....</b>               | <b>364</b> |

The Programmable Real-Time Unit Subsystem (PRUSS) consists of:

- Two programmable real-time units (PRU0 and PRU1) and their associated memories.
- An interrupt controller (INTC) for handling system interrupt events. The INTC also supports posting events back to the device level host CPU.
- A Switched Central Resource (SCR) for connecting the various internal and external masters to the resources inside the PRUSS.

The two PRUs can operate completely independently or in coordination with each other. The two PRUs can also work in coordination with the device level host CPU. This is determined by the nature of the program that is loaded into the two PRUs instruction memory. Several different signaling mechanisms are available between the two PRUs and the device level host CPU.

The two PRUs are optimized for performing embedded tasks that require manipulation of packed memory-mapped data structures, handling of system events that have tight real-time constraints and interfacing with systems external to the device.

## 14.1 Overview

The PRU is a optimized for performing embedded tasks that require manipulation of packed memory mapped data structures, handling of system events that have tight realtime constraints and interfacing with systems external to the DSP/SoC. The PRU is both very small and very efficient at handling such tasks.

The major attributes of the PRU are as follows:

| Attribute                          | Value                                                        |
|------------------------------------|--------------------------------------------------------------|
| IO Architecture                    | Load / Store                                                 |
| Data Flow Architecture             | Register to Register                                         |
| <b>Core Level Bus Architecture</b> |                                                              |
| Type                               | 4-Bus Harvard (1 Instruction, 3 Data)                        |
| Instruction I/F                    | 32-Bit                                                       |
| Memory I/F 0                       | 32-Bit                                                       |
| Memory I/F 1                       | 32-Bit                                                       |
| <b>Execution Model</b>             |                                                              |
| Issue Type                         | Scalar                                                       |
| Pipelining                         | None                                                         |
| Ordering                           | In-order                                                     |
| ALU Type                           | Unsigned Integer                                             |
| <b>Registers</b>                   |                                                              |
| General Purpose (GP)               | 30 (R1 – R30)                                                |
| External Status                    | 1 (R31)                                                      |
| GP / Indexing                      | 1 (R0)                                                       |
| Addressability                     | Bit, Byte (8-bit), Halfword (16-bit), Word (32-bit), Pointer |

| Attribute                                | Value                                                                                                                                                                                                                     |

| Instruction Width                        | 32-Bits                                                                                                                                                                                                                   |
| Accessibility to Internal PRU Structures | Provides 32-bit Slave with 3 regions: <ul style="list-style-type: none"> <li>• Instruction RAM</li> <li>• Control / Status registers</li> <li>• Debug access to internal registers (R0-R31) and constant table</li> </ul> |

## 14.2 Description

The processor is based on a four bus architecture which allows instructions to be fetched and executed concurrently with data transfers. Additionally, an input is provided in order to allow external status information to be reflected in the internal processor status register. The figure below shows a block diagram of the processing element and the associated instruction RAM/ROM that contains the code that is to be executed.

Figure 14-1. PRU Block Diagram

## 14.3 Constants Table

The PRU Constants Table is a structure connected to a dedicated interface on the PRU core within the PRU that is used to provide the base address for the Load Burst Constant + Offset (LBCO) and Store Burst Constant + Offset (SBCO) instructions. The PRU Constants Table is provided in order to maximize the usage of the PRU register file for embedded processing applications by moving many of the commonly used constant or deterministically calculated base addresses from the internal register file to an external table. Since this table is accessed using a dedicated interface, no performance difference is realized between the LBCO and LBBO or SBCO and SBBO instructions. The constants in the table are provided in Table 2.

**Table 14-1. Constants Table<sup>(1)</sup>**

| Entry # | Region Pointed To      | Value [31:0]                         |
|---------|------------------------|--------------------------------------|
| 0       | PRU0/1 Local INTC      | 0x00004000                           |
| 1       | Timer64P0              | 0x01C20000                           |
| 2       | I2C0                   | 0x01C22000                           |

| 31      | mDDR/DDR2 Data         | 0xC0nnnn00, nnnn = c31_pointer[15:0] |

<sup>(1)</sup> These constants cannot be used due to memory map restrictions.

1. Constants not in this table can be created 'on the fly' by two consecutive LDI #16 instructions. These constants are just ones that are expected to be commonly used, enough so to be hard-coded into the PRU constants table.
2. Constants table entries 24 through 31 are not fully hard-coded, but contain a programmable bitfield (ex. c24\_blk\_index[3:0]) that is programmable through the PRU control register space (0x01C3\_7000 - 0x01C3\_73FF for PRU0 and 0x01C3\_7800 - 0x01C3\_7BFF for PRU1).

## 14.4 PRU Module Interface

### 14.4.1 Event Out Mapping (R31): PRU System Events

PRU Event Interface directly feeds pulsed event information out of the PRU's internal ALU. This provides the interface logic between the PRU R31 event\_out[5:0] and the system interrupts for the PRUSS Interrupt controller(INTC).

| Bits | Name           | Description                    |
|------|----------------|--------------------------------|
| 31-6 | Reserved       |                                |
| 5    | pruX_vec_valid | Valid strobe for vector output |
| 4-0  | pruX_vec[4:0]  | Vector output                  |

Writing a '1' to pruX\_vec\_valid (R31 bit 5) simultaneously with a channel number from 0 to 31 written to pruX\_vec[4:0] (R31 bits 4:0) creates a pulse on the output of the appropriate de-multiplexer output. For example, writing '100000' will generate a pulse on demux channel 0, writing '100001' will generate a pulse on demux channel 1, ... writing '111111' will generate a pulse on demux channel 31, and writing '0xxxxx' will not generate any pulse on the demux output. The demultiplexed values from both of the PRUs are logically ORed together. The composite demultiplexed output channels 0 through 31 are connected to system interrupts 32 through 63 respectively.

This allows the PRU to assert one of the systems interrupts 32-63 by writing to its own R31 register. The system interrupt is used to either post a completion event to one of the host CPUs (ARM, DSP) or to signal the other PRU. The host to be signaled is determined by the system interrupt to interrupt channel mapping (programmable). Refer to [Section 14.7](#) for more details.

### 14.4.2 Status Mapping (R31): Interrupt Events Input

The PRU Real Time Status Interface directly feeds information into register 31(R31) of the PRU's internal register file. The firmware on the PRU uses the status information to make decisions during execution. The status interface is comprised of signals from different modules inside of the PRUSS which require some level of interaction with the PRU. More details on the Host interrupts imported into bit 30 and 31 of register R31 of both the PRUs is provided in the chapter 3, PRUSS Interrupt Controller (INTC).

| Bits | Name                  | Description                      |
|------|-----------------------|----------------------------------|
| 31   | pru_intr_in[1]        | PRU Interrupt 1 from INTC        |
| 30   | pru_intr_in[0]        | PRU Interrupt 0 from INTC        |
| 29-0 | pruX_r31_status[29:0] | Status inputs from primary input |

### 14.4.3 General Purpose Inputs (R31)

The pruX\_r31\_status[29:0] are mapped out of the PRUSS and are brought out as general purpose input pins. The values input to the pins "pruX\_R31[29:0]" are reflected in the R31 register on bits [29:0] to be used by the program running on the PRU. Each PRU of the PRUSS has a separate mapping to pins, so that there are 60 total general purpose inputs to the PRUSS.

### 14.4.4 General Purpose Outputs (R30)

The pruX\_r30[31:0] bits are exported out of the PRUSS and are brought out as general purpose output pins. The values written to register R30 will be reflected on the general purpose output pins "pruX\_R30[31:0]" to be used by the program running on the PRU. Each PRU of the PRUSS has a separate mapping to pins, so that there are 64 total general purpose outputs from the PRUSS.

## 14.5 Instruction Set

The instruction set is divided into four major categories:

1. Instructions which move data in or out of the processors internal registers
2. Instructions which perform an arithmetic operation
3. Instructions which perform a logical operation
4. Instructions which control program flow

The following sections give a complete list and short description of all of the supported instructions. In these descriptions, the following abbreviations are used:

**Table 14-2. Abbreviations for Instruction Descriptions**

| Abbreviation | Description                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------|
| Rs1          | Source register 1 from the instruction                                                           |
| Op2          | Operand 2 from the instruction – can be either a register (Rs2) or an 8-bit immediate value      |
| Rd           | Destination register from the instruction                                                        |
| BrOff        | Branch offset from the instruction – a 10-bit 2's complement relative offset                     |
| WdCnt        | Word count – the # of 32-bit data phases that occur in the burst on an external memory interface |
| CPI          | Clock Cycles Per Instruction                                                                     |

**Table 14-3. Load/Store Instructions**

| Mnemonic | Instruction                    | Description                                                                                                                                                                                         | CPI                                   |
|----------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| LDI      | Load Immediate                 | Load 16-bit immediate value into internal register                                                                                                                                                  | 1                                     |
| LBBO     | Load Burst, Base + Offset      | Load variable length burst of bytes through one of the memory interfaces into internal register(s) using a register as the base address and a register or an 8-bit immediate as the offset          | 1 + WdCnt (VBUS)<br>2 + WdCnt (VBUSP) |
| SBBO     | Store Burst, Base + Offset     | Store variable length burst of bytes through one of the memory interfaces from internal register(s) using a register as the base address and a register or 8-bit immediate as the offset            | 1 + WdCnt                             |
| LBCO     | Load Burst, Constant + Offset  | Load variable length burst of bytes through one of the memory interfaces into internal register(s) using an indexed constant as the base address and a register or an 8-bit immediate as the offset | 1 + WdCnt (VBUS)<br>2 + WdCnt (VBUSP) |
| SBCO     | Store Burst, Constant + Offset | Store variable length burst of bytes through one of the memory interfaces from internal register(s) using an indexed constant as the base address and a register or 8-bit immediate as the offset   | 1 + WdCnt                             |

**Table 14-4. Arithmetic Instructions**

| Mnemonic | Instruction                         | Description                                                                                                      | CPI |
|----------|-------------------------------------|------------------------------------------------------------------------------------------------------------------|-----|
| ADD      | Integer Add                         | Adds Rs1 and Op2, writes result to Rd, and saves carry.                                                          | 1   |
| ADC      | Integer Add With Carry              | Adds Rs1, Op2 and the saved carry, writes result to Rd, and saves carry.                                         | 1   |
| SUB      | Integer Subtract                    | Subtracts Op2 from Rs1 and writes result to Rd and saves carry (borrow).                                         | 1   |
| SUC      | Integer Subtract With Carry         | Subtracts Op2 from Rs1 then subtracts the saved carry (borrow) and writes result to Rd and saves carry (borrow). | 1   |
| RSB      | Integer Reverse Subtract            | Subtracts Rs1 from Op2 and writes result to Rd and saves carry (borrow).                                         | 1   |
| RSC      | Integer Reverse Subtract With Carry | Subtracts Rs1 from Op2 then subtracts the saved carry (borrow) and writes result to Rd and saves carry (borrow). | 1   |

**Table 14-5. Logical Instructions**

| Mnemonic | Instruction          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | CPI                                                                                                                                                         |

| LSL      | Logical Shift Left   | Shifts Rs1 left (with zero fill) by the value given in the 5 LSBs of Op2 and stores to Rd.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 1                                                                                                                                                           |
| MIN      | Minimum              | Compares Rs1 and Op2 and the smaller value is copied to Rd.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1                                                                                                                                                           |
| MAX      | Maximum              | Compares Rs1 and Op2 and the larger value is copied to Rd.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 1                                                                                                                                                           |
| CLR      | Clear Bit            | Copies Rs1 to Rd but with a bit specied by the 5 LSBs of Op2 cleared during the copy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1                                                                                                                                                           |
| SET      | Set Bit              | Copies Rs1 to Rd but with a bit specied by the 5 LSBs of Op2 set during the copy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1                                                                                                                                                           |
| LMBD     | Left-most Bit Detect | Scans Rs1 from the leftmost bit for a bit equal to bit 0 of Rs2. When found, the bit number (0 to 31) is written to Rd. If not found, the value 32 is written to Rd.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 1                                                                                                                                                           |
| SCAN     | Scan Register File   | <p>Scans the register file for a byte pattern of a programmable length (up to 4 bytes) with a programmable field count and field stride.</p> <p>The Op1 register contains 4 fields: Rn.b0 = offset in the register file from R0.b0 to start scanning Rn.b1 = fc (field count), the number of fields to scan Rn.b2 = fw (field width), the size in bytes of the field to scan for (1, 2, or 4 bytes) Rn.b3 = fs (field stride), the number of bytes to advance to the next field in the register file (1 to 4 bytes)</p> <p>Op1 is updated after the scan with the offset of the match (or 0xFF if no match) in Rn.b0, and the fields remaining in the scan (including the matching field) in Rn.b1.</p> <p>The Op2 is the field to scan for.</p> | <p>IF fw = fs<br/> <math>2 + ((fc * fw + 3) / 4)</math><br/> ELSE 2 + fc<br/> This is a worst case cycle count. Matching scans could take fewer cycles.</p> |

**Table 14-6. Program Flow Control Instructions**

| Mnemonic | Instruction                          | Description                                                                                                                                                      | CPI           |
|----------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| QBBS     | Quick Branch – Bit Set               | Adds BrOff to the program counter if the bit in Rs1 specified by the 5 LSBs of Op2 is a 1                                                                        | 1             |
| QBBC     | Quick Branch – Bit Clear             | Adds BrOff to the program counter if the bit in Rs1 specified by the 5 LSBs of Op2 is a 0                                                                        | 1             |
| QBGT     | Quick Branch – Greater Than          | Compares Op2 to Rs1 and adds BrOff to the program counter if Op2 is greater than Rs1.                                                                            | 1             |
| QBGE     | Quick Branch – Greater Than or Equal | Compares Op2 to Rs1 and adds BrOff to the program counter if Op2 is greater than or equal to Rs1.                                                                | 1             |
| QBLT     | Quick Branch – Less Than             | Compares Op2 to Rs1 and adds BrOff to the program counter if Op2 is less than Rs1.                                                                               | 1             |
| QBLE     | Quick Branch – Less Than or Equal    | Compares Op2 to Rs1 and adds BrOff to the program counter if Op2 is less than or equal to Rs1.                                                                   | 1             |
| QBEQ     | Quick Branch – Equal                 | Compares Op2 to Rs1 and adds BrOff to the program counter if Op2 is equal to Rs1.                                                                                | 1             |
| QBNE     | Quick Branch – Not Equal             | Compares Op2 to Rs1 and adds BrOff to the program counter if Op2 is not equal to Rs1.                                                                            | 1             |
| JMP      | Unconditional Jump                   | Sets the program counter equal to either the contents of a register or to a 16-bit immediate value                                                               | 1             |
| JAL      | Unconditional Jump and Link          | Saves the current program counter into Rd and sets the program counter equal to either the contents of a register or to a 16-bit immediate value.                | 1             |
| HALT     | Halt Processor                       | Disables the PRU and does not increment the program counter. When the PRU is re-enabled, it will continue processing at this instruction.                        | 1             |
| SLP      | Sleep                                | Pauses execution of the current program and disables the clock for the majority of the core until a specified external event (un-masked status bit) is asserted. | 1 to infinity |

## 14.6 Instruction Formats

A total of 7 different instruction formats are supported for the various operations. The following sections describe the position, size, and function of each of the fields within the various formats.

**Figure 14-2. Format 1a: (All Arithmetic and Logical Functions – Register Op2)**

|        |    |       |    |        |    |     |    |
|--------|----|-------|----|--------|----|-----|----|
| 31     | 29 | 28    | 24 | 23     | 21 | 20  | 16 |
| OP     |    | ALUOP | IO | Rs2Sel |    | Rs2 |    |
| 15     | 13 | 12    | 8  | 7      | 5  | 4   | 0  |
| Rs1Sel |    | Rs1   |    | RdSel  |    | Rd  |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-7. Format 1a: (All Arithmetic and Logical Functions – Register Op2)**

| Bit   | Field  | Description                                                                                                                                                                                                                                                                                                                                                                                                            |

## 14.7 PRU Interrupt Controller

### 14.7.1 Introduction

The PRUSS interrupt controller (INTC) is an hardware interface between interrupts coming from different parts of the system (these are referred to as system events), and the PRUs interrupt inputs.

The PRUSS INTC has the following features:

- Capturing up to 32 System Events external to the PRUSS
- 32 additional System events generated by the PRUs
- Supports up to 10 interrupt channels
- Generation of 10 Host Interrupts
  - 2 Host Interrupts for the PRUs
  - 8 Host Interrupts exported from the PRUSS for signaling the host (ARM/DSP) interrupt controllers
- Each system event can be enabled and disabled
- Each host event can be enabled and disabled.
- Hardware prioritization of events

### 14.7.2 Interrupt Mapping

The PRUSS INTC supports up to 64 system interrupts from different peripherals and PRUs to be mapped to 10 channels inside the INTC (see Figure 1). Interrupts from these 10 channels are further mapped to 10 Host Interrupts.

- Any of the 64 system interrupts can be mapped to any of the 10 channels.
- Multiple interrupts can be mapped to a single channel.
- An interrupt should not be mapped to more than one channel.
- Any of the 10 channels can be mapped to any of the 10 host interrupts. It is recommended to map channel "x" to host interrupt "x", where x is from 0 to 9
- A channel should not be mapped to more than one host interrupt.
- For channels mapping to the same host interrupt, lower number channels have higher priority.
- For interrupts on same channel, priority is determined by the hardware interrupt number. The lower the interrupt number, the higher the priority.
- Host Interrupt 0 is connected to bit 30 in register 31 of PRU0 and PRU1.
- Host Interrupt 1 is connected to bit 31 in register 31 for PRU0 and PRU1. Host Interrupts 2 through 9 exported from PRUSS for signaling ARM and DSP interrupt controllers generating system Events PRUSS\_EVTOUT0 to PRUSS\_EVTOUT7 respectively.

**Figure 14-22.**

### 14.7.3 PRUSS System Events

System events 0 through 31 are external to the PRUSS subsystem and generated from different peripherals. The source of the first 32 events from the device is listed in the [Table 14-27](#).

System events 32 to 63 are generated by a PRU writing to its own R31 register. The system interrupt is used to either post a completion event to one of the host CPUs (ARM/DSP) or to signal the other PRU core of the PRUSS. For more information on the steps to generate the system events 32 to 63 refer to [Section 14.4.1](#).

The device includes a mux that with a single select signal selects the PRUSS EVT inputs as shown in the table below. The control signal, PRUSSEVTSEL, can be modified by software in system register CFGCHIP3[3]. PRUSSEVTSEL defaults to 0 after reset. Note that not all system events are defined for all devices. Refer to the device datasheet or System Reference Guide for more information.

**Table 14-27. PRUSS System Events [0:31] Assignments**

### 14.7.4 ARM and DSP Interrupt Controller Mapping

Events PRUSS\_EVTOUT0 to PRUSS\_EVTOUT7 are mapped to the ARM and DSP interrupt controllers. The following tables show the interrupt mapping.

**Table 14-28. ARM Interrupt Controller Mapping**

| Event Number | Source  |
|--------------|---------|
| 3            | EVTOUT0 |
| 4            | EVTOUT1 |
| 5            | EVTOUT2 |
| 6            | EVTOUT3 |
| 7            | EVTOUT4 |

### 14.7.5 INTC Methodology

The INTC module controls the system event mapping to the host interrupt interface. System events are generated by the device peripherals or PRUs. The INTC receives the system interrupts and maps them to internal channels. The channels are used to group interrupts together and to prioritize them. These channels are then mapped onto the host interrupts. Interrupts from system side are active high in polarity. Also, they are pulse type of interrupts.

The INTC encompasses many functions to process the system interrupts and prepare them for the host interface. These functions are: processing, enabling, status, channel mapping, host interrupt mapping, prioritization, and host interfacing. Figure 14-23 illustrates the flow of system interrupts through the functions to the host. The following subsections describe each part of the flow.

**Figure 14-23.**

#### 14.7.5.1 Interrupt Processing

This block does following tasks:

- Synchronization of slower and asynchronous interrupts
- Conversion of polarity to active high
- Conversion of interrupt type to pulse interrupts

After the "processing block", all interrupts will be active high pulses.

#### 14.7.5.2 Interrupt Enabling

The next stage of INTC is to enable system interrupts based on programmed settings. The following sequence is to be followed to enable interrupts:

1. Enable all host interrupts: By setting the ENABLE bit in the global enable register (GER) to 1, all host interrupts will be enabled. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable
2. Enable required host interrupts: By writing to the INDEX field in the host interrupt enable indexed set register (HIEISR), enable the required host interrupts. The host interrupt to enable is the index value

written. This enables the host interrupt output or triggers the output again if that host interrupt is already enabled.

3. Enable required system interrupts: System interrupts that are required to get propagated to host are to be enabled individually by writing to INDEX field in the system interrupt enable indexed set register (EISR). The interrupt to enable is the index value written. This sets the Enable Register bit of the given index.

System interrupts can also be enabled by setting the bits of the system interrupt enable set registers (ESR1-ESR3). Only enabled system interrupts will generate an interrupt to the host.

### 14.7.5.3 Interrupt Status Checking

The next stage is to capture which system interrupts are pending. There are two kinds of pending status: raw status and enabled status. Raw status is the pending status of the system interrupt without regards to the enable bit for the system interrupt. The raw status of system interrupts is captured in system interrupt status raw/set registers (SRSR1-SRSR2). Enabled status is the pending status of the system interrupts with the enable bits set. When the enable bit is not set, the enabled status will always be inactive. The enabled status of system interrupts is captured in system interrupt status enabled/clear registers (SECR1-SECR2).

Status of system interrupt 'N' is indicated by the Nth bit of SECR1-SECR2. Since there are 64 system interrupts, two 32-bit registers are used to capture the enabled status of interrupts. The pending status reflects whether the system interrupt occurred since the last time the status register bit was cleared. Each bit in the status register can be individually cleared.

### 14.7.5.4 Interrupt Channel Mapping

The INTC has 10 internal channels to which enabled system interrupts can be mapped. Channel 0 has highest priority and channel 9 has the lowest priority. Channels are used to group the system interrupts into a smaller number of priorities that can be given to a host interface with a very small number of interrupt inputs.

When multiple system interrupts are mapped to the same channel their interrupts are ORed together so that when either is active the output is active. The channel map registers (CMR1-CMR16) define the channel for each system interrupt. There is one register per 4 system interrupts; therefore, there are 16 channel map registers for a system of 64 interrupts. Channels for each system interrupt can be set using these registers.

### 14.7.5.5 Host Interrupt Mapping

The INTC generates 10 host interrupts which can be . The hosts can be the two PRUs, the ARM CPU, and DSP CPU. The 10 channels from the INTC can be mapped to any of the 10 host interrupts. The host map registers (HMR1-HMR3) define the host interrupt for each channel. There is one register per 4 channels; therefore, there are 3 host map registers for 10 channels. Multiple channels can be mapped to the same host interrupt. When multiple channels are mapped to the same host interrupt prioritization is done to select which interrupt is in the highest-priority channel and which should be sent first to the host.

### 14.7.5.6 Interrupt Prioritization

The next stage of the INTC is prioritization. Since multiple interrupts can feed into a single channel and multiple channels can feed into a single host interrupt, it is necessary to read the status of all system interrupts to determine the highest priority interrupt that is pending. The INTC provides hardware to perform this prioritization with a given scheme so that software does not have to do this. There are two levels of prioritization:

- The first level of prioritization is between the active channels for a host interrupt. Channel 0 has the highest priority and channel 9 has the lowest. So the first level of prioritization picks the lowest numbered active channel.
- The second level of prioritization is between the active system interrupts for the prioritized channel. The system interrupt in position 0 has the highest priority and system interrupt 63 has the lowest priority. So the second level of prioritization picks the lowest position active system interrupt.

The highest priority interrupt pending across all host interrupts is stored in the global prioritized index register (GPIR). The highest priority pending interrupt with respect to each host interrupt can be obtained using the host interrupt prioritized index registers (HIPIRn).

#### 14.7.5.7 Interrupt Nesting

The INTC can also perform a nesting function in its prioritization. Nesting is a method of disabling certain interrupts (usually lower-priority interrupts) when an interrupt is taken so that only those desired interrupts can trigger to the host while it is servicing the current interrupt. The typical usage is to nest on the current interrupt and disable all interrupts of the same or lower priority (or channel). Then the host will only be interrupted from a higher priority interrupt.

The nesting is done in 1 of 3 methods:

- Nesting for all host interrupts, based on channel priority: When an interrupt is taken, the nesting level is set to its channel priority. From then, that channel priority and all lower priority channels will be disabled from generating host interrupts and only higher priority channels are allowed. When the interrupt is completely serviced, the nesting level is returned to its original value. When there is no interrupt being serviced, there are no channels disabled due to nesting. The global nesting level register (GNLR) allows the checking and setting of the global nesting level across all host interrupts. The nesting level is the channel (and all of lower priority channels) that are nested out because of a current interrupt.
- Nesting for individual host interrupts, based on channel priority: Always nest based on channel priority for each host interrupt individually. When an interrupt is taken on a host interrupt, then, the nesting level is set to its channel priority for just that host interrupt, and other host interrupts do not have their nesting affected. Then for that host interrupt, equal or lower priority channels will not interrupt the host but may on other host interrupts if programmed. When the interrupt is completely serviced the nesting level for the host interrupt is returned to its original value. The host interrupt nesting level registers (HINLR1 and HINLR2) display and control the nesting level for each host interrupt. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.
- Software manually performs the nesting of interrupts. When an interrupt is taken, the software will disable all the host interrupts, manually update the enables for any or all the system interrupts, and then re-enables all the host interrupts. This now allows only the system interrupts that are still enabled to trigger to the host. When the interrupt is completely serviced the software must reverse the changes to re-enable the nested out system interrupts. This method requires the most software interaction but gives the most flexibility if simple channel based nesting mechanisms are not adequate.

#### 14.7.5.8 Interrupt Status Clearing

After servicing the interrupt (after execution of the ISR), interrupt status is to be cleared. If a system interrupt status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. It is also essential to clear all system interrupts before the PRU is halted as the PRU does not power down unless all the interrupt status are cleared. For clearing the status of an interrupt, whose interrupt number is N, write a 1 to the Nth bit position in the system interrupt status enabled/clear registers (SECR1-SECR2). System interrupt N can also be cleared by writing the value N into the system interrupt status indexed clear register (SICR).

#### 14.7.5.9 Interrupt Disabling

At any time, if any interrupt is not to be propagated to the host, then that interrupt should be disabled. For disabling an interrupt whose interrupt number is N, write a 1 to the Nth bit in the system interrupt enable clear registers (ECR1-ECR2). System interrupt N can also be disabled by writing the value N in the system interrupt enable indexed clear register (EICR).

#### 14.7.5.10 Configuring the Interrupt Controller

Follow these steps to configure the interrupt controller.

1. Set polarity and type of system event through the System Interrupt Polarity Registers (SIPR1 and SPIR2) and the System Interrupt Type Registers (SITR1 and SITR2). Polarity of all system interrupts is always high. Type of all system interrupts is always pulse.

2. Map system event to INTC channel through CHANMAP registers.
3. Map channel to host interrupt through HOSTMAP registers. Recommend channel “x” be mapped to host interrupt “x”.
4. Clear system interrupt by writing 1s to SECR registers.
5. Enable host interrupt by writing index value to HOSTINTENIDX register.
6. Enable interrupt nesting if desired.
7. Globally enable all interrupts through GLBLEN register.

## 14.8 Registers

## 14.8.1 PRUSS Memory Map

### 14.8.1.1 Local Memory Map

The PRUSS comprises various distinct addressable regions. Externally the subsystem presents a single 64Kbyte range of addresses. The internal interconnect bus (also called switched central resource, or SCR) of the PRUSS decodes accesses for each of the individual regions. The PRUSS memory map is documented in [Table 14-30](#) (Instruction Space) and in [Table 14-31](#) (Data Space). Note that these two memory maps are implemented inside the PRUSS and are local to the components of the PRUSS.

**Table 14-30. Local Instruction Space Memory Map**

| Start Address | End Address | PRU0                 | PRU1                 |
|---------------|-------------|----------------------|----------------------|
| 0x00000000    | 0x00000FFF  | PRU0 Instruction RAM | PRU1 Instruction RAM |

**Table 14-31. Local Data Space Memory Map**

| Start Address | End Address | PRU0                      | PRU1                      |
|---------------|-------------|---------------------------|---------------------------|
| 0x00000000    | 0x000001FF  | Data RAM 0 <sup>(1)</sup> | Data RAM 1 <sup>(1)</sup> |
| 0x00000200    | 0x00001FFF  | Reserved                  | Reserved                  |
| 0x00002000    | 0x000021FF  | Data RAM 1 <sup>(1)</sup> | Data RAM 0 <sup>(1)</sup> |
| 0x00002200    | 0x00003FFF  | Reserved                  | Reserved                  |
| 0x00004000    | 0x00006FFF  | INTC Registers            | INTC Registers            |
| 0x00007000    | 0x000077FF  | PRU0 Registers            | PRU0 Registers            |
| 0x00007800    | 0x00007FFF  | PRU1 Registers            | PRU1 Registers            |
| 0x00008000    | 0x0000FFFF  | Reserved                  | Reserved                  |
| 0x00010000    | 0xFFFFFFFF  | Reserved                  | Reserved                  |

<sup>(1)</sup> Note that PRU0 accesses Data RAM0 at address 0x00000000, also PRU1 accesses Data RAM1 at address 0x00000000. Data RAM0 is intended to be the primary data memory for PRU0 and Data RAM1 is intended to be the primary data memory for PRU1. However for passing information between PRUs, each PRU can access the data ram of the other PRU at address 0x00002000.

### 14.8.1.2 Global Memory Map

The global view of the PRUSS internal memories and control ports is documented in [Table 14-32](#). The offset addresses of each region are implemented inside the PRUSS but the global device memory mapping places the PRUSS slave port in the address range 0x01C30000-0x01C3FFFF. The PRU0 and PRU1 can use either the local or global addresses to access their internal memories, but using the local addresses will provide access time several cycles faster than using the global addresses. This is because when accessing via the global address the access needs to be routed through the switch fabric outside PRUSS and back in through the PRUSS slave port.

**Table 14-32. Subsystem Global Memory Map**

| Start Address | End Address | Region               |
|---------------|-------------|----------------------|
| 0x01C30000    | 0x01C301FF  | Data RAM 0           |
| 0x01C30200    | 0x01C31FFF  | Reserved             |
| 0x01C32000    | 0x01C321FF  | Data RAM 1           |
| 0x01C32200    | 0x01C33FFF  | Reserved             |
| 0x01C34000    | 0x01C36FFF  | INTC Registers       |
| 0x01C37000    | 0x01C377FF  | PRU0 Registers       |
| 0x01C37800    | 0x01C37FFF  | PRU1 Registers       |
| 0x01C38000    | 0x01C38FFF  | PRU0 Instruction RAM |
| 0x01C39000    | 0x01C3BFFF  | Reserved             |
| 0x01C3C000    | 0x01C3CFFF  | PRU1 Instruction RAM |

### Table 14-32. Subsystem Global Memory Map (continued)

| Start Address | End Address | Region   |
|---------------|-------------|----------|
| 0x01C3D000    | 0x01C3FFFF  | Reserved |

Each of the PRUs can access the rest of the device memory (including memory mapped peripheral and configuration registers) using the global memory space addresses. Please refer to the device's System Reference Guide or datasheet for device specific memory mapping.

### 14.8.1.3 PRU Memory Map Overview

The PRU control and status registers region contains control and status registers for the PRU. The control / status registers region memory map is shown in [Table 14-33](#).

### Table 14-33. PRU Control/Status Register Memory Map

| Address Offset | Register Name         | Register Description                                     |
|----------------|-----------------------|----------------------------------------------------------|
| 0h             | CONTROL               | PRU Control Register                                     |
| 4h             | STATUS                | PRU Status Register                                      |
| 8h             | WAKEUP                | PRU Wakeup Enable Register                               |
| Ch             | CYCLECNT              | PRU Cycle Count                                          |
| 10h            | STALLCNT              | PRU Stall Count                                          |
| 20h            | CONTABLKIDX0          | PRU Constant Table Block Index Register 0                |
| 28h            | CONTABPROPTR0         | PRU Constant Table Programmable Pointer Register 0       |
| 2Ch            | CONTABPROPTR1         | PRU Constant Table Programmable Pointer Register 1       |
| 400h to 47Ch   | INTGPR0 to INTGPR31   | PRU Internal General Purpose Registers (for Debug)       |
| 480h to 4FCh   | INTCTER0 to INTCTER31 | PRU Internal Constants Table Entry Registers (for Debug) |

#### 14.8.1.3.1 CONTROL Register (Offset = 0h)

### Figure 14-24. CONTROL Register

| 2    | SLEEPING    | R/W  | 0     | <p>PRU Sleep Indicator: This bit indicates whether or not the PRU is currently asleep.</p> <p>0 = PRU is not asleep</p> <p>1 = PRU is asleep If this bit is written to a 0, the PRU will be forced to power up from sleep mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1    | ENABLE      | R/W  | 0     | <p>Processor Enable: This bit controls whether or not the PRU is allowed to fetch new instructions.</p> <p>0 = PRU is disabled</p> <p>1 = PRU is enabled If this bit is de-asserted while the PRU is currently running and has completed the initial cycle of a multi-cycle instruction (LBxO, SBxO, SCAN, etc.), the current instruction will be allowed to complete before the PRU pauses execution. Otherwise, the PRU will halt immediately. Because of the unpredictability/timing sensitivity of the instruction execution loop, this bit is not a reliable indication of whether or not the PRU is currently running. The pru_state bit should be consulted for an absolute indication of the run state of the core. When the PRU is halted, its internal state remains coherent therefore this bit can be reasserted without issuing a software reset and the PRU will resume processing exactly where it left off in the instruction stream.</p> |
| 0    | SOFTRESET   | R    | 0 → 1 | <p>Soft Reset: When this bit is cleared, the PRU will be reset. This bit is set back to 1 on the next cycle after it has been cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 31-0 | BITWISEENABLES | R/W  | 0     | Wakeup Enables: This field is ANDed with the incoming R31 status inputs (whose bit positions were specified in the stmap parameter) to produce a vector which is unary ORed to produce the status_wakeup source for the core. Setting any bit in this vector will allow the corresponding status input to wake up the core when it is asserted high. The PRU should set this enable vector prior to executing a SLP (sleep) instruction to ensure that the desired sources can wake up the core. |

### 14.8.1.3.4 CYCLECNT Register (Offset = Ch)

This register counts the number of cycles for which the PRU has been enabled.

| Bit  | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|----------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CYCLECOUN<br>T | R/WC | 0     | This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits "ENABLE" and "COUNTENABLE" set in the PRU control register).<br>Counting halts while the PRU is disabled or counter is disabled, and resumes when re-enabled. Counter clears the "COUNTENABLE" bit in the PRU control register when the count reaches 0xFFFFFFFF. (Count does not wrap). The register can be read at any time. The register can be cleared when the counter or PRU is disabled. Clearing this register also clears the PRU Stall Count Register. |

#### 14.8.1.3.5 STALLCNT Register (Offset = 10h)

This register counts the number of cycles for which the PRU has been enabled, but unable to fetch a new instruction. It is linked to the Cycle Count Register (0x0C) such that this register reflects the stall cycles measured over the same cycles as counted by the cycle count register. Thus the value of this register is always less than or equal to cycle count.

**Figure 14-28. STALLCNT Register**

**Table 14-38. STALLCNT Register Field Descriptions**

| Bit  | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|----------------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | STALLCOUN<br>T | R    | 0     | This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits "ENABLE" and "COUNTENABLE" set in the PRU control register), and the PRU was unable to fetch a new instruction for any reason.<br>Counting halts while the PRU is disabled or the counter is disabled, and resumes when re-enabled. The register can be read at any time. The register is cleared when PRU Cycle Count Register is cleared. |

#### 14.8.1.3.6 CONTABBLKIDX0 Register (Offset = 20h)

This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State / Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching. The format of this register is as follows:

**Figure 14-29. CONTABBLKIDX0 Register**

|          |    |       |    |

| 19-16 | C25      | R/W  | 0     | PRU Constant Entry 25 Block Index: This field sets the value that will appear in bits 11:8 of entry 25 in the PRU Constant Table |
| 15-4  | RESERVED | R    | 0     |                                                                                                                                  |
| 3-0   | C24      | R/W  | 0     | PRU Constant Entry 24 Block Index: This field sets the value that will appear in bits 11:8 of entry 24 in the PRU Constant Table |

#### 14.8.1.3.7 CONTABPROPTR0 Register (Offset = 28h)

This register allows the PRU to set up the 256-byte page index for entries 28 and 29 in the PRU Constant Table which serve as general purpose pointers which can be configured to point to any locations inside the session router address map. This register is useful when the PRU needs to frequently access certain structures inside the session router address space whose locations are not hard coded such as tables in scratchpad memory. This register is formatted as follows:

**Figure 14-30. CONTABPROPTR0 Register**

|       |       |    |   |
|-------|-------|----|---|
| 31    | 16    | 15 | 0 |
| C29   | C28   |    |   |

**Table 14-40. CONTABPROPTR0 Register Field Descriptions**

| Bit   | Field | Type | Reset | Description                                                                                                                  |
|-------|-------|------|-------|------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | C29   | R/W  | 0     | PRU Constant Entry 29 Pointer: This field sets the value that will appear in bits 23:8 of entry 29 in the PRU Constant Table |
| 15-0  | C28   | R/W  | 0     | PRU Constant Entry 28 Pointer: This field sets the value that will appear in bits 23:8 of entry 28 in the PRU Constant Table |

#### 14.8.1.3.8 CONTABPROPTR1 Register (Offset = 2Ch)

This register functions the same as the PRU Constant Table Programmable Pointer Register 0 but allows the PRU to control entries 30 and 31 in the PRU Constant Table. This register is formatted as follows:

**Figure 14-31. CONTABPROPTR1 Register**

|       |       |    |   |
|-------|-------|----|---|
| 31    | 16    | 15 | 0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-41. CONTABPROPTR1 Register Field Descriptions**

| Bit   | Field | Type | Reset | Description                                                                                                                  |
|-------|-------|------|-------|------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | C31   | R/W  | 0     | PRU Constant Entry 31 Pointer: This field sets the value that will appear in bits 23:8 of entry 31 in the PRU Constant Table |
| 15-0  | C30   | R/W  | 0     | PRU Constant Entry 30 Pointer: This field sets the value that will appear in bits 23:8 of entry 30 in the PRU Constant Table |

### 14.8.1.3.9 INTGPR0 to INTGPR31 Register (Offset = 400h + 4\*n)

This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written. This register is formatted as follows:

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Figure 14-32. INTGPR0 to INTGPR31 Register**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-42. INTGPR0 to INTGPR31 Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description                                                                                                                                          |
|------|---------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | INTGPRn | R/W  | X     | PRU Internal GP Register n: Reading / writing this field directly inspects/modifies the corresponding internal register in the PRU internal regfile. |

### 14.8.1.3.10 INTCTER0 to INTCTER31 Register (Offset = 480h + 4\*n)

This register allows an external agent to debug the PRU while it is disabled. Since some of the constants table entries may actually depend on system inputs / and or the internal state of the PRU, these registers are provided to allow an external agent to easily determine the state of the constants table. This register is formatted as follows:

**Figure 14-33. INTCTER0 to INTCTER31 Register**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-43. INTCTER0 to INTCTER31 Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                                                                                             |
|------|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | INTCTERn | R    | X     | PRU Internal Constants Table Entry n: Reading this field directly inspects the corresponding entry in the PRU internal constants table. |

#### 14.8.1.4 PRU Instruction RAM Region

The instruction RAM region contains storage for instructions. The instruction RAM region memory map is as follows:

**Table 14-44. Instruction RAM Memory Region**

| Address Offset | Register            |
|----------------|---------------------|
| 0x0000         | PRU Instruction RAM |

##### 14.8.1.4.1 PRU Instruction RAM (0h)

A total of 1K 32-bit words of instruction storage are provided for the PRU. This memory is to be initialized by an external (to the PRUSS) host processor. This region is only accessible to external masters when the PRU is not-running.

Note that the instruction RAM is accessed using byte addresses on the bus. The PC is an instruction address where each instruction is a 32 bit word and is not a byte address. To compute the byte address just multiply the PC by 4 (PC of 2 = byte address of 0x8, or PC of 8 = byte address of 0x20), or to compute the PC just divide the word aligned byte address by 4 (byte address of 0x8 = PC of 2, byte address of 0x20 = PC of 8).

#### 14.8.2 INTC Registers

[Table 14-45](#) lists the memory-mapped registers for the INTC. See [Section 14.8.1](#) for the memory address of these registers.

**Table 14-45. PRUSS Interrupt Controller (INTC) Registers**

| Address Offset | Register Name                    | Description                                      |
|----------------|----------------------------------|--------------------------------------------------|
| 0h             | REVID                            | Revision ID Register                             |

| 0    | ENABLE   | R/W  | 0     | The current global enable value when read. Writes set the global enable |

#### 14.8.2.4 GLBLNSTLVL Register (Offset = 1Ch)

The Global Nesting Level Register allows the checking and setting of the global nesting level across all host interrupts when automatic global nesting mode is set. The nesting level is the channel (and all of lower priority) that are nested out because of a current interrupt. *This register is only available when nesting is configured.*

**Table 14-52. GLBLNSTLVL Register**

|              |          |   |   |           |

|------|-----------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | OVERRIDE  | W/O  | X     | Always read as 0. Writes of 1 override the automatic nesting and set the nesting_level to the written data.                                                                                 |
| 30-9 | RESERVED  | R    | 0     |                                                                                                                                                                                             |
| 8-0  | NESTLEVEL | R/W  | Ah    | The current global nesting level (highest channel that is nested). Writes set the nesting level. In auto nesting mode this value is updated internally unless the auto_override bit is set. |

#### 14.8.2.5 STATIDXSET Register (Offset = 20h)

The System Interrupt Status Indexed Set Register allows setting the status of an interrupt. The interrupt to set is the index value written. This sets the Raw Status Register bit of the given index.

**Table 14-54. STATIDXSET Register**

|          |    |   |       |

| 31-10 | RESERVED | R    | 0     |                                                                                    |
| 9-0   | INDEX    | W/C  | 0     | Writes clear the enable of the interrupt given in the index value. Reads return 0. |

#### 14.8.2.9 HSTINTENIDXSET Register (Offset = 34h)

The Host Interrupt Enable Indexed Set Register allows enabling a host interrupt output. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if already enabled.

**Table 14-62. HSTINTENIDXSET Register**

|          |    |   |       |
|----------|----|---|-------|
| 31       | 10 | 9 | 0     |
| RESERVED |    |   | INDEX |

| 31-0 | RAW_STATU<br>S | W/S  | 0     | System interrupt raw status and setting of the system interrupts 32 to 63. Reads return the raw status. Write a 1 in a bit position to set the status of the system interrupt. Writing a 0 has no effect. |

#### 14.8.2.14 STATCLRINT0 Register (Offset = 280h)

The System Interrupt Status Enabled/Clear Registers show the pending enabled status of the system interrupts. Software can write to the Status Clear Registers to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt.

**Table 14-72. STATCLRINT0 Register**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 14-81. ENABLECLR0 Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description                                                                                                                                                                                   |
|------|--------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENABLE | W/C  | 0     | System interrupt enables system interrupts 0 to 31.<br>Read returns the enable value (0 = disabled, 1 = enabled) Write a 1 in a bit position to clear that enable. Writing a 0 has no effect. |

#### 14.8.2.19 ENABLECLR1 Register (Offset = 384h)

The System Interrupt Enable Clear Register disables system interrupts to map to channels. System interrupts that are not enabled do not interrupt the host. There is a bit per system interrupt.

**Table 14-82. ENABLECLR1 Register**

**Table 14-85. CHANMAP0 to CHANMAP15 Register Field Descriptions**

| Bit   | Field     | Type | Reset | Description                                      |
|-------|-----------|------|-------|--------------------------------------------------|
| 31-24 | SYSN3_MAP | R/W  | 0     | Sets the channel for the system interrupt N + 3. |
| 23-16 | SYSN2_MAP | R/W  | 0     | Sets the channel for the system interrupt N + 2. |
| 15-8  | SYSN1_MAP | R/W  | 0     | Sets the channel for the system interrupt N + 1. |
| 7-0   | SYSN_MAP  | R/W  | 0     | Sets the channel for the system interrupt N.     |

#### 14.8.2.21 HOSTMAP0 to HOSTMAP2 Register (Offset = 800h to 808h)

The Host Interrupt Map Registers define the host interrupt for each channel. There is one register per 4 channels. *Channels with forced host interrupt mappings will have their fields read-only.*

**Table 14-86. HOSTMAP0 to HOSTMAP2 Register**

| 31         | 24 | 23 | 16 | 15         | 8 | 7 | 0 |

| <b>15.3 Supported Use Cases .....</b> | <b>414</b>  |
| <b>15.4 Registers .....</b>           | <b>419</b>  |

## 15.1 Introduction

### 15.1.1 Purpose of the Peripheral

The DDR2/mDDR memory controller is used to interface with JESD79D-2 standard compliant DDR2 SDRAM devices and JESD209 standard mobile DDR (mDDR) SDRAM devices. Memories types such as DDR1 SDRAM, SDR SDRAM, SDRAM, and asynchronous memories are not supported. The DDR2/mDDR memory is the major memory location for program and data storage.

### 15.1.2 Features

The DDR2/mDDR memory controller supports the following features:

- JESD79D-2 standard compliant DDR2 SDRAM
- JESD209 standard compliant mobile DDR (mDDR)
- Data bus width of 16 bits
- CAS latencies:
  - DDR2: 2, 3, 4, and 5
  - mDDR: 2 and 3
- Internal banks:
  - DDR2: 1, 2, 4, and 8
  - mDDR: 1, 2, and 4
- Burst length: 8
- Burst type: sequential
- 1 CS signal
- Page sizes: 256, 512, 1024, and 2048
- SDRAM auto-initialization
- Self-refresh mode
- Partial array self-refresh (for mDDR)
- Power-down mode
- Prioritized refresh
- Programmable refresh rate and backlog counter
- Programmable timing parameters
- Little-endian mode

### 15.1.3 Functional Block Diagram

The DDR2/mDDR memory controller is the main interface to external DDR2/mDDR memory. [Figure 15-1](#) displays the general data paths to on-chip peripherals and external DDR2/mDDR SDRAM.

Master peripherals, EDMA, and the CPU can access the DDR2/mDDR memory controller through the switched central resource (SCR).

### 15.1.4 Supported Use Case Statement

The DDR2/mDDR memory controller supports JESD79D-2 DDR2 SDRAM memories and the JESD209 mobile DDR (mDDR) SDRAM memories utilizing 16 bits of the DDR2/mDDR memory controller data bus. See [Section 15.3](#) for more details.

### 15.1.5 Industry Standard(s) Compliance Statement

The DDR2/mDDR memory controller is compliant with the JESD79D-2 DDR2 SDRAM standard and the JESD209 mobile DDR (mDDR) standard with the following exception:

- On-Die Termination (ODT). The DDR2/mDDR memory controller does not include any on-die terminating resistors. Furthermore, the on-die terminating resistors of the DDR2/mDDR SDRAM device must be disabled by tying the ODT input pin of the DDR2/mDDR SDRAM to ground.

## 15.2 Architecture

This section describes the architecture of the DDR2/mDDR memory controller as well as how it is structured and how it works within the context of the system-on-a-chip. The DDR2/mDDR memory controller can gluelessly interface to most standard DDR2/mDDR SDRAM devices and supports such features as self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to interface and properly configure the DDR2/mDDR memory controller to perform read and write operations to externally-connected DDR2/mDDR SDRAM devices. Also, [Section 15.3](#) provides a detailed example of interfacing the DDR2/mDDR memory controller to a common DDR2/mDDR SDRAM device.

### 15.2.1 Clock Control

The DDR2/mDDR memory controller receives two input clocks from internal clock sources, VCLK and 2X\_CLK ([Figure 15-2](#)). VCLK is a divided-down version of the PLL0 clock. 2X\_CLK is the PLL1 clock. 2X\_CLK should be configured to clock at the frequency of the desired data rate, or stated similarly, it should operate at twice the frequency of the desired DDR2/mDDR memory clock. DDR\_CLK and  $\overline{\text{DDR\_CLK}}$  are the two output clocks of the DDR2/mDDR memory controller providing the interface clock to the DDR2/mDDR SDRAM memory. These two clocks operate at a frequency of  $2\text{X\_CLK}/2$ .

#### 15.2.1.1 Clock Source

VCLK and 2X\_CLK are sourced from two independent PLLs ([Figure 15-2](#)). VCLK is sourced from PLL controller 0 (PLL0) and 2X\_CLK is sourced from PLL controller 1 (PLL1).

VCLK is clocked at a fixed divider ratio of PLL0. This divider is fixed at 2, meaning VCLK is clocked at a frequency of  $\text{PLL0}/2$ .

The clock from PLL1 is not divided before reaching 2X\_CLK. PLL1 should be configured to supply 2X\_CLK at the desired frequency. For example, if a 138-MHz DDR2/mDDR interface clock (DDR\_CLK) is desired, then PLL1 must be configured to generate a 276-MHz clock on 2X\_CLK.

**Figure 15-2. DDR2/mDDR Memory Controller Clock Block Diagram**

### 15.2.1.2 Clock Configuration

The frequency of 2X\_CLK is configured by selecting the appropriate PLL multiplier. The PLL multiplier is selected by programming registers within PLLC1. The PLLC1 divider ration is fixed at 1. For information on programming the PLL controllers, see the *Phase-Locked Loop Controller (PLLC)* chapter. For information on supported clock frequencies, see the *Device Clocking* chapter and your device-specific data manual.

**NOTE:** PLLC1 should be configured and a stable clock present on 2X\_CLK before releasing the DDR2/mDDR memory controller from reset.

### 15.2.1.3 DDR2/mDDR Memory Controller Internal Clock Domains

There are two clock domains within the DDR2/mDDR memory controller. The two clock domains are driven by VCLK and a divided-down by 2 version of 2X\_CLK called MCLK. The command FIFO, write FIFO, and read FIFO described in [Section 15.2.6](#) are all on the VCLK domain. From this, VCLK drives the interface to the peripheral bus.

The MCLK domain consists of the DDR2/mDDR memory controller state machine and memory-mapped registers. This clock domain is clocked at the rate of the external DDR2/mDDR memory, 2X\_CLK/2.

To conserve power within the DDR2/mDDR memory controller, VCLK, MCLK, and 2X\_CLK may be stopped. See [Section 15.2.16](#) for proper clock stop procedures.

## 15.2.2 Signal Descriptions

The DDR2/mDDR memory controller signals are shown in [Figure 15-3](#) and described in [DDR2/mDDR Memory Controller Signal Descriptions](#). The following features are included:

- The maximum data bus is 16-bits wide.
- The address bus is 14-bits wide with an additional three bank address pins.
- Two differential output clocks driven by internal clock sources.
- Command signals: Row and column address strobe, write enable strobe, data strobe, and data mask.
- One chip select signal and one clock enable signal.

**Figure 15-3. DDR2/mDDR Memory Controller Signals**

### DDR2/mDDR Memory Controller Signal Descriptions

| Pin                 | Type <sup>(1)</sup> | Description                                                                                                                                                                                                             |
|---------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| DDR_CAS             | O/Z                 | <b>Column address strobe:</b> Active low, command output.                                                                                                                                                               |
| DDR_DQM[1:0]        | O/Z                 | <b>Data mask:</b> Active high, output mask signal for write data.                                                                                                                                                       |
| DDR_DQS[1:0]        | I/O/Z               | <b>Data strobe:</b> Active high, bi-directional signals. Output with write data, input with read data.                                                                                                                  |
| DDR_BA[2:0]         | O/Z                 | <b>Bank select:</b> Output, defining which bank a given command is applied.                                                                                                                                             |
| DDR_A[13:0]         | O/Z                 | <b>Address:</b> Address bus.                                                                                                                                                                                            |
| DDR_D[15:0]         | I/O/Z               | <b>Data:</b> Bi-directional data bus. Input for read data, output for write data.                                                                                                                                       |
| DDR_DQGATE0         | O/Z                 | <b>Strobe Enable:</b> Active high.                                                                                                                                                                                      |
| DDR_DQGATE1         | I/O/Z               | <b>Strobe Enable Delay:</b> Loopback signal for timing adjustment (DQS gating). Route from DDR_DQGATE0 to DDR device and back to DDR_DQGATE1 with same constraints as used for DDR clock and data.                      |
| DDR_ZP              | I/O/Z               | <b>Output drive strength reference:</b> Reference output for drive strength calibration of N and P channel outputs. Tie to ground via 50 ohm .5% tolerance 1/16th watt resistor (49.9 ohm .5% tolerance is acceptable). |
| DDR_VREF            | pwr                 | <b>Voltage reference input:</b> Voltage reference input for the SSTL_18 I/O buffers. Note even in the case of mDDR an external resistor divider connected to this pin is necessary.                                     |

<sup>(1)</sup> Legend: I = input, O = Output, Z = high impedance, pwr = power

### 15.2.3 Protocol Description(s)

The DDR2/mDDR memory controller supports the DDR2/mDDR SDRAM commands listed in [Table 15-1](#). [Table 15-2](#) shows the signal truth table for the DDR2/mDDR SDRAM commands.

**Table 15-1. DDR2/mDDR SDRAM Commands**

| Command                    | Function                                                                                                           |
|----------------------------|--------------------------------------------------------------------------------------------------------------------|
| ACTV                       | Activates the selected bank and row.                                                                               |
| DCAB                       | Precharge all command. Deactivates (precharges) all banks.                                                         |
| DEAC                       | Precharge single command. Deactivates (precharges) a single bank.                                                  |
| DESEL                      | Device Deselect.                                                                                                   |
| EMRS                       | Extended Mode Register set. Allows altering the contents of the mode register.                                     |
| MRS                        | Mode register set. Allows altering the contents of the mode register.                                              |
| NOP                        | No operation.                                                                                                      |
| Power Down                 | Power-down mode.                                                                                                   |
| READ                       | Inputs the starting column address and begins the read operation.                                                  |
| READ with<br>autoprecharge | Inputs the starting column address and begins the read operation. The read operation is followed by a precharge.   |
| REFR                       | Autorefresh cycle.                                                                                                 |
| SLFREFR                    | Self-refresh mode.                                                                                                 |
| WRT                        | Inputs the starting column address and begins the write operation.                                                 |
| WRT with<br>autoprecharge  | Inputs the starting column address and begins the write operation. The write operation is followed by a precharge. |

**Table 15-2. Truth Table for DDR2/mDDR SDRAM Commands**

### 15.2.3.1 Refresh Mode

The DDR2/mDDR memory controller issues refresh commands to the DDR2/mDDR SDRAM memory (Figure 15-4). REFR is automatically preceded by a DCAB command, ensuring the deactivation of all CE spaces and banks selected. Following the DCAB command, the DDR2/mDDR memory controller begins performing refreshes at a rate defined by the refresh rate (RR) bit in the SDRAM refresh control register (SDRCR). Page information is always invalid before and after a REFR command; thus, a refresh cycle always forces a page miss. This type of refresh cycle is often called autorefresh. Autorefresh commands may not be disabled within the DDR2/mDDR memory controller. See Section 15.2.7 for more details on REFR command scheduling.

**Figure 15-4. Refresh Command**

### 15.2.3.2 Deactivation (DCAB and DEAC)

The precharge all banks command (DCAB) is performed after a reset to the DDR2/mDDR memory controller or following the initialization sequence. DDR2/mDDR SDRAMs also require this cycle prior to a refresh (REFR) and mode set register commands (MRS and EMRS). During a DCAB command, DDR\_A[10] is driven high to ensure the deactivation of all banks. Figure 15-5 shows the timing diagram for a DCAB command.

**Figure 15-5. DCAB Command**

The DEAC command closes a single bank of memory specified by the bank select signals. [Figure 15-6](#) shows the timings diagram for a DEAC command.

**Figure 15-6. DEAC Command**

### 15.2.3.3 Activation (ACTV)

The DDR2/mDDR memory controller automatically issues the activate (ACTV) command before a read or write to a closed row of memory. The ACTV command opens a row of memory, allowing future accesses (reads or writes) with minimum latency. The value of DDR\_BA[2:0] selects the bank and the value of DDR\_A[13:0] selects the row. When the DDR2/mDDR memory controller issues an ACTV command, a delay of  $t_{RCD}$  is incurred before a read or write command is issued. [Figure 15-7](#) shows an example of an ACTV command. Reads or writes to the currently active row and bank of memory can achieve much higher throughput than reads or writes to random areas because every time a new row is accessed, the ACTV command must be issued and a delay of  $t_{RCD}$  incurred.

**Figure 15-7. ACTV Command**

### 15.2.3.4 READ Command

Figure 15-8 shows the DDR2/mDDR memory controller performing a read burst from DDR2/mDDR SDRAM. The READ command initiates a burst read operation to an active row. During the READ command,  $\overline{\text{DDR\_CAS}}$  drives low,  $\overline{\text{DDR\_WE}}$  and  $\overline{\text{DDR\_RAS}}$  remain high, the column address is driven on  $\text{DDR\_A}[13:0]$ , and the bank address is driven on  $\text{DDR\_BA}[2:0]$ .

The DDR2/mDDR memory controller uses a burst length of 8, and has a programmable CAS latency of 2, 3, 4, or 5. The CAS latency is three cycles in Figure 15-8. Read latency is equal to CAS latency plus additive latency. The DDR2/mDDR memory controller always configures the memory to have an additive latency of 0, so read latency equals CAS latency. Since the default burst size is 8, the DDR2/mDDR memory controller returns 8 pieces of data for every read command. If additional accesses are not pending to the DDR2/mDDR memory controller, the read burst completes and the unneeded data is disregarded. If additional accesses are pending, depending on the scheduling result, the DDR2/mDDR memory controller can terminate the read burst and start a new read burst. Furthermore, the DDR2/mDDR memory controller does not issue a DAB/DEAC command until page information becomes invalid.

**Figure 15-8. DDR2/mDDR READ Command**

### 15.2.3.5 Write (WRT) Command

Prior to a WRT command, the desired bank and row are activated by the ACTV command. Following the WRT command, a write latency is incurred. For DDR2, write latency is equal to CAS latency minus 1 cycles. For mDDR, write latency is equal to 1 cycle, always. All writes have a burst length of 8. The use of the DDR\_DQM outputs allows byte and halfword writes to be executed. Figure 15-9 shows the timing for a DDR2 write on the DDR2/mDDR memory controller.

If the transfer request is for less than 8 words, depending on the scheduling result and the pending commands, the DDR2/mDDR memory controller can:

- Mask out the additional data using DDR\_DQM outputs
- Terminate the write burst and start a new write burst

The DDR2/mDDR memory controller does not perform the DEAC command until page information becomes invalid.

**Figure 15-9. DDR2/mDDR WRT Command**

NOTE: This diagrams shows write latency for DDR2. For mDDR, write latency is always equal to 1 cycle.

### 15.2.3.6 Mode Register Set (MRS and EMRS)

DDR2/mDDR SDRAM contains mode and extended mode registers that configure the DDR2/mDDR memory for operation. These registers control burst type, burst length, CAS latency, DLL enable/disable (on DDR2/mDDR device), single-ended strobe, differential strobe etc.

The DDR2/mDDR memory controller programs the mode and extended mode registers of the DDR2/mDDR memory by issuing MRS and EMRS commands. When the MRS or EMRS command is executed, the value on DDR\_BA[2:0] selects the mode register to be written and the data on DDR\_A[13:0] is loaded into the register. [Figure 15-10](#) shows the timing for an MRS and EMRS command.

The DDR2/mDDR memory controller only issues MRS and EMRS commands during the DDR2/mDDR memory controller initialization sequence. See [Section 15.2.13](#) for more information.

**Figure 15-10. DDR2/mDDR MRS and EMRS Command**

### 15.2.4 Memory Width and Byte Alignment

The DDR2/mDDR memory controller supports memory widths of 16 bits. [Table 15-3](#) summarizes the addressable memory ranges on the DDR2/mDDR memory controller. Only little-endian format is supported. [Figure 15-11](#) shows the byte lanes used on the DDR2/mDDR memory controller. The external memory is always right aligned on the data bus.

**Table 15-3. Addressable Memory Ranges**

| Memory Width | Maximum addressable bytes per CS space | Description      |
|--------------|----------------------------------------|------------------|
| ×16          | 256 Mbytes                             | Halfword address |

**Figure 15-11. Byte Alignment**

### 15.2.5 Address Mapping

The memory controller views the DDR2/mDDR SDRAM device as one continuous block of memory. The memory controller receives memory access requests with a 32-bit logical address, and it uses the logical address to generate a row, column, and bank address for accessing the DDR2/mDDR SDRAM device.

The memory controller supports two address mapping schemes: normal address mapping and special address mapping. Special address mapping is typically used only with mDDR devices using partial array self-refresh.

When the internal bank position (IBANKPOS) bit in the SDRAM configuration register (SDCR) is cleared, the memory controller operates with normal address mapping. In this case, the number of column and bank address bits is determined by the IBANK and PAGESIZE fields in SDCR. The number of row address bits is determined by the number of valid address pins for the device and does not need to be set in a register.

When IBANKPOS is set to 1, the memory controller operates with special address mapping. In this case, the number of column, row, and bank address bits is determined by the PAGESIZE, ROWSIZE, and IBANK fields. The ROWSIZE field is in the SDRAM configuration register 2 (SDCR2). See [Table 15-4](#) for a descriptions of these bit fields.

**Table 15-4. Configuration Register Fields for Address Mapping**

| Bit Field | Bit Value | Bit Description                                                        |
|-----------|-----------|------------------------------------------------------------------------|
| IBANK     |           | Defines the number of internal banks in the external DDR2/mDDR memory. |
|           | 0         | 1 bank                                                                 |
|           | 1h        | 2 banks                                                                |
|           | 2h        | 4 banks                                                                |
|           | 3h        | 8 banks                                                                |
| PAGESIZE  |           | Defines the page size of each page in the external DDR2/mDDR memory.   |
|           | 0         | 256 words (requires 8 column address bits)                             |
|           | 1h        | 512 words (requires 9 column address bits)                             |
|           | 2h        | 1024 words (requires 10 column address bits)                           |
|           | 3h        | 2048 words (requires 11 column address bits)                           |
| ROWSIZE   |           | Defines the row size of each row in the external DDR2/mDDR memory      |
|           | 0         | 512 (requires 9 row address bits)                                      |
|           | 1h        | 1024 (requires 10 row address bits)                                    |
|           | 2h        | 2048 (requires 11 row address bits)                                    |
|           | 3h        | 4096 (requires 12 row address bits)                                    |
|           | 4h        | 8192 (requires 13 row address bits)                                    |
|           | 5h        | 16384 (requires 14 row address bits)                                   |

### 15.2.5.1 Normal Address Mapping (IBANKPOS = 0)

As stated in [Table 15-4](#), the IBANK and PAGESIZE fields of SDCR control the mapping of the logical, source address of the DDR2/mDDR memory controller to the DDR2/mDDR SDRAM row, column, and bank address bits. The DDR2/mDDR memory controller logical address always contains up to 14 row address bits, whereas the number of column and bank bits are determined by the IBANK and PAGESIZE fields. [Table 15-5](#) show how the logical address bits map to the DDR2/mDDR SDRAM row, column, and bank bits for combinations of IBANK and PAGESIZE values. The same DDR2/mDDR memory controller pins provide the row and column address to the DDR2/mDDR SDRAM, thus the DDR2/mDDR memory controller appropriately shifts the address during row and column address selection.

[Logical Address-to-DDR2/mDDR SDRAM Address Map](#) shows how this address-mapping scheme organizes the DDR2/mDDR SDRAM rows, columns, and banks into the device memory-map. Note that during a linear access, the DDR2/mDDR memory controller increments the column address as the logical address increments. When the DDR2/mDDR memory controller reaches a page/row boundary, it moves onto the same page/row in the next bank. This movement continues until the same page has been accessed in all banks. To the DDR2/mDDR SDRAM, this process looks as shown in [Figure 15-12](#).

By traversing across banks while remaining on the same row/page, the DDR2/mDDR memory controller maximizes the number of activated banks for a linear access. This results in the maximum number of open pages when performing a linear access being equal to the number of banks. Note that the DDR2/mDDR memory controller never opens more than one page per bank.

Ending the current access is not a condition that forces the active DDR2/mDDR SDRAM row to be closed. The DDR2/mDDR memory controller leaves the active row open until it becomes necessary to close it. This decreases the deactivate-reactivate overhead.

**Table 15-5. Logical Address-to-DDR2/mDDR SDRAM Address Map for 16-bit SDRAM**

| SDCR Bit |          | Logical Address |    |    |    |        |        |        |        |        |    |        |    |    |       |       |       |        |        |        |        |       |  |
|----------|----------|-----------------|----|----|----|--------|--------|--------|--------|--------|----|--------|----|----|-------|-------|-------|--------|--------|--------|--------|-------|--|
| IBANK    | PAGESIZE | 31              | 30 | 29 | 28 | 27     | 26     | 25     | 24     | 23     | 22 | 21:15  | 14 | 13 | 12    | 11    | 10    | 9      | 8:1    | 0      |        |       |  |
| 0        | 0        |                 |    |    |    |        |        |        |        |        |    | nrb=14 |    |    |       |       |       |        |        |        | ncb=8  |       |  |
| 1        | 0        |                 |    |    |    |        |        |        |        | nrb=14 |    |        |    |    |       |       |       |        |        | nbb=1  |        | ncb=8 |  |
| 2h       | 0        |                 |    |    |    |        |        |        | nrb=14 |        |    |        |    |    |       |       |       | nbb=2  |        |        | ncb=8  |       |  |
| 3h       | 0        |                 |    |    |    |        |        | nrb=14 |        |        |    |        |    |    |       |       | nbb=3 |        |        |        | ncb=8  |       |  |
| 0        | 1        |                 |    |    |    |        |        |        |        | nrb=14 |    |        |    |    |       |       |       |        |        | ncb=9  |        |       |  |
| 1        | 1        |                 |    |    |    |        |        |        | nrb=14 |        |    |        |    |    |       |       |       |        | nbb=1  |        | ncb=9  |       |  |
| 2h       | 1        |                 |    |    |    |        |        | nrb=14 |        |        |    |        |    |    |       |       | nbb=2 |        |        | ncb=9  |        |       |  |
| 3h       | 1        |                 |    |    |    |        | nrb=14 |        |        |        |    |        |    |    |       | nbb=3 |       |        |        | ncb=9  |        |       |  |
| 0        | 2h       |                 |    |    |    |        |        |        |        | nrb=14 |    |        |    |    |       |       |       |        | ncb=10 |        |        |       |  |
| 1        | 2h       |                 |    |    |    |        |        |        | nrb=14 |        |    |        |    |    |       |       |       |        | nbb=1  |        | ncb=10 |       |  |
| 2h       | 2h       |                 |    |    |    |        |        | nrb=14 |        |        |    |        |    |    |       |       | nbb=2 |        |        | ncb=10 |        |       |  |
| 3h       | 2h       |                 |    |    |    |        | nrb=14 |        |        |        |    |        |    |    |       | nbb=3 |       |        |        | ncb=10 |        |       |  |
| 0        | 3h       |                 |    |    |    |        |        |        | nrb=14 |        |    |        |    |    |       |       |       | ncb=11 |        |        |        |       |  |
| 1        | 3h       |                 |    |    |    |        |        | nrb=14 |        |        |    |        |    |    |       |       | nbb=1 |        | ncb=11 |        |        |       |  |
| 2h       | 3h       |                 |    |    |    |        | nrb=14 |        |        |        |    |        |    |    |       | nbb=2 |       |        | ncb=11 |        |        |       |  |
| 3h       | 3h       |                 |    |    |    | nrb=14 |        |        |        |        |    |        |    |    | nbb=3 |       |       |        | ncb=11 |        |        |       |  |

|        |        |        |        |        | ... |          |        | •             |
|        |        |        |        |        | ... |          |        | •             |
|        |        |        |        |        | ... |          |        | •             |
|        |        |        |        |        | ... |          |        | Row N, bank 0 |
|        |        |        |        |        | ... |          |        | Row N, bank 1 |
|        |        |        |        |        | ... |          |        | Row N, bank 2 |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
|        |        |        |        |        | ... |          |        | Row N, bank P |

NOTE: M is number of columns (as determined by PAGESIZE) minus 1, P is number of banks (as determined by IBANK) minus 1, and N is number of rows (as determined by both PAGESIZE and IBANK) minus 1.

## Logical Address-to-DDR2/mDDR SDRAM Address Map (continued)

**Figure 15-12. DDR2/mDDR SDRAM Column, Row, and Bank Access**

NOTE: M is number of columns (as determined by PAGESIZE) minus 1, P is number of banks (as determined by IBANK) minus 1, and N is number of rows (as determined by both PAGESIZE and IBANK) minus 1.

### 15.2.5.2 Special Address Mapping (IBANKPOS = 1)

When the internal bank position (IBANKPOS) bit is set to 1, the PAGESIZE, ROWSIZE, and IBANK fields control the mapping of the logical source address of the memory controller to the column, row, and bank address bits of the SDRAM device. [Table 15-6](#) shows which source address bits map to the SDRAM column, row, and bank address bits for all combinations of PAGESIZE, ROWSIZE, and IBANK.

When IBANKPOS is set to 1, the effect of the address-mapping scheme is that as the source address increments across an SDRAM page boundary, the memory controller proceeds to the next page in the same bank. This movement along the same bank continues until all the pages have been accessed in the same bank. The memory controller then proceeds to the next bank in the device. This sequence is shown in [Figure 15-13](#) and [Figure 15-14](#).

Since, in this address mapping scheme, the memory controller can keep only one bank open, this scheme is lower in performance than the case when IBANKPOS is cleared to 0. Therefore, this case is only recommended to be used with Partial Array Self-refresh for mDDR SDRAM where performance may be traded-off for power savings.

**Table 15-6. Address Mapping Diagram for 16-Bit SDRAM (IBANKPOS = 1)**

| 31                                                       | Source Address                                                           |                                                                     | 1 |
|----------------------------------------------------------|--------------------------------------------------------------------------|---------------------------------------------------------------------|---|
| Bank Address                                             | Row Address                                                              | Column Address                                                      |   |
| Number of bank bits is defined by IBANK nbb = 1, 2, or 3 | Number of row bits is defined by ROWSIZE: nrb = 9, 10, 11, 12, 13, or 14 | Number of column bits is defined by PAGESIZE: ncb = 8, 9, 10, or 11 |   |

**Figure 15-13. Address Mapping Diagram (IBANKPOS = 1)**

| Col. 0 | Col. 1 | Col. 2 | Col. 3 | Col. 4 | ... | Col. M-1 | Col. M |               |
|--------|--------|--------|--------|--------|-----|----------|--------|---------------|
|        |        |        |        |        | ... |          |        | Row 1, bank 0 |
|        |        |        |        |        | ... |          |        | Row 2, bank 0 |
|        |        |        |        |        | ... |          |        | Row 3, bank 0 |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
|        |        |        |        |        | ... |          |        | Row N, bank 0 |
|        |        |        |        |        | ... |          |        | Row 1, bank 1 |
|        |        |        |        |        | ... |          |        | Row 2, bank 1 |
|        |        |        |        |        | ... |          |        | Row 3, bank 1 |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
|        |        |        |        |        | ... |          |        | Row N, bank 1 |
|        |        |        |        |        | ... |          |        | •             |
|        |        |        |        |        | ... |          |        | •             |
|        |        |        |        |        | ... |          |        | •             |
|        |        |        |        |        | ... |          |        | Row 1, bank P |
|        |        |        |        |        | ... |          |        | Row 2, bank P |
|        |        |        |        |        | ... |          |        | Row 3, bank P |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
| •      | •      | •      | •      | •      | ... | •        | •      | •             |
|        |        |        |        |        | ... |          |        | Row N, bank P |

NOTE: M is number of columns (as determined by PAGESIZE) minus 1, P is number of banks (as determined by IBANK) minus 1, and N is number of rows (as determined by ROWSIZE) minus 1.

**Figure 15-14. SDRAM Column, Row, Bank Access (IBANKPOS = 1)**

NOTE: M is number of columns (as determined by PAGESIZE) minus 1, P is number of banks (as determined by IBANK) minus 1, and N is number of rows (as determined by ROWSIZE) minus 1.

### 15.2.6 DDR2/mDDR Memory Controller Interface

To move data efficiently from on-chip resources to external DDR2/mDDR SDRAM memory, the DDR2/mDDR memory controller makes use of a command FIFO, a write FIFO, a read FIFO, and command and data schedulers. [Table 15-7](#) describes the purpose of each FIFO.

[Figure 15-15](#) shows the block diagram of the DDR2/mDDR memory controller FIFOs. Commands, write data, and read data arrive at the DDR2/mDDR memory controller parallel to each other. The same peripheral bus is used to write and read data from external memory as well as internal memory-mapped registers.

**Table 15-7. DDR2/mDDR Memory Controller FIFO Description**

| FIFO    | Description                                                | Depth (64-bit doublewords) |
|---------|------------------------------------------------------------|----------------------------|
| Command | Stores all commands coming from on-chip requestors         | 7                          |
| Write   | Stores write data coming from on-chip requestors to memory | 11                         |
| Read    | Stores read data coming from memory to on-chip requestors  | 17                         |

**Figure 15-15. DDR2/mDDR Memory Controller FIFO Block Diagram**

### 15.2.6.1 Command Ordering and Scheduling, Advanced Concept

The DDR2/mDDR memory controller performs command re-ordering and scheduling in an attempt to achieve efficient transfers with maximum throughput. The goal is to maximize the utilization of the data, address, and command buses while hiding the overhead of opening and closing DDR2/mDDR SDRAM rows. Command re-ordering takes place within the command FIFO.

Typically, a given master issues commands on a single priority. EDMA transfer controller read and write ports are different masters. The DDR2/mDDR memory controller first reorders commands from each master based on the following rules:

- Selects the oldest command (first command in the queue)
- Selects a read before a write if:
  - The read is to a different block address (2048 bytes) than the write
  - The read has greater or equal priority

The second bullet above may be viewed as an exception to the first bullet. This means that for an individual master, all of its commands will complete from oldest to newest, with the exception that a read may be advanced ahead of an older, lower or equal priority write. Following this scheduling, each master may have one command ready for execution.

Next, the DDR2/mDDR memory controller examines each of the commands selected by the individual masters and performs the following reordering:

- Among all pending reads, selects reads to rows already open. Among all pending writes, selects writes to rows already open.
- Selects the highest priority command from pending reads and writes to open rows. If multiple commands have the highest priority, then the DDR2/mDDR memory controller selects the oldest command.

The DDR2/mDDR memory controller may now have a final read and write command. If the Read FIFO is not full, then the read command will be performed before the write command, otherwise the write command will be performed first.

Besides commands received from on-chip resources, the DDR2/mDDR memory controller also issues refresh commands. The DDR2/mDDR memory controller attempts to delay refresh commands as long as possible to maximize performance while meeting the SDRAM refresh requirements. As the DDR2/mDDR memory controller issues read, write, and refresh commands to DDR2/mDDR SDRAM memory, it adheres to the following rules:

1. Refresh request resulting from the Refresh Must level of urgency being reached
2. Read request without a higher priority write (selected from above reordering algorithm)
3. Refresh request resulting from the Refresh Need level of urgency being reached
4. Write request (selected from above reordering algorithm)
5. Refresh request resulting from Refresh May level of urgency being reached
6. Request to enter self-refresh mode

The following results from the above scheduling algorithm:

- All writes from a single master will complete in order
- All reads from a single master will complete in order
- From the same master, any read to the same location (or within 2048 bytes) as a previous write will complete in order

#### 15.2.6.2 Command Starvation

The reordering and scheduling rules listed above may lead to command starvation, which is the prevention of certain commands from being processed by the DDR2/mDDR memory controller. Command starvation results from the following conditions:

- A continuous stream of high-priority read commands can block a low-priority write command
- A continuous stream of DDR2/mDDR SDRAM commands to a row in an open bank can block commands to the closed row in the same bank.

To avoid these conditions, the DDR2/mDDR memory controller can momentarily raises the priority of the oldest command in the command FIFO after a set number of transfers have been made. The PR\_OLD\_COUNT bit in the peripheral bus burst priority register (PBBPR) sets the number of the transfers that must be made before the DDR2/mDDR memory controller will raise the priority of the oldest command.

#### 15.2.6.3 Possible Race Condition

A race condition may exist when certain masters write data to the DDR2/mDDR memory controller. For example, if master A passes a software message via a buffer in DDR2/mDDR memory and does not wait for indication that the write completes, when master B attempts to read the software message it may read stale data and therefore receive an incorrect message. In order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write completion status from the DDR2/mDDR memory controller before indicating to master B that the data is ready to be read. If master A does not wait for indication that a write is complete, it must perform the following workaround:

1. Perform the required write.
2. Perform a dummy write to the DDR2/mDDR memory controller SDRAM status register.
3. Perform a dummy read to the DDR2/mDDR memory controller SDRAM status register.
4. Indicate to master B that the data is ready to be read after completion of the read in step 3. The completion of the read in step 3 ensures that the previous write was done.

The EDMA peripheral does not need to implement the above workaround. The above workaround is required for all other peripherals. See your device-specific data manual for more information.

### 15.2.7 Refresh Scheduling

The DDR2/mDDR memory controller issues autorefresh (REFR) commands to DDR2/mDDR SDRAM devices at a rate defined in the refresh rate (RR) bit field in the SDRAM refresh control register (SDRCR). A refresh interval counter is loaded with the value of the RR bit field and decrements by 1 each cycle until it reaches zero. Once the interval counter reaches zero, it reloads with the value of the RR bit. Each time the interval counter expires, a refresh backlog counter increments by 1. Conversely, each time the DDR2/mDDR memory controller performs a REFR command, the backlog counter decrements by 1. This means the refresh backlog counter records the number of REFR commands the DDR2/mDDR memory controller currently has outstanding.

The DDR2/mDDR memory controller issues REFR commands based on the level of urgency. The level of urgency is defined in [Table 15-8](#). Whenever the refresh must level of urgency is reached, the DDR2/mDDR memory controller issues a REFR command before servicing any new memory access requests. Following a REFR command, the DDR2/mDDR memory controller waits T<sub>RFC</sub> cycles, defined in the SDRAM timing register 1 (SDTIMR1), before rechecking the refresh urgency level.

In addition to the refresh counter previously mentioned, a separate backlog counter ensures the interval between two REFR commands does not exceed 8× the refresh rate. This backlog counter increments by 1 each time the interval counter expires and resets to zero when the DDR2/mDDR memory controller issues a REFR command. When this backlog counter is greater than 7, the DDR2/mDDR memory controller issues four REFR commands before servicing any new memory requests.

The refresh counters do not operate when the DDR2/mDDR memory is in self-refresh mode.

**Table 15-8. Refresh Urgency Levels**

| Urgency Level   | Description                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Refresh May     | Backlog count is greater than 0. Indicates there is a backlog of REFR commands, when the DDR2/mDDR memory controller is not busy it will issue the REFR command.                   |
| Refresh Release | Backlog count is greater than 3. Indicates the level at which enough REFR commands have been performed and the DDR2/mDDR memory controller may service new memory access requests. |
| Refresh Need    | Backlog count is greater than 7. Indicates the DDR2/mDDR memory controller should raise the priority level of a REFR command above servicing a new memory access.                  |
| Refresh Must    | Backlog count is greater than 11. Indicates the level at which the DDR2/mDDR memory controller should perform a REFR command before servicing new memory access requests.          |

### 15.2.8 Self-Refresh Mode

Clearing the self refresh/low power (SR\_PD) bit to 0 and then setting the low power mode enable (LPMODEN) bit to 1 in the SDRAM refresh control register (SDRCR), forces the DDR2/mDDR memory controller to place the external DDR2/mDDR SDRAM in a low-power mode (self refresh), in which the DDR2/mDDR SDRAM maintains valid data while consuming a minimal amount of power. When the LPMODEN bit is set to 1, the DDR2/mDDR memory controller continues normal operation until all outstanding memory access requests have been serviced and the refresh backlog has been cleared. At this point, all open pages of DDR2/mDDR SDRAM are closed and a self-refresh (SLFRFR) command (an autorefresh command with self refresh/low power) is issued.

The memory controller exits the self-refresh state when a memory access is received, when the LPMODEN bit in SDRCR is cleared to 0, or when the SR\_PD bit in SDRCR changed to 1. While in the self-refresh state, if a request for a memory access is received, the DDR2/mDDR memory controller services the memory access request, returning to the self-refresh state upon completion. The DDR2/mDDR memory controller will not wake up from the self-refresh state (whether from a memory access request, from clearing the LPMODEN bit, or from clearing the SR\_PD bit) until T<sub>CKE</sub> + 1 cycles have expired since the self-refresh command was issued. The value of T<sub>CKE</sub> is defined in the SDRAM timing register 2 (SDTIMR2).

In the case of DDR2, after exiting from the self-refresh state, the memory controller will not immediately start executing commands. Instead, it will wait T<sub>SXNR</sub> + 1 clock cycles before issuing non-read/write commands and T<sub>SXRD</sub> + 1 clock cycles before issuing read or write commands. The SDRAM timing register 2 (SDTIMR2) programs the values of T<sub>SXNR</sub> and T<sub>SXRD</sub>.

In the case of mDDR, after exiting from the self-refresh state, the memory controller will not immediately start executing commands. Instead, it will wait  $T_{\text{SXNR}}+1$  clock cycles and then execute auto-refresh command before issuing any other commands. The SDRAM timing register 2 (SDTIMR2) programs the value of  $T_{\text{SXNR}}$ .

Once in self-refresh mode, the DDR2/mDDR memory controller input clocks (VCLK and 2X\_CLK) may be gated off or changed in frequency. Stable clocks must be present before exiting self-refresh mode. See [Section 15.2.16](#) for more information describing the proper procedure to follow when shutting down DDR2/mDDR memory controller input clocks.

See [Section 15.2.16.1](#) for a description of the self-refresh programming sequence.

### 15.2.9 Partial Array Self Refresh for Mobile DDR

For additional power savings during self-refresh, the partial array self-refresh (PASR) feature of the mDDR allows you to select the amount of memory that will be refreshed during self-refresh. Use the partial array self-refresh (PASR) bit field in the SDRAM configuration register 2 (SDCR2) to select the amount of memory to refresh during self-refresh. As shown in [Table 15-9](#) you may select either 4, 2, 1, 1/2, or 1/4 bank(s). The PASR bits are loaded into the extended mode register of the mDDR device, during autoinitialization (see [Section 15.2.13](#)).

The mDDR performs bank interleaving when the internal bank position (IBANKPOS) bit in SDRAM configuration register (SDCR) is cleared to 0. Since the SDRAM banks are only partially refreshed during partial array self-refresh, it is recommended that you set IBANKPOS to 1 to avoid bank interleaving. When IBANKPOS is cleared to 0, it is the responsibility of software to move critical data into the banks that are to be refreshed during partial array self-refresh. Refer to [Section 15.2.5.2](#) for more information on IBANKPOS and addressing mapping in general.

**Table 15-9. Configuration Bit Field for Partial Array Self-refresh**

| Bit Field | Bit Value | Bit Description              |
|-----------|-----------|------------------------------|
| PASR      |           | Partial array self refresh.  |
|           | 0         | Refresh banks 0, 1, 2, and 3 |
|           | 1h        | Refresh banks 0 and 1        |
|           | 2h        | Refresh bank 0               |
|           | 5h        | Refresh 1/2 of bank 0        |
|           | 6h        | Refresh 1/4 of bank 0        |

### 15.2.10 Power-Down Mode

Setting the self-refresh/low power (SR\_PD) bit and the low-power mode enable (LPMODEN) bit in the SDRAM refresh control register (SDRCR) to 1, forces the DDR2/mDDR memory controller to place the external DDR2 SDRAM in the power-down mode. When the LPMODEN bit is asserted, the DDR2/mDDR memory controller continues normal operation until all outstanding memory access requests have been serviced and the refresh backlog has been cleared. At this point, all open pages of DDR2 SDRAM are closed and a Power Down command (same as NOP command but driving DDR\_CKE low on the same cycle) is issued.

The DDR2/mDDR memory controller exits the power-down state when a memory access is received, when a Refresh Must level is reached, when the LPMODEN bit in SDCR is cleared to 0, or when the SR\_PD bit in SDCR changed to 0. While in the power-down state, if a request for a memory access is received, the DDR2/mDDR memory controller services the memory access request, returning to the power-down state upon completion. The DDR2/mDDR memory controller will not wake-up from the power-down state (whether from a memory access request, from reaching a Refresh Must level, from clearing the LPMODEN bit, or from clearing the SR\_PD bit) until  $T_{\text{CKE}} + 1$  cycles have expired since the power-down command was issued. The value of  $T_{\text{CKE}}$  is defined in the SDRAM timing register 2 (SDTIMR2).

After exiting from the power-down state, the DDR2/mDDR memory controller will drive DDR\_CKE high and then not immediately start executing commands. Instead, it will wait  $T_{XP} + 1$  clock cycles before issuing commands. The SDRAM timing register 2 (SDTIMR2) programs the values of  $T_{XP}$ .

See [Section 15.2.16.1](#) for a description of the power-down mode programming sequence.

**NOTE:** Power-down mode is best suited as a power savings mode when SDRAM is being used intermittently and the system requires power savings as well as a short recovery time. You may use self-refresh mode if you desire additional power savings from disabling clocks.

### 15.2.11 Reset Considerations

The DDR2/mDDR memory controller has two reset signals, `chip_rst_n` and `mod_g_rst_n`. The `chip_rst_n` is a module-level reset that resets both the state machine as well as the DDR2/mDDR memory controller memory-mapped registers. The `mod_g_rst_n` resets the state machine only; it does not reset the controller's registers, which allows soft reset (from PSC or WDT) to reset the module without resetting the configuration registers and reduces the programming overhead for setting up access to the DDR2/mDDR device. If the DDR2/mDDR memory controller is reset independently of other peripherals, the user's software should not perform memory, as well as register accesses, while `chip_rst_n` or `mod_g_rst_n` are asserted. If memory or register accesses are performed while the DDR2/mDDR memory controller is in the reset state, other masters may hang. Following the rising edge of `chip_rst_n` or `mod_g_rst_n`, the DDR2/mDDR memory controller immediately begins its initialization sequence. Command and data stored in the DDR2/mDDR memory controller FIFOs are lost. [Table 15-10](#) describes the different methods for asserting each reset signal. The Power and Sleep Controller (PSC) acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter. [Figure 15-16](#) shows the DDR2/mDDR memory controller reset diagram.

**Table 15-10. Reset Sources**

| Reset Signal             | Reset Source               |
|--------------------------|----------------------------|
| <code>chip_rst_n</code>  | Hardware/device reset      |
| <code>mod_g_rst_n</code> | Power and sleep controller |

**Figure 15-16. DDR2/mDDR Memory Controller Reset Block Diagram**

### 15.2.12 VTP IO Buffer Calibration

The DDR2/mDDR memory controller is able to control the impedance of the output IO. This feature allows the DDR2/mDDR memory controller to tune the output impedance of the IO to match that of the PCB board. Control of the output impedance of the IO is an important feature because impedance matching reduces reflections, creating a cleaner board design. Calibrating the output impedance of the IO will also reduce the power consumption of the DDR2/mDDR memory controller. The calibration is performed with respect to voltage, temperature, and process (VTP). The VTP information obtained from the calibration is used to control the output impedance of the IO.

The impedance of the output IO is selected by the value of a reference resistor connected to pin DDR\_ZP. The DDR2/mDDR reference design requires the reference resistor to be a 50 ohm, 5.0% tolerance, 1/16th watt resistor (49.9 ohm, 0.5% tolerance is acceptable).

The VTP IO control register (VTPIO\_CTL) is written to begin the calibration process. The VTP calibration process is described in the DDR2/mDDR initialization sequence in [Section 15.2.13.1](#).

---

**NOTE:** VTP IO calibration must be performed following device power up and device reset. If the DDR2/mDDR memory controller is reset via the Power and Sleep Controller (PSC) and the VTP input clock is disabled, accesses to the DDR2/mDDR memory controller will not complete. To re-enable accesses to the DDR2/mDDR memory controller, enable the VTP input clock and then perform the VTP calibration sequence again.

---

### 15.2.13 Auto-Initialization Sequence

The DDR2/mDDR SDRAM contains mode and extended mode registers that configure the DDR2/mDDR memory for operation. These registers control burst type, burst length, CAS latency, DLL enable/disable (on the DDR2/mDDR device), single-ended strobe, differential strobe, etc. The DDR2/mDDR memory controller programs the mode and extended mode registers of the DDR2/mDDR memory by issuing MRS and EMRS commands during the initialization sequence. The SDRAMEN, MSDRAMEN, DDREN, and DDR2EN bits in the SDRAM configuration register (SDCR) determine if the DDR2/mDDR memory controller will perform a DDR2 or mobile DDR initialization sequence. Set these bits as follows for DDR2: SDRAMEN = 1, MSDRAMEN = 0, DDREN = 1, DDR2EN = 1. Set these bits as follow for mDDR: SDRAMEN = 1, MSDRAMEN = 1, DDREN = 1, DDR2EN = 0. The DDR2 initialization sequence performed by the DDR2/mDDR memory controller is compliant with the JESD79D-2 specification and the mDDR initialization sequence is compliant with the JESD209 specification. The DDR2/mDDR memory controller performs an initialization sequence under the following conditions:

- Following reset (rising edge of chip\_rst\_n or mod\_g\_rst\_n)
- Following a write to the DDRDRIVE, CL, IBANK, or PAGESIZE bit fields in the SDRAM configuration register (SDCR)

During the initialization sequence, the memory controller issues MRS and EMRS commands that configure the DDR2/mobile DDR SDRAM mode register and extended mode register 1. The register values for DDR2 are described in [Table 15-11](#) and [Table 15-12](#), and the register values for mDDR are described in [Table 15-13](#) and [Table 15-14](#). The extended mode registers 2 and 3 are configured with a value of 0h. At the end of the initialization sequence, the memory controller performs an autorefresh cycle, leaving the memory controller in an idle state with all banks deactivated.

When a reset occurs, the DDR2/mDDR memory controller immediately begins the initialization sequence. Under this condition, commands and data stored in the DDR2/mDDR memory controller FIFOs will be lost. However, when the initialization sequence is initiated by a write to the two least-significant bytes in SDCR, data and commands stored in the DDR2/mDDR memory controller FIFOs will not be lost and the DDR2/mDDR memory controller will ensure read and write commands are completed before starting the initialization sequence.

**Table 15-11. DDR2 SDRAM Configuration by MRS Command**

| Memory Controller Address Bus | Value  | DDR2/mDDR SDRAM Register Bit | DDR2/mDDR SDRAM Field | Function Selection                                                                                                                                  |
|-------------------------------|--------|------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| DDR_A[12]                     | 0      | 12                           | Power Down Exit       | Fast exit                                                                                                                                           |
| DDR_A[11:9]                   | t_WR   | 11:9                         | Write Recovery        | Write recovery from autoprecharge. Value of 2, 3, 4, 5, or 6 is programmed based on value of the T_WR bit in the SDRAM timing register 1 (SDTIMR1). |
| DDR_A[8]                      | 0      | 8                            | DLL Reset             | Out of reset                                                                                                                                        |
| DDR_A[7]                      | 0      | 7                            | Mode: Test or Normal  | Normal mode                                                                                                                                         |
| DDR_A[6:4]                    | CL bit | 6:4                          | CAS Latency           | Value of 2, 3, 4, or 5 is programmed based on value of the CL bit in the SDRAM configuration register (SDCR).                                       |
| DDR_A[3]                      | 0      | 3                            | Burst Type            | Sequential                                                                                                                                          |
| DDR_A[2:0]                    | 3h     | 2:0                          | Burst Length          | Value of 8                                                                                                                                          |

**Table 15-12. DDR2 SDRAM Configuration by EMRS(1) Command**

| Memory Controller Address Bus | Value       | DDR2/mDDR SDRAM Register Bit | DDR2/mDDR SDRAM Field          | Function Selection                                                                                          |
|-------------------------------|-------------|------------------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| DDR_A[12]                     | 0           | 12                           | Output Buffer Enable           | Output buffer enable                                                                                        |
| DDR_A[11]                     | 0           | 11                           | RDQS Enable                    | RDQS disable                                                                                                |
| DDR_A[10]                     | 1           | 10                           | $\overline{\text{DQS enable}}$ | Disables differential DQS signaling.                                                                        |
| DDR_A[9:7]                    | 0           | 9:7                          | OCD Calibration Program        | Exit OCD calibration                                                                                        |
| DDR_A[6]                      | 0           | 6                            | ODT Value (Rtt)                | Cleared to 0 to select 75 ohms. This feature is not supported because the DDR_ODT signal is not pinned out. |
| DDR_A[5:3]                    | 0           | 5:3                          | Additive Latency               | 0 cycles of additive latency                                                                                |
| DDR_A[2]                      | 1           | 2                            | ODT Value (Rtt)                | Set to 1 to select 75 ohms. This feature is not supported because the DDR_ODT signal is not pinned out.     |
| DDR_A[1]                      | DDRDRIVE[0] | 1                            | Output Driver Impedance        | Value of 0 or 1 is programmed based on value of DDRDRIVE0 bit in SDRAM configuration register (SDCR).       |
| DDR_A[0]                      | 0           | 0                            | DLL enable                     | DLL enable                                                                                                  |

**Table 15-13. Mobile DDR SDRAM Configuration by MRS Command**

| Memory Controller Address Bus | Value  | mDDR SDRAM Register Bit | mDDR SDRAM Field | Function Selection                                                                             |
|-------------------------------|--------|-------------------------|------------------|------------------------------------------------------------------------------------------------|
| DDR_A[11:7]                   | 0      | 11:7                    | Operating mode   | Normal operating mode                                                                          |
| DDR_A[6:4]                    | CL bit | 6:4                     | CAS Latency      | Value of 2 or 3 is programmed based on value of CL bit in SDRAM configuration register (SDCR). |

| DDR_A[2:0]                    | 3h     | 2:0                     | Burst Length     | Value of 8                                                                                     |

**Table 15-14. Mobile DDR SDRAM Configuration by EMRS(1) Command**

| Memory Controller Address Bus | Value         | mDDR SDRAM Register Bit | mDDR SDRAM Field                     | Function Selection                                                                                                |
|-------------------------------|---------------|-------------------------|--------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| DDR_A[11:7]                   | 0             | 11:7                    | Operating Mode                       | Normal operating mode                                                                                             |
| DDR_A[6:5]                    | DDRDRIVE[1:0] | 6:5                     | Output Driver Impedance              | Value of 0, 1, 2, or 3 is programmed based on value of DDRDRIVE[1:0] bits in SDRAM configuration register (SDCR). |
| DDR_A[4:3]                    | 0             | 4:3                     | Temperature Compensated Self Refresh | Value of 0                                                                                                        |
| DDR_A[2:0]                    | PASR bits     | 2:0                     | Partial Array Self Refresh           | Value of 0, 1, 2, 5, or 6 is programmed based on value of PASR bits in SDRAM configuration register 2 (SDCR2).    |

### 15.2.13.1 Initializing Following Device Power Up or Reset

Following device power up or reset, the DDR2/mDDR memory controller is held in reset with the internal clocks to the module gated off. Before releasing the DDR2/mDDR memory controller from reset, the clocks to the module must be turned on. Perform the following steps when turning the clocks on and initializing the module:

1. Program PLLC1 registers to start the PLL1\_SYSCCLK1 (that drives 2X\_CLK). For information on programming PLLC1, see the *Phase-Locked Loop Controller (PLLC)* chapter.
2. Program Power and Sleep Controller (PSC) to enable the DDR2/mDDR memory controller clock.
3. Perform VTP IO calibration:
  - (a) Clear POWERDN bit in the VTP IO control register (VTPIO\_CTL).
  - (b) Clear LOCK bit in VTPIO\_CTL.
  - (c) Pulse CLKRZ bit in VTPIO\_CTL:
    - (i) Set CLKRZ bit and wait at least 1 VTP clock cycle (clock cycle wait can be achieved by performing a read-modify-write of VTPIO\_CTL in the next step).
    - (ii) Clear CLKRZ bit and wait at least 1 VTP clock cycle (clock cycle wait can be achieved by performing a read-modify-write of VTPIO\_CTL in the next step).
    - (iii) Set CLKRZ bit.
  - (d) Poll READY bit in VTPIO\_CTL until it changes to 1.
  - (e) Set LOCK bit in VTPIO\_CTL. VTP is locked and dynamic calibration is disabled.
  - (f) Set POWERDN bit in VTPIO\_CTL to save power.
4. Set IOPWRDN bit in VTPIO\_CTL to allow the input receivers to save power when the PWRDNEN bit in the DDR PHY control register 1 (DRPYC1R) is set.
5. Configure DRPYC1R. All of the following steps may be done with a single register write to DRPYC1R:
  - (a) Set EXT\_STRBEN bit to select external DQS strobe gating.
  - (b) Set PWRDNEN bit to allow the input receivers to power down when they are idle.
  - (c) Program RL bit value to meet the memory data sheet specification.
6. Configure the DDR slew register (DDR\_SLEW):
  - (a) For DDR2, clear DDR\_PDENA and CMOSSEN bits.
  - (b) For mDDR, set the DDR\_PDENA and CMOSSEN bits.
7. Set the BOOTUNLOCK bit (unlocked) in the SDRAM configuration register (SDCR).
8. Program SDCR to the desired value with BOOTUNLOCK bit cleared to 0 and TIMUNLOCK bit set to 1 (unlocked).
9. For mDDR only, program the SDRAM configuration register 2 (SDCR2) to the desired value.
10. Program the SDRAM timing register 1 (SDTIMR1) and SDRAM timing register 2 (SDTIMR2) to the desired values to meet the memory data sheet specification.
11. Clear TIMUNLOCK bit (locked) in SDCR.

12. Program the SDRAM refresh control register (SDRCR). All of the following steps may be done with a single register write to SDRCR:
  - (a) Set LPMODEN bit to enable self-refresh. This is necessary for the next two steps.
  - (b) Set MCLKSTOPEN bit to enable MCLK stopping. This is necessary for the next two steps.
  - (c) Clear SR\_PD bit to select self-refresh. This is necessary for the next two steps.
  - (d) Program RR refresh rate value to meet the memory data sheet specification.
13. Program the Power and Sleep Controller (PSC) to reset (SyncReset) the DDR2/mDDR memory controller.
14. Program the Power and Sleep Controller (PSC) to re-enable the DDR2/mDDR memory controller.
15. Clear LPMODEN and MCLKSTOPEN bits in SDRCR to disable self-refresh.
16. Configure the peripheral bus burst priority register (PBBPR) to a value lower than the default value of FFh. A lower value reduces the likelihood of prolonged command starvation for accesses made from different master/peripherals to mDDR/DDR2 memory. The optimal value should be determined based on system considerations; however, a value of 20h or 30h is sufficient for typical applications.

---

**NOTE:** Some memory data sheet timing values such as those programmed into the SDRAM timing register 1 (SDTIMR1) and SDRAM timing register 2 (SDTIMR2) may need to be relaxed in order to compensate for signal delays introduced by board layout.

---

#### 15.2.14 Interrupt Support

The DDR2/mDDR memory controller supports two addressing modes, linear incrementing and cache line wrap. Upon receipt of an access request for an unsupported addressing mode, the DDR2/mDDR memory controller generates an interrupt by setting the LT bit in the interrupt raw register (IRR). The DDR2/mDDR memory controller will then treat the request as a linear incrementing request.

This interrupt is called the line trap interrupt and is the only interrupt the DDR2/mDDR memory controller supports. It is an active-high interrupt and is enabled by the LTMSET bit in the interrupt mask set register (IMSR). This interrupt is mapped to the CPU and is multiplexed with RTCINT.

#### 15.2.15 DMA Event Support

The DDR2/mDDR memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests may be made directly by masters and by the DMA.

### 15.2.16 Power Management

Power dissipation from the DDR2/mDDR memory controller may be managed by the following methods:

- Self-refresh mode (see [Section 15.2.8](#))
- Power-down mode (see [Section 15.2.10](#))
- Disabling the DDR PHY to reduce power

The DDR2/mDDR memory controller supports low-power modes where the DLL internal to the PHY and the receivers at the I/O pins can be disabled. These functions are controlled through the DDR2/mDDR memory controller. Even if the PHY is active, the receivers can be configured to disable whenever writes are in progress and the receivers are not needed.

- Gating input clocks to the module off

Gating input clocks off to the DDR2/mDDR memory controller achieves higher power savings when compared to the power savings of self-refresh mode and power-down mode. The input clocks are turned off outside of the DDR2/mDDR memory controller through the use of the Power and Sleep Controller (PSC) and the PLL controller 1 (PLL1). [Figure 15-17](#) shows the connections between the DDR2/mDDR memory controller, PSC, and PLL1. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

Before gating clocks off, the DDR2/mDDR memory controller must place the DDR2/mDDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the DDR2/mDDR memory controller clock provided by PLL1 must not be turned off because this may result in data corruption. See the following subsections for the proper procedures to follow when stopping the DDR2/mDDR memory controller clocks. Once the clocks are stopped, to re-enable the clocks follow the clock stop procedure in each respective subsection in reverse order.

**Figure 15-17. DDR2/mDDR Memory Controller Power Sleep Controller Diagram**

### 15.2.16.1 DDR2/mDDR Memory Controller Clock Stop Procedure

**NOTE:** If a data access occurs to the DDR2/mDDR memory after completing steps 1-4, the DLL will wake up and lock, then the MCLK will turn on and the access will be performed. Following steps 5 and 6, in which the clocks are disabled, all DDR2/mDDR memory accesses are not possible until the clocks are reenabled.

In power-down mode, the DDR2/mDDR memory controller input clocks (VCLK and 2X\_CLK) may not be gated off. This is a limitation of the DDR2/mDDR controller. For this reason, power-down mode is best suited as a power savings mode when SDRAM is being used intermittently and the system requires power savings as well as a short recovery time. You may use self-refresh mode if you desire additional power savings from disabling clocks.

To achieve maximum power savings VCLK, MCLK, 2X\_CLK, DDR\_CLK, and  $\overline{\text{DDR\_CLK}}$  should be gated off. The procedure for clock gating is described in the following steps.

1. Allow software to complete the desired DDR transfers.
2. Change the SR\_PD bit to 0 and set the LPMODEN bit to 1 in the DDR2 SDRAM refresh control register (SDRCR) to enable self-refresh mode. The DDR2/mDDR memory controller will complete any outstanding accesses and backlogged refresh cycles and then place the external DDR2/mDDR memory in self-refresh mode.
3. Set the MCLKSTOPEN bit in SDRCR to 1. This enables the DDR2/mDDR memory controller to shut off the MCLK.
4. Wait 150 CPU clock cycles to allow the MCLK to stop.
5. Program the PSC to disable the DDR2/mDDR memory controller VCLK. You must not disable VCLK in power-down mode; use only for self-refresh mode (see notes in this section).
6. For maximum power savings, the PLL/PLLC1 should be placed in bypass and powered-down mode to disable 2X\_CLK. You must not disable 2X\_CLK in power-down mode; use only for self-refresh mode (see notes in this section). For information on programming PLLC1, see the *Phase-Locked Loop Controller (PLLC)* chapter.

To turn clocks back on:

1. Place the PLL/PLLC1 in PLL mode to start 2X\_CLK to the DDR2/mDDR memory controller.
2. Once 2X\_CLK is stable, program the PSC to enable VCLK.
3. Set the RESET\_PHY bit in the DDR PHY reset control register (DRPYRCR) to 1. This resets the DDR2/mDDR memory controller PHY. This bit will self-clear to 0 when reset is complete.
4. Clear the MCLKSTOPEN bit in SDRCR to 0.
5. Clear the LPMODEN bit in the DDR2 SDRAM refresh control register (SDRCR) to 0.

### 15.2.17 Emulation Considerations

The DDR2/mDDR memory controller will remain fully functional during emulation halts to allow emulation access to external memory.

**NOTE:** VTP IO calibration must be performed before emulation tools attempt to access the register or data space of the DDR2/mDDR memory controller. A bus lock-up condition will occur if the emulation tool attempts to access the register or data space of the DDR2/mDDR memory controller before completing VTP IO calibration. See [Section 15.2.12](#) for information on VTP IO calibration.

## 15.3 Supported Use Cases

The DDR2/mDDR memory controller allows a high degree of programmability for shaping DDR2/mDDR accesses. The programmability inherent to the DDR2/mDDR memory controller provides the DDR2/mDDR memory controller with the flexibility to interface with a variety of DDR2/mDDR devices. By programming the SDRAM configuration register (SDCR), SDRAM refresh control register (SDRCR), SDRAM timing register 1 (SDTMR1), and SDRAM timing register 2 (SDTMR2), the DDR2/mDDR memory controller can be configured to meet the data sheet specification for DDR2 SDRAM as well as mDDR memory devices.

This section presents an example describing how to interface the DDR2 memory controller to a DDR2/mDDR-400 device. The DDR2/mDDR memory controller is assumed to be operating at 150 MHz. A similar procedure can be followed when interfacing to a mDDR memory device.

### Connecting the DDR2/mDDR Memory Controller to DDR2/mDDR Memory

Figure 15-18 shows how to connect the DDR2/mDDR memory controller to a DDR2 device. Figure 15-18 displays a 16-bit interface; you can see that all signals are point-to-point connection.

**Figure 15-18. Connecting DDR2/mDDR Memory Controller to a 16-Bit DDR2 Memory**

## Configuring Memory-Mapped Registers to Meet DDR2 Specification

As previously stated, four memory-mapped registers must be programmed to configure the DDR2/mDDR memory controller to meet the data sheet specification of the attached DDR2/mDDR device. The registers are:

- SDRAM configuration register (SDCR)
- SDRAM refresh control register (SDRCR)
- SDRAM timing register 1 (SDTIMR1)
- SDRAM timing register 2 (SDTIMR2)

In addition to these registers, the DDR PHY control register (DRPYC1R) must also be programmed. The configuration of DRPYC1R is not dependent on the DDR2 device specification but rather on the board layout.

The following sections describe how to configure each of these registers. See [Section 15.4](#) for more information on the DDR2/mDDR memory controller registers.

---

**NOTE:** When interfacing the DDR2/mDDR memory controller to a mDDR device, the SDRAM configuration register 2 (SDCR2) must be programmed in addition to the registers mentioned above.

---

## Configuring SDRAM Configuration Register (SDCR)

The SDRAM configuration register (SDCR) contains register fields that configure the DDR2/mDDR memory controller to match the data bus width, CAS latency, number of banks, and page size of the attached memory. In this example, we assume the following DDR2 configuration:

- Data bus width = 16 bits
- CAS latency = 3
- Number of banks = 8
- Page size = 1024 words

[Table 15-15](#) shows the resulting SDCR configuration. Note that the value of the TIMING\_UNLOCK field is dependent on whether or not it is desirable to unlock SDTIMR1 and SDTIMR2. The TIMING\_UNLOCK bit should only be set to 1 when the SDTIMR1 and SDTIMR2 needs to be updated.

**Table 15-15. SDCR Configuration**

| Field         | Value | Function Selection                                                                                                                                           |
|---------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIMING_UNLOCK | x     | Set to 1 to unlock the SDRAM timing register 1 and SDRAM timing register 2.<br>Cleared to 0 to lock the SDRAM timing register 1 and SDRAM timing register 2. |
| NM            | 1h    | To configure the DDR2/mDDR memory controller for a 16-bit data bus width.                                                                                    |
| CL            | 3h    | To select a CAS latency of 3.                                                                                                                                |
| IBANK         | 3h    | To select 8 internal DDR2 banks.                                                                                                                             |
| PAGESIZE      | 2h    | To select 1024-word page size.                                                                                                                               |

## Configuring SDRAM Refresh Control Register (SDRCR)

The SDRAM refresh control register (SDRCR) configures the DDR2/mDDR memory controller to meet the refresh requirements of the attached memory device. SDRCR also allows the DDR2/mDDR memory controller to enter and exit self refresh and enable and disable the MCLK stopping. In this example, we assume that the DDR2/mDDR memory controller is not in self-refresh mode or power-down mode and that MCLK stopping is disabled.

The RR field in SDRCR is defined as the rate at which the attached memory device is refreshed in DDR2/mDDR cycles. The value of this field may be calculated using the following equation:

$$RR = \text{DDR2/mDDR clock frequency} \times \text{DDR2/mDDR memory refresh period}$$

Table 15-16 displays the DDR2-400 refresh rate specification.

**Table 15-16. DDR2 Memory Refresh Specification**

| Symbol    | Description                       | Value       |
|-----------|-----------------------------------|-------------|
| $t_{REF}$ | Average Periodic Refresh Interval | 7.8 $\mu$ s |

Therefore, the following results assuming 150 MHz DDR2/mDDR clock frequency.

$$RR = 150 \text{ MHz} \times 7.8 \text{ } \mu\text{s} = 1170$$

Therefore,  $RR = 1170 = 492h$ .

Table 15-17 shows the resulting SDRCR configuration.

**Table 15-17. SDRCR Configuration**

| Field       | Value | Function Selection                                                                   |
|-------------|-------|--------------------------------------------------------------------------------------|
| LPMODEN     | 0     | DDR2/mDDR memory controller is not in power-down mode.                               |
| MCLKSTOP_EN | 0     | MCLK stopping is disabled.                                                           |
| SR_PD       | 0     | Leave a default value.                                                               |
| RR          | 492h  | Set to 492h DDR2 clock cycles to meet the DDR2/mDDR memory refresh rate requirement. |

## Configuring SDRAM Timing Registers (SDTMR1 and SDTMR2)

The SDRAM timing register 1 (SDTMR1) and SDRAM timing register 2 (SDTMR2) configure the DDR2/mDDR memory controller to meet the data sheet timing parameters of the attached memory device. Each field in SDTMR1 and SDTMR2 corresponds to a timing parameter in the DDR2/mDDR data sheet specification. [Table 15-18](#) and [Table 15-19](#) display the register field name and corresponding DDR2 data sheet parameter name along with the data sheet value. These tables also provide a formula to calculate the register field value and displays the resulting calculation. Each of the equations include a minus 1 because the register fields are defined in terms of DDR2/mDDR clock cycles minus 1. See [Section 15.4.4](#) and [Section 15.4.5](#) for more information.

**Table 15-18. SDTMR1 Configuration**

| Register Field Name  | DDR2 Data Manual Parameter Name | Description                                      | Data Manual Value (nS) | Formula (Register field must be $\geq$ )                           | Register Value |
|----------------------|---------------------------------|--------------------------------------------------|------------------------|--------------------------------------------------------------------|----------------|
| T_RFC                | t <sub>RFC</sub>                | Refresh cycle time                               | 127.5                  | $(t_{RFC} \times f_{DDR2/mDDR\_CLK}) - 1$                          | 19             |
| T_RP                 | t <sub>RP</sub>                 | Precharge command to refresh or activate command | 15                     | $(t_{RP} \times f_{DDR2/mDDR\_CLK}) - 1$                           | 2              |
| T_RCD                | t <sub>RCD</sub>                | Activate command to read/write command           | 15                     | $(t_{RCD} \times f_{DDR2/mDDR\_CLK}) - 1$                          | 2              |
| T_WR                 | t <sub>WR</sub>                 | Write recovery time                              | 15                     | $(t_{WR} \times f_{DDR2/mDDR\_CLK}) - 1$                           | 2              |
| T_RAS                | t <sub>RAS</sub>                | Active to precharge command                      | 40                     | $(t_{RAS} \times f_{DDR2/mDDR\_CLK}) - 1$                          | 5              |
| T_RC                 | t <sub>RC</sub>                 | Activate to Activate command in the same bank    | 55                     | $(t_{RC} \times f_{DDR2/mDDR\_CLK}) - 1$                           | 8              |
| T_RRD <sup>(1)</sup> | t <sub>RRD</sub>                | Activate to Activate command in a different bank | 10                     | $((4 \times t_{RRD}) + (2 \times t_{CK})) / (4 \times t_{CK}) - 1$ | 1              |
| T_WTR                | t <sub>WTR</sub>                | Write to read command delay                      | 10                     | $(t_{WTR} \times f_{DDR2/mDDR\_CLK}) - 1$                          | 1              |

<sup>(1)</sup> The formula for the T\_RRD field applies only for 8 bank DDR2/mDDR memories; when interfacing to DDR2/mDDR memories with less than 8 banks, the T\_RRD field should be calculated using the following formula:  $(t_{RRD} \times f_{DDR2/mDDR\_CLK}) - 1$ .

**Table 15-19. SDTMR2 Configuration**

| Register Field Name | DDR2 Data Manual Parameter Name | Description                             | Data Manual Value            | Formula (Register field must be $\geq$ )                                             | Register Value |
|---------------------|---------------------------------|-----------------------------------------|------------------------------|--------------------------------------------------------------------------------------|----------------|
| T_RASMAX            | t <sub>RAS</sub> (MAX)          | Active to precharge command             | 70 $\mu$ S                   | $t_{RAS}(MAX) / \text{DDR refresh rate} - 1$                                         | 8              |
| T_XP                | t <sub>XP</sub>                 | Exit power down to a non-read command   | 2(t <sub>CK</sub> cycles)    | If $t_{XP} > t_{CKE}$ ,<br>then $T\_XP = t_{XP} - 1$ ,<br>else $T\_XP = t_{CKE} - 1$ | 2              |
| T_XSNR              | t <sub>XSNR</sub>               | Exit self refresh to a non-read command | 137.5 nS                     | $(t_{XSNR} \times f_{DDR2/mDDR\_CLK}) - 1$                                           | 18             |
| T_XSRD              | t <sub>XSRD</sub>               | Exit self refresh to a read command     | 200 (t <sub>CK</sub> cycles) | $t_{XSRD} - 1$                                                                       | 199            |
| T_RTP               | t <sub>RTP</sub>                | Read to precharge command delay         | 15 nS                        | $(t_{RTP} \times f_{DDR2/mDDR\_CLK}) - 1$                                            | 1              |
| T_CKE               | t <sub>CKE</sub>                | CKE minimum pulse width                 | 3 (t <sub>CK</sub> cycles)   | $t_{CKE} - 1$                                                                        | 2              |

## Configuring DDR PHY Control Register (DRPYC1R)

The DDR PHY control register (DRPYC1R) contains a read latency (RL) field that helps the DDR2/mDDR memory controller determine when to sample read data. The RL field should be programmed to a value equal to the CAS latency plus the round trip board delay minus 1. The minimum RL value is CAS latency plus 1 and the maximum RL value is CAS latency plus 2 (again, the RL field would be programmed to these values minus 1). [Table 15-20](#) shows the resulting DRPYC1R configuration.

When calculating round trip board delay the signals of primary concern are the differential clock signals (DDR\_CLK and  $\overline{\text{DDR\_CLK}}$ ) and data strobe signals (DDR\_DQS). For these signals, calculate the round trip board delay from the DDR memory controller to the memory and then choose the maximum delay to determine the RL value. In this example, we will assume the round trip board delay is one DDR\_CLK cycle; therefore, RL can be calculated as:

$$\text{RL} = \text{CAS latency} + \text{round trip board delay} - 1 = 4 + 1 - 1 = 4$$

**Table 15-20. DRPYC1R Configuration**

| Field      | Value | Function Selection                                                                |
|------------|-------|-----------------------------------------------------------------------------------|
| EXT_STRBEN | 1h    | Programs to select external strobe gating                                         |
| RL         | 4h    | Read latency is equal to CAS latency plus round trip board delay for data minus 1 |
| PWRDNEN    | 0     | Programmed to power up the DDR2/mDDR memory controller receivers                  |

## 15.4 Registers

**Table 15-21** lists the memory-mapped registers for the DDR2/mDDR memory controller. Note that the VTP IO control register (VTPIO\_CTL) resides in the System Configuration Module.

### 15.4.2 SDRAM Configuration Register (SDCR)

The SDRAM configuration register (SDCR) contains fields that program the DDR2/mDDR memory controller to meet the specification of the attached DDR2/mDDR memory. These fields configure the DDR2/mDDR memory controller to match the data bus width, CAS latency, number of internal banks, and page size of the attached DDR2/mDDR memory. Writing to the DDRDRIVE[1:0], CL, IBANK, and PAGESIZE bit fields causes the DDR2/mDDR memory controller to start the DDR2/mDDR SDRAM initialization sequence. The SDCR is shown in Figure 15-21 and described in Table 15-24.

**Figure 15-21. SDRAM Configuration Register (SDCR)**

|-------|------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-28 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 27    | DDR2TERM1  | 0-3h   | DDR2 termination resistor value. This bit is used in conjunction with the DDR2TERM0 bit to make a 2-bit field. This bit is writeable only when the BOOTUNLOCK bit is unlocked. See the DDR2TERM0 bit. Note that the reset value of DDR2TERM[1:0] = 10, these bits must be cleared and forced to 00 to disable the termination because the ODT feature is not supported.                                                                                                                                                                                                                                                                                                              |
| 26    | IBANK_POS  | 0<br>1 | Internal Bank position.<br>Normal addressing<br>Special addressing. Typically used with mobile DDR partial array self-refresh.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 25    | MSDRAMEN   | 0<br>1 | Mobile SDRAM enable. Use this bit in conjunction with DDR2EN, DDREN, and SDRAMEN to enable/disable mobile SDRAM. To change this bit value, use the following sequence:<br>1. Write a 1 to the BOOTUNLOCK bit.<br>2. Write a 0 to the BOOTUNLOCK bit along with the desired value of the MSDRAMEN bit.<br>0 Disable mobile SDRAM<br>1 Enable mobile SDRAM                                                                                                                                                                                                                                                                                                                             |
| 24    | DDRDRIVE1  | 0-3h   | SDRAM drive strength. This bit is used in conjunction with the DDRDRIVE0 bit to make a 2-bit field. This bit is writeable only when the BOOTUNLOCK bit is unlocked. See the DDRDRIVE0 bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 23    | BOOTUNLOCK | 0<br>1 | Boot Unlock. Controls the write permission settings for the DDR2TERM[1:0], MSDRAMEN, DDRDRIVE[1:0], DDR2DDQS, DDR2EN, DDRDLL_DIS, DDREN and SDRAMEN bit fields. To change these bits, use the following sequence:<br>1. Write a 1 to the BOOTUNLOCK bit.<br>2. Write a 0 to the BOOTUNLOCK bit along with the desired value of the DDR2TERM[1:0], MSDRAMEN, DDRDRIVE[1:0], DDR2DDQS, DDR2EN, DDRDLL_DIS, DDREN and SDRAMEN bits.<br>0 DDR2TERM[1:0], MSDRAMEN, DDRDRIVE[1:0], DDR2DDQS, DDR2EN, DDRDLL_DIS, DDREN and SDRAMEN bit fields may not be changed.<br>1 DDR2TERM[1:0], MSDRAMEN, DDRDRIVE[1:0], DDR2DDQS, DDR2EN, DDRDLL_DIS, DDREN and SDRAMEN bit fields may be changed. |

**Table 15-24. SDRAM Configuration Register (SDCR) Field Descriptions (continued)**

| Bit | Field      | Value                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 15.4.3 SDRAM Refresh Control Register (SDRCR)

The SDRAM refresh control register (SDRCR) is used to configure the DDR2/mDDR memory controller to:

- Enter and Exit the self-refresh and power-down states.
- Enable and disable MCLK, stopping when in the self-refresh state.
- Meet the refresh requirement of the attached DDR2/mDDR device by programming the rate at which the DDR2/mDDR memory controller issues autorefresh commands.

The SDRCR is shown in [Table 15-25](#) and described in [Figure 15-22](#).

**Figure 15-22. SDRAM Refresh Control Register (SDRCR)**

| 15-0  | RR         | 0-FFFFh | Refresh rate. Defines the rate at which the attached SDRAM devices will be refreshed. The value of this field may be calculated with the following equation:<br>$RR = \text{SDRAM frequency} / \text{SDRAM refresh rate}$<br>where <i>SDRAM refresh rate</i> is derived from the SDRAM data sheet. |

### 15.4.4 SDRAM Timing Register 1 (SDTIMR1)

The SDRAM timing register 1 (SDTIMR1) configures the DDR2/mDDR memory controller to meet many of the AC timing specification of the DDR2/mDDR memory. The SDTIMR1 is programmable only when the TIMUNLOCK bit is set to 1 in the SDRAM configuration register (SDCR). Note that DDR\_CLK is equal to the period of the DDR\_CLK signal. See the DDR2/mDDR memory data sheet for information on the appropriate values to program each field. The SDTIMR1 is shown in Figure 15-23 and described in Table 15-26.

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | T_RFC    | 0-7Fh | Specifies the minimum number of DDR_CLK cycles from a refresh or load mode command to a refresh or activate command, minus 1. Corresponds to the $t_{rfc}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RFC = (t_{rfc}/DDR\_CLK) - 1$                                                                                                                                    |
| 24-22 | T_RP     | 0-7h  | Specifies the minimum number of DDR_CLK cycles from a precharge command to a refresh or activate command, minus 1. Corresponds to the $t_{rp}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RP = (t_{rp}/DDR\_CLK) - 1$                                                                                                                                                  |
| 21-19 | T_RCD    | 0-7h  | Specifies the minimum number of DDR_CLK cycles from an activate command to a read or write command, minus 1. Corresponds to the $t_{rcd}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RCD = (t_{rcd}/DDR\_CLK) - 1$                                                                                                                                                     |
| 18-16 | T_WR     | 0-7h  | Specifies the minimum number of DDR_CLK cycles from the last write transfer to a precharge command, minus 1. Corresponds to the $t_{wr}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_WR = (t_{wr}/DDR\_CLK) - 1$<br>When the value of this field is changed from its previous value, the initialization sequence will begin.                                            |
| 15-11 | T_RAS    | 0-1Fh | Specifies the minimum number of DDR_CLK cycles from an activate command to a precharge command, minus 1. Corresponds to the $t_{ras}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RAS = (t_{ras}/DDR\_CLK) - 1$<br>$T\_RAS$ must be greater than or equal to $T\_RCD$ .                                                                                                 |
| 10-6  | T_RC     | 0-1Fh | Specifies the minimum number of DDR_CLK cycles from an activate command to an activate command, minus 1. Corresponds to the $t_{rc}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RC = (t_{rc}/DDR\_CLK) - 1$                                                                                                                                                            |
| 5-3   | T_RRD    | 0-7h  | Specifies the minimum number of DDR_CLK cycles from an activate command to an activate command in a different bank, minus 1. Corresponds to the $t_{rrd}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RRD = (t_{rrd}/DDR\_CLK) - 1$<br>For an 8 bank DDR2/mDDR device, this field must be equal to $((4 \times t_{RRD}) + (2 \times t_{CK})) / (4 \times t_{CK}) - 1$ . |
| 2     | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                          |
| 1-0   | T_WTR    | 0-3h  | Specifies the minimum number of DDR_CLK cycles from the last write to a read command, minus 1. Corresponds to the $t_{wtr}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_WTR = (t_{wtr}/DDR\_CLK) - 1$                                                                                                                                                                   |

### 15.4.5 SDRAM Timing Register 2 (SDTIMR2)

Like the SDRAM timing register 1 (SDTIMR1), the SDRAM timing register 2 (SDTIMR2) also configures the DDR2/mDDR memory controller to meet the AC timing specification of the DDR2/mDDR memory. The SDTIMR2 is programmable only when the TIMUNLOCK bit is set to 1 in the SDRAM configuration register (SDCR). Note that DDR\_CLK is equal to the period of the DDR\_CLK signal. See the DDR2/mDDR data sheet for information on the appropriate values to program each field. SDTIMR2 is shown in Figure 15-24 and described in Table 15-27.

**Table 15-27. SDRAM Timing Register 2 (SDTIMR2) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | Reserved | 0     | Any writes to these bit(s) must always have a value of 0.                                                                                                                                                                                                                                                                                                                                                              |
| 30-27 | T_RASMAX | 0-Fh  | Specifies the maximum number of refresh rate intervals from Activate to Precharge command. Corresponds to the $t_{ras}$ AC timing parameter and the refresh rate in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RASMAX = (t_{ras\_max}/refresh\_rate) - 1$<br>Round down to the nearest cycle.                                                                                                                      |
| 26-25 | T_XP     | 0-3h  | Specifies the minimum number of DDR_CLK cycles from Power Down exit to any other command except a read command, minus 1. Corresponds to the $t_{xp}$ or $t_{cke}$ AC timing parameter in the DDR2/mDDR data sheet. This field must satisfy the greater of $t_{xp}$ or $t_{cke}$ .<br>If $t_{xp} > t_{cke}$ , then calculate by $T\_XP = t_{xp} - 1$<br>If $t_{xp} < t_{cke}$ , then calculate by $T\_XP = t_{cke} - 1$ |
| 24-23 | T_ODT    | 0-3h  | Specifies the minimum number of DDR_CLK cycles from ODT enable to write data driven for DDR2 SDRAM. T_ODT must be equal to (CAS latency - tAOND - 1). T_ODT must be less than CAS latency minus 1. This feature is not supported because the DDR_ODT signal is not pinned out.                                                                                                                                         |
| 22-16 | T_XSNR   | 0-7Fh | Specifies the minimum number of DDR_CLK cycles from a self_refresh exit to any other command except a read command, minus 1. Corresponds to the $t_{xsnr}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_XSNR = (t_{xsnr}/DDR\_CLK) - 1$                                                                                                                                                       |
| 15-8  | T_XSRD   | 0-FFh | Specifies the minimum number of DDR_CLK cycles from a self_refresh exit to a read command, minus 1. Corresponds to the $t_{xsrdr}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_XSRD = t_{xsrdr} - 1$                                                                                                                                                                                         |
| 7-5   | T_RTP    | 0-7h  | Specifies the minimum number of DDR_CLK cycles from a last read command to a precharge command, minus 1. Corresponds to the $t_{rtp}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_RTP = (t_{rtp}/DDR\_CLK) - 1$                                                                                                                                                                              |
| 4-0   | T_CKE    | 0-1Fh | Specifies the minimum number of DDR_CLK cycles between transitions on the DDR_CKE pin, minus 1. Corresponds to the $t_{cke}$ AC timing parameter in the DDR2/mDDR data sheet. Calculate by:<br>$T\_CKE = t_{cke} - 1$                                                                                                                                                                                                  |

### 15.4.6 SDRAM Configuration Register 2 (SDCR2)

The SDRAM configuration register 2 (SDCR2) contains fields to configure partial array self-refresh and row size of the mDDR. This register is applicable only when the IBANK\_POS bit in the SDRAM configuration register (SDCR) is set to 1 for special addressing. Writing to the PASR and ROWSIZE bit fields will cause the DDR2/mDDR memory controller to start the DDR2/mDDR SDRAM initialization sequence. SDCR2 is shown in Figure 15-25 and described in Table 15-28.

**Figure 15-25. SDRAM Configuration Register 2 (SDCR2)**

### 15.4.7 Peripheral Bus Burst Priority Register (PBBPR)

The peripheral bus burst priority register (PBBPR) helps prevent command starvation within the DDR2/mDDR memory controller. To avoid command starvation, the DDR2/mDDR memory controller momentarily raises the priority of the oldest command in the command FIFO after a set number of transfers have been made. The PR\_OLD\_COUNT bit sets the number of transfers that must be made before the DDR2/mDDR memory controller raises the priority of the oldest command. See [Section 15.2.6.2](#) for more details on command starvation.

Proper configuration of the PBBPR is critical to correct system operation. The DDR2/mDDR memory controller always prioritizes accesses to open rows as highest, if there is any bank conflict regardless of master priority. This is done to allow most efficient utilization of the DDR2/mDDR. However, it could lead to excessive blocking of high priority masters. If the PR\_OLD\_COUNT bits are cleared to 00h, then the DDR2/mDDR memory controller always honors the master priority, regardless of open row/bank status. For most systems, the PBBPR should be set to a moderately low value to provide an acceptable balance of DDR2/mDDR efficiency and latency for high priority masters (for example, 10h or 20h).

The PBBPR is shown in [Figure 15-26](#) and described in [Table 15-29](#).

| 31-8 | Reserved     | 0      | Any writes to these bit(s) must always have a value of 0.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 7-0  | PR_OLD_COUNT | 0-FFh  | Priority raise old counter. Specifies the number of memory transfers after which the DDR2/mDDR memory controller will elevate the priority of the oldest command in the command FIFO. Clearing to 00h will ensure master priority is strictly honored (at the cost of decreased DDR2/mDDR memory controller efficiency, as open row will always be closed immediately if any bank conflict occurs). Recommended setting for typical system operation is between 10h and 20h. |
|      |              | 0      | 1 memory transfer                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|      |              | 3h-FFh | 4 to 256 memory transfers                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 15.4.8 Performance Counter 1 Register (PC1)

For debug or gathering performance statistics, the PC1 and PC2 counters and associated configuration registers are provided. These are intended for debug and analysis only. By configuring the performance counter configuration register (PCC) to define the type of statistics to gather and configuring the performance counter master region select register (PCMRS) to filter accesses only to specific chip select regions, performing system applications and then reading these counters, different statistics can be gathered. To reset the counters, you must reset (mod\_g\_rst\_n) the DDR2/mDDR memory controller through the PSC. For details on the PSC, see the *Power and Sleep Controller (PSC)* chapter.

The performance counter 1 register (PC1) is shown in [Figure 15-27](#) and described in [Table 15-30](#).

**Figure 15-27. Performance Counter 1 Register (PC1)**

|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | Counter2 | 0-FFFF FFFFh | 32-bit counter that can be configured as specified in the performance counter configuration register (PCC) and the performance counter master region select register (PCMRS). |

### 15.4.10 Performance Counter Configuration Register (PCC)

The performance counter configuration register (PCC) is shown in [Figure 15-29](#) and described in [Table 15-32](#).

[Table 15-33](#) shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a Master ID and/or an external chip select to obtain performance statistics for a particular master and/or an external chip select.

### Performance Counter Time Register (PCT)

The performance counter time register (PCT) is shown in [Figure 15-31](#) and described in [Table 15-35](#).

**Figure 15-31. Performance Counter Time Register (PCT)**

|            |   |
|------------|---|
| 31         | 0 |
| TOTAL_TIME |   |
| R-0        |   |

LEGEND: R = Read only; -n = value after reset

### Table 15-35. Performance Counter Time Register (PCT) Field Description

| Bit  | Field      | Value        | Description                                                                                                                              |
|------|------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TOTAL_TIME | 0-FFFF FFFFh | 32-bit counter that continuously counts number for DDR_CLK cycles elapsed after the DDR2/mDDR memory controller is brought out of reset. |

#### 15.4.12 DDR PHY Reset Control Register (DRPYRCR)

The DDR PHY reset control register (DRPYRCR) is used to reset the DDR PHY. The DRPYRCR is shown in [Figure 15-32](#) and described in [Table 15-36](#).

**Figure 15-32. DDR PHY Reset Control Register (DRPYRCR)**

|          |    |           |          |    |

### Table 15-36. DDR PHY Reset Control Register (DRPYRCR)

| Bit   | Field     | Value    | Description                                   |
|-------|-----------|----------|-----------------------------------------------|
| 31-11 | Reserved  | 0000 04h | Always write the default value to these bits. |
| 10    | RESET_PHY | 0        | Reset DDR PHY.<br>No effect.                  |
|       |           | 1        | Resets DDR PHY.                               |
| 9-0   | Reserved  | 091h     | Always write the default value to these bits. |

### 15.4.13 Interrupt Raw Register (IRR)

The interrupt raw register (IRR) displays the raw status of the interrupt. If the interrupt condition occurs, the corresponding bit in IRR is set independent of whether or not the interrupt is enabled. The IRR is shown in [Figure 15-33](#) and described in [Table 15-37](#).

**Figure 15-33. Interrupt Raw Register (IRR)**

|          |  |  |  |  |  |  |  |  |  |         |   |          |   |   |  |    |
|----------|--|--|--|--|--|--|--|--|--|---------|---|----------|---|---|--|----|
| 31       |  |  |  |  |  |  |  |  |  |         |   |          |   |   |  | 16 |

**Table 15-37. Interrupt Raw Register (IRR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                          |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                             |
| 2    | LT       | 0     | Line trap. Write a 1 to clear LT and the LTM bit in the interrupt masked register (IMR); a write of 0 has no effect. |
|      |          | 0     | A line trap condition has not occurred.                                                                              |
|      |          | 1     | Illegal memory access type. See <a href="#">Section 15.2.14</a> for more details.                                    |
| 1-0  | Reserved | 0     | Reserved                                                                                                             |

### 15.4.14 Interrupt Masked Register (IMR)

The interrupt masked register (IMR) displays the status of the interrupt when it is enabled. If the interrupt condition occurs and the corresponding bit in the interrupt mask set register (IMSR) is set, then the IMR bit is set. The IMR bit is not set if the interrupt is not enabled in IMSR. The IMR is shown in [Figure 15-34](#) and described in [Table 15-38](#).

**Figure 15-34. Interrupt Masked Register (IMR)**

|          |  |  |  |  |  |  |  |  |  |         |   |          |   |   |  |    |

**Table 15-38. Interrupt Masked Register (IMR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                   |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                      |
| 2    | LTM      | 0     | Line trap masked. Write a 1 to clear LTM and the LT bit in the interrupt raw register (IRR); a write of 0 has no effect.      |
|      |          | 0     | A line trap condition has not occurred.                                                                                       |
|      |          | 1     | Illegal memory access type (only set if the LTMSET bit in IMSR is set). See <a href="#">Section 15.2.14</a> for more details. |
| 1-0  | Reserved | 0     | Reserved                                                                                                                      |

### 15.4.15 Interrupt Mask Set Register (IMSR)

The interrupt mask set register (IMSR) enables the DDR2/mDDR memory controller interrupt. The IMSR is shown in [Figure 15-35](#) and described in [Table 15-39](#).

**NOTE:** If the LTMSET bit in IMSR is set concurrently with the LTMCLR bit in the interrupt mask clear register (IMCR), the interrupt is not enabled and neither bit is set to 1.

**Figure 15-35. Interrupt Mask Set Register (IMSR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-39. Interrupt Mask Set Register (IMSR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                  |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                     |
| 2    | LTMSET   | 0     | Line trap interrupt set. Write a 1 to set LTMSET and the LTMCLR bit in the interrupt mask clear register (IMCR); a write of 0 has no effect. |
|      |          | 0     | Line trap interrupt is not enabled; a write of 1 to the LTMCLR bit in IMCR occurred.                                                         |
|      |          | 1     | Line trap interrupt is enabled.                                                                                                              |
| 1-0  | Reserved | 0     | Reserved                                                                                                                                     |

### 15.4.16 Interrupt Mask Clear Register (IMCR)

The interrupt mask clear register (IMCR) disables the DDR2/mDDR memory controller interrupt. Once an interrupt is enabled, it may be disabled by writing a 1 to the IMCR bit. The IMCR is shown in [Figure 15-36](#) and described in [Table 15-40](#).

**NOTE:** If the LTMCLR bit in IMCR is set concurrently with the LTMSET bit in the interrupt mask set register (IMSR), the interrupt is not enabled and neither bit is set to 1.

**Figure 15-36. Interrupt Mask Clear Register (IMCR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing 0 has no effect); -n = value after reset

**Table 15-40. Interrupt Mask Clear Register (IMCR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                    |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                       |
| 2    | LTMCLR   | 0     | Line trap interrupt clear. Write a 1 to clear LTMCLR and the LTMSET bit in the interrupt mask set register (IMSR); a write of 0 has no effect. |
|      |          | 0     | Line trap interrupt is not enabled.                                                                                                            |
|      |          | 1     | Line trap interrupt is enabled; a write of 1 to the LTMSET bit in IMSR occurred.                                                               |
| 1-0  | Reserved | 0     | Reserved                                                                                                                                       |

#### 15.4.17 DDR PHY Control Register (DRPYC1R)

The DDR PHY control register 1 (DRPYC1R) configures the DDR2/mDDR memory controller read latency. The DRPYC1R is shown in [Figure 15-37](#) and described in [Table 15-41](#).

**Figure 15-37. DDR PHY Control Register 1 (DRPYC1R)**

|          |  |  |  |                 |    |  |  |  |  |    |  |  |  |  |    |          |  |  |  |   |  |  |  |            |   |  |  |  |  |   |  |         |  |  |   |  |  |  |  |          |  |  |  |  |   |  |  |        |  |   |  |  |  |  |  |

| 2-0   | RL              | 0-7h                | Read latency. Read latency is equal to CAS latency plus round trip board delay for data minus 1. The maximum value of read latency that is supported is CAS latency plus 2. The minimum read latency value that is supported is CAS latency plus 1. The read latency value is defined in number of MCLK/DDR_CLK cycles. |

## ***Enhanced Capture (eCAP) Module***

---

---

The enhanced capture (eCAP) module is essential in systems where accurate timing of external events is important. This chapter describes the eCAP module.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>16.1 Introduction .....</b> | <b>439</b>  |
| <b>16.2 Architecture .....</b> | <b>440</b>  |
| <b>16.3 Applications .....</b> | <b>449</b>  |
| <b>16.4 Registers .....</b>    | <b>465</b>  |

## 16.1 Introduction

### 16.1.1 Purpose of the Peripheral

Uses for eCAP include:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

### 16.1.2 Features

The eCAP module includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

## 16.2 Architecture

The eCAP module represents one complete capture channel that can be instantiated multiple times depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

Multiple identical eCAP modules can be contained in a system as shown in [Figure 16-1](#). The number of modules is device-dependent and is based on target application needs. In this chapter, the letter x within a signal or module name is used to indicate a generic eCAP instance on a device.

**Figure 16-1. Multiple eCAP Modules**

### 16.2.1 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 16-2 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

**Figure 16-2. Capture and APWM Modes of Operation**

- (1) A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- (2) In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

## 16.2.2 Capture Mode Description

Figure 16-3 shows the various components that implement the capture function.

Figure 16-3. Capture Function Diagram

### 16.2.2.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 16-4 shows a functional diagram and Figure 16-5 shows the operation of the prescale function.

**Figure 16-4. Event Prescale Control**

- (1) When a prescale value of 1 is chosen ( $ECCTL1[13:9] = 0000$ ) the input capture signal by-passes the prescale logic completely.

**Figure 16-5. Prescale Function Waveforms**

### 16.2.2.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAP $n$  register by the Mod4 counter. The CAP $n$  register is loaded on the falling edge.

### 16.2.2.3 Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 16-6) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

**Figure 16-6. Continuous/One-shot Block Diagram**

#### 16.2.2.4 32-Bit Counter and Phase Control

This counter (Figure 16-7) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

**Figure 16-7. Counter and Synchronization Block Diagram**

### 16.2.2.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

### 16.2.2.6 Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP). See [Figure 16-8](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CTROVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAP<sub>n</sub> module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR = PRD, CTR = CMP) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

### 16.2.2.7 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0]

---

**NOTE:** The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR = PRD, CTR = CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

---

Figure 16-8. Interrupts in eCAP Module

### 16.2.2.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

**Figure 16-9. PWM Waveform Details Of APWM Mode Operation**

The behavior of APWM active-high mode (APWMPOL == 0) is:

- CMP = 0x00000000, output low for duration of period (0% duty)
- CMP = 0x00000001, output high 1 cycle
- CMP = 0x00000002, output high 2 cycles
- CMP = PERIOD, output high except for 1 cycle (<100% duty)
- CMP = PERIOD+1, output high for complete period (100% duty)
- CMP > PERIOD+1, output high for complete period

The behavior of APWM active-low mode (APWMPOL == 1) is:

- CMP = 0x00000000, output high for duration of period (0% duty)
- CMP = 0x00000001, output low 1 cycle
- CMP = 0x00000002, output low 2 cycles
- CMP = PERIOD, output low except for 1 cycle (<100% duty)
- CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

## 16.3 Applications

The following sections will provide Applications examples and code snippets to show how to configure and operate the eCAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define    EC_RISING            0x0
#define    EC_FALLING          0x1

// CTRRSTx bits
#define    EC_ABS_MODE          0x0
#define    EC_DELTA_MODE        0x1

// PRESCALE bits
#define    EC_BYPASS            0x0
#define    EC_DIV1              0x0
#define    EC_DIV2              0x1
#define    EC_DIV4              0x2
#define    EC_DIV6              0x3
#define    EC_DIV8              0x4
#define    EC_DIV10             0x5

// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define    EC_CONTINUOUS        0x0
#define    EC_ONESHOT          0x1

// STOPVALUE bit
#define    EC_EVENT1            0x0
#define    EC_EVENT2            0x1
#define    EC_EVENT3            0x2
#define    EC_EVENT4            0x3

// RE-ARM bit
#define    EC_ARM                0x1

// TSCTRSTOP bit
#define    EC_FREEZE            0x0
#define    EC_RUN                0x1

// SYNCO_SEL bit
#define    EC_SYNCIN            0x0
#define    EC_CTR_PRD           0x1
#define    EC_SYNCO_DIS         0x2

// CAP/APWM mode bit
#define    EC_CAP_MODE          0x0
#define    EC_APWM_MODE         0x1

// APWMPOL bit
#define    EC_ACTV_HI            0x0
#define    EC_ACTV_LO           0x1

// Generic
#define    EC_DISABLE            0x0
#define    EC_ENABLE            0x1
#define    EC_FORCE              0x1
```

### 16.3.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 16-10 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 16-10), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPn registers.

**Figure 16-10. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect**

**Table 16-1. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger**

| Register | Bit         | Value         |
|----------|-------------|---------------|
| ECCTL1   | CAP1POL     | EC_RISING     |
| ECCTL1   | CAP2POL     | EC_RISING     |
| ECCTL1   | CAP3POL     | EC_RISING     |
| ECCTL1   | CAP4POL     | EC_RISING     |
| ECCTL1   | CTRRST1     | EC_ABS_MODE   |
| ECCTL1   | CTRRST2     | EC_ABS_MODE   |
| ECCTL1   | CTRRST3     | EC_ABS_MODE   |
| ECCTL1   | CTRRST4     | EC_ABS_MODE   |
| ECCTL1   | CAPLDEN     | EC_ENABLE     |
| ECCTL1   | PRESCALE    | EC_DIV1       |
| ECCTL2   | CAP_APWM    | EC_CAP_MODE   |
| ECCTL2   | CONT_ONESHT | EC_CONTINUOUS |
| ECCTL2   | SYNCO_SEL   | EC_SYNCO_DIS  |
| ECCTL2   | SYNCL_EN    | EC_DISABLE    |
| ECCTL2   | TSCTRSTOP   | EC_RUN        |

**Example 16-1. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger

// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4

Period1 = TSt2-TSt1;        // Calculate 1st period
Period2 = TSt3-TSt2;        // Calculate 2nd period
Period3 = TSt4-TSt3;        // Calculate 3rd period
```

### 16.3.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 16-11 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...etc. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , etc. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , etc.

**Figure 16-11. Capture Sequence for Absolute Time-Stamp, Rising and Falling Edge Detect**

**Table 16-2. ECAP Initialization for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

| Register | Bit         | Value         |
|----------|-------------|---------------|
| ECCTL1   | CAP1POL     | EC_RISING     |

**Example 16-2. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers

// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4

Period1 = TSt3-TSt1;        // Calculate 1st period
DutyOnTime1 = TSt2-TSt1;    // Calculate On time
DutyOffTime1 = TSt3-TSt2;   // Calculate Off time
```

### 16.3.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 16-12 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CINTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPn contents directly give timing data without the need for CPU calculations: Period1 =  $T_1$ , Period2 =  $T_2$ ,...etc. As shown in Figure 16-12, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

**Figure 16-12. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect**

**Table 16-3. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger**

| Register | Bit         | Value         |
|----------|-------------|---------------|
| ECCTL1   | CAP1POL     | EC_RISING     |
| ECCTL1   | CAP2POL     | EC_RISING     |
| ECCTL1   | CAP3POL     | EC_RISING     |
| ECCTL1   | CAP4POL     | EC_RISING     |
| ECCTL1   | CTRRST1     | EC_DELTA_MODE |
| ECCTL1   | CTRRST2     | EC_DELTA_MODE |
| ECCTL1   | CTRRST3     | EC_DELTA_MODE |
| ECCTL1   | CTRRST4     | EC_DELTA_MODE |
| ECCTL1   | CAPLDEN     | EC_ENABLE     |
| ECCTL1   | PRESCALE    | EC_DIV1       |
| ECCTL2   | CAP_APWM    | EC_CAP_MODE   |
| ECCTL2   | CONT_ONESHT | EC_CONTINUOUS |
| ECCTL2   | SYNCO_SEL   | EC_SYNCO_DIS  |
| ECCTL2   | SYNCL_EN    | EC_DISABLE    |
| ECCTL2   | TSCTRSTOP   | EC_RUN        |

**Example 16-3. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Delta Time, Rising edge trigger

// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
Period2 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
Period3 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
```

### 16.3.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example

In Figure 16-13 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information:  $\text{Period1} = T_1 + T_2$ ,  $\text{Period2} = T_3 + T_4$ , ...etc  $\text{Duty Cycle1 (on-time \%)} = T_1 / \text{Period1} \times 100\%$ , etc  $\text{Duty Cycle1 (off-time \%)} = T_2 / \text{Period1} \times 100\%$ , etc

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

**Figure 16-13. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect**

**Table 16-4. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers**

| Register | Bit         | Value         |
|----------|-------------|---------------|
| ECCTL1   | CAP1POL     | EC_RISING     |
| ECCTL1   | CAP2POL     | EC_FALLING    |
| ECCTL1   | CAP3POL     | EC_RISING     |
| ECCTL1   | CAP4POL     | EC_FALLING    |
| ECCTL1   | CTRRST1     | EC_DELTA_MODE |
| ECCTL1   | CTRRST2     | EC_DELTA_MODE |
| ECCTL1   | CTRRST3     | EC_DELTA_MODE |
| ECCTL1   | CTRRST4     | EC_DELTA_MODE |
| ECCTL1   | CAPLDEN     | EC_ENABLE     |
| ECCTL1   | PRESCALE    | EC_DIV1       |
| ECCTL2   | CAP_APWM    | EC_CAP_MODE   |
| ECCTL2   | CONT_ONESHT | EC_CONTINUOUS |
| ECCTL2   | SYNCO_SEL   | EC_SYNCO_DIS  |
| ECCTL2   | SYNCL_EN    | EC_DISABLE    |
| ECCTL2   | TSCTRSTOP   | EC_RUN        |

**Example 16-4. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers**

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers

// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1

Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

## 16.3.5 Application of the APWM Mode

### 16.3.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM $n$ . The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

**Figure 16-14. PWM Waveform Details of APWM Mode Operation**

**Table 16-5. ECAP Initialization for APWM Mode**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 0x1000       |
| CTRPHS   | CTRPHS    | 0x0          |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_DISABLE   |
| ECCTL2   | SYNCO_SEL | EC_SYNCO_DIS |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Example 16-5. Code Snippet for APWM Mode**

```
// Code snippet for APWM mode Example 1

// Run Time (Instant 1, e.g. ISR call)
//=====
    ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value

// Run Time (Instant 2, e.g. another ISR call)
//=====
    ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
```

**16.3.5.2 Multichannel PWM Generation with Synchronization Example**

Figure 16-15 takes advantage of the synchronization feature between eCAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one eCAP module is configured as the Master and the remaining 3 are Slaves all receiving their synch pulse (CTR = PRD) from the master. Note the Master is chosen to have the lower frequency ( $F_1 = 1/20,000$ ) requirement. Here Slave2 Freq =  $2 \times F_1$ , Slave3 Freq =  $4 \times F_1$  and Slave4 Freq =  $5 \times F_1$ . Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

**Figure 16-15. Multichannel PWM Example Using 4 eCAP Modules**

**Table 16-6. ECAP1 Initialization for Multichannel PWM Generation with Synchronization**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 20000        |
| CTRPHS   | CTRPHS    | 0            |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_DISABLE   |
| ECCTL2   | SYNCO_SEL | EC_CTR_PRD   |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Table 16-7. ECAP2 Initialization for Multichannel PWM Generation with Synchronization**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 10000        |
| CTRPHS   | CTRPHS    | 0            |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_ENABLE    |
| ECCTL2   | SYNCO_SEL | EC_SYNCl     |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Table 16-8. ECAP3 Initialization for Multichannel PWM Generation with Synchronization**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 5000         |
| CTRPHS   | CTRPHS    | 0            |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_ENABLE    |
| ECCTL2   | SYNCO_SEL | EC_SYNCl     |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Table 16-9. ECAP4 Initialization for Multichannel PWM Generation with Synchronization**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 4000         |
| CTRPHS   | CTRPHS    | 0            |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_ENABLE    |
| ECCTL2   | SYNCO_SEL | EC_SYNCO_DIS |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

### Example 16-6. Code Snippet for Multichannel PWM Generation with Synchronization

```
// Code snippet for APWM mode Example 2

// Run Time (Note: Example execution of one run-time instant)
//=====
ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

#### 16.3.5.3 Multichannel PWM Generation with Phase Control Example

In [Figure 16-16](#), the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by 120° from each other. Hence if “Leg” 1 (controlled by APWM1) is the reference Leg (or phase), that is, 0°, then Leg 2 need 120° off-set and Leg 3 needs 240° off-set. The waveforms in [Figure 16-16](#) show the timing relationship between each of the phases (Legs). Note eCAP1 module is the Master and issues a sync out pulse to the slaves (modules 2, 3) whenever TSCTR = Period value.

**Figure 16-16. Multiphase (channel) Interleaved PWM Example Using 3 eCAP Modules**

**Table 16-10. ECAP1 Initialization for Multichannel PWM Generation with Phase Control**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 1200         |
| CTRPHS   | CTRPHS    | 0            |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_DISABLE   |
| ECCTL2   | SYNCO_SEL | EC_CTR_PRD   |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Table 16-11. ECAP2 Initialization for Multichannel PWM Generation with Phase Control**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 1200         |
| CTRPHS   | CTRPHS    | 800          |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_ENABLE    |
| ECCTL2   | SYNCO_SEL | EC_SYNCl     |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Table 16-12. ECAP3 Initialization for Multichannel PWM Generation with Phase Control**

| Register | Bit       | Value        |
|----------|-----------|--------------|
| CAP1     | CAP1      | 1200         |
| CTRPHS   | CTRPHS    | 400          |
| ECCTL2   | CAP_APWM  | EC_APWM_MODE |
| ECCTL2   | APWMPOL   | EC_ACTV_HI   |
| ECCTL2   | SYNCl_EN  | EC_ENABLE    |
| ECCTL2   | SYNCO_SEL | EC_SYNCO_DIS |
| ECCTL2   | TSCTRSTOP | EC_RUN       |

**Example 16-7. Code Snippet for Multichannel PWM Generation with Phase Control**

```
// Code snippet for APWM mode Example 3

// Run Time (Note: Example execution of one run-time instant)
//=====
// All phases are set to the same duty cycle
ECAP1Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP2Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP3Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
```

## 16.4 Registers

[Table 16-13](#) shows the eCAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode. The 16 least-significant bits of a 32-bit register are located on lowest address (even address).

**NOTE:** In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

**Table 16-13. Control and Status Register Set**

| Offset | Acronym | Description                         | Size (×16) | Section                         |
|--------|---------|-------------------------------------|------------|---------------------------------|
| 0h     | TSCTR   | Time-Stamp Counter Register         | 2          | <a href="#">Section 16.4.1</a>  |

### 16.4.1 Time-Stamp Counter Register (TSCTR)

The time-stamp counter register (TSCTR) is shown in [Figure 16-17](#) and described in [Table 16-14](#).

**Figure 16-17. Time-Stamp Counter Register (TSCTR)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 16-14. Time-Stamp Counter Register (TSCTR) Field Descriptions**

| Bit  | Field | Value        | Description                                                          |
|------|-------|--------------|----------------------------------------------------------------------|
| 31-0 | TSCTR | 0-FFFF FFFFh | Active 32-bit counter register that is used as the capture time-base |

### 16.4.2 Counter Phase Control Register (CTRPHS)

The counter phase control register (CTRPHS) is shown in [Figure 16-18](#) and described in [Table 16-15](#).

**Figure 16-18. Counter Phase Control Register (CTRPHS)**

|        |  |  |  |  |   |
|--------|--|--|--|--|---|
| 31     |  |  |  |  | 0 |
| CTRPHS |  |  |  |  |   |
| R/W-0  |  |  |  |  |   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 16-15. Counter Phase Control Register (CTRPHS) Field Descriptions**

| Bit  | Field  | Value        | Description                                                                                                                                                                                                                                                                          |
|------|--------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CTRPHS | 0-FFFF FFFFh | Counter phase value register that can be programmed for phase lag/lead. This register shadows TSCTR and is loaded into TSCTR upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and EPWM time-bases. |

### 16.4.3 Capture 1 Register (CAP1)

The capture 1 register (CAP1) is shown in [Figure 16-19](#) and described in [Table 16-16](#).

**Figure 16-19. Capture 1 Register (CAP1)**

|       |  |  |  |  |   |

#### 16.4.9 ECAP Interrupt Enable Register (ECEINT)

The ECAP interrupt enable register (ECEINT) is shown in [Figure 16-25](#) and described in [Table 16-22](#).

The interrupt enable bits (CEVT<sub>n</sub>) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.

The proper procedure for configuring peripheral modes and interrupts is:

1. Disable global interrupts
2. Stop eCAP counter
3. Disable eCAP interrupts
4. Configure peripheral registers
5. Clear spurious eCAP interrupt flags
6. Enable eCAP interrupts
7. Start eCAP counter
8. Enable global interrupts

**Figure 16-25. ECAP Interrupt Enable Register (ECEINT)**

## 17.1 Introduction

### 17.1.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this chapter, the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and, likewise, EPWM4A and EPWM4B belong to ePWM4.

### 17.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 17-1](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 17.2.10](#). See your device-specific data manual to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example ePWM1 is the first instance and ePWM3 is the 3rd instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations::
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 17-1](#). The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in [Figure 17-1](#). See [Section 17.2.3.3.2](#) for the synchronization scheme for a particular device. Each ePWM module consists of seven submodules and is connected within a system via the signals shown in [Figure 17-2](#).

**Figure 17-1. Multiple ePWM Modules**

**Figure 17-2. Submodules and Signal Connections for an ePWM Module**

Figure 17-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for your device.
- **Trip-zone signals ( $\overline{\text{TZ1}}$  to  $\overline{\text{TZn}}$ ).** These input signals alert the ePWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral. See your device-specific data manual to determine how many trip-zone pins are available in the device.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCl of the first enhanced capture module (eCAP1).
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 17-3 also shows the key internal submodule interconnect signals. Each submodule is described in detail in [Section 17.2](#).

Figure 17-3. ePWM Submodules and Critical Internal Signal Interconnects

### 17.1.3 Register Mapping

Table 17-1 shows the complete ePWM module control and status register set grouped by submodule. Each register set is duplicated for each instance of the ePWM module. The start address for each ePWM register file instance on a device is specified in the appropriate data manual.

**Table 17-1. ePWM Module Control and Status Registers Grouped by Submodule**

| Acronym                                                | Offset <sup>(1)</sup> | Size<br>(×16) | Shadow | Register Description                                          |

| HRCNFG                                                 | 1040h                 | 1             | No     | HRPWM Configuration Register <sup>(2)</sup>                   |

<sup>(1)</sup> Locations not shown are reserved.

<sup>(2)</sup> These registers are only available on ePWM instances that include the high-resolution PWM (HRPWM) extension; otherwise, these locations are reserved. See your device-specific data manual to determine which instances include the HRPWM.

## 17.2 Architecture

Seven submodules are included in every ePWM peripheral. There are some instances that include a high-resolution submodule that allows more precise control of the PWM outputs. Each of these submodules performs specific tasks that can be configured by software.

### 17.2.1 Overview

[Table 17-2](#) lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in [Section 17.2.4](#) for relevant details.

**Table 17-2. Submodule Configuration Parameters**

| Submodule             | Configuration Parameter or Option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Reference                      |

**17.2.2 Proper Interrupt Initialization Procedure**

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Initialize peripheral registers
4. Clear any spurious ePWM flags
5. Enable ePWM interrupts
6. Enable global interrupts

### 17.2.3 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 17-4 illustrates the time-base module's place within the ePWM.

**Figure 17-4. Time-Base Submodule Block Diagram**

#### 17.2.3.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCNT) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCNT = TBPRD) .
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (SYSCLKOUT). This allows the time-base counter to increment/decrement at a slower rate.

**Table 17-4. Key Time-Base Signals**

| Signal     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EPWMxSYNCl | Time-base synchronization input.<br><br>Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCl is generated by the ePWM1 peripheral, EPWM3SYNCl is generated by ePWM2 and so forth. See <a href="#">Section 17.2.3.3.2</a> for information on the synchronization order of a particular device. |
| EPWMxSYNCO | Time-base synchronization output.<br><br>This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources:<br><ol style="list-style-type: none"> <li>1. EPWMxSYNCl (Synchronization input pulse)</li> <li>2. CTR = 0: The time-base counter equal to zero (TBCNT = 0000h).</li> <li>3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCNT = CMPB) register.</li> </ol>                                                                                                            |
| CTR = PRD  | Time-base counter equal to the specified period.<br><br>This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CTR = 0    | Time-base counter equal to zero.<br><br>This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CTR = CMPB | Time-base counter equal to active counter-compare B register (TBCNT = CMPB).<br><br>This event is generated by the counter-compare submodule and used by the synchronization out logic.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| CTR_dir    | Time-base counter direction.<br><br>Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| CTR_max    | Time-base counter equal max value. (TBCNT = FFFFh)<br><br>Generated event when the TBCNT value reaches its maximum value. This signal is only used only as a status bit.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TBCLK      | Time-base clock.<br><br>This is a prescaled version of the system clock (SYSCLKOUT) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.                                                                                                                                                                                                                                                                                                                                                                                                 |

### 17.2.3.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. [Figure 17-6](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (SYSCLKOUT).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

**Figure 17-6. Time-Base Frequency and Period**

### 17.2.3.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCNT = 0000h). By default the TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 17.2.3.3.2 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The possible synchronization connections for the remaining ePWM modules is shown in [Figure 17-7](#).

**Figure 17-7. Time-Base Counter Synchronization Scheme 1**

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCNT) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See [Figure 17-8](#) through [Figure 17-11](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

#### 17.2.3.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit in the chip configuration register 1 (CFGCHIP1) in the System Module can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. The TBCLKSYNC bit is part of the chip configuration registers and is described in the device-specific data manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the ePWM module clocks.
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

#### 17.2.3.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, [Figure 17-8](#) to [Figure 17-11](#) show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

**Figure 17-8. Time-Base Up-Count Mode Waveforms**

Figure 17-9. Time-Base Down-Count Mode Waveforms

Figure 17-10. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down on Synchronization Event

**Figure 17-11. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up on Synchronization Event**

Figure 17-12 illustrates the counter-compare submodule within the ePWM. Figure 17-13 shows the basic structure of the counter-compare submodule.

### Figure 17-12. Counter-Compare Submodule

### Figure 17-13. Counter-Compare Submodule Signals and Registers

### 17.2.4.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare submodule:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCNT = CMPA).
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCNT = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 17.2.4.2 Controlling and Monitoring the Counter-Compare Submodule

[Table 17-5](#) lists the registers used to control and monitor the counter-compare submodule. [Table 17-6](#) lists the key signals associated with the counter-compare submodule.

**Table 17-5. Counter-Compare Submodule Registers**

| Acronym | Register Description                                      | Address Offset | Shadowed |
|---------|-----------------------------------------------------------|----------------|----------|
| CMPCTL  | Counter-Compare Control Register.                         | Eh             | No       |
| CMPAHR  | HRPWM Counter-Compare A Extension Register <sup>(1)</sup> | 10h            | Yes      |
| CMPA    | Counter-Compare A Register                                | 12h            | Yes      |
| CMPB    | Counter-Compare B Register                                | 14h            | Yes      |

<sup>(1)</sup> This register is available only on ePWM modules with the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. Refer to the device-specific data manual to determine which ePWM instances include this feature.

**Table 17-6. Counter-Compare Submodule Key Signals**

| Signal     | Description of Event                                                                                                            | Registers Compared |
|------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------|
| CTR = CMPA | Time-base counter equal to the active counter-compare A value                                                                   | TBCNT = CMPA       |
| CTR = CMPB | Time-base counter equal to the active counter-compare B value                                                                   | TBCNT = CMPB       |
| CTR = PRD  | Time-base counter equal to the active period.<br>Used to load active counter-compare A and B registers from the shadow register | TBCNT = TBPRD      |
| CTR = 0    | Time-base counter equal to zero.<br>Used to load active counter-compare A and B registers from the shadow register              | TBCNT = 0000h      |

### 17.2.4.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCNT = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCNT = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 17.2.5.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Mode:** The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

- CTR = PRD: Time-base counter equal to the period (TBCNT = TBPRD).
- CTR = 0: Time-base counter equal to zero (TBCNT = 0000h)
- Both CTR = PRD and CTR = 0

Which of these three events is specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

- **Immediate Load Mode:** If immediate load mode is selected (TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

### 17.2.4.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 17-14](#) to [Figure 17-17](#) show when events are generated and how the EPWMxSYNCl signal interacts.

**Figure 17-14. Counter-Compare Event Waveforms in Up-Count Mode**

NOTE: An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 17-15. Counter-Compare Events in Down-Count Mode**

**Figure 17-16. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down on Synchronization Event**

**Figure 17-17. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up on Synchronization Event**

## 17.2.5 Action-Qualifier (AQ) Submodule

Figure 17-18 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system. The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 17-18. Action-Qualifier Submodule

### 17.2.5.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCNT = TBPRD)
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

### 17.2.5.2 Controlling and Monitoring the Action-Qualifier Submodule

Table 17-7 lists the registers used to control and monitor the action-qualifier submodule.

Table 17-7. Action-Qualifier Submodule Registers

| Acronym | Register Description                                    | Address Offset | Shadowed |
|---------|---------------------------------------------------------|----------------|----------|
| AQCTLA  | Action-Qualifier Control Register For Output A (EPWMxA) | 16h            | No       |
| AQCTLB  | Action-Qualifier Control Register For Output B (EPWMxB) | 18h            | No       |
| AQSFRC  | Action-Qualifier Software Force Register                | 1Ah            | No       |
| AQCSFRC | Action-Qualifier Continuous Software Force              | 1Ch            | Yes      |

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in [Figure 17-19](#). The possible input events are summarized again in [Table 17-8](#).

**Figure 17-19. Action-Qualifier Submodule Inputs and Outputs**

**Table 17-8. Action-Qualifier Submodule Possible Input Events**

| Signal                | Description                                      | Registers Compared |
|-----------------------|--------------------------------------------------|--------------------|
| CTR = PRD             | Time-base counter equal to the period value      | TBCNT = TBPRD      |
| CTR = 0               | Time-base counter equal to zero                  | TBCNT = 0000h      |
| CTR = CMPA            | Time-base counter equal to the counter-compare A | TBCNT = CMPA       |
| CTR = CMPB            | Time-base counter equal to the counter-compare B | TBCNT = CMPB       |
| Software forced event | Asynchronous event initiated by software         |                    |

The software forced action is a useful asynchronous event. This control is handled by registers AQSFR and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the event-trigger submodule description in [Section 17.2.9](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 17-20](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

**Figure 17-20. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

| S/W<br>force                                                                        | TB Counter equals:                                                                  |                                                                                     |                                                                                     |                                                                                       | Actions    |

### 17.2.5.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 17-9](#). A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

**Table 17-9. Action-Qualifier Event Priority for Up-Down-Count Mode**

| Priority Level | Event if TBCNT is Incrementing<br>TBCNT = 0 up to TBCNT = TBPRD | Event if TBCNT is Decrementing<br>TBCNT = TBPRD down to TBCNT = 1 |
|----------------|-----------------------------------------------------------------|-------------------------------------------------------------------|
| 1 (Highest)    | Software forced event                                           | Software forced event                                             |
| 2              | Counter equals CMPB on up-count (CBU)                           | Counter equals CMPB on down-count (CBD)                           |
| 3              | Counter equals CMPA on up-count (CAU)                           | Counter equals CMPA on down-count (CAD)                           |
| 4              | Counter equals zero                                             | Counter equals period (TBPRD)                                     |
| 5              | Counter equals CMPB on down-count (CBD) <sup>(1)</sup>          | Counter equals CMPB on up-count (CBU) <sup>(1)</sup>              |
| 6 (Lowest)     | Counter equals CMPA on down-count (CAD) <sup>(1)</sup>          | Counter equals CMPA on up-count (CBU) <sup>(1)</sup>              |

<sup>(1)</sup> To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 17-10](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

**Table 17-10. Action-Qualifier Event Priority for Up-Count Mode**

| Priority Level | Event                                   |
|----------------|-----------------------------------------|
| 1 (Highest)    | Software forced event                   |
| 2              | Counter equal to period (TBPRD)         |
| 3              | Counter equal to CMPB on up-count (CBU) |
| 4              | Counter equal to CMPA on up-count (CAU) |
| 5 (Lowest)     | Counter equal to Zero                   |

[Table 17-11](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 17-11. Action-Qualifier Event Priority for Down-Count Mode**

| Priority Level | Event                                     |
|----------------|-------------------------------------------|
| 1 (Highest)    | Software forced event                     |
| 2              | Counter equal to Zero                     |
| 3              | Counter equal to CMPB on down-count (CBD) |
| 4              | Counter equal to CMPA on down-count (CAD) |
| 5 (Lowest)     | Counter equal to period (TBPRD)           |

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 17-12](#).

**Table 17-12. Behavior if CMPA/CMPB is Greater than the Period**

| Counter Mode       | Compare on Up-Count Event CAU/CBU                                                                                                                                                                                                                                                    | Compare on Down-Count Event CAU/CBU                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Up-Count Mode      | <p>If <math>CMPA/CMPB \leq TBPRD</math> period, then the event occurs on a compare match (<math>TBCNT = CMPA</math> or <math>CMPB</math>).</p> <p>If <math>CMPA/CMPB &gt; TBPRD</math>, then the event will not occur.</p>                                                           | Never occurs.                                                                                                                                                                                                                                                                    |
| Down-Count Mode    | Never occurs.                                                                                                                                                                                                                                                                        | <p>If <math>CMPA/CMPB &lt; TBPRD</math>, the event will occur on a compare match (<math>TBCNT = CMPA</math> or <math>CMPB</math>).</p> <p>If <math>CMPA/CMPB \geq TBPRD</math>, the event will occur on a period match (<math>TBCNT = TBPRD</math>).</p>                         |
| Up-Down-Count Mode | <p>If <math>CMPA/CMPB &lt; TBPRD</math> and the counter is incrementing, the event occurs on a compare match (<math>TBCNT = CMPA</math> or <math>CMPB</math>).</p> <p>If <math>CMPA/CMPB \geq TBPRD</math>, the event will occur on a period match (<math>TBCNT = TBPRD</math>).</p> | <p>If <math>CMPA/CMPB &lt; TBPRD</math> and the counter is decrementing, the event occurs on a compare match (<math>TBCNT = CMPA</math> or <math>CMPB</math>).</p> <p>If <math>CMPA/CMPB \geq TBPRD</math>, the event occurs on a period match (<math>TBCNT = TBPRD</math>).</p> |

#### 17.2.5.4 Waveforms for Common Configurations

**NOTE:** The waveforms in this chapter show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

**Use up-down-count mode to generate a symmetric PWM:**

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to  $TBPRD - 1$ .

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Use up-down-count mode to generate an asymmetric PWM:**

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

**When using up-count mode to generate an asymmetric PWM:**

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to  $TBPRD+1$  to achieve 0-100% PWM duty.

Figure 17-21 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 17-21. Up-Down-Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 17-22](#) through [Figure 17-27](#) show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

[Table 17-13](#) and [Table 17-14](#) contains initialization and runtime register configurations for the waveforms in [Figure 17-22](#).

**Figure 17-22. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High**

- (1)  $\text{PWM period} = (\text{TBPRD} + 1) \times T_{\text{TBCLK}}$
- (2) Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- (3) Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- (4) The "Do Nothing" actions ( X ) are shown for completeness, but will not be shown on subsequent diagrams.
- (5) Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

**Table 17-13. EPWMx Initialization for Figure 17-22**

| Register | Bit       | Value           | Comments                     |
|----------|-----------|-----------------|------------------------------|
| TBPRD    | TBPRD     | 600 (258h)      | Period = 601 TBCLK counts    |
| TBPHS    | TBPHS     | 0               | Clear Phase Register to 0    |

## 17.2.6 Dead-Band Generator (DB) Submodule

Figure 17-28 illustrates the dead-band generator submodule within the ePWM module.

Figure 17-28. Dead-Band Generator Submodule

### 17.2.6.1 Purpose of the Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

### 17.2.6.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

Table 17-25. Dead-Band Generator Submodule Registers

| Acronym | Register Description                        | Address Offset | Shadowed |
|---------|---------------------------------------------|----------------|----------|
| DBCTL   | Dead-Band Control Register                  | 1Eh            | No       |
| DBRED   | Dead-Band Rising Edge Delay Count Register  | 20h            | No       |
| DBFED   | Dead-Band Falling Edge Delay Count Register | 22h            | No       |

### 17.2.6.3 Operational Highlights for the Dead-Band Generator Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in [Figure 17-29](#).

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN\_MODE] control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the DBCTL[OUT\_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

**Figure 17-29. Configuration Options for the Dead-Band Generator Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 17-26](#) lists some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 17-26](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 17-30](#). Note that to generate equivalent waveforms to [Figure 17-30](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 17-26](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 17-26. Classical Dead-Band Operating Modes**

| Mode | Mode Description <sup>(1)</sup>                                                       | DBCTL[POLSEL] |        | DBCTL[OUT_MODE] |    |
|------|---------------------------------------------------------------------------------------|---------------|--------|-----------------|----|
|      |                                                                                       | S3            | S2     | S1              | S0 |
| 1    | EPWMxA and EPWMxB Passed Through (No Delay)                                           | x             | x      | 0               | 0  |
| 2    | Active High Complementary (AHC)                                                       | 1             | 0      | 1               | 1  |
| 3    | Active Low Complementary (ALC)                                                        | 0             | 1      | 1               | 1  |
| 4    | Active High (AH)                                                                      | 0             | 0      | 1               | 1  |
| 5    | Active Low (AL)                                                                       | 1             | 1      | 1               | 1  |
| 6    | EPWMxA Out = EPWMxA In (No Delay)<br>EPWMxB Out = EPWMxA In with Falling Edge Delay   | 0 or 1        | 0 or 1 | 0               | 1  |
| 7    | EPWMxA Out = EPWMxA In with Rising Edge Delay<br>EPWMxB Out = EPWMxB In with No Delay | 0 or 1        | 0 or 1 | 1               | 0  |

<sup>(1)</sup> These are classical dead-band modes and assume that DBCTL[IN\_MODE] = 0,0. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN\_MODE configuration.

Figure 17-30 shows waveforms for typical cases where 0% < duty < 100%.

**Figure 17-30. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$$FED = DBFED \times T_{TBCLK}$$

$$RED = DBRED \times T_{TBCLK}$$

Where  $T_{TBCLK}$  is the period of TBCLK, the prescaled version of SYSCLKOUT.

### 17.2.7 PWM-Chopper (PC) Submodule

Figure 17-31 illustrates the PWM-chopper (PC) submodule within the ePWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

Figure 17-31. PWM-Chopper Submodule

#### 17.2.7.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

#### 17.2.7.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the register in Table 17-27.

Table 17-27. PWM-Chopper Submodule Registers

| Acronym | Register Description         | Address Offset | Shadowed |
|---------|------------------------------|----------------|----------|
| PCCTL   | PWM-chopper Control Register | 3Ch            | No       |

### 17.2.7.3 Operational Highlights for the PWM-Chopper Submodule

Figure 17-32 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from SYSCLKOUT. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 17-32. PWM-Chopper Submodule Signals and Registers

#### 17.2.7.4 Waveforms

Figure 17-33 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 17-33. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only**

##### 17.2.7.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{SYSCLKOUT} \times 8 \times OSHTWTH$$

Where  $T_{SYSCLKOUT}$  is the period of the system clock (SYSCLKOUT) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 17-34 shows the first and subsequent sustaining pulses.

**Figure 17-34. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

#### 17.2.7.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 17-35 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

**Figure 17-35. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

## 17.2.8 Trip-Zone (TZ) Submodule

Figure 17-36 shows how the trip-zone (TZ) submodule fits within the ePWM module. Each ePWM module is connected to every  $\overline{TZ}$  signal that are sourced from the GPIO MUX. These signals indicates external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur. See your device-specific data manual to determine the number of trip-zone pins available for the device.

**Figure 17-36. Trip-Zone Submodule**

### 17.2.8.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZn}$  can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs  $EPWMxA$  and  $EPWMxB$  can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

### 17.2.8.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

**Table 17-28. Trip-Zone Submodule Registers**

| Acronym | Register Description                | Address Offset | Shadowed |
|---------|-------------------------------------|----------------|----------|
| TZSEL   | Trip-Zone Select Register           | 24h            | No       |
| TZCTL   | Trip-Zone Control Register          | 28h            | No       |
| TZEINT  | Trip-Zone Enable Interrupt Register | 2Ah            | No       |
| TZFLG   | Trip-Zone Flag Register             | 2Ch            | No       |
| TZCLR   | Trip-Zone Clear Register            | 2Eh            | No       |
| TZFRC   | Trip-Zone Force Register            | 30h            | No       |

### 17.2.8.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals at pin  $\overline{TZ1}$  to  $\overline{TZn}$  is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signal may or may not be synchronized to the system clock (SYSCLKOUT). A minimum of 1 SYSCLKOUT low pulse on the  $\overline{TZn}$  inputs is sufficient to trigger a fault condition in the ePWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the  $\overline{TZn}$  inputs.

The  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a ePWM module. The configuration is determined by the TZSEL[CBCn] and TZSEL[OSHTn] bits (where n corresponds to the trip pin) respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 17-29](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMxTZINT interrupt is generated if it is enabled in the TZEINT register.

The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 17-29](#) lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMxTZINT interrupt is generated if it is enabled in the TZEINT register. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL[TZA] and TZCTL[TZB] register bits. One of four possible actions, shown in [Table 17-29](#), can be taken on a trip event.

**Table 17-29. Possible Actions On a Trip Event**

| TZCTL[TZA]<br>and/or<br>TZCTL[TZB] | EPWMxA<br>and/or<br>EPWMxB | Comment                                      |
|------------------------------------|----------------------------|----------------------------------------------|
| 0                                  | High-Impedance             | Tripped                                      |
| 1h                                 | Force to High State        | Tripped                                      |
| 2h                                 | Force to Low State         | Tripped                                      |
| 3h                                 | No Change                  | Do Nothing. No change is made to the output. |

### Example 17-2. Trip-Zone Configurations

#### Scenario A:

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

#### Scenario B:

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 0: EPWM1A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM1B will ignore the trip event.

### 17.2.8.4 Generating Trip Event Interrupts

Figure 17-37 and Figure 17-38 illustrate the trip-zone submodule control and interrupt logic, respectively.

Figure 17-37. Trip-Zone Submodule Mode Control Logic

Figure 17-38. Trip-Zone Submodule Interrupt Logic

### 17.2.9 Event-Trigger (ET) Submodule

Figure 17-39 shows the event-trigger (ET) submodule in the ePWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an interrupt to the CPU.

**Figure 17-39. Event-Trigger Submodule**

#### 17.2.9.1 Purpose of the Event-Trigger Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags

#### 17.2.9.2 Controlling and Monitoring the Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in Table 17-30:

**Table 17-30. Event-Trigger Submodule Registers**

| Acronym | Register Description             | Address Offset | Shadowed |
|---------|----------------------------------|----------------|----------|
| ETSEL   | Event-Trigger Selection Register | 32h            | No       |
| ETPS    | Event-Trigger Prescale Register  | 34h            | No       |
| ETFLG   | Event-Trigger Flag Register      | 36h            | No       |
| ETCLR   | Event-Trigger Clear Register     | 38h            | No       |
| ETFRC   | Event-Trigger Force Register     | 3Ah            | No       |

### 17.2.9.3 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the interrupt controller as shown in Figure 17-40.

**Figure 17-40. Event-Trigger Submodule Inter-Connectivity to Interrupt Controller**

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 17-41) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

**Figure 17-41. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- **ETSEL**—This selects which of the possible events will trigger an interrupt.
- **ETPS**—This programs the event prescaling options previously mentioned.
- **ETFLG**—These are flag bits indicating status of the selected and prescaled events.
- **ETCLR**—These bits allow you to clear the flag bits in the ETFLG register via software.
- **ETFRC**—These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 17-42](#).

[Figure 17-42](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCNT = 0000h).
- Time-base counter equal to period (TBCNT = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When ETPS[INTCNT] reaches ETPS[INTPRD], one of the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ETFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

**Figure 17-42. Event-Trigger Interrupt Generator**

### 17.2.10 High-Resolution PWM (HRPWM) Submodule

Figure 17-43 shows the high-resolution PWM (HRPWM) submodule in the ePWM system. Some devices include the high-resolution PWM submodule, see your device-specific data manual to determine which ePWM instances include this feature.

Figure 17-43. HRPWM System Interface

### 17.2.10.1 Purpose of the High-Resolution PWM Submodule

The enhanced high-resolution pulse-width modulator (eHRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. EPWMxB output has conventional PWM capabilities

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in [Figure 17-44](#), the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 17-44. Resolution Calculations for Conventionally Generated PWM**

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, [Table 17-31](#) shows resolution in bits for various PWM frequencies. [Table 17-31](#) values assume a MEP step size of 180 ps. See your device-specific data manual for typical and maximum performance specifications for the MEP.

**Table 17-31. Resolution for PWM and HRPWM**

| PWM Frequency (kHz) | Regular Resolution (PWM) |     | High Resolution (HRPWM) |       |
|---------------------|--------------------------|-----|-------------------------|-------|
|                     | Bits                     | %   | Bits                    | %     |
| 20                  | 12.3                     | 0.0 | 18.1                    | 0.000 |
| 50                  | 11.0                     | 0.0 | 16.8                    | 0.001 |
| 100                 | 10.0                     | 0.1 | 15.8                    | 0.002 |
| 150                 | 9.4                      | 0.2 | 15.2                    | 0.003 |
| 200                 | 9.0                      | 0.2 | 14.8                    | 0.004 |
| 250                 | 8.6                      | 0.3 | 14.4                    | 0.005 |
| 500                 | 7.6                      | 0.5 | 13.8                    | 0.007 |
| 1000                | 6.6                      | 1.0 | 12.4                    | 0.018 |
| 1500                | 6.1                      | 1.5 | 11.9                    | 0.027 |
| 2000                | 5.6                      | 2.0 | 11.4                    | 0.036 |

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

### 17.2.10.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 17-45 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR).

**Figure 17-45. Operating Logic Using MEP**

A For MEP range and rounding adjustment.

To generate an HRPWM waveform, configure the TBM, CCM, and AQM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

### 17.2.10.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit TBPHS and CMPA registers used to control PWM operation.

- TBPHSHR - Time-Base Phase High-Resolution Register
- CMPAHR - Counter-Compare A High-Resolution Register

Table 17-32 lists the registers used to control and monitor the high-resolution PWM submodule.

**Table 17-32. HRPWM Submodule Registers**

| Acronym | Register Description               | Address Offset | Shadowed |
|---------|------------------------------------|----------------|----------|
| TBPHSHR | Extension Register for HRPWM Phase | 4h             | No       |
| CMPAHR  | Extension Register for HRPWM Duty  | 10h            | Yes      |
| HRCNFG  | HRPWM Configuration Register       | 1040h          | No       |

#### 17.2.10.4 Configuring the High-Resolution PWM Submodule

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register located at offset address 1040h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the CMPAHR register (duty cycle control) or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR register. BE control mode should be used with TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If TBPHSHR is used, then this option has no effect.

#### 17.2.10.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 17-33](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 17-33. Relationship Between MEP Steps, PWM Frequency and Resolution**

| System (MHz) | MEP Steps Per SYSCLKOUT <sup>(1) (2) (3)</sup> | PWM Minimum (Hz) <sup>(4)</sup> | PWM Maximum (MHz) | Resolution at Maximum (Bits) <sup>(5)</sup> |
|--------------|------------------------------------------------|---------------------------------|-------------------|---------------------------------------------|
| 50.0         | 111                                            | 763                             | 2.50              | 11.1                                        |
| 60.0         | 93                                             | 916                             | 3.00              | 10.9                                        |

| 90.0         | 62                                             | 1373                            | 4.50              | 10.3                                        |
| 100.0        | 56                                             | 1526                            | 5.00              | 10.1                                        |

<sup>(1)</sup> System frequency = SYSCLKOUT, that is, CPU clock. TBCLK = SYSCLKOUT

<sup>(2)</sup> Table data based on a MEP time resolution of 180 ps (this is an example value)

<sup>(3)</sup> MEP steps applied =  $T_{\text{SYSCLKOUT}}/180 \text{ ps}$  in this example.

<sup>(4)</sup> PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.

<sup>(5)</sup> Resolution in bits is given for the maximum PWM frequency stated.

### 17.2.10.5.1 Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, etc.) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. In [Figure 17-46](#), a compare value of 32 counts (duty = 40%) is the closest to 40.5% that you can attain. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in [Table 17-34](#).

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. [Table 17-34](#) shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

**Figure 17-46. Required PWM Waveform for a Requested Duty = 40.5%**

**Table 17-34. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)**

| CMPA<br>(count) <sup>(1)</sup> <sup>(2)</sup> <sup>(3)</sup> | DUTY<br>(%) | High Time<br>(ns) | CMPA<br>(count) | CMPAHR<br>(count) | Duty<br>(%) | High Time<br>(ns) |
|--------------------------------------------------------------|-------------|-------------------|-----------------|-------------------|-------------|-------------------|
| 28                                                           | 35.0        | 280               | 32              | 18                | 40.405      | 323.24            |
| 29                                                           | 36.3        | 290               | 32              | 19                | 40.428      | 323.42            |
| 30                                                           | 37.5        | 300               | 32              | 20                | 40.450      | 323.60            |
| 31                                                           | 38.8        | 310               | 32              | 21                | 40.473      | 323.78            |
| 32                                                           | 40.0        | 320               | 32              | 22                | 40.495      | 323.96            |
| 33                                                           | 41.3        | 330               | 32              | 23                | 40.518      | 324.14            |
| 34                                                           | 42.5        | 340               | 32              | 24                | 40.540      | 324.32            |
|                                                              |             |                   | 32              | 25                | 40.563      | 324.50            |
| Required                                                     |             |                   | 32              | 26                | 40.585      | 324.68            |
| 32.40                                                        | 40.5        | 324               | 32              | 27                | 40.608      | 324.86            |

<sup>(1)</sup> System clock, SYSCLKOUT and TBCLK = 100 MHz, 10 ns

<sup>(2)</sup> For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

<sup>(3)</sup> Assumed MEP step size for the above example = 180 ps

### 17.2.10.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (CMPA) and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

|                                                                                                 |                       |
|-------------------------------------------------------------------------------------------------|-----------------------|
| System clock, SYSCLKOUT                                                                         | = 10 ns (100 MHz)     |
| PWM frequency                                                                                   | = 1.25 MHz (1/800 ns) |
| Required PWM duty cycle, <b>PWMDuty</b>                                                         | = 0.405 (40.5%)       |
| PWM period in terms of coarse steps, <b>PWMperiod</b> (800 ns/10 ns)                            | = 80                  |
| Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), <b>MEP_SF</b>                     | = 55                  |
| Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value) | = 180h                |

#### Step 1: Percentage Integer Duty value conversion for CMPA register

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| CMPA register value | = $\text{int}(\text{PWMDuty} \times \text{PWMperiod})$ ; int means integer part |
|                     | = $\text{int}(0.405 \times 80)$                                                 |
|                     | = $\text{int}(32.4)$                                                            |
| CMPA register value | = 32 (20h)                                                                      |

#### Step 2: Fractional value conversion for CMPAHR register

|                       |                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| CMPAHR register value | = $(\text{frac}(\text{PWMDuty} \times \text{PWMperiod}) \times \text{MEP\_SF}) \ll 8) + 180\text{h}$ ; frac means fractional part |
|                       | = $(\text{frac}(32.4) \times 55 \ll 8) + 180\text{h}$ ; Shift is to move the value as CMPAHR high byte                            |
|                       | = $((0.4 \times 55) \ll 8) + 180\text{h}$                                                                                         |
|                       | = $(22 \ll 8) + 180\text{h}$                                                                                                      |
|                       | = $22 \times 256 + 180\text{h}$ ; Shifting left by 8 is the same multiplying by 256.                                              |
|                       | = $5632 + 180\text{h}$                                                                                                            |
|                       | = $1600\text{h} + 180\text{h}$                                                                                                    |
| CMPAHR value          | = 1780h; CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.                                                          |

### 17.2.10.5.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 SYSCLK cycles after the period starts.

Duty cycle range limitations are illustrated in [Figure 17-47](#). This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

**Figure 17-47. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz**

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in [Figure 17-48](#). In this case low percent duty limitation is no longer an issue.

**Figure 17-48. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz**

## 17.3 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### 17.3.1 Overview of Multiple Modules

Previously in this user's guide, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in [Figure 17-49](#). This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

**Figure 17-49. Simplified ePWM Module**

### 17.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, i.e., via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in [Figure 17-50](#).

**Figure 17-50. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

### 17.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. [Figure 17-51](#) shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. [Figure 17-52](#) shows the waveforms generated by the setup shown in [Figure 17-51](#); note that only three waveforms are shown, although there are four stages.

**Figure 17-51. Control of Four Buck Stages. (Note:  $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$ )**

NOTE:  $\Phi = X$  indicates value in phase register is a "don't care"

**Figure 17-52. Buck Waveforms for Figure 17-51 (Note: Only three bucks shown here)**

**Table 17-35. EPWM1 Initialization for Figure 17-52**

| Register | Bit       | Value           | Comments                   |
|----------|-----------|-----------------|----------------------------|
| TBPRD    | TBPRD     | 1200 (4B0h)     | Period = 1201 TBCLK counts |
| TBPHS    | TBPHS     | 0               | Clear Phase Register to 0  |
| TBCTL    | CTRMODE   | TB_UP           | Phase loading disabled     |
|          | PHSEN     | TB_DISABLE      |                            |
|          | PRDLD     | TB_SHADOW       |                            |
|          | SYNCOSEL  | TB_SYNC_DISABLE |                            |
| CMPCTL   | SHDWAMODE | CC_SHADOW       | Load on CTR = 0            |
|          | SHDWBMODE | CC_SHADOW       |                            |
|          | LOADAMODE | CC_CTR_ZERO     |                            |
|          | LOADBMODE | CC_CTR_ZERO     |                            |

**Example 17-3. Configuration for Example in [Figure 17-52](#)**

```
// Run Time (Note: Example execution of one run-time instance)
//=====
EPwm1Regs.CMPA.half.CMPA = 700;           // adjust duty for output EPWM1A
EPwm2Regs.CMPA.half.CMPA = 700;           // adjust duty for output EPWM2A
EPwm3Regs.CMPA.half.CMPA = 500;           // adjust duty for output EPWM3A
```

### 17.3.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. [Figure 17-53](#) shows such a configuration; [Figure 17-54](#) shows the waveforms generated by the configuration.

**Figure 17-53. Control of Four Buck Stages. (Note:  $F_{P\text{WM}2} = N \times F_{P\text{WM}1}$ )**

**Figure 17-54. Buck Waveforms for Figure 17-53 (Note:  $F_{PWM2} = F_{PWM1}$ )**

|          | CBD       | AQ_CLEAR    |                            |

**Example 17-4. Code Snippet for Configuration in Figure 17-53**

```
// Run Time (Note: Example execution of one run-time instance)
//=====
EPwm1Regs.CMPA.half.CMPA = 400;      // adjust duty for output EPWM1A
EPwm1Regs.CMPB = 200;                // adjust duty for output EPWM1B
EPwm2Regs.CMPA.half.CMPA = 500;      // adjust duty for output EPWM2A
EPwm2Regs.CMPB = 300;                // adjust duty for output EPWM2B
```

### 17.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 17-55 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 17-56 shows the waveforms generated by the configuration shown in Figure 17-55.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

**Figure 17-55. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ )**

**Figure 17-56. Half-H Bridge Waveforms for Figure 17-55 (Note:  $F_{PWM2} = F_{PWM1}$ )**

EPwm1Regs.CMPB = 200;           // adjust duty for output EPWM1B
EPwm2Regs.CMPA.half.CMPA = 500; // adjust duty for output EPWM2A
EPwm2Regs.CMPB = 250;           // adjust duty for output EPWM2B
```

### 17.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 17-57 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 17-57), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

**Figure 17-57. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control**

**Example 17-6. Code Snippet for Configuration in Figure 17-57**

```
// Run Time (Note: Example execution of one run-time instance)
//=====
EPwm1Regs.CMPA.half.CMPA = 500; // adjust duty for output EPWM1A
EPwm2Regs.CMPA.half.CMPA = 600; // adjust duty for output EPWM2A
EPwm3Regs.CMPA.half.CMPA = 700; // adjust duty for output EPWM3A
```

### 17.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCNT register. To illustrate this concept, [Figure 17-59](#) shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

**Figure 17-59. Configuring Two PWM Modules for Phase Control**

[Figure 17-60](#) shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 ( $200/600 \times 360^\circ = 120^\circ$ ). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCNT register so the slave time-base is always leading the master's time-base by 120°.

**Figure 17-60. Timing Waveforms Associated With Phase Control Between 2 Modules**

### 17.3.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in [Figure 17-61](#). This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be  $F = 120^\circ$ . This is achieved by setting the slave TBPMS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPMS (slave 2) = 200 and TBPMS (slave 3) = 400. Both slave modules are synchronized to the master 1 module.

This concept can be extended to four or more phases, by setting the TBPMS values appropriately. The following formula gives the TBPMS values for N phases:

$$\text{TBPMS}(N,M) = (\text{TBPRD}/N) \times (M - 1)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N = 3), TBPRD = 600,

$$\text{TBPMS}(3,2) = (600/3) \times (2 - 1) = 200 \times 1 = 200 \text{ (Phase value for Slave module 2)}$$

$$\text{TBPMS}(3,3) = (600/3) \times (3 - 1) = 200 \times 2 = 400 \text{ (Phase value for Slave module 3)}$$

[Figure 17-62](#) shows the waveforms for the configuration in [Figure 17-61](#).

**Example 17-7. Code Snippet for Configuration in Figure 17-61**

```
// Run Time (Note: Example execution of one run-time instance)
//=====
EPwm1Regs.CMPA.half.CMPA = 285;      // adjust duty for output EPWM1A
EPwm2Regs.CMPA.half.CMPA = 285;      // adjust duty for output EPWM2A
EPwm3Regs.CMPA.half.CMPA = 285;      // adjust duty for output EPWM3A
```

### 17.3.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in Figure 17-63 assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends itself to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge*. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. Figure 17-64 shows a master/slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave's phase register (TBPHS). The master's phase register is not used and therefore can be initialized to zero.

**Figure 17-63. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ )**

| DBFED    | DBFED     | 30             | FED = 30 TBCLKs            |
|          | DBRED     | 40             | RED = 40 TBCLKs            |

**Example 17-8. Code Snippet for Configuration in Figure 17-63**

```
// Run Time (Note: Example execution of one run-time instance)
//=====
EPwm2Regs.TBPHS = 1200-300;           // Set Phase reg to 300/1200 * 360 = 90 deg
EPwm1Regs.DBFED = FED1_NewValue;      // Update ZVS transition interval
EPwm1Regs.DBRED = RED1_NewValue;      // Update ZVS transition interval
EPwm2Regs.DBFED = FED2_NewValue;      // Update ZVS transition interval
EPwm2Regs.DBRED = RED2_NewValue;      // Update ZVS transition interval
```

## 17.4 Registers

This section includes the registers for the submodules.

**Table 17-50. Submodule Registers**

| Submodule                               | Section                        |
|-----------------------------------------|--------------------------------|
| Time-Base Submodule Registers           | <a href="#">Section 17.4.1</a> |
| Counter-Compare Submodule Registers     | <a href="#">Section 17.4.2</a> |
| Action-Qualifier Submodule Registers    | <a href="#">Section 17.4.3</a> |
| Dead-Band Generator Submodule Registers | <a href="#">Section 17.4.4</a> |
| PWM-Chopper Submodule Registers         | <a href="#">Section 17.4.5</a> |
| Trip-Zone Submodule Registers           | <a href="#">Section 17.4.6</a> |
| Event-Trigger Submodule Registers       | <a href="#">Section 17.4.7</a> |
| High-Resolution PWM Registers           | <a href="#">Section 17.4.8</a> |

### 17.4.1 Time-Base Submodule Registers

[Table 17-51](#) lists the memory-mapped registers for the time-base submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in [Table 17-51](#) should be considered as reserved locations and the register contents should not be modified.

**Table 17-51. Time-Base Submodule Registers**

| Offset | Acronym | Register Description                                    | Section                          |
|--------|---------|---------------------------------------------------------|----------------------------------|
| 0h     | TBCTL   | Time-Base Control Register                              | <a href="#">Section 17.4.1.1</a> |
| 2h     | TBSTS   | Time-Base Status Register                               | <a href="#">Section 17.4.1.2</a> |
| 4h     | TBPHSHR | Time-Base Phase High-Resolution Register <sup>(1)</sup> | <a href="#">Section 17.4.8.1</a> |
| 6h     | TBPHS   | Time-Base Phase Register                                | <a href="#">Section 17.4.1.3</a> |
| 8h     | TBCNT   | Time-Base Counter Register                              | <a href="#">Section 17.4.1.4</a> |
| Ah     | TBPRD   | Time-Base Period Register                               | <a href="#">Section 17.4.1.5</a> |

<sup>(1)</sup> This register is only available on ePWM instances that include the high-resolution PWM (HRPWM) extension; otherwise, this location is reserved. See your device-specific data manual to determine which instances include the HRPWM.

#### 17.4.1.1 Time-Base Control Register (TBCTL)

The time-base control register (TBCTL) is shown in [Figure 17-65](#) and described in [Table 17-52](#).

**Figure 17-65. Time-Base Control Register (TBCTL)**

|            |  |         |  |           |  |        |  |       |  |           |  |         |  |   |  |
|------------|--|---------|--|-----------|--|--------|--|-------|--|-----------|--|---------|--|---|--|
| 15         |  | 14      |  | 13        |  | 12     |  | 10    |  | 9         |  | 8       |  |   |  |
| FREE, SOFT |  |         |  | PHSDIR    |  | CLKDIV |  |       |  | HSPCLKDIV |  |         |  |   |  |
| R/W-0      |  |         |  | R/W-0     |  | R/W-0  |  |       |  | R/W-0     |  |         |  |   |  |

**Table 17-52. Time-Base Control Register (TBCTL) Field Descriptions (continued)**

| Bit | Field   | Value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|---------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | PRDLD   | 0<br>1                      | Active Period Register Load From Shadow Register Select<br>The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCNT, is equal to zero.<br>A write or read to the TBPRD register accesses the shadow register.<br>Load the TBPRD register immediately without using a shadow register.<br>A write or read to the TBPRD register directly accesses the active register.                                                                                 |
| 2   | PHSEN   | 0<br>1                      | Counter Register Load From Phase Register Enable<br>Do not load the time-base counter (TBCNT) from the time-base phase register (TBPHS)<br>Load the time-base counter with the phase register when an EPWMxSYNCl input signal occurs or when a software synchronization is forced by the SWFSYNC bit.                                                                                                                                                                                         |
| 1-0 | CTRMODE | 0-3h<br>0<br>1h<br>2h<br>3h | Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change.<br>These bits set the time-base counter mode of operation as follows:<br>Up-count mode<br>Down-count mode<br>Up-down-count mode<br>Stop-freeze counter operation (default on reset) |

#### 17.4.1.2 Time-Base Status Register (TBSTS)

The time-base status register (TBSTS) is shown in [Figure 17-66](#) and described in [Table 17-53](#).

**Figure 17-66. Time-Base Status Register (TBSTS)**

|          |  |   |         |         |        |
|----------|--|---|---------|---------|--------|
| 15       |  | 3 | 2       | 1       | 0      |
| Reserved |  |   | CTRMAX  | SYNCl   | CTRDlR |
| R-0      |  |   | R/W1C-0 | R/W1C-0 | R-1    |

LEGEND: R/W = Read/Write; R/W1C = Read/Write 1 to clear; -n = value after reset

**Table 17-53. Time-Base Status Register (TBSTS) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                     |
|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-3 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                        |
| 2    | CTRMAX   | 0<br>1 | Time-Base Counter Max Latched Status Bit<br>Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect.<br>Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.   |
| 1    | SYNCl    | 0<br>1 | Input Synchronization Latched Status Bit<br>Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred.<br>Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCl). Writing a 1 to this bit will clear the latched event. |
| 0    | CTRDlR   | 0<br>1 | Time-Base Counter Direction Status Bit. At reset, the counter is frozen; therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE].<br>Time-Base Counter is currently counting down.<br>Time-Base Counter is currently counting up.           |

#### 17.4.1.3 Time-Base Phase Register (TBPHS)

The time-base phase register (TBPHS) is shown in [Figure 17-67](#) and described in [Table 17-54](#).

**Figure 17-67. Time-Base Phase Register (TBPHS)**

|       |   |

| TBCNT |   |
| R/W-0 |   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 17-55. Time-Base Counter Register (TBCNT) Field Descriptions**

| Bits | Name  | Value   | Description                                                                                                                                                                                                                                                                                |
|------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TBCNT | 0-FFFFh | <p>Reading these bits gives the current time-base counter value.</p> <p>Writing to these bits sets the current time-base counter value. The update happens as soon as the write occurs; the write is NOT synchronized to the time-base clock (TBCLK) and the register is not shadowed.</p> |

#### 17.4.1.5 Time-Base Period Register (TBPRD)

The time-base period register (TBPRD) is shown in [Figure 17-69](#) and described in [Table 17-56](#).

### Figure 17-69. Time-Base Period Register (TBPRD)

LEGEND: R/W = Read/Write; -n = value after reset

**Table 17-56. Time-Base Period Register (TBPRD) Field Descriptions**

| Bits | Name  | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TBPRD | 0-FFFFh | <p>These bits determine the period of the time-base counter. This sets the PWM frequency.</p> <p>Shadowing of this register is enabled and disabled by the TBCTL[PRDL] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>• If TBCTL[PRDL] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero.</li> <li>• If TBCTL[PRDL] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>• The active and shadow registers share the same memory map address.</li> </ul> |

### 17.4.2 Counter-Compare Submodule Registers

Table 17-57 lists the memory-mapped registers for the counter-compare submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 17-57 should be considered as reserved locations and the register contents should not be modified.

### Table 17-57. Counter-Compare Submodule Registers

| Offset | Acronym | Register Description                                      | Section                          |

| 10h    | CMPAHR  | Counter-Compare A High-Resolution Register <sup>(1)</sup> | <a href="#">Section 17.4.8.2</a> |
| 12h    | CMPA    | Counter-Compare A Register                                | <a href="#">Section 17.4.2.2</a> |
| 14h    | CMPB    | Counter-Compare B Register                                | <a href="#">Section 17.4.2.3</a> |

<sup>(1)</sup> This register is only available on ePWM instances that include the high-resolution PWM (HRPWM) extension; otherwise, this location is reserved. See your device-specific data manual to determine which instances include the HRPWM.

#### 17.4.2.1 Counter-Compare Control Register (CMPCTL)

The counter-compare control register (CMPCTL) is shown in [Figure 17-70](#) and described in [Table 17-58](#).

**Figure 17-70. Counter-Compare Control Register (CMPCTL)**

|          |  |           |  |          |  |           |  |           |  |           |  |

**Table 17-59. Counter-Compare A Register (CMPA) Field Descriptions**

| Bits | Name | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CMPA | 0-FFFFh | <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>Do nothing; the event is ignored.</li> <li>Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.</li> <li>Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full.</li> <li>If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>In either mode, the active and shadow registers share the same memory map address.</li> </ul> |

### 17.4.2.3 Counter-Compare B Register (CMPB)

The counter-compare B register (CMPB) is shown in [Figure 17-72](#) and described in [Table 17-60](#).

**Figure 17-72. Counter-Compare B Register (CMPB)**

|------|------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CMPB | 0-FFFFh | <p>The value in the active CMPB register is continuously compared to the time-base counter (TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare B" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>Do nothing. event is ignored.</li> <li>Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register:</li> <li>Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full.</li> <li>If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>In either mode, the active and shadow registers share the same memory map address.</li> </ul> |

### 17.4.3 Action-Qualifier Submodule Registers

[Table 17-61](#) lists the memory-mapped registers for the action-qualifier submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in [Table 17-61](#) should be considered as reserved locations and the register contents should not be modified.

**Table 17-61. Action-Qualifier Submodule Registers**

| Offset | Acronym | Register Description                                | Section                          |

### 17.4.4 Dead-Band Generator Submodule Registers

[Table 17-66](#) lists the memory-mapped registers for the dead-band generator submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in [Table 17-66](#) should be considered as reserved locations and the register contents should not be modified.

**Table 17-66. Dead-Band Generator Submodule Registers**

| Offset | Acronym | Register Description                            | Section                          |
|--------|---------|-------------------------------------------------|----------------------------------|
| 1Eh    | DBCTL   | Dead-Band Generator Control Register            | <a href="#">Section 17.4.4.1</a> |
| 20h    | DBRED   | Dead-Band Generator Rising Edge Delay Register  | <a href="#">Section 17.4.4.2</a> |
| 22h    | DBFED   | Dead-Band Generator Falling Edge Delay Register | <a href="#">Section 17.4.4.3</a> |

### 17.4.4.1 Dead-Band Generator Control Register (DBCTL)

The dead-band generator control register (DBCTL) is shown in [Figure 17-77](#) and described in [Table 17-67](#).

**Figure 17-77. Dead-Band Generator Control Register (DBCTL)**

|          |   |   |   |   |   |         |        |          |

| 5-4  | IN_MODE  | 0-3h  | Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown in <a href="#">Figure 17-29</a> . This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms, the default is EPWMxA In is the source for both falling and rising-edge delays.<br><br>0 EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.<br>1h EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal.<br>EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal.<br>2h EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal.<br>EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal.<br>3h EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.                                                                                                                                                                                                                                                                                                                                        |
| 3-2  | POLSEL   | 0-3h  | Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch shown in <a href="#">Figure 17-29</a> . This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule.<br><br>The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter.<br><br>These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes.<br><br>0 Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default).<br>1h Active low complementary (ALC) mode. EPWMxA is inverted.<br>2h Active high complementary (AHC). EPWMxB is inverted.<br>3h Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1-0  | OUT_MODE | 0-3h  | Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in <a href="#">Figure 17-29</a> . This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay.<br><br>0 Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect.<br>1h Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule.<br>The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].<br>2h Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule.<br>The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE].<br>3h Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE]. |

### 17.4.4.2 Dead-Band Generator Rising Edge Delay Register (DBRED)

The dead-band generator rising edge delay register (DBRED) is shown in [Figure 17-78](#) and described in [Table 17-68](#).

**Figure 17-78. Dead-Band Generator Rising Edge Delay Register (DBRED)**

|          |    |   |       |
|----------|----|---|-------|

## 17.4.6 Trip-Zone Submodule Registers

Table 17-71 lists the memory-mapped registers for the trip-zone submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 17-71 should be considered as reserved locations and the register contents should not be modified.

**Table 17-71. Trip-Zone Submodule Registers**

| Offset | Acronym | Register Description                | Section                          |
|--------|---------|-------------------------------------|----------------------------------|
| 24h    | TZSEL   | Trip-Zone Select Register           | <a href="#">Section 17.4.6.1</a> |
| 28h    | TZCTL   | Trip-Zone Control Register          | <a href="#">Section 17.4.6.2</a> |
| 2Ah    | TZEINT  | Trip-Zone Enable Interrupt Register | <a href="#">Section 17.4.6.3</a> |
| 2Ch    | TZFLG   | Trip-Zone Flag Register             | <a href="#">Section 17.4.6.4</a> |
| 2Eh    | TZCLR   | Trip-Zone Clear Register            | <a href="#">Section 17.4.6.5</a> |
| 30h    | TZFRC   | Trip-Zone Force Register            | <a href="#">Section 17.4.6.6</a> |

### 17.4.6.1 Trip-Zone Select Register (TZSEL)

The trip-zone select register (TZSEL) is shown in Figure 17-81 and described in Table 17-72.

**Figure 17-81. Trip-Zone Select Register (TZSEL)**

|                               |   |       |                              |   |       |
|-------------------------------|---|-------|------------------------------|---|-------|
| 15                            | 9 | 8     | 7                            | 1 | 0     |
| Reserved/OSHTn <sup>(1)</sup> |   | OSHT1 | Reserved/CBCn <sup>(1)</sup> |   | CBC1  |
| R/W-0                         |   | R/W-0 | R/W-0                        |   | R/W-0 |

LEGEND: R/W = Read/Write; -n = value after reset

<sup>(1)</sup> Number of register bits depends on how many trip-zone pins are available in the device. See your device-specific data manual.

**Table 17-72. Trip-Zone Submodule Select Register (TZSEL) Field Descriptions**

| Bits | Name  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-8 | OSHTn |       | Trip-zone $n$ ( $\overline{TZn}$ ) select. One-Shot (OSHT) trip-zone enable/disable. When any of the enabled pins go low, a one-shot trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register ( <a href="#">Section 17.4.6.2</a> ) is taken on the EPWMxA and EPWMxB outputs. The one-shot trip condition remains latched until you clear the condition via the TZCLR register ( <a href="#">Section 17.4.6.5</a> ). |
|      |       | 0     | Disable $\overline{TZn}$ as a one-shot trip source for this ePWM module.                                                                                                                                                                                                                                                                                                                                                                                            |
|      |       | 1     | Enable $\overline{TZn}$ as a one-shot trip source for this ePWM module.                                                                                                                                                                                                                                                                                                                                                                                             |
| 7-0  | CBCn  |       | Trip-zone $n$ ( $\overline{TZn}$ ) select. Cycle-by-Cycle (CBC) trip-zone enable/disable. When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register ( <a href="#">Section 17.4.6.2</a> ) is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero.                           |
|      |       | 0     | Disable $\overline{TZn}$ as a CBC trip source for this ePWM module.                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |       | 1     | Enable $\overline{TZn}$ as a CBC trip source for this ePWM module.                                                                                                                                                                                                                                                                                                                                                                                                  |

### 17.4.6.2 Trip-Zone Control Register (TZCTL)

The trip-zone control register (TZCTL) is shown in [Figure 17-82](#) and described in [Table 17-73](#).

**Figure 17-82. Trip-Zone Control Register (TZCTL)**

|          |  |   |   |       |       |   |
|----------|--|---|---|-------|-------|---|

## 17.4.7 Event-Trigger Submodule Registers

Table 17-78 lists the memory-mapped registers for the event-trigger submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 17-78 should be considered as reserved locations and the register contents should not be modified.

**Table 17-78. Event-Trigger Submodule Registers**

| Offset | Acronym | Register Description             | Section                          |
|--------|---------|----------------------------------|----------------------------------|
| 32h    | ETSEL   | Event-Trigger Selection Register | <a href="#">Section 17.4.7.1</a> |

### 17.4.7.1 Event-Trigger Selection Register (ETSEL)

The event-trigger selection register (ETSEL) is shown in Figure 17-87 and described in Table 17-79.

**Figure 17-87. Event-Trigger Selection Register (ETSEL)**

|          |   |       |        |   |

|      |          | 3h    | 3 events have occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 1-0  | INTPRD   | 0-3h  | ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared.<br><br>Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear.<br><br>Writing a INTPRD value that is less than the current counter value will result in an undefined state.<br><br>If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. |
|      |          | 0     | Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|      |          | 1h    | Generate an interrupt on the first event INTCNT = 01 (first event)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|      |          | 2h    | Generate interrupt on ETPS[INTCNT] = 1,0 (second event)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|      |          | 3h    | Generate interrupt on ETPS[INTCNT] = 1,1 (third event)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 17.4.7.3 Event-Trigger Flag Register (ETFLG)

The event-trigger flag register (ETFLG) is shown in [Figure 17-89](#) and described in [Table 17-81](#).

**Figure 17-89. Event-Trigger Flag Register (ETFLG)**

|          |  |   |     |

| R-0      |  |   | R-0 |

LEGEND: R = Read only; -n = value after reset

**Table 17-81. Event-Trigger Flag Register (ETFLG) Field Descriptions**

| Bits | Name     | Value | Description                                                                                                                                                                                                                                                                                                                                           |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-1 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                              |
| 0    | INT      | 0     | Latched ePWM Interrupt (EPWMx_INT) Status Flag<br>Indicates no event occurred                                                                                                                                                                                                                                                                         |
|      |          | 1     | Indicates that an ePWMx interrupt (EPWMx_INT) was generated. No further interrupts will be generated until the flag bit is cleared. Up to one interrupt can be pending while the ETFLG[INT] bit is still set. If an interrupt is pending, it will not be generated until after the ETFLG[INT] bit is cleared. Refer to <a href="#">Figure 17-42</a> . |

### 17.4.7.4 Event-Trigger Clear Register (ETCLR)

The event-trigger clear register (ETCLR) is shown in [Figure 17-90](#) and described in [Table 17-82](#).

**Figure 17-90. Event-Trigger Clear Register (ETCLR)**

|          |  |   |     |
|----------|--|---|-----|
| 15       |  | 1 | 0   |
| Reserved |  |   | INT |
| R-0      |  |   | R-0 |

LEGEND: R = Read only; -n = value after reset

**Table 17-82. Event-Trigger Clear Register (ETCLR) Field Descriptions**

| Bits | Name     | Value | Description                                                                                    |
|------|----------|-------|------------------------------------------------------------------------------------------------|
| 15-1 | Reserved | 0     | Reserved                                                                                       |
| 0    | INT      | 0     | ePWM Interrupt (EPWMx_INT) Flag Clear Bit<br>Writing a 0 has no effect. Always reads back a 0. |
|      |          | 1     | Clears the ETFLG[INT] flag bit and enable further interrupts pulses to be generated.           |

### 17.4.7.5 Event-Trigger Force Register (ETFRC)

The event-trigger force register (ETFRC) is shown in [Figure 17-91](#) and described in [Table 17-83](#).

**Figure 17-91. Event-Trigger Force Register (ETFRC)**

|          |  |   |     |
|----------|--|---|-----|
| 15       |  | 1 | 0   |
| Reserved |  |   | INT |
| R-0      |  |   | R-0 |

LEGEND: R = Read only; -n = value after reset

**Table 17-83. Event-Trigger Force Register (ETFRC) Field Descriptions**

| Bits | Name     | Value | Description                                                                                                                                 |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 15-1 | Reserved | 0     | Reserved                                                                                                                                    |
| 0    | INT      | 0     | INT Force Bit. The interrupt will only be generated if the event is enabled in the ETSEL register. The INT flag bit will be set regardless. |
|      |          | 0     | Writing 0 to this bit will be ignored. Always reads back a 0.                                                                               |
|      |          | 1     | Generates an interrupt on $\overline{\text{EPWMxINT}}$ and set the INT flag bit. This bit is used for test purposes.                        |

### 17.4.8 High-Resolution PWM Submodule Registers

[Table 17-84](#) lists the memory-mapped registers for the high-resolution PWM submodule. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in [Table 17-84](#) should be considered as reserved locations and the register contents should not be modified.

**Table 17-84. High-Resolution PWM Submodule Registers**

| Offset | Acronym | Register Description                       | Section                          |
|--------|---------|--------------------------------------------|----------------------------------|
| 4h     | TBPHSHR | Time-Base Phase High-Resolution Register   | <a href="#">Section 17.4.8.1</a> |
| 10h    | CMPAHR  | Counter-Compare A High-Resolution Register | <a href="#">Section 17.4.8.2</a> |
| 1040h  | HRCNFG  | HRPWM Configuration Register               | <a href="#">Section 17.4.8.3</a> |

### 17.4.8.1 Time-Base Phase High-Resolution Register (TBPHSHR)

The time-base phase high-resolution register (TBPHSHR) is shown in [Figure 17-92](#) and described in [Table 17-85](#).

**Figure 17-92. Time-Base Phase High-Resolution Register (TBPHSHR)**

|        |   |   |          |
|--------|---|---|----------|
| 15     | 8 | 7 | 0        |
| TBPHSH |   |   | Reserved |
| R/W-0  |   |   | R/W-0    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 17-85. Time-Base Phase High-Resolution Register (TBPHSHR) Field Descriptions**

| Bit  | Field    | Value | Description                          |
|------|----------|-------|--------------------------------------|

## ***Enhanced Direct Memory Access (EDMA3) Controller***

The enhanced direct memory access (EDMA3) controller is a high-performance, multichannel, multithreaded DMA controller that allows you to program a wide variety of transfer geometries and transfer sequences. This chapter describes the features and operations of the EDMA3 controller.

[Section 18.1](#) provides a brief overview, features, and terminology. [Section 18.2](#) provides the architecture details and common operations of the EDMA3 channel controllers (EDMA3\_m\_CC0) and the EDMA3 transfer controllers (EDMA3\_m\_TCn). [Section 18.3](#) contains examples and common usage scenarios. [Section 18.4](#) describes the memory-mapped registers associated with the EDMA3 controller.

## 18.1 Introduction

### 18.1.1 Overview

The enhanced direct memory access (EDMA3) controller's primary purpose is to service user-programmed data transfers between two memory-mapped slave endpoints on the device. Typical usage includes, but is not limited to:

- Servicing software driven paging transfers (for example, from external memory to internal device memory)
- Servicing event driven peripherals, such as a serial port
- Performing sorting or subframe extraction of various data structures
- Offloading data transfers from the main device CPU(s) or DSP(s) (See your device-specific data manual for specific peripherals that are accessible via EDMA3. See the section on SCR connectivity in your device-specific data manual for EDMA3 connectivity.)

The EDMA3 controller consists of two principal blocks:

- EDMA3 channel controller: (EDMA3\_m\_CC0)
- EDMA3 transfer controller: (EDMA3\_m\_TCn)

The EDMA3 channel controller serves as the user interface for the EDMA3 controller. The EDMA3CC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA3CC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TR) to the EDMA3 transfer controller.

The EDMA3 transfer controllers are responsible for data movement. The transfer request packets (TRP) submitted by the EDMA3CC contains the transfer context, based on which the transfer controller issues read/write commands to the source and destination addresses programmed for a given transfer.

### 18.1.2 Features

The EDMA3 channel controller (EDMA3CC) has the following features:

- Fully orthogonal transfer description
  - 3 transfer dimensions
  - A-synchronized transfers: 1 dimension serviced per event
  - AB-synchronized transfers: 2 dimensions serviced per event
  - Independent indexes on source and destination
  - Chaining feature allows 3-D transfer based on single event
- Flexible transfer definition
  - Increment or constant addressing modes
  - Linking mechanism allows automatic PaRAM set update. Useful for ping-pong type transfers, auto-reload transfers.
  - Chaining allows multiple transfers to execute with a single event
- Interrupt generation for:
  - Transfer completion
  - Error conditions (illegal addresses, illegal modes, exceeding queue threshold)
- Debug visibility
  - Queue watermarking
  - Error and status recording to facilitate debug
  - Missed event detection

- EDMA3\_0\_CC0:
  - 32 DMA channels
  - 8 QDMA channels
  - 128 parameter RAM (PaRAM) entries
  - 2 event queues
  - 4 shadow regions
  - 2 transfer controllers (EDMA3\_0\_TC0 and EDMA3\_0\_TC1)
  - 5 interrupts:
    - EDMA3\_0\_CC0\_INT0
    - EDMA3\_0\_CC0\_INT1
    - EDMA3\_0\_CC0\_INT2
    - EDMA3\_0\_CC0\_INT3
    - EDMA3\_0\_CC0\_ERRINT
- EDMA3\_1\_CC0:
  - 32 DMA channels
  - 8 QDMA channels
  - 128 parameter RAM (PaRAM) entries
  - 1 event queue
  - 4 shadow regions
  - 1 transfer controller (EDMA3\_1\_TC0)
  - 5 interrupts:
    - EDMA3\_1\_CC0\_INT0
    - EDMA3\_1\_CC0\_INT1
    - EDMA3\_1\_CC0\_INT2
    - EDMA3\_1\_CC0\_INT3
    - EDMA3\_1\_CC0\_ERRINT

The EDMA3 transfer controller (EDMA3TC) has the following features:

- Supports 2-dimensional transfers with independent indexes on source and destination (EDMA3CC manages the 3rd dimension)
- More than one transfer controller allows concurrent transfers
- Programmable priority level for each transfer controller relative to each other and other masters in the system.
- Support for increment or constant addressing mode transfers
- Error conditions with interrupt support
- Supports more than one in-flight transfer requests
- Debug/status visibility
- 64-bit wide read and write ports
- Little-endian mode
- EDMA3\_0\_TC0:
  - FIFIOSIZE = 128 bytes
  - BUSWIDTH (Read/Write Controllers) = 8 byte (64 bits)
  - DSTREGDEPTH = 4
  - DBS (default) = 16 bytes. The default burst size (DBS) is programmable, and can be configured for 16-, 32-, or 64-bytes burst size. See the Chip Configuration 0 Register (CFGCHIP0) in the *System Configuration (SYSCFG) Module* chapter for details to change the default burst size value.
  - Error interrupt: EDMA3\_0\_TC0\_ERRINT
  - EDMA3 channel controller used: EDMA3\_0\_CC0
- EDMA3\_0\_TC1:
  - FIFIOSIZE = 128 bytes
  - BUSWIDTH (Read/Write Controllers) = 8 byte (64 bits)
  - DSTREGDEPTH = 4
  - DBS (default) = 16 bytes. The default burst size (DBS) is programmable, and can be configured for 16-, 32-, or 64-bytes burst size. See the Chip Configuration 0 Register (CFGCHIP0) in the *System Configuration (SYSCFG) Module* chapter for details to change the default burst size value.
  - Error interrupt: EDMA3\_0\_TC1\_ERRINT
  - EDMA3 channel controller used: EDMA3\_0\_CC0
- EDMA3\_1\_TC0:
  - FIFIOSIZE = 256 bytes
  - BUSWIDTH (Read/Write Controllers) = 8 byte (64 bits)
  - DSTREGDEPTH = 4
  - DBS (default) = 16 bytes. The default burst size (DBS) is programmable, and can be configured for 16-, 32-, or 64-bytes burst size. See the Chip Configuration 1 Register (CFGCHIP1) in the *System Configuration (SYSCFG) Module* chapter for details to change the default burst size value.
  - Error interrupt: EDMA3\_1\_TC0\_ERRINT
  - EDMA3 channel controller used: EDMA3\_1\_CC0

### 18.1.3 Functional Block Diagram

Figure 18-1 shows a block diagram of the EDMA3 controller.

Figure 18-1. EDMA3 Controller Block Diagram

### 18.1.4 Terminology Used in This Document

The following are some terms used in this chapter.

| Term                         | Meaning                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A-synchronized transfer      | A transfer type where 1 dimension is serviced per synchronization event.                                                                                                            |
| AB-synchronized transfer     | A transfer type where 2 dimensions are serviced per synchronization event.                                                                                                          |
| Chaining                     | A trigger mechanism in which a transfer can be initiated at the completion of another transfer or subtransfer.                                                                      |
| CPU(s)                       | The main processing engine or engines on a device. Typically a DSP or general-purpose processor. (See your device-specific data manual to learn more about the CPU on your system.) |
| DMA channel                  | A channel that can be triggered by external, manual, and chained events. All DMA channels exist in the EDMA3CC.                                                                     |
| Dummy set or Dummy PaRAM set | A PaRAM set for which at least one of the count fields is equal to 0 and at least one of the count fields is nonzero. A null PaRAM set has all the count set fields cleared.        |

| Term                                             | Meaning                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dummy transfer                                   | A dummy set results in the EDMA3CC performing a dummy transfer. This is not an error condition. A null set results in an error condition.                                                                                                                                                                                                              |
| EDMA3 channel controller (EDMA3CC)               | The user-programmable portion of the EDMA3. The EDMA3CC contains the parameter RAM (PaRAM) , event processing logic, DMA/QDMA channels, event queues, etc. The EDMA3CC services events (external, manual, chained, QDMA) and is responsible for submitting transfer requests to the transfer controllers (EDMA3TC), which perform the actual transfer. |
| EDMA3 programmer                                 | Any entity on the chip that has read/write access to the EDMA3 registers and can program an EDMA3 transfer.                                                                                                                                                                                                                                            |
| EDMA3 transfer controller(s) (EDMA3TC)           | Transfer controllers are the transfer engine for the EDMA3. Performs the read/writes as dictated by the transfer requests submitted by the EDMA3CC.                                                                                                                                                                                                    |
| Enhanced direct memory access (EDMA3) controller | Consists of the EDMA3 channel controller (EDMA3CC) and EDMA3 transfer controller(s) (EDMA3TC). Is referred to as EDMA3 in this document.                                                                                                                                                                                                               |
| Link parameter set                               | A PaRAM set that is used for linking.                                                                                                                                                                                                                                                                                                                  |
| Linking                                          | The mechanism of reloading a PaRAM set with new transfer characteristics on completion of the current transfer.                                                                                                                                                                                                                                        |
| Memory-mapped slave                              | All on-chip memories, off-chip memories, and slave peripherals. These typically rely on the EDMA3 (or other master peripheral) to perform transfers to and from them.                                                                                                                                                                                  |
| Master peripherals                               | All peripherals that are capable of initiating read and write transfers to the peripherals system and may not solely rely on the EDMA3 for their data transfers.                                                                                                                                                                                       |
| Null set or Null PaRAM set                       | A PaRAM set that has all count fields cleared (except for the link field). A dummy PaRAM set has at least one of the count fields nonzero.                                                                                                                                                                                                             |
| Null transfer                                    | A trigger event for a null PaRAM set results in the EDMA3CC performing a null transfer. This is an error condition. A dummy transfer is not an error condition.                                                                                                                                                                                        |
| QDMA channel                                     | One of the 8 channels that can be triggered when writing to the trigger word (TRWORD) of a PaRAM set. All QDMA channels exist in the EDMA3CC.                                                                                                                                                                                                          |
| Parameter RAM (PaRAM)                            | Programmable RAM that stores PaRAM sets used by DMA channels, QDMA channels, and linking.                                                                                                                                                                                                                                                              |
| Parameter RAM (PaRAM) set                        | A 32-byte EDMA3 channel transfer definition. Each parameter set consists of 8 words (4-bytes each), which store the context for a DMA/QDMA/link transfer. A PaRAM set includes source address, destination address, counts, indexes, options, etc.                                                                                                     |
| Parameter RAM (PaRAM) set entry                  | One of the 4-byte components of the parameter set.                                                                                                                                                                                                                                                                                                     |
| Slave end points                                 | All on-chip memories, off-chip memories, and slave peripherals. These rely on the EDMA3 to perform transfers to and from them.                                                                                                                                                                                                                         |
| Transfer request (TR)                            | A command for data movement that is issued from the EDMA3CC to the EDMA3TC. A TR includes source and destination addresses, counts, indexes, options, etc.                                                                                                                                                                                             |
| Trigger event                                    | Action that causes the EDMA3CC to service the PaRAM set and submit a transfer request to the EDMA3TC. Trigger events for DMA channels include manual triggered (CPU triggered), external event triggered, and chain triggered. Trigger events for QDMA channels include autotriggered and link triggered.                                              |
| Trigger word                                     | For QDMA channels, the trigger word specifies the PaRAM set entry that when written results in a QDMA trigger event. The trigger word is programmed via the QDMA channel <i>n</i> mapping register (QCHMAP <sub><i>n</i></sub> ) and can point to any PaRAM set entry.                                                                                 |
| TR synchronization (sync) event                  | See Trigger event.                                                                                                                                                                                                                                                                                                                                     |

## 18.2 Architecture

This section discusses the architecture of the EDMA3 controller.

### 18.2.1 Functional Overview

This section provides an overview of the EDMA3 channel controller (EDMA3CC) and EDMA3 transfer controller (EDMA3TC).

#### 18.2.1.1 EDMA3 Channel Controller (EDMA3CC)

[Figure 18-2](#) shows a functional block diagram of the EDMA3 channel controller (EDMA3CC).

The main blocks of the EDMA3CC are:

- **DMA/QDMA Channel Logic:** This block consists of logic that captures external system or peripheral events that can be used to initiate event triggered transfers, it also includes registers that allow configuring the DMA/QDMA channels (queue mapping, PaRAM entry mapping). It includes all the registers for different trigger type (manual, external events, chained and auto triggered) for enabling/disabling events, and monitor event status.
- **Parameter RAM (PaRAM):** Maintains parameter set entries for channel and reload parameter sets. The PaRAM needs to be written with the transfer context for the desired channels and link parameter sets.
- **Event queues:** These form the interface between the event detection logic and the transfer request submission logic.
- **Transfer Request Submission Logic:** This logic processes PaRAM sets based on a trigger event submitted to the event queue and submits a transfer request (TR) to the transfer controller associated with the event queue.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA3 transfer controller (EDMA3TC) and/or slave peripherals. Completion of transfers can optionally be used to chain trigger new transfers or to assert interrupts. The logic includes the interrupt processing registers for enabling/disabling interrupt (to be sent to the CPU), interrupt status/clearing registers.

Additionally there are:

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions, which can be owned by unique EDMA programmers (a use model for hetero/multi core devices) or by unique tasks/threads (a use model for single core devices).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, channel controller status (what logic within the CC is active), and missed event status.

The EDMA3CC includes two channel types: DMA channels and QDMA channels.

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and QDMA channel is how the transfers are triggered by the system. See [Section 18.2.4](#).

A trigger event is needed to initiate a transfer. For DMA channels, a trigger event may be due to an external event, manual write to the event set register, or chained event. QDMA channels are autotriggered when a write is performed to the user-programmed trigger word. All such trigger events are logged into appropriate registers upon recognition. See DMA channel registers ([Section 18.4.2.5](#)) and QDMA channel registers ([Section 18.4.2.7](#)).

Once a trigger event is recognized, the event type/channel is queued in the appropriate EDMA3CC event queue. The assignment of each DMA/QDMA channel to event queue is programmable. Each queue is 16 deep, so up to 16 events may be queued (on a single queue) in the EDMA3CC at an instant in time. Additional pending events mapped to a full queue are queued when event queue space becomes available. See [Section 18.2.10](#).

If events on different channels are detected simultaneously, the events are queued based on fixed priority arbitration scheme with the DMA channels being higher priority than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

**Figure 18-2. EDMA3 Channel Controller (EDMA3CC) Block Diagram**

Each event in the event queue is processed in the order it was queued. On reaching the head of the queue, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMA3TC (based on the event queue to EDMA3TC association, Q0 goes to TC0, and Q1 goes to TC1, etc.). For more details, see [Section 18.2.3](#).

The EDMA3TC receives the request and is responsible for data movement as specified in the transfer request packet (TRP) and other necessary tasks like buffering, ensuring transfers are carried out in an optimal fashion wherever possible. For more details on EDMA3TC, see [Section 18.2.1.2](#).

You may have chosen to receive an interrupt or chain to another channel on completion of the current transfer in which case the EDMA3TC signals completion to the EDMA3CC completion detection logic when the transfer is done. You can alternately choose to trigger completion when a TR leaves the EDMA3CC boundary rather than wait for all the data transfers to complete. Based on the setting of the EDMA3CC interrupt registers, the completion interrupt generation logic is responsible for generating EDMA3CC completion interrupts to the CPU. For more details, see [Section 18.2.5](#).

Additionally, the EDMA3CC also has an error detection logic, which causes error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more details on error interrupts, see [Section 18.2.9.4](#).

### 18.2.1.2 EDMA3 Transfer Controller (EDMA3TC)

Figure 18-3 shows a functional block diagram of the EDMA3 transfer controller (EDMA3TC).

The main blocks of the EDMA3TC are:

- DMA program register set: The DMA program register set stores the transfer requests received from the EDMA3 channel controller (EDMA3CC).
- DMA source active register set: The DMA source active register set stores the context for the DMA transfer request currently in progress in the read controller.
- Read controller: The read controller issues read commands to the source address.
- Destination FIFO register set: The destination (Dst) FIFO register set stores the context for the DMA transfer request(s) currently in progress or pending in the write controller.
- Write controller: The write controller issues write commands/write data to the destination address.
- Data FIFO: The data FIFO holds temporary in-flight data. The source peripheral's read data is stored in the data FIFO and subsequently written to the destination peripheral/end point by the write controller.
- Completion interface: The completion interface sends completion codes to the EDMA3CC when a transfer completes, and is used for generating interrupts and chained events (see Section 18.2.5 for details on transfer completion reporting).

**Figure 18-3. EDMA3 Transfer Controller (EDMA3TC) Block Diagram**

When the EDMA3TC is idle and receives its first TR, the TR is received in the DMA program register set, where it transitions to the DMA source active set and the destination FIFO register set immediately. The source active register set tracks the commands for the source side of the transfers, and the destination FIFO register set tracks commands for the destination side of the transfer. The second TR (if pending from EDMA3CC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer (the transfer in the source active set) is completed. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the read data. The number of read commands issued depends on the TR transfer size. The TC write controller starts issuing write commands as soon as sufficient data is read in the data FIFO for the write controller to issue optimally sized write commands following the rules for command fragmentation and optimization. For details on command fragmentation and optimization, see Section 18.2.11.1.2.

The DSTREGDEPTH parameter (fixed for a given transfer controller) determines the number of entries in the Dst FIFO register set. The number of entries determines the amount of TR pipelining possible for a given TC. The write controller can manage the write context for the number of entries in the Dst FIFO register set. This allows the read controller to go ahead and issue read commands for the subsequent TRs while the Dst FIFO register set manages the write commands and data for the previous TR. In summary, if the DSTREGDEPTH is  $n$ , the read controller is able to process up to  $n$  TRs ahead of the write controller. However, the overall TR pipelining is also subject to the amount of free space in the data FIFO.

## 18.2.2 Types of EDMA3 Transfers

An EDMA3 transfer is always defined in terms of three dimensions. Figure 18-4 shows the three dimensions used by EDMA3 transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

**Figure 18-4. Definition of ACNT, BCNT, and CCNT**

### 18.2.2.1 A-Synchronized Transfers

In an A-synchronized transfer, each EDMA3 sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus,  $BCNT \times CCNT$  events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in Figure 18-5, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRCBIDX) or destination (DSTBIDX).

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 18-5, SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 18-5 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events ( $BCNT \times CCNT$ ) exhaust a PaRAM set. See Section 18.2.3.6 for details on parameter set updates.

**Figure 18-5. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)**

### 18.2.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA3 sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in [Figure 18-6](#). Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See [Section 18.2.3.6](#) for details on parameter set updates.

[Figure 18-6](#) shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of  $n$  (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

**Figure 18-6. AB-Synchronized Transfers (ACNT =  $n$ , BCNT = 4, CCNT = 3)**

**NOTE:** ABC-synchronized transfers are not directly supported. But can be logically achieved by chaining between multiple AB-synchronized transfers.

### 18.2.3 Parameter RAM (PaRAM)

The EDMA3 controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table within the EDMA3CC, referred to as PaRAM. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight 4-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc. See your device-specific data manual for the addresses of the PaRAM set entries.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and autoreloading (linking). The first  $n$  PaRAM sets are directly mapped to the DMA channels (where  $n$  is the number of DMA channels supported in the EDMA3CC for a specific device). The remaining PaRAM sets can be used for link entries or associated with QDMA channels. Additionally if the DMA channels are not used, the PaRAM sets associated with the unused DMA channels can also be used for link entries or QDMA channels.

**NOTE:** By default, QDMA channels are mapped to PaRAM set 0. These should be remapped before use, see [Section 18.2.6.2](#).

#### 18.2.3.1 PaRAM Set

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in [Figure 18-7](#) and described in [Table 18-1](#). Each PaRAM set consists of 16-bit and 32-bit parameters.

**Figure 18-7. PaRAM Set**

Note:  $n$  is the number of PaRAM sets supported in the EDMA3CC for a specific device.

**Table 18-1. EDMA3 Channel Parameter Description**

| Offset Address (bytes) | Acronym | Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|---------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0h                     | OPT     | Channel Options             | Transfer Configuration Options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 4h                     | SRC     | Channel Source Address      | The byte address from which data is transferred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8h <sup>(1)</sup>      | ACNT    | Count for 1st Dimension     | Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.                                                                                                                                                                                                                                                                                                                                                                             |
|                        | BCNT    | Count for 2nd Dimension     | Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.                                                                                                                                                                                                                                                                                                                                                                                                |
| Ch                     | DST     | Channel Destination Address | The byte address to which data is transferred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 10h <sup>(1)</sup>     | SRCBIDX | Source BCNT Index           | Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.                                                                                                                                                                                                                                                                                                                                                                            |
|                        | DSTBIDX | Destination BCNT Index      | Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.                                                                                                                                                                                                                                                                                                                                                                       |
| 14h <sup>(1)</sup>     | LINK    | Link Address                | The PaRAM address containing the PaPARAM set to be linked (copied from) when the current PaPARAM set is exhausted. A value of FFFFh specifies a null link.                                                                                                                                                                                                                                                                                                                                                                   |
|                        | BCNTRL  | BCNT Reload                 | The count value used to reload BCNT when BCNT decrements to 0 (TR submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.                                                                                                                                                                                                                                                                                                                                                                 |
| 18h <sup>(1)</sup>     | SRCCIDX | Source CCNT Index           | Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.<br><br>A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame.<br><br>AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.                     |
