|                        | DSTCIDX | Destination CCNT index      | Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.<br><br>A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame.<br><br>AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame. |
| 1Ch                    | CCNT    | Count for 3rd Dimension     | Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.                                                                                                                                                                                                                                                                                                                                                                                  |
|                        | RSVD    | Reserved                    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

<sup>(1)</sup> If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor swaps addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

### 18.2.3.2 EDMA3 Channel Parameter Set Fields

#### 18.2.3.2.1 Channel Options Parameter (OPT)

The 32-bit channel options parameter (OPT) specifies the transfer configuration options. The channel options parameter (OPT) is described in [Section 18.4.1.1](#).

#### 18.2.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA3. For SAM in constant addressing mode, you must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See [Section 18.2.11.2](#) for additional details.

#### 18.2.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA3. For DAM in constant addressing mode, you must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See [Section 18.2.11.2](#) for additional details.

#### 18.2.3.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA3TC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer.

See [Section 18.2.3.5](#) and [Section 18.2.5.3](#) for details on dummy/null completion conditions.

#### 18.2.3.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer.

See [Section 18.2.3.5](#) and [Section 18.2.5.3](#) for details on dummy/null completion conditions.

#### 18.2.3.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer.

See [Section 18.2.3.5](#) and [Section 18.2.5.3](#) for details on dummy/null completion conditions.

#### 18.2.3.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA3CC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA3CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA3CC submits the BCNT in the TR and the EDMA3TC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

### 18.2.3.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

### 18.2.3.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See SRCBIDX ([Section 18.2.3.2.8](#)) for examples.

### 18.2.3.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 18-5](#)), while the current array in an AB-synchronized transfer is the first array in the frame ([Figure 18-6](#)).

### 18.2.3.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 18-5](#)), while the current array in a AB-synchronized transfer is the first array in the frame ([Figure 18-6](#)).

### 18.2.3.2.12 Link Address (LINK)

The EDMA3CC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking.

You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA3CC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if you make use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

You should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMA3CC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see [Section 18.2.5](#) for details on terminating a transfer.

### 18.2.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA3CC, the bit corresponding to the channel is set in the associated event missed register (EMR or QEMR). This bit remains set in the associated secondary event register (SER or QSER). *This implies that any future events on the same channel are ignored by the EDMA3CC and you are required to clear the bit in SER or QSER for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. See [Section 18.4.2.5.8](#) and [Section 18.4.2.2.1](#) for more information on the SER and EMR registers, respectively.

### 18.2.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA3CC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EMR or QEMR) and the secondary event register (SER or QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. See [Section 18.4.2.5.8](#) and [Section 18.4.2.2.1](#) for more information on the SER and EMR registers, respectively.

### 18.2.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA3CC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit ( $En$ ) in EMR to get set and the  $En$  bit in SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

[Table 18-2](#) summarizes the conditions and effects of null and dummy transfer requests.

**Table 18-2. Dummy and Null Transfer Request**

| Feature                                   | Null TR | Dummy TR |
|-------------------------------------------|---------|----------|
| EMR/QEMR is set                           | Yes     | No       |
| SER/QSER remains set                      | Yes     | No       |
| Link update (STATIC = 0 in OPT)           | Yes     | Yes      |
| QER is set                                | Yes     | Yes      |
| IPR and CER is set using early completion | Yes     | Yes      |

### 18.2.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA3CC is responsible for updating the PaRAM set in anticipation of the next trigger event. For nonfinal events, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See [Table 18-3](#) for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in [Section 18.2.3.7](#).

After the TR is read from the PaRAM (and is in process of being submitted to EDMA3TC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST
- AB-synchronized: CCNT, SRC, DST

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA3TC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in [Section 18.2.11](#). For A-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMA3TC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMA3TC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

[Table 18-3](#) shows the details of parameter updates that occur within EDMA3CC for A-synchronized and AB-synchronized transfers.

**Table 18-3. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaRAM Set)**

|                    | A-Synchronized Transfer |                          |                           | AB-Synchronized Transfer |            |                |
|--------------------|-------------------------|--------------------------|---------------------------|--------------------------|------------|----------------|
|                    | B-Update                | C-Update                 | Link Update               | B-Update                 | C-Update   | Link Update    |
| Condition:         | BCNT > 1                | BCNT == 1 &&<br>CCNT > 1 | BCNT == 1 &&<br>CCNT == 1 | N/A                      | CCNT > 1   | CCNT == 1      |
| SRC                | += SRCBIDX              | += SRCCIDX               | = Link.SRC                | in EDMA3TC               | += SRCCIDX | = Link.SRC     |
| DST                | += DSTBIDX              | += DSTCIDX               | = Link.DST                | in EDMA3TC               | += DSTCIDX | = Link.DST     |
| ACNT               | None                    | None                     | = Link.ACNT               | None                     | None       | = Link.ACNT    |
| BCNT               | --= 1                   | = BCNTRLD                | = Link.BCNT               | in EDMA3TC               | N/A        | = Link.BCNT    |
| CCNT               | None                    | --= 1                    | = Link.CCNT               | in EDMA3TC               | --=1       | = Link.CCNT    |
| SRCBIDX            | None                    | None                     | = Link.SRCBIDX            | in EDMA3TC               | None       | = Link.SRCBIDX |
| DSTBIDX            | None                    | None                     | = Link.DSTBIDX            | None                     | None       | = Link.DSTBIDX |
| SRCCIDX            | None                    | None                     | = Link.SRCBIDX            | in EDMA3TC               | None       | = Link.SRCBIDX |
| DSTCIDX            | None                    | None                     | = Link.DSTBIDX            | None                     | None       | = Link.DSTBIDX |
| LINK               | None                    | None                     | = Link.LINK               | None                     | None       | = Link.LINK    |
| BCNTRLD            | None                    | None                     | = Link.BCNTRLD            | None                     | None       | = Link.BCNTRLD |
| OPT <sup>(1)</sup> | None                    | None                     | = LINK.OPT                | None                     | None       | = LINK.OPT     |

<sup>(1)</sup> In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

**NOTE:** The EDMA3CC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. You should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

### 18.2.3.7 Linking Transfers

The EDMA3CC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers all with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field (of the current parameter set). Linking only occurs when the STATIC bit in OPT is cleared to 0.

---

**NOTE:** A transfer (DMA or QDMA) should always be linked to another useful transfer. If it is required to terminate a transfer, the transfer should be linked to a NULL set.

---

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA3 channel controller has submitted all the transfers associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh then the appropriate PaRAM location pointed to by LINK is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. The EDMA3CC reads the entire PaRAM set (8 words) from the PaRAM set specified by LINK and writes all 8 words to the PaRAM set associated with the current channel. [Figure 18-8](#) shows an example of a linked transfer.

Any PaRAM set in the PaRAM can be used as a link/reload parameter set; however, it is recommended that the PaRAM sets associated with peripheral synchronization events (see [Section 18.2.6](#)) should only be used for linking if the synchronization event isolated with the channel mapped to that PaRAM set is disabled.

If a PaRAM set location is mapped to a QDMA channel (by QCHMAP<sub>n</sub>), then copying the link PaRAM set onto the current QDMA channel PaRAM set is recognized as a trigger event and is latched in QER since a write to the trigger word was performed. This feature can be used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets.

Link-to-self transfers replicate the behavior of autoinitialization, which facilitates the use of circular buffering and repetitive transfers. After an EDMA3 channel exhausts its current PaRAM set, it reloads all the parameter set entries from another PaRAM set, which is initialized with values identical to the original PaRAM set. [Figure 18-9](#) shows an example of a linked-to-self transfer. In [Figure 18-9](#), parameter set 127 has the LINK field address pointing to the address of parameter set 127, that is, linked-to-self.

---

**NOTE:** If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed. The link updates performed internally by the EDMA3CC are atomic. This implies that when the EDMA3CC is updating a PaRAM set, accesses to PaRAM by other EDMA3 programmer's (for example, CPU configuration accesses) are not allowed. Also for QDMA, for example, if the first word of the PaRAM entry is defined as a trigger word, EDMA3CC logic assures that all 8 PaRAM words are updated before the new QDMA event can trigger the transfer for that PaRAM entry.

---

#### 18.2.3.7.1 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set to 1 (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bit). The EDMA3CC does not recognize errors here but the EDMA3TC asserts an error, if this is not true. See [Section 18.2.11.2](#).

---

**NOTE:** The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. On the C674x/OMAP-L1x processors, no peripherals, memory, or memory controller support constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM = 0) by appropriately programming the count and indices values.

---

#### 18.2.3.7.2 Element Size

The EDMA3 controller does not use the concept of element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if you have 16-bit audio data and 256 audio samples that needed to be transferred to a serial port, this can be done by programming the ACNT = 2 (2 bytes) and BCNT = 256.

**Figure 18-8. Linked Transfer Example**

**Figure 18-9. Link-to-Self Transfer Example**

## 18.2.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA3 channel controller. Transfers on DMA channels are initiated by three sources:

- **Event-triggered transfer request** (this is the more typical usage of EDMA3): Allows for a peripheral, system, or externally-generated event to trigger a transfer request.
- **Manually-triggered transfer request:** The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set register (ESR).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or subtransfer.

Transfers on QDMA channels are initiated by two sources:

- **Autotriggered transfer request:** A transfer is triggered when the PaRAM set entry programmed trigger word is written to.
- **Link-triggered transfer requests:** When linking occurs, the transfer is triggered when the PaPARAM set entry programmed trigger word is written to.

### 18.2.4.1 DMA Channel

#### 18.2.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register ( $ER.En = 1$ ). If the corresponding event in the event enable register (EER) is enabled ( $EER.En = 1$ ), then the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaPARAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA3TC and the  $En$  bit in ER is cleared. At this point, a new event can be safely received by the EDMA3CC.

If the PaPARAM set associated with the channel is a NULL set (see [Section 18.2.3.3](#)), then no transfer request (TR) is submitted and the corresponding  $En$  bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register ( $EMR.En = 1$ ) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before retriggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set ( $ER.En = 1$ ), regardless of the state of  $EER.En$ . If the event is disabled when an external event is received ( $ER.En = 1$  and  $EER.En = 0$ ), the  $ER.En$  bit remains set. If the event is subsequently enabled ( $EER.En = 1$ ), then the pending event is processed by the EDMA3CC and the TR is processed/submitted, after which the  $ER.En$  bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared ( $ER.En \neq 0$ ), then the second event is registered as a missed event in the corresponding bit of the event missed register ( $EMR.En = 1$ ).

For the synchronization events associated with each of the programmable DMA channels, see your device-specific data manual to determine the event to channel mapping.

#### 18.2.4.1.2 Manually-Triggered Transfer Request

A DMA transfer is initiated by a write to the event set register (ESR) by the CPU (or any EDMA programmer). Writing a 1 to an event bit in the ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EER.En bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 18.2.3.3](#)), then no transfer request (TR) is submitted and the corresponding En bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.En = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before retriggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register (ESR.En = 1) prior to the original being cleared (ESR.En = 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.En = 1).

#### 18.2.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5:0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (CER) to be set (CER.E[TCC] = 1).

Once a bit is set in CER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 18.2.3.3](#)), then no transfer request (TR) is submitted and the corresponding En bit in CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.En = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by you before the DMA channel can be retriggered. Good programming practices might include clearing the event missed error before retriggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (CER.En != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EMR.En = 1).

---

**NOTE:** Chained event registers, event registers, and event set registers operate independently. An event (En) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

---

## 18.2.4.2 QDMA Channels

### 18.2.4.2.1 Autotriggered and Link-Triggered Transfer Request

---

**NOTE:** If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field.

---

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (QER.En = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (QER) when the following occurs:

- A CPU (or any EDMA3 programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel  $n$  mapping register (QCHMAP $n$ )) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register (QEER.En = 1).
- EDMA3CC performs a link update on a PaRAM set address that is configured as a QDMA channel (matches QCHMAP $n$  settings) and the corresponding channel is enabled via the QDMA event enable register (QEER.En = 1).

Once a bit is set in QER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If a bit is already set in QER (QER.En = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (QEMR.En = 1).

### 18.2.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either autotriggered or link triggered. Autotriggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other EDMA3 programmer) writes to the trigger word of the QDMA channel parameter set (autotriggered) or when the EDMA3CC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or EDMA3 programmer) must reprogram some portion of the QDMA PaRAM set in order to retrigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows you to initiate a linked list of QDMAs, so when EDMA3CC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

### 18.2.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 18-4](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in a:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

**Table 18-4. Expected Number of Transfers for Non-Null Transfer**

| Sync Mode       | Counts at time 0     | Total # Transfers                     | Counts prior to final TR |
|-----------------|----------------------|---------------------------------------|--------------------------|
| A-synchronized  | ACNT<br>BCNT<br>CCNT | (BCNT × CCNT ) TRs of ACNT bytes each | BCNT == 1 && CCNT == 1   |
| AB-synchronized | ACNT<br>BCNT<br>CCNT | CCNT TRs for ACNT × BCNT bytes each   | CCNT == 1                |

You must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (CER[TCC]) and/or interrupt pending register (IPR[TCC]) is set.

See [Section 18.2.9](#) for details on interrupts and [Section 18.2.8](#) for details on chaining.

You can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See [Section 18.2.8](#) for details on chaining (intermediate/final chaining) and [Section 18.2.9](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA3 channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed.

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a nonrepetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See [Section 18.2.3.7](#) for more details.

**NOTE:** Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See [Section 18.2.3.5](#).

There are three ways the EDMA3CC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

### 18.2.5.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA3 channel controller receives the completion codes from the EDMA3 transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

### 18.2.5.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA3 channel controller submits the transfer request (TR) to the EDMA3 transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

### 18.2.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set ([Section 18.2.3.4](#)) or null set ([Section 18.2.3.3](#)). In both cases, the EDMA3 channel controller does not submit the associated transfer request to the EDMA3 transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending register (IPR) or chained event register (CER). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA3CC generates the completion code).

## 18.2.6 Event, Channel, and PaRAM Mapping

Most of the DMA channels are tied to a specific hardware peripheral event, thus allowing transfers to be triggered by events from device peripherals or external hardware. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed. Each of the DMA channels has one specific event associated with it. For the synchronization events associated with each of the programmable DMA channels, see your device-specific data manual to determine the event to channel mapping.

If in an application, a channel does not make use of the associated synchronization event or does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

### 18.2.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is a fixed, one-to-one mapping (see [Table 18-5](#)). In other words, channel (event) 0 is mapped to PaRAM set 0, channel (event) 1 is mapped to PaRAM set 1, etc. So, for example, in order to program a transfer for event number 3, DMA channel 3 is associated with PaRAM set number 3 and you need to program this PaRAM set for configuring transfers associated with event number 3. See your device-specific data manual for the addresses of the PaRAM set entries.

**Table 18-5. EDMA3 DMA Channel to PaRAM Mapping**

| PaRAM Set Number  | Mapping                    |
|-------------------|----------------------------|
| PaRAM Set 0       | DMA Channel 0/Reload/QDMA  |
| PaRAM Set 1       | DMA Channel 1/Reload/QDMA  |
| PaRAM Set 2       | DMA Channel 2/Reload/QDMA  |
| PaRAM Set 3       | DMA Channel 3/Reload/QDMA  |
| PaRAM Set 4       | DMA Channel 4/Reload/QDMA  |
| PaRAM Set 5       | DMA Channel 5/Reload/QDMA  |
| PaRAM Set 6       | DMA Channel 6/Reload/QDMA  |
| PaRAM Set 7       | DMA Channel 7/Reload/QDMA  |
| PaRAM Set 8       | DMA Channel 8/Reload/QDMA  |
| PaRAM Set 9       | DMA Channel 9/Reload/QDMA  |
| PaRAM Set 10      | DMA Channel 10/Reload/QDMA |
| PaRAM Set 11      | DMA Channel 11/Reload/QDMA |
| PaRAM Set 12      | DMA Channel 12/Reload/QDMA |
| PaRAM Set 13      | DMA Channel 13/Reload/QDMA |
| PaRAM Set 14      | DMA Channel 14/Reload/QDMA |
| PaRAM Set 15      | DMA Channel 15/Reload/QDMA |
| PaRAM Set 16      | DMA Channel 16/Reload/QDMA |
| ...               | ...                        |
| PaRAM Set 30      | DMA Channel 30/Reload/QDMA |
| PaRAM Set 31      | DMA Channel 31/Reload/QDMA |
| PaRAM Set 32      | Reload/QDMA                |
| PaRAM Set 33      | Reload/QDMA                |
| ...               | ...                        |
| PaRAM Set $n - 2$ | Reload/QDMA                |
| PaRAM Set $n - 1$ | Reload/QDMA                |
| PaRAM Set $n$     | Reload/QDMA                |

### 18.2.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel  $n$  mapping register (QCHMAP $n$ ) in the EDMA3CC provides programmability for the QDMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 18-10 illustrates the use of QCHMAP.

Additionally, QCHMAP allows you to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the 8 words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA3CC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel.

**NOTE:** By default, QDMA channels are mapped to PaRAM set 0. Care must be taken to appropriately remap PaRAM set 0 before it is used.

Figure 18-10. QDMA Channel to PaRAM Mapping

Note:  $n$  is the number of PaRAM sets supported in the EDMA3CC for a specific device.

## 18.2.7 EDMA3 Channel Controller Regions

The EDMA3 channel controller (EDMA3CC) divides its address space into multiple regions. Individual channel resources can be exclusively assigned to a specific region, where each region is typically assigned to a specific EDMA programmer. This allows partitioning of EDMA channel (DMA/QDMA) resources in hetero- or multi-core devices, and devices where certain additional masters (for example, coprocessors) can also program/initiate EDMA3 transfers. The application software running on these cores/coprocessors can operate in these exclusive shadow region memory-maps, minimizing possibilities of resource conflicts.

### 18.2.7.1 Region Overview

The EDMA3CC memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA3CC memory map. These registers control EDMA3 resource mapping and provide debug visibility and error tracking information. See your device-specific data manual for the EDMA3CC memory map.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow  $n$  channel region address range(s). For example, the event enable register (EER) is visible in the global region register space at offset 1020h, or region addresses at offset 2020h for region 0 and at offset 2220h for region 1.

The underlying control register bits that are accessible via the shadow region address space (except for IEVAL $_n$ ) are controlled by the DMA region access enable registers (DRAEm) and QDMA region access enable registers (QRAEm). [Table 18-6](#) lists the registers in the shadow region memory-map. (See EDMA3CC memory-map figure for the complete global and shadow region memory-maps.) [Figure 18-11](#) illustrates the conceptual view of the regions (where  $n$  is the number of shadow regions supported in the EDMA3CC for a specific device).

**Table 18-6. Shadow Region Registers**

| DRAEm                                | QRAEm |
|--------------------------------------|-------|
| ER                                   | QER   |
| ECR                                  | QEER  |
| ESR                                  | QEECR |
| CER                                  | QEESR |
| EER                                  |       |
| EECR                                 |       |
| EESR                                 |       |
| SER                                  |       |
| SECR                                 |       |
| IER                                  |       |
| IECR                                 |       |
| IESR                                 |       |
| IPR                                  |       |
| ICR                                  |       |
| <b>Register not affected by DRAE</b> |       |
| IEVAL                                |       |

**Figure 18-11. Shadow Region Registers**

### 18.2.7.2 Channel Controller Shadow Regions

For each EDMA3 shadow region (and associated memory-maps) there is a set of registers associated with the shadow region that allows association of the DMA/QDMA channels and interrupt completion codes to the region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels and TCC values to a region.

- **DRAEm:** One register exists for each of the shadow regions. The number of bits in each register matches the number of DMA channels. These registers need to be programmed to assign ownership of DMA channels to the respective region. Accesses to DMA event registers and interrupt registers via the shadow region address map are filtered through DRAE. A value of 1 in the corresponding DRAE bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE bit forces writes to be discarded and returns a value of 0 for reads.
- **QRAEm:** One register exists for every region. The number of bits in each register matches the number of QDMA channels. These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 QEER, the respective bit in QRAE must be set or writing into QEESR will not have the desired effect.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA3 resources (DMA channels, QDMA channels, TCC, interrupts) by tasks/cores/EDMA3 programmers in a system by setting or clearing bits in the DRAE/QRAE registers. If exclusive access to any given channel/TCC code is required for a region, then only that region's DRAE/QRAE should have the associated bit set.

Additionally, with each shadow region, there is an associated shadow region completion interrupt (EDMA3CC\_INT $n$  where  $n$  denotes the shadow region number). For multi-core/hetero-core devices, the various shadow region interrupts might be tied to the interrupt controllers for different cores. For single core devices, all shadow region interrupts would be routed to the device interrupt controller. See your device-specific data manual for the shadow region interrupt hookup to the device interrupt controller(s). The DRAE associated with each shadow region acts as a secondary interrupt enable (along with the interrupt enable register) for the respective shadow region interrupts. See [Section 18.2.9](#) for more information on interrupts.

#### Example 18-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0), and 16 TCC codes (0-15). Region 1 needs to be allocated 16 DMA channels (16-31) and 7 QDMA channels (1-7), and 16 TCC codes (16-31). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

Region 0: DRAE = 0x0000FFFF QRAE = 0x00000001 Region 1: DRAE = 0xFFFF0000 QRAE = 0x000000FE

### 18.2.8 Chaining EDMA3 Channels

The channel chaining capability for the EDMA3 allows the completion of an EDMA3 channel transfer to trigger another EDMA3 channel transfer. The purpose is to allow you the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 18.2.3.7](#)). The EDMA3 link feature reloads the current channel parameter set with the linked parameter set. The EDMA3 chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see [Section 18.2.4.1.3](#) for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel  $m$  (DMA/QDMA) required to chain to channel  $n$ . Channel number  $n$  (0-31) needs to be programmed into the TCC field of channel  $m$  channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 and ITCCHEN = 0 in channel  $m$  OPT) is enabled, the chain-triggered event occurs after the *last* transfer request of channel  $m$  is submitted (early completion) or completed (normal completion).

- If intermediate transfer completion chaining (TCCHEN = 0 and ITCCHEN = 0 in channel *m* OPT) is enabled, the chain-triggered event occurs after every *intermediate* transfer request of channel *m* is submitted (early completion) or completed (normal completion).
- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in channel *m* OPT) are enabled, the chain-trigger event occurs after every transfer request of channel *m* is submitted (early completion) or completed (normal completion).

Table 18-7 shows the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

**Table 18-7. Chain Event Triggers**

| Options                 | (Number of chained event triggers on channel 30) |                         |
|-------------------------|--------------------------------------------------|-------------------------|
|                         | A-Synchronized                                   | AB-Synchronized         |
| TCCHEN = 1, ITCCHEN = 0 | 1 (Last TR)                                      | 1 (Last TR)             |
| TCCHEN = 0, ITCCHEN = 1 | 19 (All but the last TR)                         | 4 (All but the last TR) |
| TCCHEN = 1, ITCCHEN = 1 | 20 (All TRs)                                     | 5 (All TRs)             |

## 18.2.9 EDMA3 Interrupts

The EDMA3 interrupts are divided into 2 categories:

- Transfer completion interrupts
- Error interrupts

The transfer completion interrupts are listed in Table 18-8. The error interrupts are listed in Table 18-9.

**Table 18-8. EDMA3 Transfer Completion Interrupts**

| Name             | Description                                                                | Interrupt Number |         |
|------------------|----------------------------------------------------------------------------|------------------|---------|
|                  |                                                                            | AINTC            | DSPINTC |

### 18.2.9.1 Transfer Completion Interrupts

The EDMA3CC is responsible for generating transfer completion interrupts to the CPU. The EDMA3 generates a single completion interrupt per shadow region on behalf of all DMA/QDMA channels. Various control registers and bit fields facilitate EDMA3 interrupt generation.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (IPR), as shown in [Table 18-10](#). For example, if TCC = 00 0000b, IPR[0] is set after transfer completion, and results in an interrupt generation to the CPU if in the EDMA3CC and device interrupt controller are configured to allow a CPU interrupt. See [Section 18.2.9.1.1](#) for details on enabling EDMA3 transfer completion interrupts.

When a completion code is returned (as a result of early or normal completion), the corresponding bit in IPR is set. For the completion code to be returned, the PaRAM set associated with the transfer must enable the transfer completion interrupt (final/intermediate) in the channel options parameter (OPT).

The transfer completion code (TCC) can be programmed to any value for a DMA/QDMA channel. There does not need to be a direct relation between the channel number and the transfer completion code value. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

**NOTE:** The TCC field in the channel options parameter (OPT) is a 6-bit field and can be programmed for any value between 0-64. For devices with 32 DMA channels, the TCC should have a value between 0 to 31 so that it sets the appropriate bits (0 to 31) in IPR (and can interrupt the CPU(s) on enabling the IER register bits (0-31)).

**Table 18-10. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping**

| TCC Bits in OPT<br>(TCINTEN/ITCINTEN = 1) | IPR Bit Set |
|-------------------------------------------|-------------|
| 00 0000b                                  | IPR0        |
| 00 0001b                                  | IPR1        |
| 00 0010b                                  | IPR2        |
| 00 0011b                                  | IPR3        |
| 00 0100b                                  | IPR4        |
| ...                                       | ...         |
| ...                                       | ...         |
| 01 1110b                                  | IPR30       |
| 01 1111b                                  | IPR31       |

You can enable interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel  $m$  as an example.

- If the final transfer interrupt (TCINTEN = 1 and ITCINTEN = 0 in OPT) is enabled, the interrupt occurs after the *last* transfer request of channel  $m$  is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (TCINTEN = 0 and ITCINTEN = 1 in OPT) is enabled, the interrupt occurs after *every intermediate* transfer request of channel  $m$  is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCINTEN = 1 and ITCINTEN = 1 in OPT) are enabled, the interrupt occurs after *every* transfer request of channel  $m$  is submitted or completed (depending on early or normal completion).

Table 18-11 shows the number of interrupts occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

**Table 18-11. Number of Interrupts**

| Options                   | A-Synchronized           | AB-Synchronized         |
|---------------------------|--------------------------|-------------------------|
| TCINTEN = 1, ITCINTEN = 0 | 1 (Last TR)              | 1 (Last TR)             |
| TCINTEN = 0, ITCINTEN = 1 | 19 (All but the last TR) | 4 (All but the last TR) |
| TCINTEN = 1, ITCINTEN = 1 | 20 (All TRs)             | 5 (All TRs)             |

#### 18.2.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA3 channel controller to assert a transfer completion to the external world, the interrupts have to be enabled in the EDMA3CC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

The EDMA3 channel controller has interrupt enable registers (IER) and each bit location in IER serves as a primary enable for the corresponding interrupt pending register (IPR).

All the interrupt registers (IER, IESR, IECR, and IPR) are either manipulated from the global DMA channel region or by way of the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA3 channel controller has a hierarchical completion interrupt scheme that makes use of a single set of interrupt pending register (IPR) and single set of interrupt enable registers (IER). A second level of interrupt masking is provided by the programmable DMA region access enable registers (DRAE). See Figure 18-12.

For the EDMA3CC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA3CC\_INT0: (IPR.E0 & IER.E0 & DRAE0.E0) | (IPR.E1 & IER.E1 & DRAE0.E1) | ... | (IPR.En & IER.En & DRAE0.En)
- EDMA3CC\_INT1: (IPR.E0 & IER.E0 & DRAE1.E0) | (IPR.E1 & IER.E1 & DRAE1.E1) | ... | (IPR.En & IER.En & DRAE1.En)

where  $n$  is the number of shadow regions supported in the EDMA3CC for a specific device.

### Figure 18-12. Interrupt Diagram

**NOTE:** The DRAE for all regions is expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.

Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 31 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, IPR.E31 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, you must program the DRAE that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 31 (corresponding to IPR.E31 bit that is set upon completion).

#### 18.2.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending register (IPR) is cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (ICR). For example, a write of 1 to ICR.E0 clears a pending interrupt in IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in IPR, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMA3CC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

### 18.2.9.2 EDMA3 Interrupt Servicing

On completion of a transfer (early or normal completion), the EDMA3 channel controller sets the appropriate bit in the interrupt pending register (IPR) as specified by the transfer completion codes. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted. Since there is a single completion interrupt for all DMA/QDMA channels.

After servicing the interrupt, the ISR should clear the corresponding bit in IPR; therefore, enabling recognition of future interrupts. Only when all IPR bits are cleared, the EDMA3CC will assert additional completion interrupts.

It is possible that when one interrupt is serviced; many other transfer completions result in additional bits being set in IPR, thereby resulting in additional interrupts. It is likely that each of these bits in IPR would need different types of service; therefore, the ISR must check all pending interrupts and continue until all the posted interrupts are appropriately serviced.

Following are examples (pseudo code) for a CPU interrupt service routine for an EDMA3CC completion interrupt.

The ISR routine in [Example 18-2](#) is more exhaustive and incurs a higher latency.

#### Example 18-2. Interrupt Servicing

The pseudo code:

1. Read the interrupt pending register (IPR).
2. Perform the operations needed.
3. Write to the interrupt pending clear register (ICR) to clear the corresponding IPR bit.
4. Read IPR again:
  - (a) If IPR is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
  - (b) If IPR is equal to 0, this should assure you that all enabled interrupts are inactive.

---

**NOTE:** It is possible that during step 4, an event occurs while the IPR bits are read to be 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt is generated as soon as the application exits the interrupt service routine.

---

[Example 18-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition, as mentioned above.

### Example 18-3. Interrupt Servicing

If it is desired to leave any enabled and pending (possibly lower priority) interrupts, it is required to force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (IEVAL).

The pseudo code:

1. Enter ISR.
2. Read IPR.
3. For the condition set in IPR that you desire to service:
  - (a) Service interrupt as required by application.
  - (b) Clear bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA3CC after step 2).
4. Read IPR prior to exiting ISR:
  - (a) If IPR is equal to 0, then exit ISR.
  - (b) If IPR is not equal to 0, then set IEVAL so that upon exit of ISR, a new interrupt is triggered if any enabled interrupts are still pending.

The EVAL bit must not be set when IPR is read to be 0, to avoid generation of extra interrupt pulses.

---

**NOTE:** Since the DMA region access registers (DRAE) are required to enable the transfer completion region interrupts, it is assumed that there will be a unique and nonoverlapping (in most cases) assignment of the channels and interrupts among the different shadow regions. This allows the interrupt registers (IER, IESR, IECR, IPR, and ICR) in the different shadow regions to functionally operate in an independent manner and nonoverlapping. The above examples for the interrupt service routine is based on this assumption.

---

### 18.2.9.3 Interrupt Evaluation Operations

The EDMA3CC has interrupt evaluate registers (IEVAL) in each shadow region. These registers are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE). A write of 1 to the EVAL bit in these registers associated with a particular shadow region results in pulsing the associated region interrupt, if any enabled interrupt (via IER) is still pending (IPR). This register can be used in order to assure that the interrupts are not missed by the CPU (or the EDMA3 master associated with the shadow region) if the software architecture chooses not to use all interrupts. See [Example 18-3](#) for the use of IEVAL in the EDMA3 interrupt service routine (ISR).

Similarly an error evaluate register (EEVAL) exists in the global region. A write of 1 to the EVAL bit in EEVAL causes the pulsing of the error interrupt if any pending errors are in EMR, QEMR, or CCERR. See [Section 18.2.9.4](#) for additional details on error interrupts.

---

**NOTE:** While using IEVAL for shadow region completion interrupts, you should make sure that the IEVAL operated upon is from that particular shadow region memory map.

---

### 18.2.9.4 Error Interrupts

The EDMA3CC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, if the error bits are set in these registers, it results in asserting the EDMA3CC error interrupt. If EDMA3CC error interrupt is enabled in the device interrupt controller, then it allows the CPU to handle the error conditions.

The EDMA3CC has a single error interrupt (EDMA3\_m\_CC0\_ERRINT) that gets asserted for all EDMA3CC error conditions. There are four conditions that cause the error interrupt to be pulsed:

- DMA missed events: for all 32 DMA channels. These get latched in the event missed registers (EMR).
- QDMA missed events: for all QDMA channels. These get latched in the QDMA event missed register (QEMR).
- Threshold exceed: for all event queues. These get latched in EDMA3CC error register (CCERR).
- TCC error: for outstanding transfer requests expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of 31. This also gets latched in the EDMA3CC error register (CCERR).

Figure 18-13 illustrates the EDMA3CC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the (EDMA3\_m\_CC0\_ERRINT) always is asserted, as there are no enables for masking these error events. Similar to the transfer completion interrupts, the error interrupt also is pulsed only when the error interrupt condition transitions from a state where no errors are set to a state where at least one error bit is set. If additional error events are latched prior to the original error bits being cleared, the EDMA3CC does not generate additional interrupt pulses.

To reduce the burden on the software, similar to the interrupt evaluate register (IEVAL), there is an error evaluate register (EEVAL) that allows reevaluation of pending set error events/bits. This can be used so that the CPU(s) does not miss any error events.

**NOTE:** It is a good practice to have the error interrupt enabled in the device interrupt controller and associate an interrupt service routine with it to address the various error conditions appropriately. This puts less burden on software (polling for error status) and additionally provides a good debug mechanism for unexpected error conditions.

Figure 18-13. Error Interrupt Operation

Note: *n* is the number of queues supported in the EDMA3CC for a specific device.

### 18.2.10 Event Queue(s)

Event queues are a part of the EDMA3 channel controller. Event queues form the interface between the event detection logic in the EDMA3CC and the transfer request (TR) submission logic of the EDMA3CC. Each queue is 16 entries deep, that is, a maximum of 16 queued events per event queue. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register.

The number of event queues in the EDMA3CC determines the number of transfer controllers connected to the EDMA3CC. By default, there is a one-to-one mapping between the queues and transfer controllers. Therefore, the transfer requests (TRs) associated with events in Q0 get submitted to TC0. Similarly, transfer requests associated with events in Q1 get submitted to TC1, and so on.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the end of the appropriate event queue. Each event queue is serviced in a FIFO (first in–first out) order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is dequeued and the PaRAM set corresponding to the dequeued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA3 transfer controller.

A lower numbered queue has a higher dequeuing priority than a higher numbered queue. For example, Q0 has higher priority than Q1, if Q0 and Q1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Q0 is dequeued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

All the event entries in all the event queues are software readable (not writeable) by accessing the event queue entry registers (QxEy). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or autotriggered) and the event number. See [Section 18.4.2.4.1](#) for a description of the bit fields in the queue event entry registers.

#### 18.2.10.1 DMA/QDMA Channel to Event Queue Mapping

Each DMA channel and QDMA channel is independently programmed to map to a specific queue using the DMA queue number register  $n$  (DMAQNUM $n$ ) and the QDMA channel queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly in meeting real-time deadlines.

---

**NOTE:** If an event is ready to be queued and both the event queue and the EDMA3 transfer controller associated to the event queue are empty, then the event bypasses the event queue, and goes to the PaRAM processing logic and eventually to the transfer request submission logic for submission to the EDMA3TC. In this case, the event is not logged in the event queue status registers.

---

### 18.2.10.2 Queue RAM Debug Visibility

Each event queue has 16 entries. These 16 entries are managed in a circular FIFO manner. All event queue entries for all event queues are software readable by the event queue entry register (QxEx). Additionally, for each queue there is a queue status register (QSTAT $n$ ).

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources. The event queue entry register (QxEx) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for DMA/QDMA channels) that are in the queue or have been de-queued (passed through the queue). QSTAT $n$  includes fields for the start pointer (STRTPTR) that provides the offset to the head entry of an event. It also includes a NUMVAL field that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR field may be used to index appropriately into the 16 event entries. The NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entries may be read to determine which events have already been de-queued and submitted to the associated transfer controller.

### 18.2.10.3 Queue Resource Tracking

The EDMA3CC event queue includes watermarking/threshold logic that allows you to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA3 event queue.

You can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT $n$ ) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT $n$  and the maximum number of entries (WM bit in QSTAT $n$ ).

If the queue usage is exceeded, this status is visible in the EDMA3CC registers: the QTHRXCD $n$  bit in the channel controller error register (CCERR) and the THRXCD bit in QSTAT $n$ , where  $n$  stands for the event queue number. Any bits that are set in CCERR also generate an EDMA3CC error interrupt.

## 18.2.11 EDMA3 Transfer Controller (EDMA3TC)

The EDMA3 channel controller is the user-interface of the EDMA3 and the EDMA3 transfer controller (EDMA3TC) is the data movement engine of the EDMA3. The EDMA3CC submits transfer requests (TR) to the EDMA3TC and the EDMA3TC performs the data transfers dictated by the TR.

### 18.2.11.1 Architecture Details

#### 18.2.11.1.1 EDMA3TC Configuration

Each transfer controller on a device is designed differently based on considerations like performance requirements, system topology (main SCR bus width, external memory bus width), gate count, etc. The parameters that determine the TC configurations are:

- **FIFOSIZE:** Determines the size in bytes for the Data FIFO that is the temporary buffer for the in-flight data. The data FIFO is where the read return data read by the TC read controller from the source endpoint is stored and subsequently written out to the destination endpoint by the TC write controller.
- **Default Burst Size (DBS):** The DBS is the maximum number of bytes per read/write command issued by a transfer controller.
- **BUSWIDTH:** The width of the read and write data buses in bytes, for the TC read and write controller, respectively. This is typically equal to the bus width of the main SCR interface.
- **DSTREGDEPTH:** This determines the number of Destination FIFO register set. The number of Destination FIFO register set for a transfer controller, determines the maximum number of outstanding transfer requests (TR pipelining).

Of the four parameters, the FIFOSIZE, BUSWIDTH, and DSTREGDEPTH values are fixed in design for a given device. The default burst size (DBS) for EDMA3\_0\_TC0 and EDMA3\_0\_TC1 is configurable by the chip configuration 0 register (CFGCHIP0) in the System Configuration Module and for EDMA3\_1\_TC0 is configurable by the chip configuration 1 register (CFGCHIP1) in the System Configuration Module. [Table 18-12](#) provides the configuration of the individual EDMA3 transfer controllers on the device.

The burst size for each transfer controlled can be programmed to be 16-, 32-, or 64-bytes. The default values for DBS are typically chosen for optimal performance in most intended-use conditions; therefore, if you decide to use a value other than the default, you should evaluate the impact on performance. Depending on the FIFOSIZE and source/destination locations the performance for the transfer can vary significantly for different burst size values.

---

**NOTE:** It is expected that the DBS value for a transfer controller is static and should be based on the application requirement. It is not recommended that the DBS value be changed on-the-fly.

---

**Table 18-12. EDMA3 Transfer Controller Configurations**

| Parameter                     | EDMA3_0_TC0        | EDMA3_0_TC1        | EDMA3_1_TC0        |
|-------------------------------|--------------------|--------------------|--------------------|
| FIFOSIZE                      | 128 bytes          | 128 bytes          | 256 bytes          |
| BUSWIDTH                      | 8 bytes (64 bits)  | 8 bytes (64 bits)  | 8 bytes (64 bits)  |
| DSTREGDEPTH                   | 4 entries          | 4 entries          | 4 entries          |
| DBS (default)                 | 16 bytes           | 16 bytes           | 16 bytes           |
| Error interrupt               | EDMA3_0_TC0_ERRINT | EDMA3_0_TC1_ERRINT | EDMA3_1_TC0_ERRINT |
| EDMA3 channel controller used | EDMA3_0_CC0        | EDMA3_0_CC0        | EDMA3_1_CC0        |

### 18.2.11.1.2 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. The transfer controller read/write transaction as specified by the transfer request packet is internally broken down into smaller bursts; this determines the default burst size (DBS) for the transfer controller. See [Section 18.2.11.1.1](#) for the DBS value of each EDMA3TC.

The EDMA3TC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMA3TC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer is always issued so that subsequent commands align to the DBS value.

[Example 18-4](#) shows the command fragmentation for a DBS of 32 bytes. In summary, if the ACNT value is larger than the DBS value, then the EDMA3TC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

#### Example 18-4. Command Fragmentation (DBS = 32)

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1.

Cmd0 = 32 byte, Cmd0 = 32 byte

Write Controller: Since DSTBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. ACNT = 64, BCNT = 1, SRCADDR = 31, DSTADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SRCADDR is aligned to 32 for the next command)

Cmd1 = 32 bytes

Cmd2 = 31 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 31 bytes, (now the DSTADDR is aligned to 32 for the next command)

Cmd1 = 32 bytes

Cmd2 = 1 byte

### 18.2.11.1.3 TR Pipelining and Data Ordering

The transfer controller(s) can issue back-to-back transfer requests (TR). The number of outstanding TRs for a TC is limited by the number of destination FIFO register entries that is controlled by the DSTREGDEPTH parameter (fixed in design for a given transfer controller). TR pipelining refers to the ability of the TC read controller to issue read commands for a subsequent TR, while the TC write controller is still performing writes for the previous TR. Consider the case of 2 TRs (TR0 followed by TR1), because of TR pipelining, the TC read controller can start issuing the read commands for TR1 as soon as the last read command for TR0 has been issued, meanwhile the write commands and write data for TR0 are tracked by the destination FIFO registers. In summary, the TC read controller is able to process  $n$  TRs ahead of the write controller, where  $n$  is the number of destination FIFO register entries (typically 4).

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It eliminates the read overhead because reads start in the background of a previous TR writes.

It should be noted that back-to-back TRs are targeted to different end points even though the read return data for the two TRs might get returned out of order (that is, read data for TR1 might come in before read data for TR0), the transfer controller issues that the write commands are issued in order (that is, write commands for TR0 will be issued before write commands for TR1).

### 18.2.11.2 Error Generation

Similar to the channel controller, the transfer controllers are capable of detecting and reporting several error conditions. The TC errors are generated, under three main conditions:

- **BUSERR:** The TC read or write controllers detect an error signaled by the source or destination address. The additional details on the type of error is also recorded in the ERRDET register, which indicates whether it is a read error (source address errors) or write error (destination address error).
- **MMRAERR:** CPU accesses illegal/reserved addresses in the EDMA3CC/TC memory-map.
- **TRERR:** A transfer request packet is detected to be violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

You can poll for the errors, as the status of the errors can be read from the ERRSTAT registers, additionally if the error bits are enabled in the ERREN register, a bit set in the ERRSTAT will cause the error condition to interrupt the CPU(s). You can decide to enable/disable either or all error types.

### 18.2.11.3 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA3TC status register (TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and you must realize that there is a chance that the values read from the EDMA3TC status registers will be inconsistent since the EDMA3TC may change the values of these registers due to ongoing activities.

It is recommended that you ensure no additional submission of TRs to the EDMA3TC in order to facilitate ease of debug.

#### 18.2.11.3.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA3TC maintains two important status details in TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

### 18.2.12 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA3CC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the ER.En (or CER.En, ESR.En, QER.En) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the SER.En (or QSER.En) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA3CC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA3CC clears the ER.En (or CER.En, ESR.En, QER.En) bit and the SER.En bit as soon as it determines the TR is non-null. In the case of a null set, the SER.En bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA3CC immediately sets the interrupt pending register (IPR.I[TCC]).
5. If the TR was programmed for normal completion, the EDMA3CC sets the interrupt pending register (IPR.I[TCC]) when the EDMA3TC informs the EDMA3CC about completion of the transfer (returns transfer completion codes).
6. The EDMA3CC programs the associated EDMA3TCn Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the Dst FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA3TCn.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and on receiving the acknowledgement signal from the destination slave end point, the EDMA3TCn then signals completion status to the EDMA3CC.

### 18.2.13 EDMA3 Prioritization

The EDMA3 controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 18-14 shows the different places EDMA3 priorities come into play.

#### 18.2.13.1 Channel Priority

The DMA event register (ER) captures all external/peripheral events connected to the EDMA3CC; likewise, the QDMA event register (QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 31 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

Figure 18-14. EDMA3 Prioritization

### 18.2.13.2 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel ( $ER.En = 1$ ,  $ESR.En = 1$ ,  $CER.En = 1$ ), then the EDMA3CC always services these events in the following priority order: event trigger (via ER) is higher priority than chain trigger (via CER) and chain trigger is higher priority than manual trigger (via ESR).

This implies that if for channel 0, both  $ER.E0 = 1$  and  $CER.E0 = 1$  at the same time, then the  $ER.E0$  event is always queued before the  $CER.E0$  event.

### 18.2.13.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by  $DMAQNUMn$  and  $QDMAQNUM$ ). For submission of a TR to the transfer controller, events need to be dequeued from the event queues. A lower numbered queue has a higher dequeuing priority than a higher numbered queue. For example, if there are events in Q0 and Q1 and the respective transfer controllers (TC0 and TC1) are ready to receive the next TR from the EDMA3CC, then the transfer requests associated with events in Q0 will get submitted to TC0 prior to any transfer requests associated with events in Q1 getting submitted to TC1.

---

**NOTE:** At any given time, if there are outstanding events in multiple queues, when the transfer controller associated with the lower numbered (higher priority) queue is busy processing earlier transfer requests and the transfer controller associated with the higher numbered (lower priority) queue is idle, then the event in the higher numbered (lower priority) queue will dequeue first.

---

### 18.2.13.4 Master (Transfer Controller) Priority

All master peripherals on the device have a programmable priority level. When multiple masters are trying to access common shared resources (slave memory or peripherals), this priority value allows the system interconnect to arbitrate requests from different masters based on their priority. This priority assignment is determined in the Master Priority Registers (MSTPRI0-MSTPRI2) in the System Configuration Module (see the *System Configuration (SYSCFG) Module* chapter), where each master has an allocated priority value (power on reset default value), which can be re programmed based on the applications prioritization requirements. The priority value can be configured between 0 to 7, with 0 being the highest priority and 7 being the lowest priority.

Each transfer controller on the device is also a master peripheral. The priority of the transfer requests (read/write commands) issued by the individual EDMA3TC read/write ports in the system can be programmed via these registers.

The dequeue priority has a relatively secondary effect as compared to this Master priority; therefore, it is important to program the priority of each transfer controller with respect to each other and also with respect to other masters in the system.

---

**NOTE:** On previous architectures, the EDMA3TC priority was controlled by the QUEPRI register in the EDMA3CC memory-map. However for this device, the priority control for the transfer controllers is controlled by the chip-level registers in the System Configuration Module.

---

## 18.2.14 EDMA3CC and EDMA3TC Performance and System Considerations

### 18.2.14.1 System Priority Considerations

The main switched central resource (SCR) (see your device-specific data manual) arbitrates bus requests from all the masters (CPU, master peripherals, and the EDMA3 transfer controllers) to the shared slave resources (peripherals and memories). The priorities of transfer requests (read and write commands) from the EDMA3 transfer controllers with respect to each other and the other masters within the system is configured as explained in [Section 18.2.13.4](#).

It is recommended that this priority be altered based on system level considerations. For example, peripherals servicing audio/video/display threads that typically have real-time deadlines should be programmed as highest priority requestors in the systems, where as, peripherals responsible for doing bulk/block/paging transfers with no real-time deadlines, should be programmed as a lower system priority.

The default priority for all transfer controllers is the same, 0 or highest priority relative to other masters; therefore, it is recommended that a TC servicing audio data requests from serial ports should be configured at a higher priority as compared to TC service memory to memory (paging/bulk) transfer requests.

### 18.2.14.2 TC Transfer Optimization Considerations

The transfer controller can internally optimize the way it issues read commands and write commands for a given transfer under certain conditions. For 2D transfers (that is, BCNT arrays of ACNT bytes), if the ACNT value is less than or equal to the DBS value, then the transfer controller will try to optimize the TR into a 1D transfer in order to maximize efficiency. The optimization only takes place if the EDMA3TC recognizes that the 2D transfer is organized as a single dimension (SAM/DAM = 0, increment mode), SRC/DST BIDX = ACNT, the ACNT value is a power of 2, and the BCNT value is less than or equal to 1023. If these conditions are met, then instead of issuing ACNT bytes worth read and/or write commands, the TC will try to optimize the bus usage by issuing commands as if  $ACNT' = ACNT \times BCNT$  and  $BCNT = 1$ .

[Table 18-13](#) summarizes the conditions in which the optimizations are performed.

**Table 18-13. Read/Write Command Optimization Rules**

| ACNT ≤ DBS | ACNT is power of 2 | BIDX = ACNT | BCNT ≤ 1023 | SAM/DAM = 0<br>(Increment) | Description   |
|------------|--------------------|-------------|-------------|----------------------------|---------------|
| Yes        | Yes                | Yes         | Yes         | Yes                        | Optimized     |
| Yes        | No                 | x           | x           | Yes                        | Not Optimized |
| Yes        | x                  | No          | x           | Yes                        | Not Optimized |
| No         | x                  | x           | x           | Yes                        | Not Optimized |
| x          | x                  | x           | x           | No                         | Not Optimized |

Consider a case in which it is needed to transfer 4096 bytes where the data is arranged linearly in both the source and destination locations (SAM/DAM = 0, SRC/DST BIDX = ACNT): Scenario A programs the ACNT = 4, BCNT = 1024, AB-synchronized transfer; and Scenario B programs the ACNT = 64, BCNT = 64. Scenario B will yield a much optimized transfer and higher throughput, as the transfer meets all the optimization rules, which would result in TC internally treating it as a transfer with an  $ACNT' = 4096$  ( $ACNT \times BCNT$ ). The TC will optimally size, default burst size worth read and write commands. In the case of Scenario B, since one of the optimization rules is not met (BCNT value is greater than 1023), the TC will end up issuing several ACNT byte (4 byte) size commands to complete the transfers, which will result in inefficient usage of the read/write buses.

### 18.2.14.3 Throttling the Read Command Rate in a Transfer Controller

By default, the transfer controller issues reads as fast as possible. In some cases, the reads issued by the EDMA3TC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA3TC is controlled by the read command rate register (RDRATE), and this can be used to throttle the rate at which the commands are issued from the TC read interface. RDRATE defines the number of cycles that the EDMA3TC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA3TC consuming all available slave resources. The RDRATE value should be set to a relatively small value (or kept at default, which implies issuing read requests as fast as possible) if the transfer controller is targeted for high-priority transfers and set to a high value if the transfer controller is targeted for low-priority transfers. In contrast, the write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

### 18.2.15 EDMA3 Operating Frequency (Clock Control)

The EDMA3 channel controller and transfer controller are clocked from PLL controller 0 (PLL0). For details, see the *Phase-Locked Loop Controller (PLL)* chapter.

### 18.2.16 Reset Considerations

A hardware reset resets the EDMA3 (EDMA3CC and EDMA3TC) and the EDMA3 configuration registers. The PaRAM memory contents are undefined after device reset and you should not rely on parameters to be reset to a known state. The PaRAM set must be initialized to a desired value before it is used.

### 18.2.17 Power Management

The EDMA3 (EDMA3CC and EDMA3TC) can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the device Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

The EDMA3 controller can be idled on receiving a clock stop request from the PSC. The requests to EDMA3CC and EDMA3TC are separate. In general, you should verify that there are no pending activities in the EDMA3 controller before issuing a clock stop request via PSC.

The EDMA3CC checks for the following conditions:

- No pending DMA/QDMA events
- No outstanding events in the event queues
- Transfer request processing logic is not active
- No completion requests outstanding (early or normal completion)
- No configuration bus requests in progress

The first four conditions are software readable by the channel controller status register (CCSTAT) in the EDMA3CC.

Similarly, from the EDMA3TC perspective, you should check that there are no outstanding TRs that are getting processed and essentially the read/write controller is not busy processing a TR. The activity of EDMA3TC logic is read in TCSTAT for each EDMA3TC.

It is generally recommended to first disable the EDMA3CC and then the EDMA3TC(s) to put the EDMA3 controller in reduced-power modes.

Additionally, when EDMA3 is involved in servicing a peripheral and it is required to power-down both the peripheral and the EDMA, the recommended sequence is to first disable the peripheral, then disable the DMA channel associated with the peripheral (clearing the EER bit for the channel), then disable the EDMA3CC, and finally disable the EDMA3TC(s).

### 18.3.2 Subframe Extraction Example

The EDMA3 can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA3 retrieves a portion of data for the CPU to process. In this example, a  $640 \times 480$ -pixel frame of video data is stored in external memory, SDRAM. Each pixel is represented by a 16-bit halfword. The CPU extracts a  $16 \times 12$ -pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA3 places the subframe in internal L2 SRAM. Figure 18-17 shows the transfer of a subframe from external memory to L2. Figure 18-18 shows the parameters for this transfer.

The same PaPARAM set options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to 1 to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

### 18.3.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA3 can reorganize the data into the desired format. [Figure 18-19](#) shows the data sorting.

In order to determine the parameter entry values, the following need to be considered:

- ACNT – Program this to be the size in bytes of an array.
- BCNT – Program this to be the number of arrays in a frame.
- CCNT – Program this to be the number of frames.
- SRCBIDX – Program this to be the size of the array or ACNT.
- DSTBIDX = CCNT × ACNT
- SRCCIDX = ACNT × BCNT
- DSTCIDX = ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal DMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT arrays get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT arrays and so on. [Figure 18-20](#) shows the parameter set programming for this transfer, assuming channel 0 and an array size of 4 bytes.

**Figure 18-19. Data Sorting Example**

### 18.3.4 Peripheral Servicing Example

**NOTE:** Examples in this section are sample examples. The peripherals, channels, and addresses used in these examples may not apply to your specific device. See your device-specific data manual for supported peripherals.

The EDMA3 channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the DMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA3 has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EER). When programming a DMA channel to service a peripheral, it is necessary to know how data is to be presented to the CPU. Data is always provided with some kind of synchronization event as either one element per event (nonbursting) or multiple elements per event (bursting).

#### 18.3.4.1 Nonbursting Peripherals

Nonbursting peripherals include the on-chip multichannel buffered serial port (McBSP) and many external devices, such as codecs. Regardless of the peripheral, the DMA channel configuration is the same.

The McBSP transmit and receive data streams are treated independently by the EDMA3. The transmit and receive data streams can have completely different counts, data sizes, and formats. [Figure 18-21](#) shows servicing incoming McBSP data.

To transfer the incoming data stream to its proper location in L2 memory, the DMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Since an event (REVT) is generated for every word as it arrives, it is necessary to have the EDMA3 issue the transfer request for each element individually. [Figure 18-22](#) shows the parameters for this transfer. The source address of the DMA channel is set to the data receive register (DDR) address for the McBSP, and the destination address is set to the start of the data block in L2. Since the address of DDR is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the DMA channel should be programmed to be on queue 0.

### 18.3.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the CPU for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the CPU. In this example, a port is receiving a video frame from a camera and presenting it to the CPU one array at a time. The video image is  $640 \times 480$  pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. Figure 18-23 shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on  $EVT_n$ , channel  $n$  must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 18-24 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Since the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 since the source address undergoes no increment. The DSTCIDX is equal to the difference between the starting addresses of each array. Since a pixel is 16 bits (2 bytes), DSTCIDX is equal to  $640 \times 2$ .

### 18.3.4.3 Continuous Operation

Configuring a DMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the CPU. In this case, it is necessary to implement some form of linking such that the DMA channels continuously reload the necessary parameter sets. In this example, the multichannel buffered serial port (McBSP) is configured to transmit and receive data on an array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to L2 memory and from L2 memory to the serial port, as shown in Figure 18-25.

The McBSP generates REVT for every element received and generates XEVT for every element transmitted. To service the data streams, the DMA channels associated with the McBSP must be set up for 1D-to-1D transfers with A-synchronization.

Figure 18-26 shows the parameters for the parameter entries for the channel for these transfers. In order to service the McBSP continuously throughout CPU operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the DMA channels reload and continue. Figure 18-27 shows the reload parameters for the channel.

#### 18.3.4.3.1 Receive Channel

DMA channel 3 services the incoming data stream of the McBSP. The source address is set to that of the data receiver register (DRR), and the destination address is set to the first element of the data block. Since there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

In order to facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 3 parameter set, the parameters located at the link address are loaded into the channel 3 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

#### 18.3.4.3.2 Transmit Channel

DMA channel 2 services the outgoing data stream of the McBSP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the DMA channel, with duplicate PaRAM set entries at PaRAM set 65.

#### 18.3.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA3 to service a peripheral continuously, it presents a number of restrictions to the CPU. Since the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA3 very closely in order to process the data. The EDMA3 receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA3 transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA3 activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA3 transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA3 activity completes, they switch. The EDMA3 then writes over the old input data and transfers the new output data. [Figure 18-28](#) shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the DMA channels need only a moderate change. Instead of one link parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. [Figure 18-29](#) shows the DMA channel configuration required.

Each channel has two link parameter sets, ping and pong. The DMA channel is initially loaded with the ping parameters ([Figure 18-29](#)). The link address for the ping set is set to the PaRAM offset of the pong parameter set ([Figure 18-30](#)). The link address for the pong set is set to the PaRAM offset of the ping parameter set ([Figure 18-31](#)). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

### 18.3.4.4.1 Synchronization with the CPU

In order to utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA3 to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to 1 to generate an interrupt after completion. When channel 3 fills an input buffer, the E3 bit in the interrupt pending register (IPR) is set to 1; when channel 2 empties an output buffer, the E2 bit in IPR is set to 1. The CPU must manually clear these bits. With the channel parameters set, the CPU polls IPR to determine when to switch. The EDMA3 and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA3 to complete.

### 18.3.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

#### 18.3.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA3 channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA3 needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). [Figure 18-32](#) shows the EDMA3 setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 16, intermediate transfer complete chaining sets the E31 bit (specified by TCC of 31) in the chained event register (CER) and provides a synchronization event to channel 31. Upon completion of the last array transfer of channel 16, transfer complete chaining—not intermediate transfer complete chaining—sets the E31 bit in CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 31. The completion of channel 31 sets the I31 bit (specified by TCCMODE:TCC) in the interrupt pending register (IPR), which can generate an interrupt to the CPU, if the I31 bit in the interrupt enable register (IER) is set to 1.

#### 18.3.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA3 transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. [Figure 18-33](#) shows the EDMA3 setup and illustration of an example single large block transfer.

The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA3 performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1K byte is a reasonable small transfer in this example. The EDMA3 is set up to transfer 16 arrays of 1K byte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, DMA channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1K byte array is transferred. The CPU starts the EDMA3 transfer by writing to the appropriate bit of the event set register (ESR.E25). The EDMA3 transfers the first 1K byte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes DMA channel 25 to transfer the next 1K byte array. This process continues until the transfer parameters are exhausted, at which point the EDMA3 has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. [Figure 18-34](#) shows the EDMA3 setup and illustration of the broken up smaller packet transfers.

**Figure 18-32. Intermediate Transfer Completion Chaining Example**

**Setup**

Channel 16 parameters for chaining

- ☐ Enable transfer complete chaining:  
OPT.TCCCHEN = 1  
OPT.TCC = 001 1111b
- ☐ Enable intermediate transfer complete chaining:  
OPT.ITCCHEN = 1  
OPT.TCC = 001 1111b

Channel 16 parameters for chaining

- ☐ Enable transfer completion interrupt:  
OPT.TCINTEN = 1  
OPT.TCC = 001 1111b
- ☐ Disable intermediate transfer complete chaining:  
OPT.ITCCHEN = 0

Event enable register (EER)

- ☐ Enable channel 16  
EER.E16 = 1

**Figure 18-33. Single Large Block Transfer Example**

**Figure 18-34. Smaller Packet Data Transfers Example**

EDMA channel 25 setup

- ACNT = 1024
- BCNT = 16
- CCNT = 1
- OPT.SYNCDIM = A SYNC
- OPT.ITCCHEN = 1
- OPT.TCINTEN = 1
- OPT.TCC = 25

## 18.4 Registers

This section discusses the registers of the EDMA3 controller.

### 18.4.1 Parameter RAM (PaRAM) Entries

[Table 18-14](#) lists the parameter RAM (PaRAM) entries for the EDMA3 channel controller (EDMA3CC). See your device-specific data manual for the memory address of these registers.

**Table 18-14. EDMA3 Channel Controller (EDMA3CC) Parameter RAM (PaRAM) Entries**

| Offset | Acronym      | Parameter                          | Section                          |

### 18.4.1.1 Channel Options Parameter (OPT)

The channel options parameter (OPT) is shown in [Figure 18-35](#) and described in [Table 18-15](#).

**NOTE:** The TCC field in OPT is a 6-bit field and can be programmed for any value between 0-64. For devices with 32 DMA channels, the TCC field should have a value between 0 to 31 so that it sets the appropriate bits (0 to 31) in the interrupt pending register (IPR) (and can interrupt the CPU(s) on enabling the interrupt enable register (IER) bits (0-31)).

| 7-4   | Reserved | 0                                                | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3     | STATIC   | 0<br>1                                           | Static PaRAM set.<br>0 PaRAM set is not static. PaRAM set is updated or linked after TR is submitted. A value of 0 should be used for DMA channels and for nonfinal transfers in a linked list of QDMA transfers.<br>1 PaRAM set is static. PaRAM set is not updated or linked after TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2     | SYNCDIM  | 0<br>1                                           | Transfer synchronization dimension.<br>0 A-synchronized. Each event triggers the transfer of a single array of ACNT bytes.<br>1 AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1     | DAM      | 0<br>1                                           | Destination address mode.<br>0 Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO.<br>1 Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.<br><br>Note: The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. On the C674x/OMAP-L1x processors, no peripherals, memory, or memory controller support constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM = 0) by appropriately programming the count and indices values. |
| 0     | SAM      | 0<br>1                                           | Source address mode.<br>0 Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO.<br>1 Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.<br><br>Note: The constant addressing (CONST) mode has limited applicability. ### 18.4.1.2 Channel Source Address Parameter (SRC)

The channel source address parameter (SRC) specifies the starting byte address of the source. The SRC is shown in [Figure 18-36](#) and described in [Table 18-16](#).

**Figure 18-36. Channel Source Address Parameter (SRC)**

LEGEND: R = Read only; -n = value after reset

**Table 18-16. Channel Source Address Parameter (SRC) Field Descriptions**

| Bit  | Field | Value        | Description                                                        |
|------|-------|--------------|--------------------------------------------------------------------|
| 31-0 | SRC   | 0-FFFF FFFFh | Source address. Specifies the starting byte address of the source. |

### 18.4.1.3 A Count/B Count Parameter (A\_B\_CNT)

The A count/B count parameter (A\_B\_CNT) specifies the number of bytes within the 1st dimension of a transfer and the number of arrays of length ACNT. The A\_B\_CNT is shown in [Figure 18-37](#) and described in [Table 18-17](#).

**Figure 18-37. A Count/B Count Parameter (A\_B\_CNT)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 18-17. A Count/B Count Parameter (A\_B\_CNT) Field Descriptions**

| Bit   | Field | Value   | Description                                                                                                                                                                 |
|-------|-------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | BCNT  | 0-FFFFh | B count. Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.                                      |
| 15-0  | ACNT  | 0-FFFFh | A count for 1st Dimension. Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535. |

#### 18.4.1.4 Channel Destination Address Parameter (DST)

The channel destination address parameter (DST) specifies the starting byte address of the source. The DST is shown in [Figure 18-38](#) and described in [Table 18-18](#).

**Figure 18-38. Channel Destination Address Parameter (DST)**

LEGEND: R = Read only; -n = value after reset

**Table 18-18. Channel Destination Address Parameter (DST) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                            |
|------|-------|--------------|--------------------------------------------------------------------------------------------------------|
| 31-0 | DST   | 0-FFFF FFFFh | Destination address. Specifies the starting byte address of the destination where data is transferred. |

#### 18.4.1.5 Source B Index/Destination B Index Parameter (SRC\_DST\_BIDX)

The source B index/destination B index parameter (SRC\_DST\_BIDX) specifies the value (2s complement) used for source address modification between each array in the 2nd dimension and the value (2s complement) used for destination address modification between each array in the 2nd dimension. The SRC\_DST\_BIDX is shown in [Figure 18-39](#) and described in [Table 18-19](#).

**Figure 18-39. Source B Index/Destination B Index Parameter (SRC\_DST\_BIDX)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 18-19. Source B Index/Destination B Index Parameter (SRC\_DST\_BIDX) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                                                                 |
|-------|---------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | DSTBIDX | 0-FFFFh | Destination B index. Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767. |
| 15-0  | SRCBIDX | 0-FFFFh | Source B index. Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.           |

#### 18.4.1.6 Link Address/B Count Reload Parameter (LINK\_BCNTRLD)

The link address/B count reload parameter (LINK\_BCNTRLD) specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking and the value used to reload the BCNT field in the A count/B count parameter (A\_B\_CNT) once the last array in the 2nd dimension is transferred. The LINK\_BCNTRLD is shown in [Figure 18-40](#) and described in [Table 18-20](#).

**Figure 18-40. Link Address/B Count Reload Parameter (LINK\_BCNTRLD)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 18-20. Link Address/B Count Reload Parameter (LINK\_BCNTRLD) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                                                                                                                                                                                                |
|-------|---------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | BCNTRLD | 0-FFFFh | B count reload. The count value used to reload BCNT in the A count/B count parameter (A_B_CNT) when BCNT decrements to 0 (TR submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.                                                                                    |
| 15-0  | LINK    | 0-FFFFh | Link address. The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0. A value of FFFFh specifies a null link. |

### 18.4.1.7 Source C Index/Destination C Index Parameter (SRC\_DST\_CIDX)

The source C index/destination C index parameter (SRC\_DST\_CIDX) specifies the value (2s complement) used for source address modification between each array in the 3rd dimension and the value (2s complement) used for destination address modification between each array in the 3rd dimension. The SRC\_DST\_CIDX is shown in [Figure 18-41](#) and described in [Table 18-21](#).

**Figure 18-41. Source C Index/Destination C Index Parameter (SRC\_DST\_CIDX)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 18-21. Source C Index/Destination C Index Parameter (SRC\_DST\_CIDX) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                                                     |
|-------|---------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | DSTCIDX | 0-FFFFh | Destination C index. Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. |
| 15-0  | SRCCIDX | 0-FFFFh | Source C index. Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.      |

### 18.4.1.8 C Count Parameter (CCNT)

The C count parameter (CCNT) specifies the number of frames in a block. The CCNT is shown in [Figure 18-42](#) and described in [Table 18-22](#).

**Figure 18-42. C Count Parameter (CCNT)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 18-22. C Count Parameter (CCNT) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                            |
|-------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                                                                                               |
| 15-0  | CCNT     | 0-FFFFh | C counter. Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535. |

## 18.4.2 EDMA3 Channel Controller (EDMA3CC) Registers

Table 18-23 lists the memory-mapped registers for the EDMA3 channel controller (EDMA3CC). See your device-specific data manual for the memory address of these registers and for the shadow region addresses. All other register offset addresses not listed in Table 18-23 should be considered as reserved locations and the register contents should not be modified.

**Table 18-23. EDMA3 Channel Controller (EDMA3CC) Registers**

| Offset                  | Acronym    | Register Description                            | Section                            |
|-------------------------|------------|-------------------------------------------------|------------------------------------|

<sup>(1)</sup> On previous architectures, the EDMA3TC priority was controlled by the queue priority register (QUEPRI) in the EDMA3CC memory-map. However for this device, the priority control for the transfer controllers is controlled by the chip-level registers in the System Configuration Module. You should use the chip-level registers and not QUEPRI to configure the TC priority.

**Table 18-23. EDMA3 Channel Controller (EDMA3CC) Registers (continued)**

| Offset                                   | Acronym | Register Description                | Section                            |

## 18.4.2.1 Global Registers

### 18.4.2.1.1 Revision Identification Register (REVID)

The revision identification register (REVID) uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC. The REVID is shown in [Figure 18-43](#) and described in [Table 18-24](#).

**Figure 18-43. Revision ID Register (REVID)**

|              |   |
|--------------|---|
| 31           | 0 |

### 18.4.2.1.2 EDMA3CC Configuration Register (CCCFG)

The EDMA3CC configuration register (CCCFG) provides the features/resources for the EDMA3CC in a particular device. The CCCFG is shown in [Figure 18-44](#) and described in [Table 18-25](#).

**Figure 18-44. EDMA3CC Configuration Register (CCCFG)**

### 18.4.2.1.3 QDMA Channel $n$ Mapping Register (QCHMAP $n$ )

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel  $n$  mapping register (QCHMAP $n$ ). The QCHMAP $n$  is shown in [Figure 18-45](#) and described in [Table 18-26](#).

**NOTE:** At reset the QDMA channel mapping registers for all QDMA channels point to the PaRAM set 0. Prior to using any QDMA channel, QCHMAP $n$  should be programmed appropriately to point to a different PaRAM set.

**Figure 18-45. QDMA Channel  $n$  Mapping Register (QCHMAP $n$ )**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

#### 18.4.2.1.4 DMA Channel Queue Number Register $n$ (DMAQNUM $n$ )

The DMA channel queue number register  $n$  (DMAQNUM $n$ ) allows programmability of each of the 32 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0. The DMAQNUM $n$  is shown in Figure 18-46 and described in . Table 18-28 shows the channels and their corresponding bits in DMAQNUM $n$ .

**NOTE:** Since the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0 and Q1 TRs are submitted to TC1, by programming DMAQNUM $n$  for a particular DMA channel also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

**Figure 18-46. DMA Channel Queue Number Register  $n$  (DMAQNUM $n$ )**

### 18.4.2.1.5 QDMA Channel Queue Number Register (QDMAQNUM)

The QDMA channel queue number register (QDMAQNUM) is used to program all the QDMA channels in the EDMA3CC to submit the associated QDMA event to any of the event queues in the EDMA3CC. The QDMAQNUM is shown in [Figure 18-47](#) and described in .

**Figure 18-47. QDMA Channel Queue Number Register (QDMAQNUM)**

### 18.4.2.1.6 Queue Priority Register (QUEPRI)

On previous architectures, the EDMA3TC priority was controlled by the queue priority register (QUEPRI) in the EDMA3CC memory-map. However for this device, the priority control for the transfer controllers is controlled by the chip-level registers in the System Configuration Module. You should use the chip-level registers and not QUEPRI to configure the TC priority.

## 18.4.2.2 Error Registers

The EDMA3CC contains a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

### 18.4.2.2.1 Event Missed Registers (EMR)

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed register (EMR). All trigger types are treated individually, that is, manual triggered (ESR), chain triggered (CER), and event triggered (ER) are all treated separately. The EMR bit for a channel is also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. See [Section 18.2.9.4](#) for details on EDMA3CC error interrupt generation.

The EMR is shown in [Figure 18-48](#) and described in [Table 18-30](#).

**Figure 18-48. Event Missed Register (EMR)**

**Table 18-30. Event Missed Register (EMR) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                        |
|------|-----------|-------|------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | <i>En</i> |       | Channel 0-31 event missed. <i>En</i> is cleared by writing a 1 to the corresponding bit in the event missed clear register (EMCR). |
|      |           | 0     | No missed event.                                                                                                                   |
|      |           | 1     | Missed event occurred.                                                                                                             |

### 18.4.2.2.2 Event Missed Clear Registers (EMCR)

Once a missed event is posted in the event missed register (EMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear register (EMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR; writing a 0 has no effect.

The EMCR is shown in [Figure 18-49](#) and described in [Table 18-31](#).

**Figure 18-49. Event Missed Clear Register (EMCR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 | W-0 |

LEGEND: W = Write only; -n = value after reset

**Table 18-31. Event Missed Clear Register (EMCR) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                 |
|------|-------|-------|-----------------------------------------------------------------------------------------------------------------------------|
| 31-0 | $E_n$ |       | Event missed 0-31 clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC. |
|      |       | 0     | No effect.                                                                                                                  |
|      |       | 1     | Corresponding missed event bit in the event missed register (EMR) is cleared ( $E_n = 0$ ).                                 |

### 18.4.2.2.3 QDMA Event Missed Register (QEMR)

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR or CCERR) were previously cleared), the EDMA3CC generates an error interrupt. See [Section 18.2.9.4](#) for details on EDMA3CC error interrupt generation.

The QEMR is shown in [Figure 18-50](#) and described in [Table 18-32](#).

**Figure 18-50. QDMA Event Missed Register (QEMR)**

LEGEND: R = Read only; -n = value after reset

| Bit  | Field    | Value | Description                                                                                                                              |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                                                                 |
| 7-0  | $E_n$    | 0     | Channel 0-7 QDMA event missed. $E_n$ is cleared by writing a 1 to the corresponding bit in the QDMA event missed clear register (QEMCR). |
|      |          | 1     | No missed event.                                                                                                                         |
|      |          | 1     | Missed event occurred.                                                                                                                   |

#### 18.4.2.2.4 QDMA Event Missed Clear Register (QEMCR)

Once a missed event is posted in the QDMA event missed registers (QEMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the QDMA event missed clear registers (QEMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in QEMR; writing a 0 has no effect.

The QEMCR is shown in [Figure 18-51](#) and described in [Table 18-33](#).

**Figure 18-51. QDMA Event Missed Clear Register (QEMCR)**

| 7-0  | En       | 0     | QDMA event missed clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC. |
|      |          | 0     | No effect.                                                                                                                  |
|      |          | 1     | Corresponding missed event bit in the QDMA event missed register (QEMR) is cleared (En = 0).                                |

### 18.4.2.2.5 EDMA3CC Error Register (CCERR)

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs that have the TCINTEN or TCCHEN bit in OPT set to 1) to the EDMA3CC has exceeded the maximum allowed value of 31. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR or QEMR) were previously cleared), the EDMA3CC generates an error interrupt. See [Section 18.2.9.4](#) for details on EDMA3CC error interrupt generation. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR).

The CCERR is shown in [Figure 18-52](#) and described in [Table 18-34](#).

### 18.4.2.2.6 EDMA3CC Error Clear Register (CCERRCLR)

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTAT $n$ ) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect.

The CCERRCLR is shown in [Figure 18-53](#) and described in [Table 18-35](#).

**Figure 18-53. EDMA3CC Error Clear Register (CCERRCLR)**

| 16    | TCCERR   | 0     | Transfer completion code error clear.                                                                                             |
|       |          | 1     | No effect.                                                                                                                        |
|       |          | 1     | Clears the TCCERR bit in the EDMA3CC error register (CCERR).                                                                      |
| 15-2  | Reserved | 0     | Reserved                                                                                                                          |
| 1     | QTHRXCD1 | 0     | Queue threshold error clear for queue 1.                                                                                          |
|       |          | 1     | No effect.                                                                                                                        |
|       |          | 1     | Clears the QTHRXCD1 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 1 (QSTAT1). |
| 0     | QTHRXCD0 | 0     | Queue threshold error clear for queue 0.                                                                                          |
|       |          | 1     | No effect.                                                                                                                        |
|       |          | 1     | Clears the QTHRXCD0 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 0 (QSTAT0). |

#### 18.4.2.2.7 Error Evaluate Register (EEVAL)

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an “all the error bits cleared” to “at least one error bit is set”. Alternatively, a CPU write of 1 to the EVAL bit in the error evaluate register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect.

The EEVAL is shown in [Figure 18-54](#) and described in [Table 18-36](#).

**Figure 18-54. Error Evaluate Register (EEVAL)**

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 18-36. Error Evaluate Register (EEVAL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                             |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                                                                |
| 1    | Reserved | 0     | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 0    | EVAL     | 0     | Error interrupt evaluate.<br>No effect.                                                                                                 |
|      |          | 1     | EDMA3CC error interrupt will be pulsed if any errors have not been cleared in any of the error registers (EMR, QEMR, or CCERR).         |

### 18.4.2.3 Region Access Enable Registers

The region access enable register group consists of the DMA access enable registers (DRAEm) and the QDMA access enable registers (QRAEm). Where  $m$  is the number of shadow regions in the EDMA3CC memory-map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

#### 18.4.2.3.1 DMA Region Access Enable for Region $m$ (DRAEm)

The DMA region access enable registers for shadow region  $m$  (DRAEm) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region  $m$  view of the DMA channel registers. See the EDMA3CC register memory-map for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the DRAEm configuration determines completion of which DMA channels will result in assertion of the shadow region  $m$  DMA completion interrupt (see [Section 18.2.9](#)).

The DRAEm is shown in [Figure 18-55](#) and described in [Table 18-37](#).

**Figure 18-55. DMA Region Access Enable Register for Region  $m$  (DRAEm)**

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

### 18.4.2.3.2 QDMA Region Access Enable Registers (QRAEm)

The QDMA region access enable registers for shadow region  $m$  (QRAEm) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all QDMA registers in the shadow region  $m$  view of the QDMA registers. This includes all 8-bit QDMA registers.

The QRAEm is shown in [Figure 18-56](#) and described in [Table 18-38](#).

### 18.4.2.4 Status/Debug Visibility Registers

The following set of registers provide visibility into the event queues and a TR lifecycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

#### 18.4.2.4.1 Event Queue Entry Registers (QxEy)

The event queue entry registers (QxEy) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues (Q0 and Q1) in the EDMA3CC: Q0E0 to Q0E15 and Q1E0 to Q1E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 0000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15.

The QxEy is shown in [Figure 18-57](#) and described in [Table 18-39](#).

**Figure 18-57. Event Queue Entry Registers (QxEy)**

LEGEND: R = Read only; -n = value after reset; -x = value is indeterminate after reset

#### 18.4.2.4.4 EDMA3CC Status Register (CCSTAT)

The EDMA3CC status register (CCSTAT) has a number of status bits that reflect which parts of the EDMA3CC logic is active at any given instant of time. The CCSTAT is shown in [Figure 18-60](#) and described in [Table 18-42](#).

**Figure 18-60. EDMA3CC Status Register (CCSTAT)**

| 13-8  | COMPACTV  | 0-3Fh<br>0<br>1h-3Fh | Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set to 1). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMA3CC will not service any new TRs until the count is less than 63 (or return a transfer completion code from a transfer controller, which would decrement the count).<br>No completion requests outstanding.<br>Total of 1 completion request to 63 completion requests are outstanding. |

### 18.4.2.5 DMA Channel Registers

The following registers pertain to the 32 DMA channels. The 32 DMA channels consist of registers (with the exception of DMAQNUM $n$ ) that each have 32 bits and the bit position of each register matches the DMA channel number.

The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region is controlled by the DMA region access registers (DRAEm). These registers are described in [Section 18.4.2.3.1](#) and the details for shadow region/global region usage is explained in [Section 18.2.7](#).

#### 18.4.2.5.1 Event Register (ER)

All external events are captured in the event register (ER). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.En = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.En = 0) once the corresponding events are prioritized and serviced. If ER.En are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.En), provided that the event was enabled (EER.En = 1).

Event  $n$  can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR would be set since an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The ER is shown in [Figure 18-61](#) and described in [Table 18-43](#).

**Figure 18-61. Event Register (ER)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | En    | 0     | Event 0-31. Events 0-31 are captured by the EDMA3CC and are latched into ER. The events are set (En = 1) even when events are disabled (En = 0 in the event enable register, EER). |
|      |       | 1     | EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.                                              |

### 18.4.2.5.2 Event Clear Register (ECR)

Once an event has been posted in the event register (ER), the event is cleared in two ways. If the event is enabled in the event enable register (EER) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER), the CPU can clear the event by way of the event clear register (ECR).

Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR.

The ECR is shown in [Figure 18-62](#) and described in [Table 18-44](#).

**Figure 18-62. Event Clear Register (ECR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| Bit  | Field | Value | Description                                                                                                                                          |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | En    |       | Event clear for event 0-31. Any of the event bits in ECR is set to 1 to clear the event (En) in the event register (ER). A write of 0 has no effect. |
|      |       | 0     | No effect.                                                                                                                                           |
|      |       | 1     | EDMA3CC event is cleared in the event register (ER).                                                                                                 |

### 18.4.2.5.3 Event Set Register (ESR)

The event set register (ESR) allows the CPU (or EDMA programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register ( $En$ ) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect.

The event set register operates independent of the event register (ER), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in  $EER.En$ ).

Once the event is set in the event set register, it cannot be cleared by CPU writes, in other words, the event clear register (ECR) has no effect on the state of ESR. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR would be set since an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Manually-triggered transfers via writes to ESR allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the  $ESR.En$  bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers ( $EMR.En = 1$ ).

The ESR is shown in [Figure 18-63](#) and described in [Table 18-45](#).

**Figure 18-63. Event Set Register (ESR)**

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

|------|-------|-------|------------------------------------------------------------------------------------------------------------|
| 31-0 | $En$  | 0     | Event set for event 0-31.                                                                                  |
|      |       | 1     | No effect.                                                                                                 |
|      |       | 1     | Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC. |

#### 18.4.2.5.4 Chained Event Register (CER)

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event register (CER). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer.

The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The *En* bit is set (regardless of the state of EER.En) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced.

If the *En* bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed register (EMR.En = 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR would be set since an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The CER is shown in [Figure 18-64](#) and described in [Table 18-46](#).

| 31-0 | <i>En</i> | 0     | Chained event for event 0-31.<br>No effect.                                                                |
|      |           | 1     | Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC. |

#### 18.4.2.5.5 Event Enable Register (EER)

The EDMA3CC provides the option of selectively enabling/disabling each event in the event register (ER) by using the event enable register (EER). If an event bit in EER is set to 1 (using the event enable set register, EESR), it will enable that corresponding event. Alternatively, if an event bit in EER is cleared (using the event enable clear register, EECR), it will disable the corresponding event.

The event register latches all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event register enables the EDMA3CC to process the already set event like any other new event. The EER settings do not have any effect on chained events ( $CER.En = 1$ ) and manually set events ( $ESR.En = 1$ ).

The EER is shown in [Figure 18-65](#) and described in [Table 18-47](#).

**Figure 18-65. Event Enable Register (EER)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

|      |           | 1     | Event is enabled. An external event latched in the event register (ER) is evaluated by the EDMA3CC.                                          |

### 18.4.2.5.6 Event Enable Clear Register (EECR)

The event enable register (EER) cannot be modified by directly writing to it. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear register (EECR) is used to disable events. Writes of 1 to the bits in EECR clear the corresponding event bits in EER; writes of 0 have no effect.

The EECR is shown in [Figure 18-66](#) and described in [Table 18-48](#).

**Figure 18-66. Event Enable Clear Register (EECR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| Bit  | Field | Value | Description                                                                                  |
|------|-------|-------|----------------------------------------------------------------------------------------------|
| 31-0 | En    | 0     | Event enable clear for events 0-31.<br>No effect.                                            |
|      |       | 1     | Event is disabled. Corresponding bit in the event enable register (EER) is cleared (En = 0). |

### 18.4.2.5.7 Event Enable Set Register (EESR)

The event enable register (EER) cannot be modified by directly writing to it. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable set register (EESR) is used to enable events. Writes of 1 to the bits in EESR set the corresponding event bits in EER; writes of 0 have no effect.

The EESR is shown in [Figure 18-67](#) and described in [Table 18-49](#).

**Figure 18-67. Event Enable Set Register (EESR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| Bit  | Field | Value | Description                                                                             |
|------|-------|-------|-----------------------------------------------------------------------------------------|
| 31-0 | En    | 0     | Event enable set for events 0-31.<br>No effect.                                         |
|      |       | 1     | Event is enabled. Corresponding bit in the event enable register (EER) is set (En = 1). |

#### 18.4.2.5.8 Secondary Event Register (SER)

The secondary event register (SER) provides information on the state of a DMA channel or event (0 through 31). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source ( $ESR.En = 1$ ,  $ER.En = 1$ , or  $CER.En = 1$ ), which results in the setting of a corresponding event bit in SER ( $SER.En = 1$ ), it implies that the corresponding DMA event is in the queue.

Once a bit corresponding to an event is set in SER, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that leads to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR) needs to clear the SER bits for the EDMA3CC to evaluate subsequent events and perform subsequent transfers on the same channel. Based on whether the associated TR is valid, or it is a null or dummy TR, the implications on the state of SER and the required user action in order to submit another DMA transfer might be different.

The SER is shown in [Figure 18-68](#) and described in [Table 18-50](#).

**Figure 18-68. Secondary Event Register (SER)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| Bit  | Field     | Value | Description                                                                                                     |
|------|-----------|-------|-----------------------------------------------------------------------------------------------------------------|
| 31-0 | <i>En</i> |       | Secondary event register. The secondary event register is used to provide information on the state of an event. |
|      |           | 0     | Event is not currently stored in the event queue.                                                               |
|      |           | 1     | Event is currently stored in the event queue. Event arbiter will not prioritize additional events.              |

#### 18.4.2.5.9 Secondary Event Clear Register (SECR)

The secondary event clear register (SECR) clears the status of the secondary event registers (SER). CPU writes of 1 clear the corresponding set bits in SER. Writes of 0 have no effect.

The SECR is shown in [Figure 18-69](#) and described in [Table 18-51](#).

**Figure 18-69. Secondary Event Clear Register (SECR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| Bit  | Field     | Value | Description                                                                      |
|------|-----------|-------|----------------------------------------------------------------------------------|
| 31-0 | <i>En</i> |       | Secondary event clear register                                                   |
|      |           | 0     | No effect.                                                                       |
|      |           | 1     | Corresponding bit in the secondary event register (SER) is cleared ( $En = 0$ ). |

### 18.4.2.6 Interrupt Registers

All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. The following registers are used for the transfer completion interrupt reporting/generating by the EDMA3CC. See [Section 18.2.9](#) for more details on EDMA3CC completion interrupt generation.

#### 18.4.2.6.1 Interrupt Enable Registers (IER)

Interrupt enable register (IER) is used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER cannot be written to directly. To set any interrupt bit in IER, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR). Similarly, to clear any interrupt bit in IER, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear register (IECR).

The IER is shown in [Figure 18-70](#) and described in [Table 18-52](#).

**Figure 18-70. Interrupt Enable Register (IER)**

|     |     |     |     |      |     |     |     |     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

| Bit  | Field | Value | Description                         |
|------|-------|-------|-------------------------------------|
| 31-0 | En    | 0     | Interrupt enable for channels 0-31. |
|      |       | 0     | Interrupt is not enabled.           |
|      |       | 1     | Interrupt is enabled.               |

#### 18.4.2.6.2 Interrupt Enable Clear Register (IECR)

The interrupt enable clear register (IECR) is used to clear interrupts. Writes of 1 to the bits in IECR clear the corresponding interrupt bits in the interrupt enable registers (IER); writes of 0 have no effect.

The IECR is shown in [Figure 18-71](#) and described in [Table 18-53](#).

**Figure 18-71. Interrupt Enable Clear Register (IECR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| Bit  | Field | Value | Description                                                                   |
|------|-------|-------|-------------------------------------------------------------------------------|
| 31-0 | En    |       | Interrupt enable clear for channels 0-31.                                     |
|      |       | 0     | No effect                                                                     |
|      |       | 1     | Corresponding bit in the interrupt enable register (IER) is cleared (In = 0). |

#### 18.4.2.6.3 Interrupt Enable Set Register (IESR)

The interrupt enable set register (IESR) is used to enable interrupts. Writes of 1 to the bits in IESR set the corresponding interrupt bits in the interrupt enable registers (IER); writes of 0 have no effect.

The IESR is shown in [Figure 18-72](#) and described in [Table 18-54](#).

**Figure 18-72. Interrupt Enable Set Register (IESR)**

| Bit  | Field | Value | Description                                                               |
|------|-------|-------|---------------------------------------------------------------------------|
| 31-0 | En    |       | Interrupt enable set for channels 0-31.                                   |
|      |       | 0     | No effect.                                                                |
|      |       | 1     | Corresponding bit in the interrupt enable register (IER) is set (In = 1). |

#### 18.4.2.6.4 Interrupt Pending Register (IPR)

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set to 1 in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel.

When an interrupt transfer completion code with  $TCC = n$  is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR. $ln$ , if  $n = 0$  to 31). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR).

The IPR is shown in [Figure 18-73](#) and described in [Table 18-55](#).

**Figure 18-73. Interrupt Pending Register (IPR)**

| Bit  | Field | Value | Description                                                                       |
|------|-------|-------|-----------------------------------------------------------------------------------|
| 31-0 | $ln$  | 0     | Interrupt pending for $TCC = 0-31$ .                                              |
|      |       | 0     | Interrupt transfer completion code is not detected or was cleared.                |
|      |       | 1     | Interrupt transfer completion code is detected ( $ln = 1$ , $n = EDMA3TC[5:0]$ ). |

### 18.4.2.6.5 Interrupt Clear Register (ICR)

The bits in the interrupt pending register (IPR) are cleared by writing a 1 to the corresponding bits in the interrupt clear register (ICR); writes of 0 have no effect. All set bits in IPR must be cleared to allow EDMA3CC to assert additional transfer completion interrupts.

The ICR is shown in [Figure 18-74](#) and described in [Table 18-56](#).

**Figure 18-74. Interrupt Clear Register (ICR)**

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

|      |           | 1     | No effect.                                                                             |
|      |           | 1     | Corresponding bit in the interrupt pending register (IPR) is cleared ( <i>In</i> = 0). |

### 18.4.2.6.6 Interrupt Evaluate Register (IEVAL)

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAEm and QRAEm). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU.

The IEVAL is shown in [Figure 18-75](#) and described in [Table 18-57](#).

**Figure 18-75. Interrupt Evaluate Register (IEVAL)**

LEGEND: R = Read only; W = Write only; -n = value after reset

For example, writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt, but writing to the EVAL bit in IEVAL1 pulses the region 1 completion interrupt.</p> |

### 18.4.2.7 QDMA Channel Registers

The following registers pertain to the 8 QDMA channels. The 8 QDMA channels consist of registers (with the exception of QDMAQNUM) that each have 8 bits and the bit position of each register matches the QDMA channel number.

The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region is controlled by the QDMA region access registers (QRAEm). These registers are described in [Section 18.4.2.3.2](#) and the details for shadow region/global region usage is explained in [Section 18.2.7](#).

#### 18.4.2.7.1 QDMA Event Register (QER)

The QDMA event register (QER) channel  $n$  bit is set ( $En = 1$ ) when the CPU or any EDMA programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel  $n$  mapping register (QCHMAP $n$ )) in the PaRAM entry associated with QDMA channel  $n$  (which is also programmed using QCHMAP $n$ ). The  $En$  bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAP $n$  settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel  $n$  bit is also enabled ( $QEER.En = 1$ ). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers.

The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the  $En$  bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR ( $En = 1$ ).

The QER is shown in [Figure 18-76](#) and described in [Table 18-58](#).

**Figure 18-76. QDMA Event Register (QER)**

|      |          | 1     | Corresponding QDMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC. |

### 18.4.2.7.2 QDMA Event Enable Register (QEER)

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set to 1 (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER.

The QEER is shown in [Figure 18-77](#) and described in [Table 18-59](#).

**Figure 18-77. QDMA Event Enable Register (QEER)**

|          |          |  |  |  |  |  |  |     |     |     |     |     |     |     |     |     |    |

|      |          | 1     | QDMA channel $n$ is enabled. QDMA events will be recognized and will get latched in the QDMA event register (QER).                                             |

### 18.4.2.7.3 QDMA Event Enable Clear Register (QEECR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, in order to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEECR is shown in [Figure 18-78](#) and described in [Table 18-60](#).

**Figure 18-78. QDMA Event Enable Clear Register (QEECR)**

### 18.4.2.7.5 QDMA Secondary Event Register (QSER)

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user action in order to submit another QDMA transfer might be different.

The QSER is shown in [Figure 18-80](#) and described in [Table 18-62](#).

**Figure 18-80. QDMA Secondary Event Register (QSER)**

|          |  |  |  |  |  |  |  |     |     |     |     |     |     |     |     |     |    |

|      |          | 1     | QDMA event is currently stored in event queue. EDMA3CC will not prioritize additional events.             |

### 18.4.2.7.6 QDMA Secondary Event Clear Register (QSECR)

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers.

The QSECR is shown in [Figure 18-81](#) and described in [Table 18-63](#).

**Figure 18-81. QDMA Secondary Event Clear Register (QSECR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

| 7-0  | $E_n$    | 0     | QDMA secondary event clear register for channels 0-7.                                                                     |
|      |          | 1     | No effect.                                                                                                                |
|      |          | 1     | Corresponding bit in the QDMA secondary event register (QSER) and the QDMA event register (QER) is cleared ( $E_n = 0$ ). |

### 18.4.3 EDMA3 Transfer Controller (EDMA3TC) Registers

Table 18-64 lists the memory-mapped registers for the EDMA3 transfer controller (EDMA3TC). See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 18-64 should be considered as reserved locations and the register contents should not be modified.

**Table 18-64. EDMA3 Transfer Controller (EDMA3TC) Registers**

### 18.4.3.1 Revision Identification Register (REVID)

The revision identification register (REVID) is a constant register that uniquely identifies the EDMA3TC and specific revision of the EDMA3TC. The REVID is shown in [Figure 18-82](#) and described in [Table 18-65](#).

**Figure 18-82. Revision ID Register (REVID)**

LEGEND: R = Read only; -n = value after reset

**Table 18-65. Revision ID Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description                                                                                         |
|------|-------|------------|-----------------------------------------------------------------------------------------------------|
| 31-0 | REV   | 4000 3B00h | Peripheral identifier.<br>Uniquely identifies the EDMA3TC and the specific revision of the EDMA3TC. |

### 18.4.3.2 EDMA3TC Configuration Register (TCCFG)

The EDMA3TC configuration register (TCCFG) is shown in [Figure 18-83](#) and described in [Table 18-66](#).

**Figure 18-83. EDMA3TC Configuration Register (TCCFG)**

LEGEND: R = Read only; -n = value after reset; -x = value is indeterminate after reset

| 6-4   | DSTACTV   | 0-7h   | Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging.<br><br>0<br>Destination FIFO is empty.<br>1h<br>Destination FIFO contains 1 TR.<br>2h<br>Destination FIFO contains 2 TR.<br>3h<br>Destination FIFO contains 3 TR.<br>4h<br>Destination FIFO contains 4 TR. (Full if DSTREGDEPTH == 4)<br><br>If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle.<br><br>If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed. |

### 18.4.3.4 Error Registers

#### 18.4.3.4.1 Error Status Register (ERRSTAT)

The error status register (ERRSTAT) is shown in [Figure 18-85](#) and described in [Table 18-68](#).

**Figure 18-85. Error Status Register (ERRSTAT)**

LEGEND: R = Read only; -n = value after reset

**Table 18-68. Error Status Register (ERRSTAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                       |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0     | Reserved                                                                                                                                          |
| 3    | MMRAERR  | 0     | MMR address error.                                                                                                                                |
|      |          | 0     | MMR address error is not detected.                                                                                                                |
|      |          | 1     | User attempted to read or write to an invalid address in configuration memory map.                                                                |
| 2    | TRERR    | 0     | Transfer request (TR) error event.                                                                                                                |
|      |          | 0     | Transfer request (TR) error is not detected.                                                                                                      |
|      |          | 1     | Transfer request (TR) detected that violates constant addressing mode transfer (SAM or DAM is set to 1) alignment rules or has ACNT or BCNT == 0. |
| 1    | Reserved | 0     | Reserved                                                                                                                                          |
| 0    | BUSERR   | 0     | Bus error event.                                                                                                                                  |
|      |          | 0     | Bus error is not detected.                                                                                                                        |
|      |          | 1     | EDMA3TC has detected an error at source or destination address. Error information can be read from the error details register (ERRDET).           |

#### 18.4.3.4.2 Error Enable Register (ERREN)

The error enable register (ERREN) is shown in [Figure 18-86](#) and described in [Table 18-69](#). When any of the enable bits in ERREN is set, a bit set in the corresponding error status register (ERRSTAT) causes an assertion of the EDMA3TC interrupt.

**Figure 18-86. Error Enable Register (ERREN)**

|     |          |  |  |         |       |          |        |   |  |  |  |  |    |
|-----|----------|--|--|---------|-------|----------|--------|---|--|--|--|--|----|
| 31  | Reserved |  |  |         |       |          |        |   |  |  |  |  | 16 |
| R-0 |          |  |  |         |       |          |        |   |  |  |  |  |    |
| 15  | Reserved |  |  | 4       | 3     | 2        | 1      | 0 |  |  |  |  |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-69. Error Enable Register (ERREN) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                             |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0     | Reserved                                                                                                                                |
| 3    | MMRAERR  | 0     | Interrupt enable for MMR address error (MMRAERR).<br>MMRAERR is disabled.                                                               |
|      |          | 1     | MMRAERR is enabled and contributes to the state of EDMA3TC error interrupt generation                                                   |
| 2    | TRERR    | 0     | Interrupt enable for transfer request error (TRERR).<br>TRERR is disabled.                                                              |
|      |          | 1     | TRERR is enabled and contributes to the state of EDMA3TC error interrupt generation.                                                    |
| 1    | Reserved | 0     | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 0    | BUSERR   | 0     | Interrupt enable for bus error (BUSERR).<br>BUSERR is disabled.                                                                         |
|      |          | 1     | BUSERR is enabled and contributes to the state of EDMA3TC error interrupt generation.                                                   |

### 18.4.3.4.3 Error Clear Register (ERRCLR)

The error clear register (ERRCLR) is shown in [Figure 18-87](#) and described in [Table 18-70](#).

**Figure 18-87. Error Clear Register (ERRCLR)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 18-70. Error Clear Register (ERRCLR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                             |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0     | Reserved                                                                                                                |
| 3    | MMRAERR  | 0     | Interrupt enable clear for the MMR address error (MMRAERR) bit in the error status register (ERRSTAT).<br>No effect.    |
|      |          | 1     | Clears the MMRAERR bit in the error status register (ERRSTAT) but does not clear the error details register (ERRDET).   |
| 2    | TRERR    | 0     | Interrupt enable clear for the transfer request error (TRERR) bit in the error status register (ERRSTAT).<br>No effect. |
|      |          | 1     | Clears the TRERR bit in the error status register (ERRSTAT) but does not clear the error details register (ERRDET).     |
| 1    | Reserved | 0     | Reserved                                                                                                                |
| 0    | BUSERR   | 0     | Interrupt clear for the bus error (BUSERR) bit in the error status register (ERRSTAT).<br>No effect.                    |
|      |          | 1     | Clears the BUSERR bit in the error status register (ERRSTAT) and clears the error details register (ERRDET).            |

#### 18.4.3.4.4 Error Details Register (ERRDET)

The error details register (ERRDET) is shown in [Figure 18-88](#) and described in [Table 18-71](#).

**Figure 18-88. Error Details Register (ERRDET)**

LEGEND: R = Read only; -n = value after reset

**Table 18-71. Error Details Register (ERRDET) Field Descriptions**

| Bit    | Field    | Value | Description                                                                                                                                                                                                                                                                                            |
|--------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8   | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                               |
| 17     | TCCHEN   | 0-1   | Transfer completion chaining enable. Contains the TCCHEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.                                                                                                |
| 16     | TCINTEN  | 0-1   | Transfer completion interrupt enable. Contains the TCINTEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.                                                                                              |
| 15-14  | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                               |
| 13 - 8 | TCC      | 0-3Fh | Transfer complete code. Contains the TCC value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.                                                                                                                |
| 7-4    | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                               |
| 3-0    | STAT     | 0-Fh  | Transaction status. Stores the nonzero status/error code that was detected on the read status or write status bus. If read status and write status are returned on the same cycle, then the EDMA3TC chooses nonzero version. If both are nonzero, then the write status is treated as higher priority. |
|        |          | 0     | No error                                                                                                                                                                                                                                                                                               |

#### 18.4.3.4.5 Error Interrupt Command Register (ERRCMD)

The error interrupt command register (ERRCMD) is shown in [Figure 18-89](#) and described in [Table 18-72](#).

**Figure 18-89. Error Interrupt Command Register (ERRCMD)**

LEGEND: R = Read only; W = Write only; -n = value after reset

**Table 18-72. Error Interrupt Command Register (ERRCMD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                   |
|------|----------|-------|-----------------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                                                      |
| 0    | EVAL     | 0     | Error evaluate.<br>No effect.                                                                 |
|      |          | 1     | EDMA3TC error line is pulsed if any of the error status register (ERRSTAT) bits are set to 1. |

### 18.4.3.5 Read Command Rate Register (RDRATE)

The EDMA3 transfer controller issues Read commands at a rate controlled by the Read command rate register (RDRATE). The RDRATE defines the number of idle cycles that the Read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 32 inactive cycles between reads.

RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles.

The RDRATE is shown in [Figure 18-90](#) and described in [Table 18-73](#).

**NOTE:** It is expected that the RDRATE value for a transfer controller is static, as it is decided based on the application requirement. It is not recommended to change this setting on the go.

**Figure 18-90. Read Command Rate Register (RDRATE)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-73. Read Command Rate Register (RDRATE) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                        |

|      |          | 4h    | 32 EDMA3TC cycles between reads.                                                                                                   |
|      |          | 5h-7h | Reserved                                                                                                                           |

### 18.4.3.6 EDMA3TC Channel Registers

The EDMA3TC channel registers are split into three parts: the programming registers, the source active registers, and the destination FIFO registers. This section describes the registers and their functions. The program register set is programmed by the channel controller and is for internal use. The source active registers and the destination FIFO registers are read-only and are provided to facilitate advanced debug capabilities. The number of destination FIFO register sets depends on the destination FIFO depth. Both TC0 and TC1 have a destination FIFO depth of 4, and there are four sets of destination FIFO registers.

#### 18.4.3.6.1 Source Active Options Register (SAOPT)

The source active options register (SAOPT) is shown in [Figure 18-91](#) and described in [Table 18-74](#).

**Figure 18-91. Source Active Options Register (SAOPT)**

|          |  |    |      |      |       |        |                    |         |       |          |     |     |       |       |       |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

- <sup>(1)</sup> On previous architectures, the EDMA3TC priority was controlled by the queue priority register (QUEPRI) in the EDMA3CC memory-map. However for this device, the priority control for the transfer controllers is controlled by the chip-level registers in the System Configuration Module. You should use the chip-level registers and not QUEPRI to configure the TC priority.

**Table 18-74. Source Active Options Register (SAOPT) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                            |
|-----|-------|-------|------------------------------------------------------------------------------------------------------------------------|
| 1   | DAM   | 0     | Destination address mode within an array.<br>Increment (INCR) mode. Destination addressing within an array increments. |
|     |       | 1     | Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.        |
| 0   | SAM   | 0     | Source address mode within an array.<br>Increment (INCR) mode. Source addressing within an array increments.           |
|     |       | 1     | Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.             |

#### 18.4.3.6.2 Source Active Source Address Register (SASRC)

The source active source address register (SASRC) is shown in [Figure 18-92](#) and described in [Table 18-75](#).

**Figure 18-92. Source Active Source Address Register (SASRC)**

|       |   |
|-------|---|
| 31    | 0 |
| SADDR |   |
| R-0   |   |

LEGEND: R = Read only; -n = value after reset

**Table 18-75. Source Active Source Address Register (SASRC) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                 |
|------|-------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | SADDR | 0-FFFF FFFFh | Source address for program register set. EDMA3TC updates value according to source addressing mode (SAM bit in the source active options register, SAOPT) . |

#### 18.4.3.6.3 Source Active Count Register (SACNT)

The source active count register (SACNT) is shown in [Figure 18-93](#) and described in [Table 18-76](#).

**Figure 18-93. Source Active Count Register (SACNT)**

|      |    |
|------|----|
| 31   | 16 |
| BCNT |    |
| R-0  |    |
| 15   | 0  |
| ACNT |    |
| R-0  |    |

LEGEND: R = Read only; -n = value after reset

**Table 18-76. Source Active Count Register (SACNT) Field Descriptions**

| Bit   | Field | Value   | Description                                                                                                                                                                                                                                                    |
|-------|-------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | BCNT  | 0-FFFFh | B dimension count. Number of arrays to be transferred, where each array is ACNT in length. It is decremented after each Read command appropriately. Represents the amount of data remaining to be Read. It should be 0 when transfer request (TR) is complete. |
| 15-0  | ACNT  | 0-FFFFh | A dimension count. Number of bytes to be transferred in first dimension. It is decremented after each Read command appropriately. Represents the amount of data remaining to be Read. It should be 0 when transfer request (TR) is complete.                   |

#### 18.4.3.6.4 Source Active Destination Address Register (SADST)

The source active destination address register (SADST) is shown in [Figure 18-94](#) and described in [Table 18-77](#).

**Figure 18-94. Source Active Destination Address Register (SADST)**

LEGEND: R = Read only; -n = value after reset

**Table 18-77. Source Active Destination Address Register (SADST) Field Descriptions**

| Bit  | Field | Value | Description       |
|------|-------|-------|-------------------|
| 31-0 | DADDR | 0     | Always reads as 0 |

#### 18.4.3.6.5 Source Active B-Index Register (SABIDX)

The source active B-index register (SABIDX) is shown in [Figure 18-95](#) and described in [Table 18-78](#).

**Figure 18-95. Source Active B-Index Register (SABIDX)**

LEGEND: R = Read only; -n = value after reset

**Table 18-78. Source Active B-Index Register (SABIDX) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                                    |
|-------|---------|---------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | DSTBIDX | 0       | B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination. Always reads as 0. |
| 15-0  | SRCBIDX | 0-FFFFh | B-Index offset between source arrays. Represents the offset in bytes between the starting address of each source array.                        |

#### 18.4.3.6.6 Source Active Memory Protection Proxy Register (SAMPPRXY)

The source active memory protection proxy register (SAMPPRXY) is shown in [Figure 18-96](#) and described in [Table 18-79](#).

**Figure 18-96. Source Active Memory Protection Proxy Register (SAMPPRXY)**

LEGEND: R = Read only; -n = value after reset

**Table 18-79. Source Active Memory Protection Proxy Register (SAMPPRXY) Field Descriptions**

| Bit  | Field    | Value                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 18.4.3.6.7 Source Active Count Reload Register (SACNTRLD)

The source active count reload register (SACNTRLD) is shown in [Figure 18-97](#) and described in [Table 18-80](#).

**Figure 18-97. Source Active Count Reload Register (SACNTRLD)**

|     |          |    |
|-----|----------|----|
| 31  | Reserved | 16 |
| R-0 |          |    |
| 15  | ACNTRLD  | 0  |
| R-0 |          |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-80. Source Active Count Reload Register (SACNTRLD) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                           |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                                                                                              |
| 15-0  | ACNTRLD  | 0-FFFFh | A-count reload value. Represents the originally programmed value of ACNT. The reload value is used to reinitialize ACNT after each array is serviced. |

### 18.4.3.6.8 Source Active Source Address B-Reference Register (SASRCBREF)

The source active source address B-reference register (SASRCBREF) is shown in [Figure 18-98](#) and described in [Table 18-81](#).

**Figure 18-98. Source Active Source Address B-Reference Register (SASRCBREF)**

|     |           |   |
|-----|-----------|---|
| 31  | SADDRBREF | 0 |
| R-0 |           |   |

LEGEND: R = Read only; -n = value after reset

**Table 18-81. Source Active Source Address B-Reference Register (SASRCBREF) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                     |
|------|-----------|--------------|-------------------------------------------------------------------------------------------------|
| 31-0 | SADDRBREF | 0-FFFF FFFFh | Source address B-reference. Represents the starting address for the array currently being Read. |

### 18.4.3.6.9 Source Active Destination Address B-Reference Register (SADSTBREF)

The source active destination address B-reference register (SADSTBREF) is shown in [Figure 18-99](#) and described in [Table 18-82](#).

**Figure 18-99. Source Active Destination Address B-Reference Register (SADSTBREF)**

LEGEND: R = Read only; -n = value after reset

**Table 18-82. Source Active Destination Address B-Reference Register (SADSTBREF) Field Descriptions**

| Bit  | Field     | Value | Description       |
|------|-----------|-------|-------------------|
| 31-0 | DADDRBREF | 0     | Always reads as 0 |

### 18.4.3.6.10 Destination FIFO Set Count Reload Register (DFCNTRLD)

The destination FIFO set count reload register (DFCNTRLD) is shown in [Figure 18-100](#) and described in [Table 18-83](#).

**Figure 18-100. Destination FIFO Set Count Reload Register (DFCNTRLD)**

LEGEND: R = Read only; -n = value after reset

**Table 18-83. Destination FIFO Set Count Reload Register (DFCNTRLD) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                           |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                                                                                              |
| 15-0  | ACNTRLD  | 0-FFFFh | A-count reload value. Represents the originally programmed value of ACNT. The reload value is used to reinitialize ACNT after each array is serviced. |

#### 18.4.3.6.11 Destination FIFO Set Source Address B-Reference Register (DFSRCBREF)

The destination FIFO set source address B-reference register (DFSRCBREF) is shown in [Figure 18-101](#) and described in [Table 18-84](#).

**Figure 18-101. Destination FIFO Set Source Address B-Reference Register (DFSRCBREF)**

LEGEND: R = Read only; -n = value after reset

**Table 18-84. Destination FIFO Set Source Address B-Reference Register (DFSRCBREF)  
Field Descriptions**

| Bit  | Field     | Value | Description                       |
|------|-----------|-------|-----------------------------------|
| 31-0 | SADDRBREF | 0     | Not applicable. Always Read as 0. |

#### 18.4.3.6.12 Destination FIFO Set Destination Address B-Reference (DFDSTBREF)

The destination FIFO set destination address B-reference register (DFDSTBREF) is shown in [Figure 18-102](#) and described in [Table 18-85](#).

**Figure 18-102. Destination FIFO Set Destination Address B-Reference Register (DFDSTBREF)**

LEGEND: R = Read only; -n = value after reset

**Table 18-85. Destination FIFO Set Destination Address B-Reference Register (DFDSTBREF)  
Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                                                 |
|------|-----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | DADDRBREF | 0-FFFF FFFFh | Destination address reference for the destination FIFO register set. Represents the starting address for the array currently being written. |

### 18.4.3.6.13 Destination FIFO Options Register $n$ (DFOPT $n$ )

The destination FIFO options register  $n$  (DFOPT $n$ ) is shown in [Figure 18-103](#) and described in [Table 18-86](#).

**Figure 18-103. Destination FIFO Options Register  $n$  (DFOPT $n$ )**

### 18.4.3.6.14 Destination FIFO Source Address Register $n$ (DFSRC $n$ )

The destination FIFO source address register  $n$  (DFSRC $n$ ) is shown in [Figure 18-104](#) and described in [Table 18-87](#).

**Figure 18-104. Destination FIFO Source Address Register  $n$  (DFSRC $n$ )**

LEGEND: R = Read only; - $n$  = value after reset

**Table 18-87. Destination FIFO Source Address Register  $n$  (DFSRC $n$ ) Field Descriptions**

| Bit  | Field | Value | Description       |
|------|-------|-------|-------------------|
| 31-0 | SADDR | 0     | Always Read as 0. |

### 18.4.3.6.15 Destination FIFO Count Register $n$ (DFCNT $n$ )

The destination FIFO count register  $n$  (DFCNT $n$ ) is shown in [Figure 18-105](#) and described in [Table 18-88](#).

**Figure 18-105. Destination FIFO Count Register  $n$  (DFCNT $n$ )**

LEGEND: R = Read only; - $n$  = value after reset

**Table 18-88. Destination FIFO Count Register  $n$  (DFCNT $n$ ) Field Descriptions**

| Bit   | Field | Value   | Description                                                                                                                                                                                           |
|-------|-------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | BCNT  | 0-FFFFh | B-dimension count. Number of arrays to be transferred, where each array is ACNT in length. Count/count remaining for destination register set. Represents the amount of data remaining to be written. |
| 15-0  | ACNT  | 0-FFFFh | A-dimension count. Number of bytes to be transferred in first dimension count/count remaining for destination register set. Represents the amount of data remaining to be written.                    |

### 18.4.3.6.16 Destination FIFO Destination Address Register $n$ (DFDST $n$ )

The destination FIFO destination address register  $n$  (DFDST $n$ ) is shown in [Figure 18-106](#) and described in [Table 18-89](#).

**Figure 18-106. Destination FIFO Destination Address Register  $n$  (DFDST $n$ )**

LEGEND: R = Read only; - $n$  = value after reset

**Table 18-89. Destination FIFO Destination Address Register  $n$  (DFDST $n$ ) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                  |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | DADDR | 0     | Destination address for the destination FIFO register set. When a transfer request (TR) is complete, the final value should be the address of the last write command issued. |

### 18.4.3.6.17 Destination FIFO B-Index Register $n$ (DFBIDX $n$ )

The destination FIFO B-index register  $n$  (DFBIDX $n$ ) is shown in [Figure 18-107](#) and described in [Table 18-90](#).

**Figure 18-107. Destination FIFO B-Index Register  $n$  (DFBIDX $n$ )**

LEGEND: R = Read only; - $n$  = value after reset

**Table 18-90. Destination FIFO B-Index Register  $n$  (DFBIDX $n$ ) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                               |
|-------|---------|---------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | DSTBIDX | 0-FFFFh | B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination.               |
| 15-0  | SRCBIDX | 0       | B-Index offset between source arrays. Represents the offset in bytes between the starting address of each source array. Always Read as 0. |

### 18.4.3.6.18 Destination FIFO Memory Protection Proxy Register $n$ (DFMPPRXY $n$ )

The destination FIFO memory protection proxy register  $n$  (DFMPPRXY $n$ ) is shown in [Figure 18-108](#) and described in [Table 18-91](#).

**Figure 18-108. Destination FIFO Memory Protection Proxy Register  $n$  (DFMPPRXY $n$ )**

LEGEND: R = Read only; - $n$  = value after reset

**Table 18-91. Destination FIFO Memory Protection Proxy Register  $n$  (DFMPPRXY $n$ )  
Field Descriptions**

| Bit  | Field    | Value          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 18.5 Tips

### 18.5.1 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA3. [Table 18-92](#) provides some common issues and their probable causes and resolutions.

**Table 18-92. Debug List**

| Issue                                                                                                               | Description/Solution                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The transfer associated with the channel does not happen. The channel does not get serviced.                        | <p>The EDMA3 channel controller (EDMA3CC) may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:</p> <ol style="list-style-type: none"> <li>1) Verify that events are enabled, that is, if an external/peripheral event is latched in the event register (ER), make sure that the event is enabled in the event enable register (EER). Similarly for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA event enable register (QEER).</li> <li>2) Verify that the DMA or QDMA secondary event register (SER) bits corresponding to the particular event or channel are not set.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| The secondary event register bits are set, not allowing additional transfers to occur on a channel.                 | <p>It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:</p> <ol style="list-style-type: none"> <li>1) QDMA channels: Typically if the parameter set is nonstatic and expected to be terminated by a NULL set (OPT.STATIC = 0, LINK = FFFFh), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are autotriggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in QEMR and QSER. This will disable further prioritization of the channel.</li> <li>2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of the McBSP, every time the data shifts out from DXR, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in SER.En and EMR.En, preventing further event prioritization. You must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or you must ensure that bits corresponding to a particular channel or event are not set in the secondary event registers (SER/QSER) and the event missed registers (EMR/QEMR) before trying to perform subsequent transfers for the event/channel.</li> </ol> |
| Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt. | <p>You must ensure the following:</p> <ol style="list-style-type: none"> <li>1) The interrupt generation is enabled in the OPT of the associated PaRAM set (TCINTEN = 1 and/or ITCINTEN = 1).</li> <li>2) The interrupts are enabled in the EDMA3 channel controller (EDMA3CC), via the interrupt enable register (IER).</li> <li>3) The corresponding interrupts are enabled in the device interrupt controller.</li> <li>4) The set interrupts are cleared in the interrupt pending register (IPR) before exiting the transfer completion interrupt service routine (ISR). See <a href="#">Section 18.2.9.1.2</a> for details on writing EDMA3 ISRs.</li> <li>5) If working with shadow region interrupts, make sure that the DMA region access enable registers (DRAE) are set up properly, because DRAE act as secondary enables for shadow region completion interrupts, along with IER.</li> </ol> <p>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in DRAE. For instance, if the PaRAM set associated with channel 0 returns a completion code of 31 (OPT.TCC = 31), make sure that DRAE.E31 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be IPR.I31.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 18.5.2 Miscellaneous Programming/Debug Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the event register (ER) bits can only be cleared by writing a 1 to the corresponding bits in the event clear register (ECR). Similarly, the event enable register (EER) bits can only be set with writes of 1 to the corresponding bits in the event enable set registers (EESR) and can only be cleared with writes of 1 to the corresponding bits in the event enable clear register (EECR).
2. Writes to the shadow region memory maps are governed by region access enable registers (DRAE/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA region access enable registers (DRAE) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of interrupt pending register bits) in the region resource allocation, it results in multiple shadow region completion interrupts. For example, if DRAE0.E0 and DRAE1.E0 are both set, then on completion of a transfer that returns a TCC = 0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the CCNT is not left to zero.
5. Enable the EDMA3CC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, you may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, you might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA3CC internally signals completion when the TR is submitted to the EDMA3TC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).
9. In order to put the EDMA3CC and EDMA3TC in power-down modes, you should ensure that there is no activity with the EDMA3CC and EDMA3TC. The EDMA3CC status register (CCSTAT) and the EDMA3TC channel status register (TCSTAT) should be used.

## 18.6 Setting Up a Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

1. Initiating a DMA/QDMA channel:
  - (a) Determine the type of channel (QDMA or DMA) to be used.
  - (b) If using a QDMA channel, program the QDMA channel  $n$  mapping register (QCHMAP $n$ ) with the parameter set number to which the channel maps and the trigger word.
  - (c) If the channel is being used in the context of a shadow region, ensure the DMA region access enable register (DRAE) for the region is properly set up to allow read/write accesses to bits in the event register and interrupt register in the shadow region memory-map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 18.2.7.1](#).)
  - (d) Determine the type of triggering used.
    - (i) If external events are used for triggering (DMA channels), enable the respective event in EER by writing into EESR.
    - (ii) If a QDMA channel is used, enable the channel in QEER by writing into QEESR.
  - (e) Queue setup.
    - (i) If a QDMA channel is used, set up QDMAQNUM to map the channel to the respective event queue.
    - (ii) If a DMA channel is used, set up DMAQNUM to map the event to the respective event queue.
2. Parameter set setup: Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written last. Alternatively, enable the QDMA channel just before the write to the trigger word.  
 See [Section 18.3](#) for parameter set field setups for different types of transfers. See the sections on chaining ([Section 18.2.8](#)) and interrupt completion ([Section 18.2.9](#)) on how to set up final/intermediate completion chaining and/or interrupts.
3. Interrupt setup:
  - (a) If working in the context of a shadow region, ensure the relevant bits in DRAE are set.
  - (b) Enable the interrupt in IER by writing into IESR.
  - (c) Ensure that the EDMA3CC completion interrupt is enabled properly in the device interrupt controller.
  - (d) Set up the interrupt controller properly to receive the expected EDMA3 interrupt.
4. Initiate transfer (this step is highly dependent on the event trigger source):
  - (a) If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA3 events that can be latched to the ER transfer.
  - (b) For QDMA events, writes to the trigger word will initiate the transfer.
  - (c) Manually-triggered transfers will be initiated by writes to the event set register (ESR).
  - (d) Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.
5. Wait for completion:
  - (a) If the interrupts are enabled as mentioned in step 3, then the EDMA3CC generates a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register (IPR). The set bits must be cleared in IPR by writing to the corresponding bit in ICR.
  - (b) If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in IPR. Again, the set bits in IPR must be manually cleared by writing to ICR before the next set of transfers is performed for the same transfer completion code values.

## ***EMAC/MDIO Module***

---

---

---

This chapter provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the device.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>19.1 Introduction .....</b> | <b>728</b>  |
| <b>19.2 Architecture .....</b> | <b>731</b>  |
| <b>19.3 Registers .....</b>    | <b>774</b>  |

## 19.1 Introduction

### 19.1.1 Purpose of the Peripheral

The EMAC module is used to move data between the device and another host connected to the same network, in compliance with the Ethernet protocol.

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC control module and is considered integral to the EMAC/MDIO peripheral.

### 19.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100 Mbps operation.
- Standard Media Independent Interface (MII) and/or Reduced Media Independent Interface (RMII) to physical layer device (PHY).
- EMAC acts as DMA master to either internal or external device memory space.
- Eight receive channels with VLAN tag discrimination for receive quality-of-service (QOS) support.
- Eight transmit channels with round-robin or fixed priority for transmit quality-of-service (QOS) support.
- Ether-Stats and 802.3-Stats statistics gathering.
- Transmit CRC generation selectable on a per channel basis.
- Broadcast frames selection for reception on a single channel.
- Multicast frames selection for reception on a single channel.
- Promiscuous receive mode frames selection for reception on a single channel (all frames, all good frames, short frames, error frames).
- Hardware flow control.
- 8k-byte local EMAC descriptor memory that allows the peripheral to operate on descriptors without affecting the CPU. The descriptor memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. (This memory is also known as CPPI RAM.)
- Programmable interrupt logic permits the software driver to restrict the generation of back-to-back interrupts, which allows more work to be performed in a single call to the interrupt service routine.

### 19.1.3 Functional Block Diagram

Figure 19-1 shows the three main functional modules of the EMAC/MDIO peripheral:

- EMAC control module
- EMAC module
- MDIO module

The EMAC control module is the main interface between the device core processor to the EMAC and MDIO modules. The EMAC control module controls device interrupts and incorporates an 8k-byte internal RAM to hold EMAC buffer descriptors (also known as CPPI RAM).

The MDIO module implements the 802.3 serial management interface to interrogate and control up to 32 Ethernet PHYs connected to the device by using a shared two-wire bus. Host software uses the MDIO module to configure the autonegotiation parameters of each PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC module for correct operation. The module is designed to allow almost transparent operation of the MDIO interface, with very little maintenance from the core processor.

The EMAC module provides an efficient interface between the processor and the network. The EMAC on this device supports 10Base-T (10 Mbits/sec) and 100BaseTX (100 Mbits/sec), half-duplex and full-duplex mode, and hardware flow control and quality-of-service (QoS) support.

Figure 19-1 shows the main interface between the EMAC control module and the CPU. The following connections are made to the device core:

- The DMA bus connection from the EMAC control module allows the EMAC module to read and write both internal and external memory through the DMA memory transfer controller.
- The EMAC control, EMAC, and MDIO modules all have control registers. These registers are memory-mapped into device memory space via the device configuration bus. Along with these registers, the control module's internal CPPI RAM is mapped into this same range.
- The EMAC and MDIO interrupts are combined into four interrupt signals within the control module. Three configurable interrupt cores within the control module receive all four interrupt signals from the combiner and submit interrupt requests to the CPU.

**Figure 19-1. EMAC and MDIO Block Diagram**

### 19.1.4 Industry Standard(s) Compliance Statement

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

However, the EMAC deviates from the standard in the way it handles transmit underflow errors. The EMAC MII interface does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

### 19.1.5 Terminology

The following is a brief explanation of some terms used in this chapter.

| Term                                  | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Broadcast MAC Address                 | A special Ethernet MAC address used to send data to all Ethernet devices on the local network. The broadcast address is FFh-FFh-FFh-FFh-FFh-FFh. The LSB of the first byte is odd, qualifying it as a group address; however, its value is reserved for broadcast. It is classified separately by the EMAC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Descriptor (Packet Buffer Descriptor) | A small memory structure that describes a larger block of memory in terms of size, location, and state. Descriptors are used by the EMAC and application to describe the memory buffers that hold Ethernet data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Device                                | In this chapter, device refers to the processor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Ethernet MAC Address (MAC Address)    | <p>A unique 6-byte address that identifies an Ethernet device on the network. In an Ethernet packet, a MAC address is used twice, first to identify the packet's destination, and second to identify the packet's sender or source. An Ethernet MAC address is normally specified in hexadecimal, using dashes to separate bytes. For example, 08h-00h-28h-32h-17h-42h.</p> <p>The first three bytes normally designate the manufacturer of the device. However, when the first byte of the address is odd (LSB is 1), the address is a group address (broadcast or multicast). The second bit specifies whether the address is globally or locally administrated (not considered in this chapter).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Ethernet Packet (Packet)              | An Ethernet packet is the collection of bytes that represents the data portion of a single Ethernet frame on the wire.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Full Duplex                           | <p>Full-duplex operation allows simultaneous communication between a pair of stations using point-to-point media (dedicated channel). Full-duplex operation does not require that transmitters defer, nor do they monitor or react to receive activity, as there is no contention for a shared medium in this mode. Full-duplex mode can only be used when all of the following are true:</p> <ul style="list-style-type: none"> <li>• The physical medium is capable of supporting simultaneous transmission and reception without interference.</li> <li>• There are exactly two stations connected with a full duplex point-to-point link. As there is no contention for use of a shared medium, the multiple access (that is, CSMA/CD) algorithms are unnecessary.</li> <li>• Both stations on the LAN are capable of, and have been configured to use, full-duplex operation.</li> </ul> <p>The most common configuration envisioned for full-duplex operation consists of a central bridge (also known as a switch) with a dedicated LAN connecting each bridge port to a single device.</p> <p>Full-duplex operation constitutes a proper subset of the MAC functionality required for half-duplex operation.</p> |

| Term                              | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Half Duplex                       | In half-duplex mode, the CSMA/CD media access method is the means by which two or more stations share a common transmission medium. To transmit, a station waits (defers) for a quiet period on the medium, that is, no other station is transmitting. It then sends the intended message in bit-serial form. If, after initiating a transmission, the message collides with that of another station, then each transmitting station intentionally transmits for an additional predefined period to ensure propagation of the collision throughout the system. The station remains silent for a random amount of time (backoff) before attempting to transmit again.                                                                                                                                                                                                                  |
| Host                              | The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port (EMAC) interrupts. In this chapter, host refers to the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Jabber                            | A condition wherein a station transmits for a period of time longer than the maximum permissible packet length, usually due to a fault condition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Link                              | The transmission path between any two instances of generic cabling.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Multicast MAC Address             | A class of MAC address that sends a packet to potentially more than one recipient. A group address is specified by setting the LSB of the first MAC address byte to 1. Thus, 01h-02h-03h-04h-05h-06h is a valid multicast address. Typically, an Ethernet MAC looks for only certain multicast addresses on a network to reduce traffic load. The multicast address list of acceptable packets is specified by the application.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Physical Layer and Media Notation | To identify different Ethernet technologies, a simple, three-field, type notation is used. The Physical Layer type used by the Ethernet is specified by these fields:<br><data rate in Mb/s><medium type><maximum segment length (×100m)><br>The definitions for the technologies mentioned in this chapter are: <ul style="list-style-type: none"> <li>• 10Base-T: IEEE 802.3 Physical Layer specification for a 10 Mb/s CSMA/CD local area network over two pairs of twisted-pair telephone wire.</li> <li>• 100Base-T: IEEE 802.3 Physical Layer specification for a 100 Mb/s CSMA/CD local area network over two pairs of Category 5 unshielded twisted-pair (UTP) or shielded twisted-pair (STP) wire.</li> <li>• Twisted pair: A cable element that consists of two insulated conductors twisted together in a regular fashion to form a balanced transmission line.</li> </ul> |
| Port                              | Ethernet device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Promiscuous Mode                  | EMAC receives frames that do not match its address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 19.2 Architecture

This section discusses the architecture and basic function of the EMAC/MDIO module.

### 19.2.1 Clock Control

All internal EMAC logic is clocked synchronously on one clock domain. See your device-specific data manual for information.

The MDIO clock is based on a divide-down of the peripheral clock and is specified to run up to 2.5 MHz (although typical operation would be 1.0 MHz). Because the peripheral clock frequency is variable, the application software or driver must control the divide-down value.

The transmit and receive clock sources are provided by the external PHY to the MII\_TXCLK and MII\_RXCLK pins or to the RMII reference clock pin. Data is transmitted and received with respect to the reference clocks of the interface pins.

The MII interface frequencies for the transmit and receive clocks are fixed by the IEEE 802.3 specification as:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

The RMII interface frequency for the transmit and receive clocks are fixed at 50 MHz for both 10 Mbps and 100 Mbps.

### 19.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold buffer descriptions of the Ethernet packets to be received and transmitted. This internal RAM is  $2K \times 32$  bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. This EMAC RAM is also referred to as the CPPI buffer descriptor memory because it complies with the Communications Port Programming Interface (CPPI) v3.0 standard.

The packet buffer descriptors can also be placed in other on- and off-chip memories such as L2 and EMIF. There are some tradeoffs in terms of cache performance and throughput when descriptors are placed in the system memory, versus when they are placed in the EMAC's internal memory. In general, the EMAC throughput is better when the descriptors are placed in the local EMAC CPPI RAM.

### 19.2.3 Signal Descriptions

Support of interfaces (MII and/or RMII) varies between devices. See your device-specific data manual for information.

#### 19.2.3.1 Media Independent Interface (MII) Connections

Figure 19-2 shows a device with integrated EMAC and MDIO interfaced via a MII connection in a typical system. The EMAC module does not include a transmit error (MTXER) pin. In the case of transmit error, CRC inversion is used to negate the validity of the transmitted frame.

The individual EMAC and MDIO signals for the MII interface are summarized in Table 19-1. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 19-2. Ethernet Configuration—MII Connections**

**Table 19-1. EMAC and MDIO Signals for MII Interface**

| Signal       | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MII_TXCLK    | I    | Transmit clock (MII_TXCLK). The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MII_TXD and MII_TXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.                                                                                                                                                                                                                                                                                                                       |
| MII_TXD[3-0] | O    | Transmit data (MII_TXD). The transmit data pins are a collection of 4 data signals comprising 4 bits of data. MTDX0 is the least-significant bit (LSB). The signals are synchronized by MII_TXCLK and valid only when MII_TXEN is asserted.                                                                                                                                                                                                                                                                                                                                                                             |
| MII_TXEN     | O    | Transmit enable (MII_TXEN). The transmit enable signal indicates that the MII_TXD pins are generating nibble data for use by the PHY. It is driven synchronously to MII_TXCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| MII_COL      | I    | Collision detected (MII_COL). In half-duplex operation, the MII_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK.<br><br>In full-duplex operation, the MII_COL pin is used for hardware transmit flow control. Asserting the MII_COL pin will stop packet transmissions; packets in the process of being transmitted when MII_COL is asserted will complete transmission. The MII_COL pin should be held low if hardware transmit flow control is not used. |
| MII_CRS      | I    | Carrier sense (MII_CRS). In half-duplex operation, the MII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK.<br><br>In full-duplex operation, the MII_CRS pin should be held low.                                                                                                                                                                                                                                                        |
| MII_RXCLK    | I    | Receive clock (MII_RXCLK). The receive clock is a continuous clock that provides the timing reference for receive operations. The MII_RXD, MII_RXDV, and MII_RXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.                                                                                                                                                                                                                                                                                                               |
| MII_RXD[3-0] | I    | Receive data (MII_RXD). The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRDX0 is the least-significant bit (LSB). The signals are synchronized by MII_RXCLK and valid only when MII_RXDV is asserted.                                                                                                                                                                                                                                                                                                                                                                               |
| MII_RXDV     | I    | Receive data valid (MII_RXDV). The receive data valid signal indicates that the MII_RXD pins are generating nibble data for use by the EMAC. It is driven synchronously to MII_RXCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| MII_RXER     | I    | Receive error (MII_RXER). The receive error signal is asserted for one or more MII_RXCLK periods to indicate that an error was detected in the received frame. This is meaningful only during data reception when MII_RXDV is active.                                                                                                                                                                                                                                                                                                                                                                                   |
| MDIO_CLK     | O    | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).                                                                                                                                                                                                                                                                                                                                     |
| MDIO_D       | I/O  | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.                                                                                                                                                                                                                                                       |

### 19.2.3.2 Reduced Media Independent Interface (RMII) Connections

Figure 19-3 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system.

The individual EMAC and MDIO signals for the RMII interface are summarized in Table 19-2. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 19-3. Ethernet Configuration—RMII Connections**

**Table 19-2. EMAC and MDIO Signals for RMII Interface**

| Signal          | Type | Description                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RMII_TXD[1-0]   | O    | Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.                                                                                                                                        |
| RMII_TXEN       | O    | Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.                                                                                                                                                                                     |
| RMII_MHZ_50_CLK | I    | RMII reference clock (RMII_MHZ_50_CLK). The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.                                                                                                                                                                                                      |
| RMII_RXD[1-0]   | I    | Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is deasserted.                                                                                                            |
| RMII_CRS_DV     | I    | Carrier sense/receive data valid (RMII_CRS_DV). Multiplexed signal between carrier sense and receive data valid.                                                                                                                                                                                                                                                  |
| RMII_RXER       | I    | Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame.                                                                                                                                                                                                                                     |
| MDIO_CLK        | O    | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).                                                                               |
| MDIO_D          | I/O  | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

## 19.2.4 Ethernet Protocol Overview

A brief overview of the Ethernet protocol is given in the following subsections. See the IEEE 802.3 standard document for in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method.

### 19.2.4.1 Ethernet Frame Format

All the Ethernet technologies use the same frame structure. The format of an Ethernet frame is shown in [Figure 19-4](#) and described in [Table 19-3](#). The Ethernet packet, which is the collection of bytes representing the data portion of a single Ethernet frame on the wire, is shown outlined in bold. The Ethernet frames are of variable lengths, with no frame smaller than 64 bytes or larger than RXMAXLEN bytes (header, data, and CRC).

**Figure 19-4. Ethernet Frame Format**

Legend: SFD=Start Frame Delimiter; FCS=Frame Check Sequence (CRC)

**Table 19-3. Ethernet Frame Description**

| Field       | Bytes                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Preamble    | 7                     | Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SFD         | 1                     | Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Destination | 6                     | Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame.                                                                                                                                                                                                        |
| Source      | 6                     | Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Len         | 2                     | Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Data        | 46 to (RXMAXLEN - 18) | Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less than 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS. |
| FCS         | 4                     | Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to 1514 bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured.                                                                                                                                                                                                                                                                             |

### 19.2.4.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel -- when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium because there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layer protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle, it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it no longer senses energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal, the port enters an exponential backoff phase. If a data frame encounters back-to-back collisions, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is a multiple of this random value and returns to step 2.

## 19.2.5 Programming Interface

### 19.2.5.1 Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in [Figure 19-5](#) and described in [Table 19-4](#).

For example, consider three packets to be transmitted: Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in [Figure 19-6](#).

**Figure 19-5. Basic Descriptor Format**

| Word<br>Offset | Bit Fields              |    |               |
|----------------|-------------------------|----|---------------|
|                | 31                      | 16 | 15 0          |
| 0              | Next Descriptor Pointer |    |               |
| 1              | Buffer Pointer          |    |               |
| 2              | Buffer Offset           |    | Buffer Length |
| 3              | Flags                   |    | Packet Length |

**Table 19-4. Basic Descriptor Description**

| Word Offset | Field                   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Next Descriptor Pointer | The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list. |
| 1           | Buffer Pointer          | The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations.                                                                                                                                                                                                                                                                                                                                                            |
| 2           | Buffer Offset           | The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data.                                                                                                                                                                                                                                                                                                                                          |
|             | Buffer Length           | The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer.                                                                                                                                                                                                                                                                                                                                                      |
| 3           | Flags                   | The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in <a href="#">Section 19.2.5.4</a> and <a href="#">Section 19.2.5.5</a> .                                                                                                                                                                                                                        |
|             | Packet Length           | The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers.                                                                                                                                                                                                                                       |

**Figure 19-6. Typical Descriptor Linked List**

### 19.2.5.2 Transmit and Receive Descriptor Queues

The EMAC module processes descriptors in linked lists as discussed in [Section 19.2.5.1](#). The lists used by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). The EMAC supports eight channels for transmit and eight channels for receive. The corresponding head descriptor pointers are:

- TX $n$ HDP - Transmit Channel  $n$  DMA Head Descriptor Pointer Register
- RX $n$ HDP - Receive Channel  $n$  DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send and receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its "next" pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. Therefore, in the case where only a single descriptor is added, its "next descriptor" pointer must be initialized to 0.

The HDP must never be written to while a list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL "next" pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor of the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the "next" pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor's "next" pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, the application may at that time submit the new list, or the portion of the appended list that was missed by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list.

### 19.2.5.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in [Section 19.2.5.1](#), using the linked list queue mechanism discussed in [Section 19.2.5.2](#).

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

The EMAC supports eight channels for transmit and eight channels for receive. The corresponding completion pointer registers are:

- TX $n$ CP - Transmit Channel  $n$  Completion Pointer (Interrupt Acknowledge) Register
- RX $n$ CP - Receive Channel  $n$  Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt is active.

Interrupts in the EMAC control module are routed to three independent interrupt cores which are then mapped to CPU interrupt controllers. The system configuration determines whether or not an active interrupt actually interrupts the CPU. In general the following settings are required for basic EMAC transmit and receive interrupts:

1. EMAC transmit and receive interrupts are enabled by setting the mask registers RXINTMASKSET and TXINTMASKSET
2. Global interrupts for the appropriate interrupt core registers are set in the EMAC control module: C $n$ RXEN and C $n$ TXEN on core  $n$
3. The CPU interrupt controller is configured to accept C $n$ \_RX\_PULSE and C $n$ \_TX\_PULSE interrupts from the EMAC control module

Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the EMAC receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

After servicing transmit or receive interrupts, the application software must acknowledge both the EMAC and EMAC control module interrupts.

EMAC interrupts are acknowledged when the application software updates the value of TX $n$ CP or RX $n$ CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt because the interrupt acknowledgment is tied directly to the buffer descriptor processing.

EMAC control module interrupts are acknowledged when the application software writes the appropriate C $n$ TX or C $n$ RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

### 19.2.5.4 Transmit Buffer Descriptor Format

A transmit (TX) buffer descriptor ([Figure 19-7](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. [Example 19-1](#) shows the transmit buffer descriptor described by a C structure.

**Figure 19-7. Transmit Buffer Descriptor Format**

**Example 19-1. Transmit Buffer Descriptor in C Structure Format**

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u

```

#### **19.2.5.4.1 Next Descriptor Pointer**

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

#### **19.2.5.4.2 Buffer Pointer**

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### **19.2.5.4.3 Buffer Offset**

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte-aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

#### **19.2.5.4.4 Buffer Length**

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

#### **19.2.5.4.5 Packet Length**

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

#### **19.2.5.4.6 Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

#### **19.2.5.4.7 End of Packet (EOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

#### **19.2.5.4.8 Ownership (OWNER) Flag**

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

#### **19.2.5.4.9 End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

#### **19.2.5.4.10 Teardown Complete (TDOWNCMPLT) Flag**

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

#### **19.2.5.4.11 Pass CRC (PASSCRC) Flag**

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

### 19.2.5.5 Receive Buffer Descriptor Format

A receive (RX) buffer descriptor ([Figure 19-8](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. [Example 19-2](#) shows the receive buffer descriptor described by a C structure.

#### 19.2.5.5.1 Next Descriptor Pointer

This pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active receive queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

#### 19.2.5.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

**Figure 19-8. Receive Buffer Descriptor Format**

### Example 19-2. Receive Buffer Descriptor in C Structure Format

```
/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u
#define EMAC_DSC_FLAG_JABBER 0x02000000u
#define EMAC_DSC_FLAG_OVERSIZE 0x01000000u
#define EMAC_DSC_FLAG_FRAGMENT 0x00800000u
#define EMAC_DSC_FLAG_UNDERSIZED 0x00400000u
#define EMAC_DSC_FLAG_CONTROL 0x00200000u
#define EMAC_DSC_FLAG_OVERRUN 0x00100000u
#define EMAC_DSC_FLAG_CODEERROR 0x00080000u
#define EMAC_DSC_FLAG_ALIGNERROR 0x00040000u
#define EMAC_DSC_FLAG_CRCERROR 0x00020000u
#define EMAC_DSC_FLAG_NOMATCH 0x00010000u
```

#### 19.2.5.5.3 Buffer Offset

This 16-bit field must be initialized to zero by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a non-zero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

#### 19.2.5.5.4 Buffer Length

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

#### 19.2.5.5.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to zero by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

#### 19.2.5.5.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

#### 19.2.5.5.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

#### 19.2.5.5.8 Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

#### 19.2.5.5.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

#### 19.2.5.5.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

**19.2.5.5.11 Pass CRC (PASSCRC) Flag**

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

**19.2.5.5.12 Jabber Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

**19.2.5.5.13 Oversize Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**19.2.5.5.14 Fragment Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**19.2.5.5.15 Undersized Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

**19.2.5.5.16 Control Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

**19.2.5.5.17 Overrun Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

**19.2.5.5.18 Code Error (CODEERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**19.2.5.5.19 Alignment Error (ALIGNERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**19.2.5.5.20 CRC Error (CRCERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**19.2.5.5.21 No Match (NOMATCH) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

## 19.2.6 EMAC Control Module

The EMAC control module (Figure 19-9) interfaces the EMAC and MDIO modules to the rest of the system, and also provides a local memory space to hold EMAC packet buffer descriptors. Local memory is used to help avoid contention with device memory spaces. Other functions include the bus arbiter, and interrupt logic control.

**Figure 19-9. EMAC Control Module Block Diagram**

### 19.2.6.1 Internal Memory

The EMAC control module includes 8K bytes of internal memory (CPPI buffer descriptor memory). The internal memory block is essential for allowing the EMAC to operate more independently of the CPU. It also prevents memory underflow conditions when the EMAC issues read or write requests to descriptor memory. (Memory accesses to read or write the actual Ethernet packet data are protected by the EMAC's internal FIFOs).

A descriptor is a 16-byte memory structure that holds information about a single Ethernet packet buffer, which may contain a full or partial Ethernet packet. Thus with the 8K memory block provided for descriptor storage, the EMAC module can send and received up to a combined 512 packets before it needs to be serviced by application or driver software.

### 19.2.6.2 Bus Arbiter

The EMAC control module bus arbiter operates transparently to the rest of the system. It is used:

- To arbitrate between the CPU and EMAC buses for access to internal descriptor memory.
- To arbitrate between internal EMAC buses for access to system memory.

### 19.2.6.3 Interrupt Control

Interrupt conditions generated by the EMAC and MDIO modules are combined into four interrupt signals that are routed to three independent interrupt cores in the EMAC control module; the interrupt cores then relay the interrupt signals to the CPU interrupt controller. The EMAC control module uses two sets of registers to control the interrupt signals to the CPU:

- *CnRXTHRESHEN*, *CnRXEN*, *CnTXEN*, and *CnMISCEN* registers enable the interrupt core pulse signals that are mapped to the CPU interrupt controller
- *INTCONTROL*, *CnRXIMAX*, and *CnTXIMAX* registers enable interrupt pacing to limit the number of interrupt pulses generated per millisecond

Interrupts must be acknowledged by writing the appropriate value to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

## 19.2.7 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.

The MDIO module does not support the "Clause 45" interface.

### 19.2.7.1 MDIO Module Components

The MDIO module ([Figure 19-10](#)) interfaces to the PHY components through two MDIO pins (MDIO\_CLK and MDIO), and to the CPU through the EMAC control module and the configuration bus. The MDIO module consists of the following logical components:

- MDIO clock generator
- Global PHY detection and link state monitoring
- Active PHY monitoring
- PHY register user access

**Figure 19-10. MDIO Module Block Diagram**

#### 19.2.7.1.1 MDIO Clock Generator

The MDIO clock generator controls the MDIO clock based on a divide-down of the peripheral clock in the EMAC control module. The MDIO clock is specified to run up to 2.5 MHz, although typical operation would be 1.0 MHz. Since the peripheral clock frequency is variable, the application software or driver controls the divide-down amount. See your device-specific data manual for peripheral clock speeds.

#### 19.2.7.1.2 Global PHY Detection and Link State Monitoring

The MDIO module continuously polls all 32 MDIO addresses in order to enumerate the PHY devices in the system. The module tracks whether or not a PHY on a particular address has responded, and whether or not the PHY currently has a link. Using this information allows the software application to quickly determine which MDIO address the PHY is using.

#### 19.2.7.1.3 Active PHY Monitoring

Once a PHY candidate has been selected for use, the MDIO module transparently monitors its link state by reading the MDIO PHY link status register (LINK). Link change events are stored on the MDIO device and can optionally interrupt the CPU. This allows the system to poll the link status of the PHY device without continuously performing costly MDIO accesses.

#### 19.2.7.1.4 PHY Register User Access

When the CPU must access MDIO for configuration and negotiation, the PHY access module performs the actual MDIO read or write operation independent of the CPU. This allows the CPU to poll for completion or receive an interrupt when the read or write operation has been performed. The user access registers USERACCESS $n$  allows the software to submit the access requests for the PHY connected to the device.

### 19.2.7.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL<sub>n</sub>). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL<sub>n</sub>. Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS<sub>n</sub>).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS<sub>n</sub> causes ALIVE to be updated.

The USERPHYSEL<sub>n</sub> is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL<sub>n</sub>.

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS<sub>n</sub>. When the application sets the GO bit in USERACCESS<sub>n</sub>, the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS<sub>n</sub> used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS<sub>0</sub> and USERACCESS<sub>1</sub>. The application software must check the status of the GO bit in USERACCESS<sub>n</sub> before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS<sub>n</sub> to determine the status of a read transaction.

### 19.2.7.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL $n$ ), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS $n$ ). Since only one PHY is used in this device, the application software can use one USERACCESS $n$  to trigger a completion interrupt; the other USERACCESS $n$  is not setup.

### 19.2.7.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS $n$ ) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS $n$ ) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS $n$  corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS $n$  for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

### 19.2.7.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS $n$ ) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS $n$ ) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS $n$  corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS $n$  after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS $n$ . Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

#### 19.2.7.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS $n$ ) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG\_read( regadr, phyadr )                      Start the process of reading a PHY register
- PHYREG\_write( regadr, phyadr, data )              Start the process of writing a PHY register
- PHYREG\_wait( )                                          Synchronize operation (make sure read/write is idle)
- PHYREG\_waitResults( results )                      Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG\_wait() after every write, and PHYREG\_waitResults( ) after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in [Example 19-3](#) (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS $n$  on PHY register reads (does not follow the procedure outlined in [Section 19.2.7.2.3](#)). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

#### Example 19-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_G0,1u)           | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)     | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)
#define PHYREG_write(regadr, phyadr, data)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_G0,1u)           | /
        CSL_FMK(MDIO_USERACCESS0_WRITE,1)          | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)     | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)     | /
        CSL_FMK(MDIO_USERACCESS0_DATA, data)
#define PHYREG_wait()
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_G0) )
#define PHYREG_waitResults( results ) {
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_G0) );
    results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

## 19.2.8 EMAC Module

This section discusses the architecture and basic function of the EMAC module.

### 19.2.8.1 EMAC Module Components

The EMAC module ([Figure 19-11](#)) interfaces to the outside world through the Media Independent Interface (MII) and/or Reduced Media Independent Interface (RMII). The interface between the EMAC module and the system core is provided through the EMAC control module. The EMAC consists of the following logical components:

- The receive path includes: receive DMA engine, receive FIFO, and MAC receiver
- The transmit path includes: transmit DMA engine, transmit FIFO, and MAC transmitter
- Statistics logic
- State RAM
- Interrupt controller
- Control registers and logic
- Clock and reset logic

**Figure 19-11. EMAC Module Block Diagram**

#### 19.2.8.1.1 Receive DMA Engine

The receive DMA engine is the interface between the receive FIFO and the system core. It interfaces to the CPU through the bus arbiter in the EMAC control module. This DMA engine is totally independent of the device DMA.

#### 19.2.8.1.2 Receive FIFO

The receive FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers receive data in preparation for writing into packet buffers in device memory.

### 19.2.8.1.3 MAC Receiver

The MAC receiver detects and processes incoming network frames, de-frames them, and puts them into the receive FIFO. The MAC receiver also detects errors and passes statistics to the statistics RAM.

### 19.2.8.1.4 Transmit DMA Engine

The transmit DMA engine is the interface between the transmit FIFO and the CPU. It interfaces to the CPU through the bus arbiter in the EMAC control module.

### 19.2.8.1.5 Transmit FIFO

The transmit FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers data in preparation for transmission.

### 19.2.8.1.6 MAC Transmitter

The MAC transmitter formats frame data from the transmit FIFO and transmits the data using the CSMA/CD access protocol. The frame CRC can be automatically appended, if required. The MAC transmitter also detects transmission errors and passes statistics to the statistics registers.

### 19.2.8.1.7 Statistics Logic

The Ethernet statistics are counted and stored in the statistics logic RAM. This statistics RAM keeps track of 36 different Ethernet packet statistics.

### 19.2.8.1.8 State RAM

State RAM contains the head descriptor pointers and completion pointers registers for both transmit and receive channels.

### 19.2.8.1.9 EMAC Interrupt Controller

The interrupt controller contains the interrupt related registers and logic. The 26 raw EMAC interrupts are input to this submodule and masked module interrupts are output.

### 19.2.8.1.10 Control Registers and Logic

The EMAC is controlled by a set of memory-mapped registers. The control logic also signals transmit, receive, and status related interrupts to the CPU through the EMAC control module.

### 19.2.8.1.11 Clock and Reset Logic

The clock and reset submodule generates all the EMAC clocks and resets. For more details on reset capabilities, see [Section 30.2.15.1](#).

## 19.2.8.2 EMAC Module Operational Overview

After reset, initialization, and configuration, the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII or RMII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC control module (CPPI buffer descriptor memory).

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

## 19.2.9 MAC Interface

The following sections discuss the operation of the Media Independent Interface (MII) and Reduced Media Independent Interface (RMII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

### 19.2.9.1 Data Reception

#### 19.2.9.1.1 Receive Control

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MAC interface.

#### 19.2.9.1.2 Receive Inter-Frame Interval

The 802.3 standard requires an interpacket gap (IPG), which is 96 bit times. However, the EMAC can tolerate a reduced IPG of 8 bit times with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5Dh).

### 19.2.9.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive buffer flow control are available:

- Collision-based flow control for half-duplex mode
- IEEE 802.3x pause frames flow control for full-duplex mode

In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control prevents reception of frames on the EMAC until all of the triggering conditions clear, at which time frames may again be received by the EMAC.

Receive flow control is enabled by the RXBUFFERFLOWEN bit in the MAC control register (MACCONTROL). The EMAC is configured for collision or IEEE 802.3X flow control using the FULLDUPLEX bit in MACCONTROL. Receive flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RXnFREEBUFFER) is less than or equal to the receive channel flow control threshold register (RXnFLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

#### 19.2.9.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

#### 19.2.9.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).

- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

### 19.2.9.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

#### 19.2.9.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MII\_CRD) and collision-sensing (MII\_COL) modes are disabled.

#### 19.2.9.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

#### 19.2.9.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG) delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

#### 19.2.9.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MII\_CRD is deasserted within approximately 48 bit times of MII\_TXEN being deasserted, then 96 bit times is measured from MII\_TXEN. If the frame suffered a collision or MII\_CRD is not deasserted until more than approximately 48 bit times after MII\_TXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MII\_CRD.

#### 19.2.9.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

### 19.2.9.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MII\_RXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
  - The reserved multicast destination address 01.80.C2.00.00.01h
  - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

### 19.2.9.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

## 19.2.10 Packet Receive Operation

### 19.2.10.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel  $n$  DMA head descriptor pointer registers (RX $n$ HDP) to 0.
- Write the MAC address hash  $n$  registers (MACHASH1 and MACHASH2), if multicast addressing is desired.
- If flow control is to be enabled, initialize:
  - the receive channel  $n$  free buffer count registers (RX $n$ FREEBUFFER)
  - the receive channel  $n$  flow control threshold register (RX $n$ FLOWTHRESH)
  - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET) and the receive interrupt mask clear register (RXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
- Setup the receive channel(s) buffer descriptors and initialize RX $n$ HDP.
- Enable the receive DMA controller by setting the RXEN bit in the receive control register (RXCONTROL).
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

### 19.2.10.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH $n$ EN) in the receive unicast set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH $n$ EN bits determine whether the given channel is enabled (when set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled (when set to 1), then they are copied to only a single channel selected by the RXBROADCH bit in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set then the frame hash matches and will be transferred to the channel selected by the RXMULTCH bit in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash  $n$  registers (MACHASH1 and MACHASH2).

The RXPROMCH bit in RXMBPENABLE selects the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

### 19.2.10.3 Receive Address Matching

All eight MAC addresses corresponding to the eight receive channels share the upper 40 bits. Only the lower byte is unique for each address. All eight receive addresses should be initialized, because pause frames are acted upon regardless of whether a channel is enabled or not.

A MAC address is written by first writing the address number (channel) to be written into the MAC index register (MACINDEX). The upper 32 bits of address are then written to the MAC address high bytes register (MACADDRHI), which is followed by writing the lower 16 bits of address to the MAC address low bytes register (MACADDRLO). Since all eight MAC addresses share the upper 40 bits of address, MACADDRHI needs to be written only the first time (for the first channel configured).

#### 19.2.10.4 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
  - The destination station's individual unicast address.
  - The destination station's multicast address (MACHASH1 and MACHASH2).
  - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) and the receive channel *n* free buffer count registers (RXnFREEBUFFER) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (RXnFREEBUFFER) for the frame channel is less than or equal to the filter low threshold (RXFILTERLOWTHRESH) value. Hardware QOS is enabled by the RXQOSEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

#### 19.2.10.5 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (RXnFREEBUFFER). The EMAC decrements the appropriate channel's free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. RXnFREEBUFFER only needs to be updated by the host if receive QOS or flow control is used.

#### 19.2.10.6 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (RXTEARDOWN). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The TDOWNCMPLT flag is set in the next buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel *n* completion pointer register (RXnCP) contains the value FFFF FFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFCh acknowledge value to RXnCP (note that there is no buffer descriptor in this case). Software may read RXnCP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFCh, if the interrupt was due to a teardown command.

### 19.2.10.7 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. Following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.
- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

### 19.2.10.8 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. [Table 19-5](#) shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

**Table 19-5. Receive Frame Treatment Summary**

| Address Match | RXCAFEN | RXCEFEN | RXCMFEN | RXCSFEN | Receive Frame Treatment                                                                                                                            |
|---------------|---------|---------|---------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0       | X       | X       | X       | No frames transferred.                                                                                                                             |
| 0             | 1       | 0       | 0       | 0       | Proper frames transferred to promiscuous channel.                                                                                                  |
| 0             | 1       | 0       | 0       | 1       | Proper/undersized data frames transferred to promiscuous channel.                                                                                  |
| 0             | 1       | 0       | 1       | 0       | Proper data and control frames transferred to promiscuous channel.                                                                                 |
| 0             | 1       | 0       | 1       | 1       | Proper/undersized data and control frames transferred to promiscuous channel.                                                                      |
| 0             | 1       | 1       | 0       | 0       | Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred.    |
| 0             | 1       | 1       | 0       | 1       | Proper/undersized/fragment/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control frames are transferred.       |
| 0             | 1       | 1       | 1       | 0       | Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred.            |
| 0             | 1       | 1       | 1       | 1       | All nonaddress matching frames with and without errors transferred to promiscuous channel.                                                         |
| 1             | X       | 0       | 0       | 0       | Proper data frames transferred to address match channel.                                                                                           |
| 1             | X       | 0       | 0       | 1       | Proper/undersized data frames transferred to address match channel.                                                                                |
| 1             | X       | 0       | 1       | 0       | Proper data and control frames transferred to address match channel.                                                                               |
| 1             | X       | 0       | 1       | 1       | Proper/undersized data and control frames transferred to address match channel.                                                                    |
| 1             | X       | 1       | 0       | 0       | Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred.           |
| 1             | X       | 1       | 0       | 1       | Proper/oversize/jabber/fragment/undersized/code/align/CRC data frames transferred to address match channel. No control frames are transferred.     |
| 1             | X       | 1       | 1       | 0       | Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred. |
| 1             | X       | 1       | 1       | 1       | All address matching frames with and without errors transferred to the address match channel                                                       |

### 19.2.10.9 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO\_SOF)
- FIFO middle of frame overrun (FIFO\_MOF)
- DMA start of frame overrun (DMA\_SOF)
- DMA middle of frame overrun (DMA\_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. [Table 19-6](#) shows how the overrun condition is handled for the middle of frame overrun.

**Table 19-6. Middle of Frame Overrun Treatment**

| Address Match | RXCAFEN | RXCEFEN | Middle of Frame Overrun Treatment                                                                                                                                                                                                                                                                                                                         |
|---------------|---------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0       | X       | Overrun frame filtered.                                                                                                                                                                                                                                                                                                                                   |
| 0             | 1       | 0       | Overrun frame filtered.                                                                                                                                                                                                                                                                                                                                   |
| 0             | 1       | 1       | As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize). |
| 1             | X       | 0       | Overrun frame filtered with the appropriate overrun statistic(s) incremented.                                                                                                                                                                                                                                                                             |
| 1             | X       | 1       | As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated).                                         |

### 19.2.11 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

#### 19.2.11.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel  $n$  DMA head descriptor pointer registers (TX $n$ HDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TX $n$ HDP with the pointer to the first descriptor to start transmit operations.

#### 19.2.11.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel  $n$  completion pointer register (TX $n$ CP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TX $n$ CP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TX $n$ CP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

### 19.2.12 Receive and Transmit Latency

The transmit and receive FIFOs each contain three 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH (configurable through the FIFO control register) cells, or a complete packet, are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH times 64 bytes (or less). For larger packet sizes, transmit underrun occurs if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 5.12  $\mu$ s in 100 Mbps mode and 51.2  $\mu$ s in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire: 5.12  $\mu$ s in 100 Mbps mode, or 51.2  $\mu$ s in 10 Mbps mode. The latency time includes any required buffer descriptor reads for the cell data.

Latency to system's internal and external RAM can be controlled through the use of the transfer node priority allocation register available at the device level. Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC control module.

### 19.2.13 Transfer Node Priority

The device contains a chip-level master priority register that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64 byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12  $\mu$ s.
- Any single latency event in request servicing can be no longer than  $(5.12 \times \text{TXCELLTHRESH}) \mu$ s.

## 19.2.14 Reset Considerations

### 19.2.14.1 Software Reset Considerations

Peripheral clock and reset control is done through the Power and Sleep Controller (PSC) module included with the device. For more on how the EMAC, MDIO, and EMAC control module are disabled or placed in reset at runtime from the registers located in the PSC module, see [Section 30.2.16](#).

With the EMAC still in reset (PSC in the default state):

1. Program the PINMUX register(s) as required for the desired interface (MII or RMI), see the Pin Multiplexing Control Registers (PINMUX0-PINMUX19) in the *System Configuration (SYSCFG) Module* chapter and your device-specific data manual for details.
2. Program the PSC to enable the EMAC. For information on how to enable the EMAC peripheral from the PSC, see the *Power and Sleep Controller (PSC)* chapter.

Within the peripheral itself, the EMAC component of the Ethernet MAC peripheral can be placed in a reset state by writing to the soft reset register (SOFTRESET). Writing a 1 to the SOFTRESET bit, causes the EMAC logic to be reset and the register values to be set to their default values. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the configuration bus; it is the responsibility of the software to verify that there are no pending frames to be transferred. After writing a 1 to the SOFTRESET bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then a reset has occurred.

After a software reset operation, all the EMAC registers need to be reinitialized for proper data transmission, including the FULLDUPLEX bit setting in the MAC control register (MACCONTROL).

Unlike the EMAC module, the MDIO and EMAC control modules cannot be placed in reset from a register inside their memory map.

### 19.2.14.2 Hardware Reset Considerations

When a hardware reset occurs, the EMAC peripheral has its register values reset and all the components return to their default state. After the hardware reset, the EMAC needs to be initialized before being able to resume its data transmission, as described in [Section 30.2.19](#).

A hardware reset is the only means of recovering from the error interrupts (HOSTPEND), which are triggered by errors in packet buffer descriptors. Before doing a hardware reset, you should inspect the error codes in the MAC status register (MACSTATUS) that gives information about the type of software error that needs to be corrected. For detailed information on error interrupts, see [Section 19.2.16.1.4](#).

## 19.2.15 Initialization

### 19.2.15.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral may be in a disabled state. Before any EMAC specific initialization can take place, the EMAC needs to be enabled; otherwise, its registers cannot be written and the reads will all return a value of zero.

The EMAC/MDIO is enabled through the Power and Sleep Controller (PSC) registers. For information on how to enable the EMAC peripheral from the PSC, see the *Power and Sleep Controller (PSC)* chapter.

When first enabled, the EMAC peripheral registers are set to their default values. After enabling the peripheral, you may proceed with the module specific initialization.

### 19.2.15.2 EMAC Control Module Initialization

The EMAC control module is used for global interrupt enables and to pace interrupts using 1ms time windows. There is also an 8K block of CPPI RAM local to the EMAC that is used to hold packet buffer descriptors.

Note that although the EMAC control module and the EMAC module have slightly different functions, in practice, the type of maintenance performed on the EMAC control module is more commonly conducted from the EMAC module software (as opposed to the MDIO module).

The initialization of the EMAC control module consists of two parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC control module:
  - Setting the interrupt pace counts using the EMAC control module registers INTCONTROL, CnRXIMAX, and CnTXIMAX
  - Initializing the EMAC and MDIO modules
  - Enabling interrupts in the EMAC control module using the EMAC control module interrupt control registers CnRXTHRESHEN, CnRXEN, CnTXEN, and CnMISCEN.

The process of mapping the EMAC interrupts to the CPU is done through the CPU interrupt controller. Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of interrupts (to control reentrancy) should be done at the chip level by manipulating the interrupt core enable mask registers.

### 19.2.15.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHz. For example, if the peripheral clock is 50 MHz, the divider can be set to 50.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access.

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSELn) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50  $\mu$ s to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

#### 19.2.15.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. If enabled, clear the device interrupt enable bits in the EMAC control module interrupt control registers *CnRXTHRESHEN*, *CnRXEN*, *CnTXEN*, and *CnMISCEN*.
2. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
3. Initialize all 16 header descriptor pointer registers (RX*n*HDP and TX*n*HDP) to 0.
4. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
5. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC address registers - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
6. If buffer flow control is to be enabled, initialize the receive channel *n* free buffer count registers (RX*n*FREEBUFFER), receive channel *n* flow control threshold register (RX*n*FLOWTHRESH), and receive filter low priority frame threshold register (RXFILTERLOWTHRESH).
7. Most device drivers open with no multicast addresses, so clear the MAC address hash registers (MACHASH1 and MACHASH2) to 0.
8. Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
9. Initially clear all unicast channels by writing FFh to the receive unicast clear register (RXUNICASTCLEAR). If unicast is desired, it can be enabled now by writing the receive unicast set register (RXUNICASTSET). Some drivers will default to unicast on device open while others will not.
10. Setup the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
11. Set the appropriate configuration bits in MACCONTROL (do not set the GMIIEN bit yet).
12. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register (RXINTMASKCLEAR) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
13. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register (RXINTMASKSET) and the transmit interrupt mask set register (TXINTMASKSET) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register (MACINTMASKSET).
14. Initialize the receive and transmit descriptor list queues.
15. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to RX*n*HDP.
16. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIIEN bit in MACCONTROL.
17. Enable the device interrupt in EMAC control module registers *CnRXTHRESHEN*, *CnRXEN*, *CnTXEN*, and *CnMISCEN*.

## 19.2.16 Interrupt Support

### 19.2.16.1 EMAC Module Interrupt Events and Requests

The EMAC module generates 26 interrupt events:

- TXPEND $n$ : Transmit packet completion interrupt for transmit channels 0 through 7
- RXPEND $n$ : Receive packet completion interrupt for receive channels 0 through 7
- RXTRESHPEND $n$ : Receive packet completion interrupt for receive channels 0 through 7 when flow control is enabled and the number of free buffers is below the threshold
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt

#### 19.2.16.1.1 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND $n$ ). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the appropriate bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 to the transmit interrupt mask clear register (TXINTMASKCLEAR). The raw and masked transmit interrupt status may be read by reading the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU (via the EMAC control module) when it writes the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel  $n$  completion pointer register (TX $n$ CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate C $n$ RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

#### 19.2.16.1.2 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND $n$ ). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the appropriate bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel *n* completion pointer register (RXnCP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate CnTX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

#### 19.2.16.1.3 Statistics Interrupt

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

The application software must acknowledge the EMAC control module after receiving statistics interrupts by writing the appropriate CnMISC key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

#### 19.2.16.1.4 Host Error Interrupt

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit by writing a 1 in the MAC interrupt mask clear register (MACINTMASKCLEAR). The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

The application software must acknowledge the EMAC control module after receiving host error interrupts by writing the appropriate *CnMISC* key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

#### 19.2.16.1.5 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt (RXnTHRESHPEND). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to 1 the appropriate bit in the RXINTMASKSET register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked interrupt receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

An RXnTHRESHPEND interrupt bit is asserted when enabled and when the channel's associated free buffer count (RXnFREEBUFFER) is less than or equal to the channel's associated flow control threshold register (RXnFLOWTHRESH). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

The applications software must acknowledge the EMAC control module after receiving threshold interrupts by writing the appropriate *CnRXTHRESH* key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

#### 19.2.16.2 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT0: Serial interface link change interrupt. Indicates a change in the state of the PHY link selected by the USERPHYSEL0 register
- USERINT0: Serial interface user command event complete interrupt selected by the USERACCESS0 register

##### 19.2.16.2.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT0) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO register USERPHYSEL0, and if the LINKINTENB bit is also set in USERPHYSEL0. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate *CnMISC* key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

### 19.2.16.2.2 User Access Completion Interrupt

When the GO bit in one of the MDIO register USERACCESS0 transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW).

USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate CnMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

### 19.2.16.3 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core may require edge- or pulse-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge- or pulse-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC control module.

[Section 19.2.6.3](#) discusses the interrupt control contained in the EMAC control module. For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC control module registers CnRXTHRESHEN, CnRXEN, CnTXEN, CnMISCEN, and then reenables them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC control module also uses the EMAC control module registers INTCONTROL, CnTXIMAX, and CnRXIMAX to implement interrupt pacing. The application software must acknowledge the EMAC control module by writing the appropriate key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 19.3.3.12](#) for the acknowledge key values.

### 19.2.16.4 Interrupt Multiplexing

The EMAC control module combines different interrupt signals from both the EMAC and MDIO modules into four interrupt signals (CnRXTHRESHPULSE, CnRXPULSE, CnTXPULSE, CnMISCPULSE) that are routed to three independent interrupt cores in the control module. Each interrupt core is capable of relaying all four interrupt signals out of the control module. Some devices may have an individual interrupt core dedicated to a specific CPU or interrupt controller. This configuration gives users of devices greater flexibility when allocating system resources for EMAC management.

When an interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (MACINVECTOR) located in the EMAC memory map. MACINVECTOR combines the status of the following 28 interrupt signals: TXPENDn, RXPENDn, RXTHRESHPENDn, STATPEND, HOSTPEND, LINKINT0, and USERINT0.

For more details on the interrupt mapping, see the *DSP Subsystem* chapter and the *ARM Interrupt Controller (AINTC)* chapter.

### 19.2.17 Power Management

Each of the three main components of the EMAC peripheral can independently be placed in reduced-power modes to conserve power during periods of low activity. The power management of the EMAC peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management on behalf of all of the peripherals on the device.

The power conservation modes available for each of the three components of the EMAC/MDIO peripheral are:

- *Idle/Disabled state.* This mode stops the clocks going to the peripheral, and prevents all the register accesses. After reenabling the peripheral from this idle state, all the registers values prior to setting into the disabled state are restored, and data transmission can proceed. No reinitialization is required.
- *Synchronized reset.* This state is similar to the Power-on Reset (POR) state, when the processor is turned-on; reset to the peripheral is asserted, and clocks to the peripheral are gated after that. The registers are reset to their default value. When powering-up after a synchronized reset, all the EMAC submodules need to be reinitialized before any data transmission can happen.

For more information on the use of the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 19.2.18 Emulation Considerations

EMAC emulation control is implemented for compatibility with other peripherals. The SOFT and FREE bits in the emulation control register (EMCONTROL) allow EMAC operation to be suspended.

When the emulation suspend state is entered, the EMAC stops processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission is completed normally without suspension. For transmission, any complete or partial frame in the transmit cell FIFO is transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics are kept for ignored frames.

Table 19-7 shows how the SOFT and FREE bits affect the operation of the emulation suspend.

---

**NOTE:** Emulation suspend has not been tested.

---

**Table 19-7. Emulation Control**

| SOFT | FREE | Description       |
|------|------|-------------------|
| 0    | 0    | Normal operation  |
| 1    | 0    | Emulation suspend |
| X    | 1    | Normal operation  |

## 19.3 Registers

This section discusses the registers of the EMAC/MDIO module.

### 19.3.1 EMAC Control Module Registers

[Table 19-8](#) lists the memory-mapped registers for the EMAC control module. See your device-specific data manual for the memory address of these registers.

**Table 19-8. EMAC Control Module Registers**

### 19.3.1.12 EMAC Control Module Interrupt Core Receive Interrupts Per Millisecond Registers (C0RXIMAX-C2RXIMAX)

The EMAC control module interrupt core 0-2 receive interrupts per millisecond register (CnRXIMAX) is shown in [Figure 19-23](#) and described in [Table 19-20](#)

**Figure 19-23. EMAC Control Module Interrupt Core 0-2 Receive Interrupts Per Millisecond Register (CnRXIMAX)**

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

**Table 19-20. EMAC Control Module Interrupt Core 0-2 Receive Interrupts Per Millisecond Register (CnRXIMAX)**

| Bit  | Field    | Value | Description                                                                                                              |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved                                                                                                                 |
| 5-0  | RXIMAX   | 2-3Fh | RXIMAX is the desired number of CnRXPULSE interrupts generated per millisecond when CnRXPACEEN is enabled in INTCONTROL. |

The pacing mechanism can be described by the following pseudo-code:

```
while(1) {
    interrupt_count = 0;

    /* Count interrupts over a 1ms window */
    for(i = 0; i < INTCONTROL[INTPRESCALE]*250; i++) {
        interrupt_count += NEW_INTERRUPT_EVENTS();

        if(i < INTCONTROL[INTPRESCALE]*pace_counter)
            BLOCK_EMAC_INTERRUPTS();
        else
            ALLOW_EMAC_INTERRUPTS();
    }

    ALLOW_EMAC_INTERRUPTS();

    if(interrupt_count > 2*RXIMAX)
        pace_counter = 255;
    else if(interrupt_count > 1.5*RXIMAX)
        pace_counter = previous_pace_counter*2 + 1;
    else if(interrupt_count > 1.0*RXIMAX)
        pace_counter = previous_pace_counter + 1;
    else if(interrupt_count > 0.5*RXIMAX)
        pace_counter = previous_pace_counter - 1;
    else if(interrupt_count != 0)
        pace_counter = previous_pace_counter/2;
    else
        pace_counter = 0;

    previous_pace_counter = pace_counter;
}
```

### 19.3.1.13 EMAC Control Module Interrupt Core Transmit Interrupts Per Millisecond Registers (C0TXIMAX-C2TXIMAX)

The EMAC control module interrupt core 0-2 transmit interrupts per millisecond register (CnTXIMAX) is shown in [Figure 19-24](#) and described in [Table 19-21](#)

**Figure 19-24. EMAC Control Module Interrupt Core 0-2 Transmit Interrupts Per Millisecond Register (CnTXIMAX)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-21. EMAC Control Module Interrupt Core 0-2 Transmit Interrupts Per Millisecond Register (CnTXIMAX)**

| Bit  | Field    | Value | Description                                                                                                              |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved                                                                                                                 |
| 5-0  | TXIMAX   | 2-3Fh | TXIMAX is the desired number of CnTXPULSE interrupts generated per millisecond when CnTXPACEEN is enabled in INTCONTROL. |

The pacing mechanism can be described by the following pseudo-code:

```

while(1) {
    interrupt_count = 0;

    /* Count interrupts over a 1ms window */
    for(i = 0; i < INTCONTROL[INTPRESCALE]*250; i++) {
        interrupt_count += NEW_INTERRUPT_EVENTS();

        if(i < INTCONTROL[INTPRESCALE]*pace_counter)
            BLOCK_EMAC_INTERRUPTS();
        else
            ALLOW_EMAC_INTERRUPTS();
    }

    ALLOW_EMAC_INTERRUPTS();

    if(interrupt_count > 2*TXIMAX)
        pace_counter = 255;
    else if(interrupt_count > 1.5*TXIMAX)
        pace_counter = previous_pace_counter*2 + 1;
    else if(interrupt_count > 1.0*TXIMAX)
        pace_counter = previous_pace_counter + 1;
    else if(interrupt_count > 0.5*TXIMAX)
        pace_counter = previous_pace_counter - 1;
    else if(interrupt_count != 0)
        pace_counter = previous_pace_counter/2;
    else
        pace_counter = 0;

    previous_pace_counter = pace_counter;
}

```

### 19.3.2 MDIO Registers

Table 19-22 lists the memory-mapped registers for the MDIO module. See your device-specific data manual for the memory address of these registers.

**Table 19-22. Management Data Input/Output (MDIO) Registers**

| 28-24 | HIGHEST_USER_CHANNEL | 0-1Fh   | Highest user channel that is available in the module. It is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel.                                                                                                                                                                         |
| 23-21 | Reserved             | 0       | Reserved                                                                                                                                                                                                                                                                                                                                |
| 20    | PREAMBLE             | 0<br>1  | Preamble disable<br>Standard MDIO preamble is used.<br>Disables this device from sending MDIO frame preambles.                                                                                                                                                                                                                          |
| 19    | FAULT                | 0<br>1  | Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to this bit clears this bit, writing a 0 has no effect.<br>No failure<br>Physical layer fault; the MDIO state machine is reset. |
| 18    | FAULTENB             | 0<br>1  | Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection.<br>Disables the physical layer fault detection.<br>Enables the physical layer fault detection.                                                                                                                                           |
| 17-16 | Reserved             | 0       | Reserved                                                                                                                                                                                                                                                                                                                                |
| 15-0  | CLKDIV               | 0-FFFFh | Clock Divider bits. This field specifies the division ratio between the peripheral clock and the frequency of MDIO_CLK. MDIO_CLK is disabled when CLKDIV is cleared to 0. MDIO_CLK frequency = peripheral clock frequency/(CLKDIV + 1).                                                                                                 |

### 19.3.2.3 PHY Acknowledge Status Register (ALIVE)

The PHY acknowledge status register (ALIVE) is shown in [Figure 19-27](#) and described in [Table 19-25](#).

**Figure 19-27. PHY Acknowledge Status Register (ALIVE)**

LEGEND: R/W = Read/Write; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 19-25. PHY Acknowledge Status Register (ALIVE) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ALIVE |       | MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect. |
|      |       | 0     | The PHY fails to acknowledge the access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|      |       | 1     | The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY.                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 19.3.2.4 PHY Link Status Register (LINK)

The PHY link status register (LINK) is shown in [Figure 19-28](#) and described in [Table 19-26](#).

**Figure 19-28. PHY Link Status Register (LINK)**

LEGEND: R = Read only; -n = value after reset

**Table 19-26. PHY Link Status Register (LINK) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                            |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | LINK  |       | MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. |
|      |       | 0     | The PHY indicates it does not have a link or fails to acknowledge the read transaction                                                                                                                                                                                                                                                                                 |
|      |       | 1     | The PHY with the corresponding address has a link and the PHY acknowledges the read transaction.                                                                                                                                                                                                                                                                       |

### 19.3.2.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in [Figure 19-29](#) and described in [Table 19-27](#).

**Figure 19-29. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)**

|          |  |  |  |  |  |  |  |  |  |  |          |   |          |  |    |

When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event, writing a 0 has no effect.</div> <div>No MDIO link change event.</div> <div>An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0 and the LINKINTENB bit in USERPHYSEL0 is set to 1.</div> |

### 19.3.2.7 MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)

The MDIO user command complete interrupt (unmasked) register (USERINTRAW) is shown in [Figure 19-31](#) and described in [Table 19-29](#).

**Figure 19-31. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 19-29. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW) Field Descriptions**

| Bit  | Field       | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0                         | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                      |

When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS1 register has completed. Writing a 1 will clear the event, writing a 0 has no effect.</div> <div>No MDIO user command complete event.</div> <div>The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed.</div> |
| 0    | USERACCESS0 | <div>0</div> <div>1</div> | <div>MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS0 register has completed. Writing a 1 will clear the event, writing a 0 has no effect.</div> <div>No MDIO user command complete event.</div> <div>The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed.</div> |

### 19.3.2.8 MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)

The MDIO user command complete interrupt (masked) register (USERINTMASKED) is shown in [Figure 19-32](#) and described in [Table 19-30](#).

**Figure 19-32. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 19-30. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                               |
|------|-------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                                                                                  |
| 1    | USERACCESS1 |       | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS1 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect. |
|      |             | 0     | No MDIO user command complete event.                                                                                                                                                                                                                                      |
|      |             | 1     | The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed and the corresponding bit in USERINTMASKSET is set to 1.                                                                                                     |
| 0    | USERACCESS0 |       | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS0 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect. |
|      |             | 0     | No MDIO user command complete event.                                                                                                                                                                                                                                      |
|      |             | 1     | The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed and the corresponding bit in USERINTMASKSET is set to 1.                                                                                                     |

### 19.3.2.9 MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

The MDIO user command complete interrupt mask set register (USERINTMASKSET) is shown in [Figure 19-33](#) and described in [Table 19-31](#).

**Figure 19-33. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)**

|          |  |  |  |  |  |  |  |  |  |             |    |             |   |

| R-0      |  |  |  |  |  |  |  |  |  | R/W1S-0     |    | R/W1S-0     |   |

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 19-31. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                                 |
|------|-------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                                                                                    |
| 1    | USERACCESS1 |       | MDIO user interrupt mask set for USERINTMASKED[1]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS1 register. MDIO user interrupt for USERACCESS1 is disabled if the corresponding bit is 0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                                                                                            |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                                                                                             |
| 0    | USERACCESS0 |       | MDIO user interrupt mask set for USERINTMASKED[0]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS0 register. MDIO user interrupt for USERACCESS0 is disabled if the corresponding bit is 0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                                                                                            |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                                                                                             |

### 19.3.2.10 MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)

The MDIO user command complete interrupt mask clear register (USERINTMASKCLEAR) is shown in [Figure 19-34](#) and described in [Table 19-32](#).

**Figure 19-34. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 19-32. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                              |
|------|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                 |
| 1    | USERACCESS1 | 0     | MDIO user command complete interrupt mask clear for USERINTMASKED[1]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS1. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is enabled.                                                                                                          |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is disabled.                                                                                                         |
| 0    | USERACCESS0 | 0     | MDIO user command complete interrupt mask clear for USERINTMASKED[0]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                          |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                         |

### 19.3.2.11 MDIO User Access Register 0 (USERACCESS0)

The MDIO user access register 0 (USERACCESS0) is shown in [Figure 19-35](#) and described in [Table 19-33](#).

**Figure 19-35. MDIO User Access Register 0 (USERACCESS0)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 19-33. MDIO User Access Register 0 (USERACCESS0) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | GO       | 0-1     | Go bit. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1. |
| 30    | WRITE    | 0<br>1  | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.<br>The user command is a read operation.<br>The user command is a write operation.                                                                                                                                                                                                |
| 29    | ACK      | 0-1     | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.                                                                                                                                                                                                                                                                                                                                  |
| 28-26 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25-21 | REGADR   | 0-1Fh   | Register address bits. This field specifies the PHY register to be accessed for this transaction                                                                                                                                                                                                                                                                                                                |
| 20-16 | PHYADR   | 0-1Fh   | PHY address bits. This field specifies the PHY to be accessed for this transaction.                                                                                                                                                                                                                                                                                                                             |
| 15-0  | DATA     | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register.                                                                                                                                                                                                                                                                                                     |

### 19.3.2.12 MDIO User PHY Select Register 0 (USERPHYSEL0)

The MDIO user PHY select register 0 (USERPHYSEL0) is shown in [Figure 19-36](#) and described in [Table 19-34](#).

**Figure 19-36. MDIO User PHY Select Register 0 (USERPHYSEL0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-34. MDIO User PHY Select Register 0 (USERPHYSEL0) Field Descriptions**

| Bit  | Field      | Value                     | Description                                                                                                                                                                                                                                                                                                                                            |

| 15-0  | DATA     | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register.                                                                                                                                                                                                                                                                                                 |

### 19.3.2.14 MDIO User PHY Select Register 1 (USERPHYSEL1)

The MDIO user PHY select register 1 (USERPHYSEL1) is shown in [Figure 19-38](#) and described in [Table 19-36](#).

**Figure 19-38. MDIO User PHY Select Register 1 (USERPHYSEL1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-36. MDIO User PHY Select Register 1 (USERPHYSEL1) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                     |
|------|------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                        |
| 7    | LINKSEL    | 0<br>1 | Link status determination select bit. Default value is 0, which implies that the link status is determined by the MDIO state machine. This is the only option supported on this device.<br>The link status is determined by the MDIO state machine.<br>Not supported.                                                           |
| 6    | LINKINTENB | 0<br>1 | Link change interrupt enable. Set to 1 to enable link change status interrupts for the PHY address specified in PHYADDRMON. Link change interrupts are disabled if this bit is cleared to 0.<br>Link change interrupts are disabled.<br>Link change status interrupts for PHY address specified in PHYADDRMON bits are enabled. |
| 5    | Reserved   | 0      | PHY address whose link status is to be monitored.                                                                                                                                                                                                                                                                               |
| 4-0  | PHYADDRMON | 0-1Fh  | PHY address whose link status is to be monitored.                                                                                                                                                                                                                                                                               |

### 19.3.3 EMAC Module Registers

Table 19-37 lists the memory-mapped registers for the EMAC. See your device-specific data manual for the memory address of these registers.

**Table 19-37. Ethernet Media Access Controller (EMAC) Registers**

| Offset | Acronym           | Register Description                                            | Section                           |
|--------|-------------------|-----------------------------------------------------------------|-----------------------------------|
| 0h     | TXREVID           | Transmit Revision ID Register                                   | <a href="#">Section 19.3.3.1</a>  |
| 4h     | TXCONTROL         | Transmit Control Register                                       | <a href="#">Section 19.3.3.2</a>  |
| 8h     | TXTEARDOWN        | Transmit Teardown Register                                      | <a href="#">Section 19.3.3.3</a>  |
| 10h    | RXREVID           | Receive Revision ID Register                                    | <a href="#">Section 19.3.3.4</a>  |
| 14h    | RXCONTROL         | Receive Control Register                                        | <a href="#">Section 19.3.3.5</a>  |
| 18h    | RXTEARDOWN        | Receive Teardown Register                                       | <a href="#">Section 19.3.3.6</a>  |
| 80h    | TXINTSTATRAW      | Transmit Interrupt Status (Unmasked) Register                   | <a href="#">Section 19.3.3.7</a>  |
| 84h    | TXINTSTATMASKED   | Transmit Interrupt Status (Masked) Register                     | <a href="#">Section 19.3.3.8</a>  |
| 88h    | TXINTMASKSET      | Transmit Interrupt Mask Set Register                            | <a href="#">Section 19.3.3.9</a>  |
| 8Ch    | TXINTMASKCLEAR    | Transmit Interrupt Clear Register                               | <a href="#">Section 19.3.3.10</a> |
| 90h    | MACINVECTOR       | MAC Input Vector Register                                       | <a href="#">Section 19.3.3.11</a> |
| 94h    | MACEOIVECTOR      | MAC End Of Interrupt Vector Register                            | <a href="#">Section 19.3.3.12</a> |
| A0h    | RXINTSTATRAW      | Receive Interrupt Status (Unmasked) Register                    | <a href="#">Section 19.3.3.13</a> |
| A4h    | RXINTSTATMASKED   | Receive Interrupt Status (Masked) Register                      | <a href="#">Section 19.3.3.14</a> |
| A8h    | RXINTMASKSET      | Receive Interrupt Mask Set Register                             | <a href="#">Section 19.3.3.15</a> |
| ACH    | RXINTMASKCLEAR    | Receive Interrupt Mask Clear Register                           | <a href="#">Section 19.3.3.16</a> |
| B0h    | MACINTSTATRAW     | MAC Interrupt Status (Unmasked) Register                        | <a href="#">Section 19.3.3.17</a> |
| B4h    | MACINTSTATMASKED  | MAC Interrupt Status (Masked) Register                          | <a href="#">Section 19.3.3.18</a> |
| B8h    | MACINTMASKSET     | MAC Interrupt Mask Set Register                                 | <a href="#">Section 19.3.3.19</a> |
| BCh    | MACINTMASKCLEAR   | MAC Interrupt Mask Clear Register                               | <a href="#">Section 19.3.3.20</a> |
| 100h   | RXMBPENABLE       | Receive Multicast/Broadcast/Promiscuous Channel Enable Register | <a href="#">Section 19.3.3.21</a> |
| 104h   | RXUNICASTSET      | Receive Unicast Enable Set Register                             | <a href="#">Section 19.3.3.22</a> |
| 108h   | RXUNICASTCLEAR    | Receive Unicast Clear Register                                  | <a href="#">Section 19.3.3.23</a> |
| 10Ch   | RXMAXLEN          | Receive Maximum Length Register                                 | <a href="#">Section 19.3.3.24</a> |
| 110h   | RXBUFFEROFFSET    | Receive Buffer Offset Register                                  | <a href="#">Section 19.3.3.25</a> |
| 114h   | RXFILTERLOWTHRESH | Receive Filter Low Priority Frame Threshold Register            | <a href="#">Section 19.3.3.26</a> |
| 120h   | RX0FLOWTHRESH     | Receive Channel 0 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 124h   | RX1FLOWTHRESH     | Receive Channel 1 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 128h   | RX2FLOWTHRESH     | Receive Channel 2 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 12Ch   | RX3FLOWTHRESH     | Receive Channel 3 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 130h   | RX4FLOWTHRESH     | Receive Channel 4 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 134h   | RX5FLOWTHRESH     | Receive Channel 5 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 138h   | RX6FLOWTHRESH     | Receive Channel 6 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 13Ch   | RX7FLOWTHRESH     | Receive Channel 7 Flow Control Threshold Register               | <a href="#">Section 19.3.3.27</a> |
| 140h   | RX0FREEBUFFER     | Receive Channel 0 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 144h   | RX1FREEBUFFER     | Receive Channel 1 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 148h   | RX2FREEBUFFER     | Receive Channel 2 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 14Ch   | RX3FREEBUFFER     | Receive Channel 3 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 150h   | RX4FREEBUFFER     | Receive Channel 4 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 154h   | RX5FREEBUFFER     | Receive Channel 5 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 158h   | RX6FREEBUFFER     | Receive Channel 6 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 15Ch   | RX7FREEBUFFER     | Receive Channel 7 Free Buffer Count Register                    | <a href="#">Section 19.3.3.28</a> |
| 160h   | MACCONTROL        | MAC Control Register                                            | <a href="#">Section 19.3.3.29</a> |

**Table 19-37. Ethernet Media Access Controller (EMAC) Registers (continued)**

| Offset | Acronym      | Register Description                                              | Section                           |
|--------|--------------|-------------------------------------------------------------------|-----------------------------------|

| 670h   | RX4CP        | Receive Channel 4 Completion Pointer Register                     | <a href="#">Section 19.3.3.49</a> |
| 674h   | RX5CP        | Receive Channel 5 Completion Pointer Register                     | <a href="#">Section 19.3.3.49</a> |

**Table 19-37. Ethernet Media Access Controller (EMAC) Registers (continued)**

| Offset                              | Acronym           | Register Description                                        | Section                              |
|-------------------------------------|-------------------|-------------------------------------------------------------|--------------------------------------|
| 678h                                | RX6CP             | Receive Channel 6 Completion Pointer Register               | <a href="#">Section 19.3.3.49</a>    |
| 67Ch                                | RX7CP             | Receive Channel 7 Completion Pointer Register               | <a href="#">Section 19.3.3.49</a>    |
| <b>Network Statistics Registers</b> |                   |                                                             |                                      |
| 200h                                | RXGOODFRAMES      | Good Receive Frames Register                                | <a href="#">Section 19.3.3.50.1</a>  |
| 204h                                | RXBCASTFRAMES     | Broadcast Receive Frames Register                           | <a href="#">Section 19.3.3.50.2</a>  |
| 208h                                | RXMCASTFRAMES     | Multicast Receive Frames Register                           | <a href="#">Section 19.3.3.50.3</a>  |
| 20Ch                                | RXPAUSEFRAMES     | Pause Receive Frames Register                               | <a href="#">Section 19.3.3.50.4</a>  |
| 210h                                | RXCRCERRORS       | Receive CRC Errors Register                                 | <a href="#">Section 19.3.3.50.5</a>  |
| 214h                                | RXALIGNCODEERRORS | Receive Alignment/Code Errors Register                      | <a href="#">Section 19.3.3.50.6</a>  |
| 218h                                | RXOVERSIZED       | Receive Oversized Frames Register                           | <a href="#">Section 19.3.3.50.7</a>  |
| 21Ch                                | RXJABBER          | Receive Jabber Frames Register                              | <a href="#">Section 19.3.3.50.8</a>  |
| 220h                                | RXUNDERSIZED      | Receive Undersized Frames Register                          | <a href="#">Section 19.3.3.50.9</a>  |
| 224h                                | RXFRAGMENTS       | Receive Frame Fragments Register                            | <a href="#">Section 19.3.3.50.10</a> |
| 228h                                | RXFILTERED        | Filtered Receive Frames Register                            | <a href="#">Section 19.3.3.50.11</a> |
| 22Ch                                | RXQOSFILTERED     | Receive QOS Filtered Frames Register                        | <a href="#">Section 19.3.3.50.12</a> |
| 230h                                | RXOCTETS          | Receive Octet Frames Register                               | <a href="#">Section 19.3.3.50.13</a> |
| 234h                                | TXGOODFRAMES      | Good Transmit Frames Register                               | <a href="#">Section 19.3.3.50.14</a> |
| 238h                                | TXBCASTFRAMES     | Broadcast Transmit Frames Register                          | <a href="#">Section 19.3.3.50.15</a> |
| 23Ch                                | TXMCASTFRAMES     | Multicast Transmit Frames Register                          | <a href="#">Section 19.3.3.50.16</a> |
| 240h                                | TXPAUSEFRAMES     | Pause Transmit Frames Register                              | <a href="#">Section 19.3.3.50.17</a> |
| 244h                                | TXDEFERRED        | Deferred Transmit Frames Register                           | <a href="#">Section 19.3.3.50.18</a> |
| 248h                                | TXCOLLISION       | Transmit Collision Frames Register                          | <a href="#">Section 19.3.3.50.19</a> |
| 24Ch                                | TXSINGLECOLL      | Transmit Single Collision Frames Register                   | <a href="#">Section 19.3.3.50.20</a> |
| 250h                                | TXMULTICOLL       | Transmit Multiple Collision Frames Register                 | <a href="#">Section 19.3.3.50.21</a> |
| 254h                                | TXEXCESSIVECOLL   | Transmit Excessive Collision Frames Register                | <a href="#">Section 19.3.3.50.22</a> |
| 258h                                | TXLATECOLL        | Transmit Late Collision Frames Register                     | <a href="#">Section 19.3.3.50.23</a> |
| 25Ch                                | TXUNDERRUN        | Transmit Underrun Error Register                            | <a href="#">Section 19.3.3.50.24</a> |
| 260h                                | TXCARRIERSENSE    | Transmit Carrier Sense Errors Register                      | <a href="#">Section 19.3.3.50.25</a> |
| 264h                                | TXOCTETS          | Transmit Octet Frames Register                              | <a href="#">Section 19.3.3.50.26</a> |
| 268h                                | FRAME64           | Transmit and Receive 64 Octet Frames Register               | <a href="#">Section 19.3.3.50.27</a> |
| 26Ch                                | FRAME65T127       | Transmit and Receive 65 to 127 Octet Frames Register        | <a href="#">Section 19.3.3.50.28</a> |
| 270h                                | FRAME128T255      | Transmit and Receive 128 to 255 Octet Frames Register       | <a href="#">Section 19.3.3.50.29</a> |
| 274h                                | FRAME256T511      | Transmit and Receive 256 to 511 Octet Frames Register       | <a href="#">Section 19.3.3.50.30</a> |
| 278h                                | FRAME512T1023     | Transmit and Receive 512 to 1023 Octet Frames Register      | <a href="#">Section 19.3.3.50.31</a> |
| 27Ch                                | FRAME1024TUP      | Transmit and Receive 1024 to RXMAXLEN Octet Frames Register | <a href="#">Section 19.3.3.50.32</a> |
| 280h                                | NETOCTETS         | Network Octet Frames Register                               | <a href="#">Section 19.3.3.50.33</a> |
| 284h                                | RXSOFOVERRUNS     | Receive FIFO or DMA Start of Frame Overruns Register        | <a href="#">Section 19.3.3.50.34</a> |
| 288h                                | RXMOFOVERRUNS     | Receive FIFO or DMA Middle of Frame Overruns Register       | <a href="#">Section 19.3.3.50.35</a> |
| 28Ch                                | RXDMAOVERRUNS     | Receive DMA Overruns Register                               | <a href="#">Section 19.3.3.50.36</a> |

### 19.3.3.1 Transmit Revision ID Register (TXREVID)

The transmit revision ID register (TXREVID) is shown in [Figure 19-39](#) and described in [Table 19-38](#).

**Figure 19-39. Transmit Revision ID Register (TXREVID)**

LEGEND: R = Read only; -n = value after reset

**Table 19-38. Transmit Revision ID Register (TXREVID) Field Descriptions**

| Bit  | Field | Value      | Description                                                 |
|------|-------|------------|-------------------------------------------------------------|
| 31-0 | TXREV | 4EC0 020Dh | Transmit module revision<br>Current transmit revision value |

### 19.3.3.2 Transmit Control Register (TXCONTROL)

The transmit control register (TXCONTROL) is shown in [Figure 19-40](#) and described in [Table 19-39](#).

**Figure 19-40. Transmit Control Register (TXCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-39. Transmit Control Register (TXCONTROL) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                 |
| 0    | TXEN     | 0     | Transmit enable<br>Transmit is disabled. |
|      |          | 1     | Transmit is enabled.                     |

### 19.3.3.3 Transmit Teardown Register (TXTEARDOWN)

The transmit teardown register (TXTEARDOWN) is shown in [Figure 19-41](#) and described in [Table 19-40](#).

**Figure 19-41. Transmit Teardown Register (TXTEARDOWN)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-40. Transmit Teardown Register (TXTEARDOWN) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                     |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                                                        |
| 2-0  | TXTDNCH  | 0-7h  | Transmit teardown channel. The transmit channel teardown is commanded by writing the encoded value of the transmit channel to be torn down. The teardown register is read as 0. |
|      |          | 0     | Teardown transmit channel 0                                                                                                                                                     |
|      |          | 1h    | Teardown transmit channel 1                                                                                                                                                     |
|      |          | 2h    | Teardown transmit channel 2                                                                                                                                                     |
|      |          | 3h    | Teardown transmit channel 3                                                                                                                                                     |
|      |          | 4h    | Teardown transmit channel 4                                                                                                                                                     |
|      |          | 5h    | Teardown transmit channel 5                                                                                                                                                     |
|      |          | 6h    | Teardown transmit channel 6                                                                                                                                                     |
|      |          | 7h    | Teardown transmit channel 7                                                                                                                                                     |

### 19.3.3.4 Receive Revision ID Register (RXREVID)

The receive revision ID register (RXREVID) is shown in [Figure 19-42](#) and described in [Table 19-41](#).

**Figure 19-42. Receive Revision ID Register (RXREVID)**

LEGEND: R = Read only; -n = value after reset

**Table 19-41. Receive Revision ID Register (RXREVID) Field Descriptions**

| Bit  | Field | Value      | Description                                               |
|------|-------|------------|-----------------------------------------------------------|
| 31-0 | RXREV | 4EC0 020Dh | Receive module revision<br>Current receive revision value |

### 19.3.3.5 Receive Control Register (RXCONTROL)

The receive control register (RXCONTROL) is shown in [Figure 19-43](#) and described in [Table 19-42](#).

**Figure 19-43. Receive Control Register (RXCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-42. Receive Control Register (RXCONTROL) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-1 | Reserved | 0     | Reserved                               |
| 0    | RXEN     | 0     | Receive enable<br>Receive is disabled. |
|      |          | 1     | Receive is enabled.                    |

### 19.3.3.6 Receive Teardown Register (RXTEARDOWN)

The receive teardown register (RXTEARDOWN) is shown in [Figure 19-44](#) and described in [Table 19-43](#).

**Figure 19-44. Receive Teardown Register (RXTEARDOWN)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-43. Receive Teardown Register (RXTEARDOWN) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                  |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                                                     |
| 2-0  | RXTDNCH  | 0-7h  | Receive teardown channel. The receive channel teardown is commanded by writing the encoded value of the receive channel to be torn down. The teardown register is read as 0. |
|      |          | 0     | Teardown receive channel 0                                                                                                                                                   |
|      |          | 1h    | Teardown receive channel 1                                                                                                                                                   |
|      |          | 2h    | Teardown receive channel 2                                                                                                                                                   |

### 19.3.3.7 Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW)

The transmit interrupt status (unmasked) register (TXINTSTATRAW) is shown in [Figure 19-45](#) and described in [Table 19-44](#).

**Figure 19-45. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW)**

LEGEND: R = Read only; -n = value after reset

**Table 19-44. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                 |
| 7    | TX7PEND  | 0-1   | TX7PEND raw interrupt read (before mask) |
| 6    | TX6PEND  | 0-1   | TX6PEND raw interrupt read (before mask) |
| 5    | TX5PEND  | 0-1   | TX5PEND raw interrupt read (before mask) |
| 4    | TX4PEND  | 0-1   | TX4PEND raw interrupt read (before mask) |
| 3    | TX3PEND  | 0-1   | TX3PEND raw interrupt read (before mask) |
| 2    | TX2PEND  | 0-1   | TX2PEND raw interrupt read (before mask) |
| 1    | TX1PEND  | 0-1   | TX1PEND raw interrupt read (before mask) |
| 0    | TX0PEND  | 0-1   | TX0PEND raw interrupt read (before mask) |

### 19.3.3.8 Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)

The transmit interrupt status (masked) register (TXINTSTATMASKED) is shown in [Figure 19-46](#) and described in [Table 19-45](#).

**Figure 19-46. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)**

LEGEND: R = Read only; -n = value after reset

**Table 19-45. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED) Field Descriptions**

| Bit  | Field    | Value | Description                   |
|------|----------|-------|-------------------------------|
| 31-8 | Reserved | 0     | Reserved                      |
| 7    | TX7PEND  | 0-1   | TX7PEND masked interrupt read |
| 6    | TX6PEND  | 0-1   | TX6PEND masked interrupt read |
| 5    | TX5PEND  | 0-1   | TX5PEND masked interrupt read |
| 4    | TX4PEND  | 0-1   | TX4PEND masked interrupt read |
| 3    | TX3PEND  | 0-1   | TX3PEND masked interrupt read |
| 2    | TX2PEND  | 0-1   | TX2PEND masked interrupt read |
| 1    | TX1PEND  | 0-1   | TX1PEND masked interrupt read |
| 0    | TX0PEND  | 0-1   | TX0PEND masked interrupt read |

### 19.3.3.9 Transmit Interrupt Mask Set Register (TXINTMASKSET)

The transmit interrupt mask set register (TXINTMASKSET) is shown in [Figure 19-47](#) and described in [Table 19-46](#).

**Figure 19-47. Transmit Interrupt Mask Set Register (TXINTMASKSET)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 19-46. Transmit Interrupt Mask Set Register (TXINTMASKSET) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                            |
| 7    | TX7MASK  | 0-1   | Transmit channel 7 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 6    | TX6MASK  | 0-1   | Transmit channel 6 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 5    | TX5MASK  | 0-1   | Transmit channel 5 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 4    | TX4MASK  | 0-1   | Transmit channel 4 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 3    | TX3MASK  | 0-1   | Transmit channel 3 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 2    | TX2MASK  | 0-1   | Transmit channel 2 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 1    | TX1MASK  | 0-1   | Transmit channel 1 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 0    | TX0MASK  | 0-1   | Transmit channel 0 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |

### 19.3.3.10 Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)

The transmit interrupt mask clear register (TXINTMASKCLEAR) is shown in [Figure 19-48](#) and described in [Table 19-47](#).

**Figure 19-48. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 19-47. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                            |
|------|----------|-------|--------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                               |
| 7    | TX7MASK  | 0-1   | Transmit channel 7 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 6    | TX6MASK  | 0-1   | Transmit channel 6 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 5    | TX5MASK  | 0-1   | Transmit channel 5 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 4    | TX4MASK  | 0-1   | Transmit channel 4 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 3    | TX3MASK  | 0-1   | Transmit channel 3 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 2    | TX2MASK  | 0-1   | Transmit channel 2 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 1    | TX1MASK  | 0-1   | Transmit channel 1 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 0    | TX0MASK  | 0-1   | Transmit channel 0 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |

### 19.3.3.11 MAC Input Vector Register (MACINVECTOR)

The MAC input vector register (MACINVECTOR) is shown in [Figure 19-49](#) and described in [Table 19-48](#).

**Figure 19-49. MAC Input Vector Register (MACINVECTOR)**

|              |    |          |          |          |          |        |    |
|--------------|----|----------|----------|----------|----------|--------|----|
| 31           | 28 | 27       | 26       | 25       | 24       | 23     | 16 |
| Reserved     |    | STATPEND | HOSTPEND | LINKINT0 | USERINT0 | TXPEND |    |
| R-0          |    | R-0      | R-0      | R-0      | R-0      | R-0    |    |
| 15           |    |          |          |          | 8        | 7      | 0  |
| RXTHRESHPEND |    |          |          |          |          | RXPEND |    |
| R-0          |    |          |          |          |          | R-0    |    |

LEGEND: R = Read only; -n = value after reset

**Table 19-48. MAC Input Vector Register (MACINVECTOR) Field Descriptions**

| Bit   | Field        | Value | Description                                                                            |
|-------|--------------|-------|----------------------------------------------------------------------------------------|
| 31-28 | Reserved     | 0     | Reserved                                                                               |
| 27    | STATPEND     | 0-1   | EMAC module statistics interrupt (STATPEND) pending status bit                         |
| 26    | HOSTPEND     | 0-1   | EMAC module host error interrupt (HOSTPEND) pending status bit                         |
| 25    | LINKINT0     | 0-1   | MDIO module USERPHYSEL0 (LINKINT0) status bit                                          |
| 24    | USERINT0     | 0-1   | MDIO module USERACCESS0 (USERINT0) status bit                                          |
| 23-16 | TXPEND       | 0-FFh | Transmit channels 0-7 interrupt (TXnPEND) pending status. Bit 16 is TX0PEND.           |
| 15-8  | RXTHRESHPEND | 0-FFh | Receive channels 0-7 interrupt (RXnTHRESHPEND) pending status. Bit 8 is RX0THRESHPEND. |
| 7-0   | RXPEND       | 0-FFh | Receive channels 0-7 interrupt (RXnPEND) pending status bit. Bit 0 is RX0PEND.         |

### 19.3.3.12 MAC End Of Interrupt Vector Register (MACEOIVECTOR)

The MAC end of interrupt vector register (MACEOIVECTOR) is shown in [Figure 19-50](#) and described in [Table 19-49](#).

**Figure 19-50. MAC End Of Interrupt Vector Register (MACEOIVECTOR)**

| 2     | RX2MASK       | 0-1   | Receive channel 2 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 1     | RX1MASK       | 0-1   | Receive channel 1 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 0     | RX0MASK       | 0-1   | Receive channel 0 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |

### 19.3.3.17 MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)

The MAC interrupt status (unmasked) register (MACINTSTATRAW) is shown in [Figure 19-55](#) and described in [Table 19-54](#).

**Figure 19-55. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)**

LEGEND: R = Read only; -n = value after reset

**Table 19-54. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW) Field Descriptions**

| Bit  | Field    | Value | Description                                                                |
|------|----------|-------|----------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                   |
| 1    | HOSTPEND | 0-1   | Host pending interrupt (HOSTPEND); raw interrupt read (before mask).       |
| 0    | STATPEND | 0-1   | Statistics pending interrupt (STATPEND); raw interrupt read (before mask). |

### 19.3.3.18 MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)

The MAC interrupt status (masked) register (MACINTSTATMASKED) is shown in [Figure 19-56](#) and described in [Table 19-55](#).

**Figure 19-56. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)**

LEGEND: R = Read only; -n = value after reset

**Table 19-55. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED) Field Descriptions**

| Bit  | Field    | Value | Description                                                     |
|------|----------|-------|-----------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                        |
| 1    | HOSTPEND | 0-1   | Host pending interrupt (HOSTPEND); masked interrupt read.       |
| 0    | STATPEND | 0-1   | Statistics pending interrupt (STATPEND); masked interrupt read. |

### 19.3.3.19 MAC Interrupt Mask Set Register (MACINTMASKSET)

The MAC interrupt mask set register (MACINTMASKSET) is shown in [Figure 19-57](#) and described in [Table 19-56](#).

**Figure 19-57. MAC Interrupt Mask Set Register (MACINTMASKSET)**

|     |          |  |  |  |  |  |  |  |  |  |          |   |          |  |  |    |

### 19.3.3.23 Receive Unicast Clear Register (RXUNICASTCLEAR)

The receive unicast clear register (RXUNICASTCLEAR) is shown in [Figure 19-61](#) and described in [Table 19-60](#).

**Figure 19-61. Receive Unicast Clear Register (RXUNICASTCLEAR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 19-60. Receive Unicast Clear Register (RXUNICASTCLEAR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                          |
|------|----------|-------|------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                             |
| 7    | RXCH7EN  | 0-1   | Receive channel 7 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 6    | RXCH6EN  | 0-1   | Receive channel 6 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 5    | RXCH5EN  | 0-1   | Receive channel 5 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 4    | RXCH4EN  | 0-1   | Receive channel 4 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 3    | RXCH3EN  | 0-1   | Receive channel 3 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 2    | RXCH2EN  | 0-1   | Receive channel 2 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 1    | RXCH1EN  | 0-1   | Receive channel 1 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 0    | RXCH0EN  | 0-1   | Receive channel 0 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |

### 19.3.3.24 Receive Maximum Length Register (RXMAXLEN)

The receive maximum length register (RXMAXLEN) is shown in [Figure 19-62](#) and described in [Table 19-61](#).

**Figure 19-62. Receive Maximum Length Register (RXMAXLEN)**

|          |          |    |
|----------|----------|----|
| 31       | Reserved | 16 |

| 15       | RXMAXLEN | 0  |
| R/W-5EEh |          |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-61. Receive Maximum Length Register (RXMAXLEN) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                  |
|-------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                     |
| 15-0  | RXMAXLEN | 0-FFFFh | Receive maximum frame length. These bits determine the maximum length of a received frame. The reset value is 5EEh (1518). Frames with byte counts greater than RXMAXLEN are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. |

### 19.3.3.25 Receive Buffer Offset Register (RXBUFFEROFFSET)

The receive buffer offset register (RXBUFFEROFFSET) is shown in [Figure 19-63](#) and described in [Table 19-62](#).

**Figure 19-63. Receive Buffer Offset Register (RXBUFFEROFFSET)**

|       |                |    |
|-------|----------------|----|

| R/W-0 |                |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-62. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions**

| Bit   | Field          | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved       | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 15-0  | RXBUFFEROFFSET | 0-FFFFh | Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels. |

### 19.3.3.26 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in [Figure 19-64](#) and described in [Table 19-63](#).

**Figure 19-64. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-63. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)  
Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                                                |
|------|----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved       | 0     | Reserved                                                                                                                                                                                   |
| 7-0  | RXFILTERTHRESH | 0-FFh | Receive filter low threshold. These bits contain the free buffer count threshold value for filtering low priority incoming frames. This field should remain 0, if no filtering is desired. |

### 19.3.3.27 Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH)

The receive channel 0-7 flow control threshold register (RX<sub>n</sub>FLOWTHRESH) is shown in [Figure 19-65](#) and described in [Table 19-64](#).

**Figure 19-65. Receive Channel *n* Flow Control Threshold Register (RX<sub>n</sub>FLOWTHRESH)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-64. Receive Channel *n* Flow Control Threshold Register (RX<sub>n</sub>FLOWTHRESH)  
Field Descriptions**

| Bit  | Field                      | Value | Description                                                                                                                                     |
|------|----------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved                   | 0     | Reserved                                                                                                                                        |
| 7-0  | RX <sub>n</sub> FLOWTHRESH | 0-FFh | Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel <i>n</i> (when enabled). |

### 19.3.3.28 Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)

The receive channel 0-7 free buffer count register (RX $n$ FREEBUFFER) is shown in [Figure 19-66](#) and described in [Table 19-65](#).

**Figure 19-66. Receive Channel  $n$  Free Buffer Count Register (RX $n$ FREEBUFFER)**

| 15-0  | RX $n$ FREEBUF | 0-FFh | Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RXnFLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow.<br><br>If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing. |

### 19.3.3.29 MAC Control Register (MACCONTROL)

The MAC control register (MACCONTROL) is shown in [Figure 19-67](#) and described in [Table 19-66](#).

**Figure 19-67. MAC Control Register (MACCONTROL)**

**Table 19-66. MAC Control Register (MACCONTROL) Field Descriptions**

| Bit   | Field         | Value | Description                                                                                                                                                                                                                                            |
|-------|---------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved      | 0     | Reserved                                                                                                                                                                                                                                               |
| 15    | RMIISPEED     | 0     | RMII interface transmit and receive speed select.                                                                                                                                                                                                      |
|       |               | 0     | Operate RMII interface in 10 Mbps speed mode.                                                                                                                                                                                                          |
|       |               | 1     | Operate RMII interface in 100 Mbps speed mode.                                                                                                                                                                                                         |
| 14    | RXOFFLENBLOCK | 0     | Receive offset / length word write block.                                                                                                                                                                                                              |
|       |               | 0     | Do not block the DMA writes to the receive buffer descriptor offset / buffer length word.                                                                                                                                                              |
|       |               | 1     | Block all EMAC DMA controller writes to the receive buffer descriptor offset / buffer length words during packet processing. When this bit is set, the EMAC will never write the third word to any receive buffer descriptor.                          |
| 13    | RXOWNERSHIP   | 0     | Receive ownership write bit value.                                                                                                                                                                                                                     |
|       |               | 0     | The EMAC writes the Receive ownership bit to 0 at the end of packet processing.                                                                                                                                                                        |
|       |               | 1     | The EMAC writes the Receive ownership bit to 1 at the end of packet processing. If you do not use the ownership mechanism, you can set this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used. |
| 12    | Reserved      | 0     | Reserved                                                                                                                                                                                                                                               |
|       |               | 0     | Reserved                                                                                                                                                                                                                                               |
| 11    | CMDIDLE       | 0     | Command Idle bit                                                                                                                                                                                                                                       |
|       |               | 0     | Idle is not commanded.                                                                                                                                                                                                                                 |
|       |               | 1     | Idle is commanded (read IDLE in the MACSTATUS register).                                                                                                                                                                                               |
| 10    | TXSHORTGAPEN  | 0     | Transmit Short Gap Enable                                                                                                                                                                                                                              |
|       |               | 0     | Transmit with a short IPG is disabled. Normal 96-bit time IPG is inserted between packets.                                                                                                                                                             |
|       |               | 1     | Transmit with a short IPG is enabled. Shorter 88-bit time IPG is inserted between packets.                                                                                                                                                             |
| 9     | TXPTYPE       | 0     | Transmit queue priority type                                                                                                                                                                                                                           |
|       |               | 0     | The queue uses a round-robin scheme to select the next channel for transmission.                                                                                                                                                                       |
|       |               | 1     | The queue uses a fixed-priority (channel 7 highest priority) scheme to select the next channel for transmission.                                                                                                                                       |
| 8-7   | Reserved      | 0     | Reserved                                                                                                                                                                                                                                               |
| 6     | TXPACE        | 0     | Transmit pacing enable bit                                                                                                                                                                                                                             |
|       |               | 0     | Transmit pacing is disabled.                                                                                                                                                                                                                           |
|       |               | 1     | Transmit pacing is enabled.                                                                                                                                                                                                                            |

**Table 19-66. MAC Control Register (MACCONTROL) Field Descriptions (continued)**

| Bit | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|----------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | GMIEN          | 0<br>1 | GMII Enable Bit. This bit must be set before the MAC will transmit or receive data in any of the supported interface modes. (ex. MII, RMII). This bit does not select the interface mode but rather holds or releases the MAC TX and RX state machines from reset.<br>The MAC RX and TX state machines are held in reset<br>The MAC RX and TX state machines are released from reset and transmit/receive are enabled                                                                                          |
| 4   | TXFLOWEN       | 0<br>1 | Transmit flow control enable bit. This bit determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode, regardless of this bit setting. The RXMBPENABLE bits determine whether or not received pause frames are transferred to memory.<br>Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon.<br>Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon. |
| 3   | RXBUFFERFLOWEN | 0<br>1 | Receive buffer flow control enable bit<br>Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent.<br>Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive buffer flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.                                                                                       |
| 2   | Reserved       | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1   | LOOPBACK       | 0<br>1 | Loopback mode. The loopback mode forces internal full-duplex mode regardless of the FULLDUPLEX bit. | 10-8  | RXERRCH   | 0-7h  | Receive host error channel. These bits indicate which receive channel the host error occurred on. This field is cleared to 0 on a host read.                                                                                                                                                                                |
|       |           | 0     | The host error occurred on receive channel 0                                                                                                                                                                                                                                                                                |
|       |           | 1h    | The host error occurred on receive channel 1                                                                                                                                                                                                                                                                                |
|       |           | 2h    | The host error occurred on receive channel 2                                                                                                                                                                                                                                                                                |
|       |           | 3h    | The host error occurred on receive channel 3                                                                                                                                                                                                                                                                                |
|       |           | 4h    | The host error occurred on receive channel 4                                                                                                                                                                                                                                                                                |
|       |           | 5h    | The host error occurred on receive channel 5                                                                                                                                                                                                                                                                                |
|       |           | 6h    | The host error occurred on receive channel 6                                                                                                                                                                                                                                                                                |
|       |           | 7h    | The host error occurred on receive channel 7                                                                                                                                                                                                                                                                                |
| 7-3   | Reserved  | 0     | Reserved                                                                                                                                                                                                                                                                                                                    |
| 2     | RXQOSACT  |       | Receive Quality of Service (QOS) active bit. When asserted, indicates that receive quality of service is enabled and that at least one channel freebuffer count (RXnFREEBUFFER) is less than or equal to the RXFILTERLOWTHRESH value.                                                                                       |
|       |           | 0     | Receive quality of service is disabled.                                                                                                                                                                                                                                                                                     |
|       |           | 1     | Receive quality of service is enabled.                                                                                                                                                                                                                                                                                      |
| 1     | RXFLOWACT |       | Receive flow control active bit. When asserted, at least one channel freebuffer count (RXnFREEBUFFER) is less than or equal to the channel's corresponding RXnFILTERTHRESH value.                                                                                                                                           |
|       |           | 0     | Receive flow control is inactive.                                                                                                                                                                                                                                                                                           |
|       |           | 1     | Receive flow control is active.                                                                                                                                                                                                                                                                                             |
| 0     | TXFLOWACT |       | Transmit flow control active bit. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted, except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete. |
|       |           | 0     | Transmit flow control is inactive.                                                                                                                                                                                                                                                                                          |
|       |           | 1     | Transmit flow control is active.                                                                                                                                                                                                                                                                                            |

### 19.3.3.31 Emulation Control Register (EMCONTROL)

The emulation control register (EMCONTROL) is shown in [Figure 19-69](#) and described in [Table 19-68](#).

**Figure 19-69. Emulation Control Register (EMCONTROL)**

|------|--------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved     | 0     | Reserved                                                                                                                                                                                                                                                                                                                         |
| 1-0  | TXCELLTHRESH | 0-3h  | Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells will be initiated when the complete packet is contained in the FIFO. The default value is 2, but 3 is also valid. 0 and 1 are not valid values. |
|      |              | 0-1h  | Not a valid value.                                                                                                                                                                                                                                                                                                               |
|      |              | 2h    | Two 64-byte packet cells required to be in the transmit FIFO.                                                                                                                                                                                                                                                                    |
|      |              | 3h    | Three 64-byte packet cells required to be in the transmit FIFO.                                                                                                                                                                                                                                                                  |

### 19.3.3.33 MAC Configuration Register (MACCONFIG)

The MAC configuration register (MACCONFIG) is shown in [Figure 19-71](#) and described in [Table 19-70](#).

**Figure 19-71. MAC Configuration Register (MACCONFIG)**

LEGEND: R = Read only; -n = value after reset

**Table 19-70. MAC Configuration Register (MACCONFIG) Field Descriptions**

| Bit   | Field       | Value | Description                                                                        |
|-------|-------------|-------|------------------------------------------------------------------------------------|
| 31-24 | TXCELLDEPTH | 3h    | Transmit cell depth. These bits indicate the number of cells in the transmit FIFO. |
| 23-16 | RXCELLDEPTH | 3h    | Receive cell depth. These bits indicate the number of cells in the receive FIFO.   |
| 15-8  | ADDRESSTYPE | 2h    | Address type                                                                       |
| 7-0   | MACCFIG     | 2h    | MAC configuration value                                                            |

### 19.3.3.34 Soft Reset Register (SOFTRESET)

The soft reset register (SOFTRESET) is shown in [Figure 19-72](#) and described in [Table 19-71](#).

**Figure 19-72. Soft Reset Register (SOFTRESET)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-71. Soft Reset Register (SOFTRESET) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved  | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                          |
| 0    | SOFTRESET | 0     | Software reset. Writing a 1 to this bit causes the EMAC logic to be reset. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the Configuration bus. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred. If a 0 is read, then a reset has occurred. |
|      |           | 0     | A software reset has not occurred.                                                                                                                                                                                                                                                                                                                                                                |
|      |           | 1     | A software reset has occurred.                                                                                                                                                                                                                                                                                                                                                                    |

### 19.3.3.35 MAC Source Address Low Bytes Register (MACSRCADDRLO)

The MAC source address low bytes register (MACSRCADDRLO) is shown in [Figure 19-73](#) and described in [Table 19-72](#).

**Figure 19-73. MAC Source Address Low Bytes Register (MACSRCADDRLO)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-72. MAC Source Address Low Bytes Register (MACSRCADDRLO) Field Descriptions**

| Bit   | Field       | Value | Description                                |
|-------|-------------|-------|--------------------------------------------|
| 31-16 | Reserved    | 0     | Reserved                                   |
| 15-8  | MACSRCADDR0 | 0-FFh | MAC source address lower 8-0 bits (byte 0) |
| 7-0   | MACSRCADDR1 | 0-FFh | MAC source address bits 15-8 (byte 1)      |

### 19.3.3.36 MAC Source Address High Bytes Register (MACSRCADDRHI)

The MAC source address high bytes register (MACSRCADDRHI) is shown in [Figure 19-74](#) and described in [Table 19-73](#).

**Figure 19-74. MAC Source Address High Bytes Register (MACSRCADDRHI)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 19-73. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions**

| Bit   | Field       | Value | Description                            |
|-------|-------------|-------|----------------------------------------|
| 31-24 | MACSRCADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2) |
| 23-16 | MACSRCADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3) |
| 15-8  | MACSRCADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4) |
| 7-0   | MACSRCADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5) |

### 19.3.3.37 MAC Hash Address Register 1 (MACHASH1)

The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash\_fun) from the 48-bit destination address (DA) as follows:

$$\text{Hash\_fun}(0) = \text{DA}(0) \text{ XOR } \text{DA}(6) \text{ XOR } \text{DA}(12) \text{ XOR } \text{DA}(18) \text{ XOR } \text{DA}(24) \text{ XOR } \text{DA}(30) \text{ XOR } \text{DA}(36) \text{ XOR } \text{DA}(42);$$

$$\text{Hash\_fun}(1) = \text{DA}(1) \text{ XOR } \text{DA}(7) \text{ XOR } \text{DA}(13) \text{ XOR } \text{DA}(19) \text{ XOR } \text{DA}(25) \text{ XOR } \text{DA}(31) \text{ XOR } \text{DA}(37) \text{ XOR } \text{DA}(43);$$

$$\text{Hash\_fun}(2) = \text{DA}(2) \text{ XOR } \text{DA}(8) \text{ XOR } \text{DA}(14) \text{ XOR } \text{DA}(20) \text{ XOR } \text{DA}(26) \text{ XOR } \text{DA}(32) \text{ XOR } \text{DA}(38) \text{ XOR } \text{DA}(44);$$

$$\text{Hash\_fun}(3) = \text{DA}(3) \text{ XOR } \text{DA}(9) \text{ XOR } \text{DA}(15) \text{ XOR } \text{DA}(21) \text{ XOR } \text{DA}(27) \text{ XOR } \text{DA}(33) \text{ XOR } \text{DA}(39) \text{ XOR } \text{DA}(45);$$

$$\text{Hash\_fun}(4) = \text{DA}(4) \text{ XOR } \text{DA}(10) \text{ XOR } \text{DA}(16) \text{ XOR } \text{DA}(22) \text{ XOR } \text{DA}(28) \text{ XOR } \text{DA}(34) \text{ XOR } \text{DA}(40) \text{ XOR } \text{DA}(46);$$

$$\text{Hash\_fun}(5) = \text{DA}(5) \text{ XOR } \text{DA}(11) \text{ XOR } \text{DA}(17) \text{ XOR } \text{DA}(23) \text{ XOR } \text{DA}(29) \text{ XOR } \text{DA}(35) \text{ XOR } \text{DA}(41) \text{ XOR } \text{DA}(47);$$

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in [Figure 19-75](#) and described in [Table 19-74](#).

**Figure 19-75. MAC Hash Address Register 1 (MACHASH1)**

|          |  |   |
|----------|--|---|
| 31       |  | 0 |
| MACHASH1 |  |   |
| R/W-0    |  |   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 19-74. MAC Hash Address Register 1 (MACHASH1) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                   |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MACHASH1 | 0-FFFF FFFFh | Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

### 19.3.3.38 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in [Figure 19-76](#) and described in [Table 19-75](#).

**Figure 19-76. MAC Hash Address Register 2 (MACHASH2)**

|          |  |   |
|----------|--|---|
| 31       |  | 0 |
| MACHASH2 |  |   |
| R/W-0    |  |   |

LEGEND: R/W = Read/Write; -n = value after reset

**Table 19-75. MAC Hash Address Register 2 (MACHASH2) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                   |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MACHASH2 | 0-FFFF FFFFh | Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

### 19.3.3.39 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in [Figure 19-77](#) and described in [Table 19-76](#).

**Figure 19-77. Back Off Random Number Generator Test Register (BOFFTEST)**

|           |  |          |        |           |    |

LEGEND: R = Read only; -n = value after reset

**Table 19-76. Back Off Test Register (BOFFTEST) Field Descriptions**

| Bit   | Field     | Value  | Description                                                                                                                                                                                                                                           |
|-------|-----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-26 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                              |
| 25-16 | RNDNUM    | 0-3FFh | Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset. |
| 15-12 | COLLCOUNT | 0-Fh   | Collision count. These bits indicate the number of collisions the current frame has experienced.                                                                                                                                                      |
| 11-10 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                              |
| 9-0   | TXBACKOFF | 0-3FFh | Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.  |

### 19.3.3.40 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in [Figure 19-78](#) and described in [Table 19-77](#).

**Figure 19-78. Transmit Pacing Algorithm Test Register (TPACETEST)**

**Table 19-77. Transmit Pacing Algorithm Test Register (TPACETEST) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 4-0  | PACEVAL  | 0-1Fh | Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth. |

### 19.3.3.41 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in [Figure 19-79](#) and described in [Table 19-78](#).

**Figure 19-79. Receive Pause Timer Register (RXPAUSE)**

**Table 19-78. Receive Pause Timer Register (RXPAUSE) Field Descriptions**

| Bit   | Field      | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved   | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 15-0  | PAUSETIMER | 0-FFh | Receive pause timer value. These bits allow the contents of the receive pause timer to be observed. The receive pause timer is loaded with FF00h when the EMAC sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to 0, then another outgoing pause frame is sent and the load/decrement process is repeated. |

### 19.3.3.42 Transmit Pause Timer Register (TXPAUSE)

The transmit pause timer register (TXPAUSE) is shown in [Figure 19-80](#) and described in [Table 19-79](#).

**Figure 19-80. Transmit Pause Timer Register (TXPAUSE)**

| 15       | 8  | 7        | 0  |
| MACADDR4 |    | MACADDR5 |    |
| R/W-x    |    | R/W-x    |    |

LEGEND: R/W = Read/Write; -x = value is indeterminate after reset

**Table 19-81. MAC Address High Bytes Register (MACADDRHI) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                               |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | MACADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2)                                                                                                                                    |
| 23-16 | MACADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3)                                                                                                                                    |
| 15-8  | MACADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4)                                                                                                                                    |
| 7-0   | MACADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5). Bit 40 is the group bit. It is forced to 0 and read as 0. Therefore, only unicast addresses are represented in the address table. |

### 19.3.3.45 MAC Index Register (MACINDEX)

The MAC index register (MACINDEX) is shown in [Figure 19-83](#) and described in [Table 19-82](#).

**Figure 19-83. MAC Index Register (MACINDEX)**

|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2-0  | MACINDEX | 0-7h  | MAC address index. All eight addresses share the upper 40 bits. Only the lower byte is unique for each address. An address is written by first writing the address number (channel) into the MACINDEX register. The upper 32 bits of the address are then written to the MACADDRHI register, which is followed by writing the lower 16 bits of the address to the MACADDRLO register. Since all eight addresses share the upper 40 bits of the address, the MACADDRHI register only needs to be written the first time. |

### 19.3.3.46 Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX $n$ HDP) is shown in [Figure 19-84](#) and described in [Table 19-83](#).

**Figure 19-84. Transmit Channel  $n$  DMA Head Descriptor Pointer Register (TX $n$ HDP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 19-83. Transmit Channel  $n$  DMA Head Descriptor Pointer Register (TX $n$ HDP)  
Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                         |
|------|------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TX $n$ HDP | 0-FFFF FFFFh | Transmit channel $n$ DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

### 19.3.3.47 Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX $n$ HDP) is shown in [Figure 19-85](#) and described in [Table 19-84](#).

**Figure 19-85. Receive Channel  $n$  DMA Head Descriptor Pointer Register (RX $n$ HDP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 19-84. Receive Channel  $n$  DMA Head Descriptor Pointer Register (RX $n$ HDP)  
Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                            |
|------|------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RX $n$ HDP | 0-FFFF FFFFh | Receive channel $n$ DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

### 19.3.3.48 Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)

The transmit channel 0-7 completion pointer register (TX $n$ CP) is shown in [Figure 19-86](#) and described in [Table 19-85](#).

**Figure 19-86. Transmit Channel  $n$  Completion Pointer Register (TX $n$ CP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 19-85. Transmit Channel  $n$  Completion Pointer Register (TX $n$ CP) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                                                                                                                                                                           |
|------|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TX $n$ CP | 0-FFFF FFFFh | Transmit channel $n$ completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

### 19.3.3.49 Receive Channel Completion Pointer Registers (RX0CP-RX7CP)

The receive channel 0-7 completion pointer register (RX $n$ CP) is shown in [Figure 19-87](#) and described in [Table 19-86](#).

**Figure 19-87. Receive Channel  $n$  Completion Pointer Register (RX $n$ CP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 19-86. Receive Channel  $n$  Completion Pointer Register (RX $n$ CP) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                                                                                                                                                                          |
|------|-----------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RX $n$ CP | 0-FFFF FFFFh | Receive channel $n$ completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

### 19.3.3.50 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMIIEN bit in the MACCONTROL register is set, all statistics registers (see [Figure 19-88](#)) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMIIEN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

**Figure 19-88. Statistics Register**

|    |        |   |
|----|--------|---|
| 31 |        | 0 |
|    | COUNT  |   |
|    | R/WD-0 |   |

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

#### 19.3.3.50.1 Good Receive Frames Register (RXGOODFRAMES)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 19.3.3.50.2 Broadcast Receive Frames Register (RXBCASTFRAMES)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 19.3.3.50.3 Multicast Receive Frames Register (RXMCASTFRAMES)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 19.3.3.50.4 Pause Receive Frames Register (RXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 19.3.3.50.5 Receive CRC Errors Register (RXCRCERRORS)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
  - A frame containing an even number of nibbles
  - Fails the frame check sequence test

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 19.3.3.50.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
  - An alignment error is defined as having all of the following:
    - A frame containing an odd number of nibbles
    - Fails the frame check sequence test, if the final nibble is ignored
  - A code error is defined as a frame that has been discarded because the EMACs MII\_RXER pin is driven with a one for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

**19.3.3.50.7 Receive Oversized Frames Register (RXOVERSIZED)**

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**19.3.3.50.8 Receive Jabber Frames Register (RXJABBER)**

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**19.3.3.50.9 Receive Undersized Frames Register (RXUNDERSIZED)**

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**19.3.3.50.10 Receive Frame Fragments Register (RXFRAGMENTS)**

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**19.3.3.50.11 Filtered Receive Frames Register (RXFILTERED)**

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

#### **19.3.3.50.12 Receive QOS Filtered Frames Register (RXQOSFILTERED)**

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RX $n$ FLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RX $n$ FREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### **19.3.3.50.13 Receive Octet Frames Register (RXOCTETS)**

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 19.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### **19.3.3.50.14 Good Transmit Frames Register (TXGOODFRAMES)**

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

#### **19.3.3.50.15 Broadcast Transmit Frames Register (TXBCASTFRAMES)**

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

#### **19.3.3.50.16 Multicast Transmit Frames Register (TXMCASTFRAMES)**

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

#### **19.3.3.50.17 Pause Transmit Frames Register (TXPAUSEFRAMES)**

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octet frames register statistics.

#### **19.3.3.50.18 Deferred Transmit Frames Register (TXDEFERRED)**

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

#### **19.3.3.50.19 Transmit Collision Frames Register (TXCOLLISION)**

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
  - Was destined for any unicast, broadcast, or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

#### **19.3.3.50.20 Transmit Single Collision Frames Register (TXSINGLECOLL)**

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

#### **19.3.3.50.21 Transmit Multiple Collision Frames Register (TXMULTICOLL)**

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

#### **19.3.3.50.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL)**

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

#### **19.3.3.50.23 Transmit Late Collision Frames Register (TXLATECOLL)**

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

#### **19.3.3.50.24 Transmit Underrun Error Register (TXUNDERRUN)**

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

**19.3.3.50.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE)**

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

**19.3.3.50.26 Transmit Octet Frames Register (TXOCTETS)**

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

**19.3.3.50.27 Transmit and Receive 64 Octet Frames Register (FRAME64)**

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

**19.3.3.50.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127)**

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

**19.3.3.50.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255)**

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

### **19.3.3.50.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511)**

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

### **19.3.3.50.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023)**

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

### **19.3.3.50.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP)**

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

### **19.3.3.50.33 Network Octet Frames Register (NETOCTETS)**

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

**19.3.3.50.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS)**

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

**19.3.3.50.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS)**

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

**19.3.3.50.36 Receive DMA Overruns Register (RXDMAOVERRUNS)**

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

## ***External Memory Interface A (EMIFA)***

---

---

This chapter describes the external memory interface A (EMIFA).

The EMIFA SDRAM interface is not supported on all devices, see your device-specific data manual to see if the EMIFA SDRAM is supported on your device.

## 20.1 Introduction

### 20.1.1 Purpose of the Peripheral

EMIFA memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing 16-bit data bus of EMIFA memory controller. The purpose of this EMIFA is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash, NAND Flash, and SRAM

The most common use for the EMIFA is to interface with both a flash device and an SDRAM device simultaneously. [Section 20.3](#) contains an example of operating the EMIFA in this configuration.

### 20.1.2 Features

The EMIFA includes many features to enhance the ease and flexibility of connecting to external SDR SDRAM and asynchronous devices. For details on features of EMIFA, see your device-specific data manual.

### 20.1.3 Functional Block Diagram

[Figure 20-1](#) illustrates the connections between the EMIFA and its internal requesters, along with the external EMIFA pins. [Section 20.2.2](#) contains a description of the entities internal to the SoC that can send requests to the EMIFA, along with their prioritization. [Section 20.2.3](#) describes the EMIFA external pins and summarizes their purpose when interfacing with SDRAM and asynchronous devices.

**Figure 20-1. EMIFA Functional Block Diagram**

## 20.2 Architecture

This section provides details about the architecture and operation of the EMIFA. Both, SDRAM and asynchronous interface are covered, along with other system-related issues such as clock control and pin multiplexing.

The EMIFA SDRAM interface is not supported on all devices, see your device-specific data manual to see if the EMIFA SDRAM is supported on your device.

### 20.2.1 Clock Control

The EMIFA clock is output on the EMA\_CLK pin and should be used when interfacing to external memories. The EMIFA clock (EMA\_CLK) does not run during device reset. When the  $\overline{\text{RESET}}$  pin is released and after the PLL controller releases the device from reset, EMA\_CLK begins to oscillate at a frequency determined by the PLL controller.

For details on clock generation and control, see the *Device Clocking* chapter.

### 20.2.2 EMIFA Requests

Different sources within the SoC can make requests to the EMIFA. These requests consist of accesses to SDRAM memory, asynchronous memory, and EMIFA registers. Because the EMIFA can process only one request at a time, a high performance crossbar switch exists within the SoC to provide prioritized requests from the different sources to the EMIFA. The sources are:

1. CPU
2. EDMA
3. Other master peripherals

If a request is submitted from two or more sources simultaneously, the crossbar switch will forward the highest priority request to the EMIFA first. Upon completion of a request, the crossbar switch again evaluates the pending requests and forwards the highest priority pending request to the EMIFA.

When the EMIFA receives a request, it may or may not be immediately processed. In some cases, the EMIFA will perform one or more auto refresh cycles before processing the request. For details on the EMIFA's internal arbitration between performing requests and performing auto refresh cycles, see [Section 20.2.12](#).

### 20.2.3 Pin Descriptions

This section describes the function of each of the EMIFA pins.

**Table 20-1. EMIFA Pins Used to Access Both SDRAM and Asynchronous Memories**

| Pins(s)                     | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMA_D[x:0]                  | I/O | <b>EMIFA data bus.</b><br>The number of available data bus pins varies among devices, see your device-specific data manual for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| EMA_A[x:0]                  | O   | <b>EMIFA address bus.</b><br>The number of available address pins varies among devices, see your device-specific data manual for details.<br>When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins can be found in <a href="#">Section 20.2.4.11</a> . EMA_A[10] is also used during the PRE command to select which banks to deactivate.<br>When interfacing to an asynchronous device, these pins are used in conjunction with the EMA_BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins can be found in <a href="#">Section 20.2.5.1</a> . |
| EMA_BA[1:0]                 | O   | <b>EMIFA bank address.</b><br>When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins can be found in <a href="#">Section 20.2.4.11</a> .<br>When interfacing to an asynchronous device, these pins are used in conjunction with the EMA_A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins can be found in <a href="#">Section 20.2.5.1</a> .                                                                                                                                                                                                                 |
| EMA_WE_DQM[x:0]             | O   | <b>Active-low byte enables.</b><br>When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access.<br>When interfacing to an asynchronous device, these pins are connected to byte enables. See <a href="#">Section 20.2.5</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $\overline{\text{EMA\_WE}}$ | O   | <b>Active-low write enable.</b><br>When interfacing to SDRAM, this pin is connected to the $\overline{\text{WE}}$ pin of the SDRAM and is used to send commands to the device.<br>When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 20-2. EMIFA Pins Specific to SDRAM**

| Pin(s)                         | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{\text{EMA\_CS}}[0]$ | O   | <b>Active-low chip enable pin for SDRAM devices.</b><br>This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, the EMIFA keeps this SDRAM chip select active, even if the EMIFA is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access. |
| $\overline{\text{EMA\_RAS}}$   | O   | <b>Active-low row address strobe pin.</b><br>This pin is connected to the $\overline{\text{RAS}}$ pin of the attached SDRAM device and is used for sending commands to the device.                                                                                                                                                                                                                                                   |
| $\overline{\text{EMA\_CAS}}$   | O   | <b>Active-low column address strobe pin.</b><br>This pin is connected to the $\overline{\text{CAS}}$ pin of the attached SDRAM device and is used for sending commands to the device.                                                                                                                                                                                                                                                |
| $\text{EMA\_SDCKE}$            | O   | <b>Clock enable pin.</b><br>This pin is connected to the $\overline{\text{CKE}}$ pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self refresh mode. See <a href="#">Section 20.2.4.7</a> for details.                                                                                                                                                                   |
| $\text{EMA\_CLK}$              | O   | <b>SDRAM clock pin.</b><br>This pin is connected to the $\overline{\text{CLK}}$ pin of the attached SDRAM device. See <a href="#">Section 20.2.1</a> for details on the clock signal.                                                                                                                                                                                                                                                |

**Table 20-3. EMIFA Pins Specific to Asynchronous Memory**

| Pin(s)                           | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| $\overline{\text{EMA\_CS}}[5:2]$ | O   | <b>Active-low chip enable pins for asynchronous devices.</b><br>These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| $\text{EMA\_WAIT}$               | I   | <b>Wait input with programmable polarity / NAND Flash ready input.</b><br>Not all devices support both $\text{EMA\_WAIT}[1]$ and $\text{EMA\_WAIT}[0]$ , see your device-specific data manual to determine support on each device.<br>A connected asynchronous device can extend the strobe period of an access cycle by asserting the $\text{EMA\_WAIT}$ input to the EMIFA as described in <a href="#">Section 20.2.5.7</a> . To enable this functionality, the EW bit in the asynchronous $n$ configuration register ( $\text{CENCFG}$ ) must be set to 1. The $\text{WP0}$ and $\text{WP1}$ bits in the asynchronous wait cycle configuration register ( $\text{AWCC}$ ) must be configured to define the polarity of the $\text{EMA\_WAIT}$ pin. The $\text{CSn\_WAIT}$ bit in $\text{AWCC}$ must also be configured to determine which $\text{EMA\_WAIT}[n]$ signal is used for memory accesses.<br>When the $\text{CS2NAND}/\text{CS3NAND}/\text{CS4NAND}/\text{CS5NAND}$ bit in the NAND Flash control register ( $\text{NANDFCR}$ ) is set, this pin instead functions as a NAND Flash ready input. |
| $\overline{\text{EMA\_OE}}$      | O   | <b>Active-low pin enable for asynchronous devices.</b><br>This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $\text{EMA\_A\_RW}$              | O   | <b>EMIFA asynchronous read/write control.</b><br>This pin stays high during reads and stays low during writes (same duration as CS).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## 20.2.4 SDRAM Controller and Interface

The EMIFA can gluelessly interface to most standard SDR SDRAM devices and supports such features as self refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to interface and properly configure the EMIFA to perform read and write operations to externally connected SDR SDRAM devices. Also, [Section 20.3](#) provides a detailed example of interfacing the EMIFA to a common SDRAM device.

### 20.2.4.1 SDRAM Commands

The EMIFA supports the SDRAM commands described in [Table 20-4](#). The truth table for the SDRAM commands is shown in [Table 20-5](#) and an example timing waveform of the PRE command is shown in [Figure 20-2](#). EMA\_A[10] is pulled low in this example to deactivate only the bank specified by the EMA\_BA pins.

**Table 20-4. EMIFA SDRAM Commands**

| Command | Function                                                                                                                                                                                                                                          |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRE     | <b>Precharge.</b> Depending on the value of EMA_A[10], the PRE command either deactivates the open row in all banks (EMA_A[10] = 1) or only the bank specified by the EMA_BA[1:0] pins (EMA_A[10] = 0).                                           |
| ACTV    | <b>Activate.</b> The ACTV command activates the selected row in a particular bank for the current access.                                                                                                                                         |
| READ    | <b>Read.</b> The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EMA_A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.  |
| WRT     | <b>Write.</b> The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EMA_A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance. |
| BT      | <b>Burst terminate.</b> The BT command is used to truncate the current read or write burst request.                                                                                                                                               |
| LMR     | <b>Load mode register.</b> The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in <a href="#">Section 20.2.4.4</a> .                                       |
| REFR    | <b>Auto refresh.</b> The REFR command signals the SDRAM to perform an auto refresh according to its internal address.                                                                                                                             |
| SLFR    | <b>Self refresh.</b> The self refresh command places the SDRAM into self refresh mode, during which it provides its own clock signal and auto refresh cycles.                                                                                     |
| NOP     | <b>No operation.</b> The NOP command is issued during all cycles in which one of the above commands is not issued.                                                                                                                                |

**Table 20-5. Truth Table for SDRAM Commands**

| SDRAM Pins: | CKE       | $\overline{CS}$ | RAS     | $\overline{CAS}$ | $\overline{WE}$ | BA[1:0]     | A[12:11]     | A[10]     | A[9:0]     |
|-------------|-----------|-----------------|---------|------------------|-----------------|-------------|--------------|-----------|------------|

| NOP         | H         | L               | H       | H                | H               | X           | X            | X         | X          |

**Figure 20-2. Timing Waveform of SDRAM PRE Command**

#### 20.2.4.2 Interfacing to SDRAM

The EMIFA supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11. See your device-specific data manual for the number of column address bits supported on your device.
- The number of row address bits is 13, 14, 15, or 16. See your device-specific data manual for the number of row address bits supported on your device.
- The number of internal banks is 1, 2, or 4. See your device-specific data manual for the number of internal banks supported on your device.

Figure 20-3 shows an interface between the EMIFA and a  $2\text{M} \times 16 \times 4$  bank SDRAM device, and Figure 20-4 shows an interface between the EMIFA and a  $512\text{K} \times 16 \times 2$  bank SDRAM device. For devices supporting 16-bit interface, refer to Table 20-6 for list of commonly-supported SDRAM devices and the required connections for the address pins.

**Figure 20-3. EMIFA to 2M × 16 × 4 bank SDRAM Interface**

**Figure 20-4. EMIFA to 512K × 16 × 2 bank SDRAM Interface**

**Table 20-6. 16-bit EMIFA Address Pin Connections**

| SDRAM Size | Width | Banks | Device | Address Pins |
|------------|-------|-------|--------|--------------|
| 16M bits   | ×16   | 2     | SDRAM  | A[10:0]      |
|            |       |       | EMIFA  | EMA_A[10:0]  |
| 64M bits   | ×16   | 4     | SDRAM  | A[11:0]      |
|            |       |       | EMIFA  | EMA_A[11:0]  |
| 128M bits  | ×16   | 4     | SDRAM  | A[11:0]      |
|            |       |       | EMIFA  | EMA_A[11:0]  |
| 256M bits  | ×16   | 4     | SDRAM  | A[12:0]      |
|            |       |       | EMIFA  | EMA_A[12:0]  |
| 512M bits  | ×16   | 4     | SDRAM  | A[12:0]      |
|            |       |       | EMIFA  | EMA_A[12:0]  |

### 20.2.4.3 SDRAM Configuration Registers

The operation of the EMIFA's SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but [Section 20.4](#) should be referred for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

**NOTE:** Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDCR) causes the EMIFA to abandon whatever it is currently doing and trigger the SDRAM initialization procedure described in [Section 20.2.4.4](#).

**Table 20-7. Description of the SDRAM Configuration Register (SDCR)**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SR        | This bit controls entering and exiting of the Self-Refresh mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence.                                                                                                                                                                                                                                                                                                                                                                                                |
| PD        | This bit controls entering and exiting of the Power down mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. If both SR and PD bits are set, the EMIFA will go into Self Refresh.                                                                                                                                                                                                                                                                                                                             |
| PDWR      | Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIFA to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. This bit should be set along with PD when entering power-down mode.                                                                                                                                                                                                       |
| NM        | <b>Narrow Mode.</b> This bit defines the width of the data bus between the EMIFA and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits. This bit must always be set to 1.                                                                                                                                                                                                                                                                                                                                                 |
| CL        | <b>CAS latency.</b> This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device via the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in <a href="#">Section 20.2.4.4</a> . Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and should be written to this field. A 1 must be simultaneously written to the BIT11_9LOCK bit field of SDCR in order to write to the CL bit field. |
| IBANK     | <b>Number of Internal SDRAM Banks.</b> This field defines the number of banks inside the attached SDRAM devices in the following way: <ul style="list-style-type: none"> <li>When IBANK = 0, 1 internal bank is used</li> <li>When IBANK = 1h, 2 internal banks are used</li> <li>When IBANK = 2h, 4 internal banks are used</li> </ul> This field value affects the mapping of logical addresses to SDRAM row, column, and bank addresses. See <a href="#">Section 20.2.4.11</a> for details.                                                                                                  |
| PAGESIZE  | <b>Page Size.</b> This field defines the internal page size of the attached SDRAM devices in the following way: <ul style="list-style-type: none"> <li>When PAGESIZE = 0, 256-word pages are used</li> <li>When PAGESIZE = 1h, 512-word pages are used</li> <li>When PAGESIZE = 2h, 1024-word pages are used</li> <li>When PAGESIZE = 3h, 2048-word pages are used</li> </ul> This field value affects the mapping of logical addresses to SDRAM row, column, and bank addresses. See <a href="#">Section 20.2.4.11</a> for details.                                                            |

**Table 20-8. Description of the SDRAM Refresh Control Register (SDRCR)**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RR        | <b>Refresh Rate.</b> This field controls the rate at which attached SDRAM devices will be refreshed. The following equation can be used to determine the required value of RR for an SDRAM device: <ul style="list-style-type: none"> <li><math>RR = f_{EMA\_CLK} / (\text{Required SDRAM Refresh Rate})</math></li> </ul> More information about the operation of the SDRAM refresh controller can be found in <a href="#">Section 20.2.4.6</a> . |

**Table 20-9. Description of the SDRAM Timing Register (SDTIMR)**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T_RFC     | <b>SDRAM Timing Parameters.</b> These fields configure the EMIFA to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIFA to avoid violating SDRAM timing constraints and to more efficiently schedule its operations. More details about each of these parameters can be found in the register description in <a href="#">Section 20.4.6</a> . These parameters should be set to satisfy the corresponding timing requirements found in the SDRAM's datasheet. |
| T_RP      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T_RCD     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T_WR      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T_RAS     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T_RC      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T_RRD     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 20-10. Description of the SDRAM Self Refresh Exit Timing Register (SDSRETR)**

| Parameter | Description                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T_XS      | <b>Self Refresh Exit Parameter.</b> The T_XS field of this register informs the EMIFA about the minimum number of EMA_CLK cycles required between exiting Self Refresh and issuing any command. This parameter should be set to satisfy the $t_{XSR}$ value for the attached SDRAM device. |

#### 20.2.4.4 SDRAM Auto-Initialization Sequence

The EMIFA automatically performs an SDRAM initialization sequence, regardless of whether it is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIFA comes out of reset. No memory accesses to the SDRAM and Asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least significant bytes of the SDRAM configuration register (SDCR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDCR, and if any of the SDRAM banks are open, the EMIFA issues a PRE command with EMA\_A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIFA drives EMA\_SDCKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of SDRAM refresh control register (SDRCR), divided by the frequency of EMA\_CLK ( $RR/f_{EMA\_CLK}$ ). This step is used to avoid violating the Power-up constraint of most SDRAM devices that requires 200  $\mu$ s (sometimes 100  $\mu$ s) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EMA\_CLK, this step may or may not be sufficient to avoid violating the SDRAM constraint. See [Section 20.2.4.5](#) for more information.
3. After the refresh intervals have elapsed, the EMIFA issues a PRE command with EMA\_A[10] held high to indicate all banks.
4. The EMIFA issues eight AUTO REFRESH commands.
5. The EMIFA issues the LMR command with the EMA\_A[9:0] pins set as described in [Table 20-11](#).
6. Finally, the EMIFA performs a refresh cycle, which consists of the following steps:
  - (a) Issuing a PRE command with EMA\_A[10] held high if any banks are open
  - (b) Issuing an REF command

**Table 20-11. SDRAM LOAD MODE REGISTER Command**

| EMA_A[9:7]                                                        | EMA_A[6:4]                                                                                                                                                                                                                                                                                    | EMA_A[3]                                                        | EMA_A[2:0]                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (Write bursts are of the programmed burst length in EMA_A[2:0]) | These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDCR) as follows: <ul style="list-style-type: none"> <li>If CL = 2, EMA_A[6:4] = 2h (CAS latency = 2)</li> <li>If CL = 3, EMA_A[6:4] = 3h (CAS latency = 3)</li> </ul> | 0 (Sequential Burst Type. Interleaved Burst Type not supported) | These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDCR) as follows: <ul style="list-style-type: none"> <li>If NM = 0, EMA_A[2:0] = 2h (Burst Length = 4)</li> <li>If NM = 1, EMA_A[2:0] = 3h (Burst Length = 8)</li> </ul> |

#### 20.2.4.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although EMIFA automatically performs the SDRAM initialization sequence described in [Section 20.2.4.4](#) when coming out of reset, it is recommended to follow one of the procedures listed below before performing any EMIFA memory requests. Procedure A should be followed if it is determined that the SDRAM Power-up constraint was not violated during the SDRAM Auto-Initialization Sequence detailed in [Section 20.2.4.4](#) on coming out of Reset. The SDRAM Power-up constraint specifies that 200  $\mu$ s (sometimes 100  $\mu$ s) should elapse between receiving stable Vdd and CLK and the issuing of a PRE command. Procedure B should be followed if the SDRAM Power-up constraint was violated. The 200  $\mu$ s (100  $\mu$ s) SDRAM Power-up constraint will be violated if the frequency of EMA\_CLK is greater than 50 MHz (100 MHz for 100  $\mu$ s SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B should be followed if there is any doubt that the Power-up constraint was met.

**Procedure A** — Following is the procedure to be followed if the SDRAM Power-up constraint was NOT violated:

1. Place the SDRAM into Self-Refresh Mode by setting the SR bit of SDCR to 1. A byte-write to the upper byte of SDCR should be used to avoid restarting the SDRAM Auto-Initialization Sequence described in [Section 20.2.4.4](#). The SDRAM should be placed into Self-Refresh mode when changing the frequency of EMA\_CLK to avoid incurring the 200  $\mu$ s Power-up constraint again.
2. Program the CPU's PLL Controller to provide the desired EMA\_CLK clock frequency. Refer to the device Data Manual for details on programming the PLL Controller. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device Data Manual.
3. Remove the SDRAM from Self-Refresh Mode by clearing the SR bit of SDCR to 0. A byte-write to the upper byte of SDCR should be used to avoid restarting the SDRAM Auto-Initialization Sequence described in [Section 20.2.4.4](#).
4. Program SDTIMR and SDSRETR to satisfy the timing requirements for the attached SDRAM device. The timing parameters should be taken from the SDRAM datasheet.
5. Program the RR field of SDCR to match that of the attached device's refresh interval. See [Section 20.2.4.6.1](#) details on determining the appropriate value.
6. Program SDCR to match the characteristics of the attached SDRAM device. This will cause the auto-initialization sequence in [Section 20.2.4.4](#) to be re-run. This second initialization generally takes much less time due to the increased frequency of EMA\_CLK.

**Procedure B** — Following is the procedure to be followed if the SDRAM Power-up constraint was violated:

1. Program the CPU's PLL Controller to provide the desired EMA\_CLK clock frequency. Refer to the device Data Manual for details on programming the PLL Controller. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device Data Manual.
2. Program SDTIMR and SDSRETR to satisfy the timing requirements for the attached SDRAM device. The timing parameters should be taken from the SDRAM datasheet.

3. Program the RR field of SDRCR such that the following equation is satisfied:  $(RR \times 8)/(f_{EMA\_CLK}) > 200 \mu s$  (sometimes  $100 \mu s$ ). For example, an EMA\_CLK frequency of 100 MHz would require setting RR to 2501 (9C5h) or higher to meet a 200  $\mu s$  constraint.
4. Program SDCR to match the characteristics of the attached SDRAM device. This will cause the auto-initialization sequence in [Section 20.2.4.4](#) to be re-run with the new value of RR.
5. Perform a read from the SDRAM to assure that step 5 of this procedure will occur after the initialization process has completed. Alternatively, wait for 200  $\mu s$  instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See [Section 20.2.4.6.1](#) details on determining the appropriate value.

After following the above procedure, the EMIFA is ready to perform accesses to the attached SDRAM device. See [Section 20.3](#) for an example of configuring the SDRAM interface.

#### 20.2.4.6 EMIFA Refresh Controller

An SDRAM device requires that each of its rows be refreshed at a minimum required rate. The EMIFA can meet this constraint by performing auto refresh cycles at or above this required rate. An auto refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIFA of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRCR) must be programmed. The EMIFA will use this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto refresh cycles cannot be disabled, even if the EMIFA is not interfaced with an SDRAM. The remainder of this section details the EMIFA's refresh scheme and provides an example for determining the appropriate value to place in the RR field of SDRCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIFA clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless it has already reached its maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIFA currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIFA uses the refresh backlog counter to determine the urgency with which an auto refresh cycle should be performed. The four levels of urgency are described in [Table 20-12](#). This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

**Table 20-12. Refresh Urgency Levels**

| Urgency Level   | Refresh Backlog Counter Range | Action Taken                                                                                                                                                                                                        |
|-----------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Refresh May     | 1-3                           | An auto-refresh cycle is performed only if the EMIFA has no requests pending and none of the SDRAM banks are open.                                                                                                  |
| Refresh Release | 4-7                           | An auto-refresh cycle is performed if the EMIFA has no requests pending, regardless of whether any SDRAM banks are open.                                                                                            |
| Refresh Need    | 8-11                          | An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending.                                                                                                  |
| Refresh Must    | 12-15                         | Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIFA can begin servicing any new read or write requests. |

#### 20.2.4.6.1 Determining the Appropriate Value for the RR Field

The value that should be programmed into the RR field of SDCR can be calculated by using the frequency of the EMA\_CLK signal ( $f_{\text{EMA\_CLK}}$ ) and the required refresh rate of the SDRAM ( $f_{\text{Refresh}}$ ). The following formula can be used:

$$\text{RR} = f_{\text{EMA\_CLK}} / f_{\text{Refresh}}$$

The SDRAM datasheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval ( $n_{\text{cycles}}$ ) by the time interval given in the datasheet ( $t_{\text{Refresh Period}}$ ):

$$f_{\text{Refresh}} = n_{\text{cycles}} / t_{\text{Refresh Period}}$$

Combining these formulas, the value that should be programmed into the RR field can be computed as:

$$\text{RR} = f_{\text{EMA\_CLK}} \times t_{\text{Refresh Period}} / n_{\text{cycles}}$$

The following example illustrates calculating the value of RR. Given that:

- $f_{\text{EMA\_CLK}} = 100 \text{ MHz}$  (frequency of the EMIFA clock)
- $t_{\text{Refresh Period}} = 64 \text{ ms}$  (required refresh interval of the SDRAM)
- $n_{\text{cycles}} = 8192$  (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

$$\text{RR} = 100 \text{ MHz} \times 64 \text{ ms} / 8192$$

$$\text{RR} = 781.25$$

$$\text{RR} = 782 \text{ cycles} = 30\text{Eh cycles}$$

#### 20.2.4.7 Self-Refresh Mode

The EMIFA can be programmed to enter the self-refresh state by setting the SR bit of SDCR to 1. This will cause the EMIFA to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which it consumes a minimal amount of power while performing its own refresh cycles. The SR bit should be set and cleared using a byte-write to the upper byte of the SDRAM configuration register (SDCR) to avoid triggering the SDRAM initialization sequence.

While in the self-refresh state, the EMIFA continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIFA will not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIFA tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIFA is in the self-refresh state, in order to prevent floating inputs on the data bus. More information about data bus parking can be found in [Section 20.2.6](#).

The EMIFA will exit from the self-refresh state if either of the following events occur:

- The SR bit of SDCR is cleared to 0.
- An SDRAM accesses is requested.

The EMIFA exits from the self-refresh state by driving EMA\_SDCKE high and performing an auto refresh cycle.

The attached SDRAM device should also be placed into Self-Refresh Mode when changing the frequency of EMA\_CLK using the PLL Controller. If the frequency of EMA\_CLK changes while the SDRAM is not in Self-Refresh Mode, Procedure B in [Section 20.2.4.5](#) should be followed to reinitialize the device.

#### 20.2.4.8 Power Down Mode

To support low-power modes, the EMIFA can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDCR). When this bit is set, the EMIFA will continue normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point the EMIFA will enter the power-down state. Upon entering this state, the EMIFA will issue a POWER DOWN command (same as a NOP command but driving EMA\_SDCKE low on the same cycle). The EMIFA then maintains EMA\_SDCKE low until it exits the power-down state.

Since the EMIFA services the refresh backlog before it enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIFA only supports Precharge Power Down. The EMIFA does not support Active Power Down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIFA services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in SDCR indicates whether the EMIFA should perform refreshes in power-down state. If the PDWR bit is set, the EMIFA exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIFA does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not assured upon power down exit if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIFA will come out of the power-down state. The EMIFA:

- Drives EMA\_SDCKE high.
- Enters its idle state.

### 20.2.4.9 SDRAM Read Operation

When the EMIFA receives a read request to SDRAM from one of the requesters listed in [Section 20.2.2](#), it performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIFA proceeds to issue a READ command while specifying the desired bank and column address. EMA\_A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to start bursting data from the specified address while the EMIFA issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDCR) defines how many delay cycles will be present before the read data appears on the data bus. This is referred to as the CAS latency.

[Figure 20-5](#) shows the signal waveforms for a basic SDRAM read operation in which a burst of data is read from a single page. When the EMIFA SDRAM interface is configured to 16 bit by setting the NM bit of the SDRAM configuration register (SDCR) to 1, a burst size of eight is used. [Figure 20-5](#) shows a burst size of eight.

The EMIFA will truncate a series of bursting data if the remaining addresses of the burst are not required to complete the request. The EMIFA can truncate the burst in three ways:

- By issuing another READ to the same page in the same bank.
- By issuing a PRE command in order to prepare for accessing a different page of the same bank.
- By issuing a BT command in order to prepare for accessing a page in a different bank.

**Figure 20-5. Timing Waveform for Basic SDRAM Read Operation**

Several other pins are also active during a read access. The  $\overline{\text{EMA\_WE\_DQM}}[1:0]$  pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIFA pins during each command can be found in [Table 20-5](#).

The EMIFA schedules its commands based on the timing information that is provided to it in the SDRAM timing register (SDTIMR). The values for the timing parameters in this register should be chosen to satisfy the timing requirements listed in the SDRAM datasheet. The EMIFA uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDTIMR in [Section 20.4.6](#) for more details on the various timing parameters.

#### 20.2.4.10 SDRAM Write Operations

When the EMIFA receives a write request to SDRAM from one of the requesters listed in [Section 20.2.2](#), it performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIFA proceeds to issue a WRT command while specifying the desired bank and column address. EMA\_A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing a burst of data to the specified address while the EMIFA issues NOP commands. The associated write data will be placed on the data bus in the cycle concurrent with the WRT command and with subsequent burst continuation NOP commands.

[Figure 20-6](#) shows the signal waveforms for a basic SDRAM write operation in which a burst of data is read from a single page. When the EMIFA SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDCR) to 1, a burst size of eight is used. [Figure 20-6](#) shows a burst size of eight.

**Figure 20-6. Timing Waveform for Basic SDRAM Write Operation**

The EMIFA will truncate a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIFA can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command in order to prepare for accessing a different page of the same bank
- By issuing a BT command in order to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EMA\_WE\_DQM[1:0] pins are driven to select which bytes of the data word will be written to the SDRAM device. They are also used to mask out entire undesired data words during a burst access. The state of the other EMIFA pins during each command can be found in [Table 20-5](#).

The EMIFA schedules its commands based on the timing information that is provided to it in the SDRAM timing register (SDTIMR). The values for the timing parameters in this register should be chosen to satisfy the timing requirements listed in the SDRAM datasheet. The EMIFA uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDTIMR in [Section 20.4.6](#) for more details on the various timing parameters.

### 20.2.4.11 Mapping from Logical Address to EMIFA Pins

When the EMIFA receives an SDRAM access request, it must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in [Table 20-13](#) for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDCR), the EMIFA determines which bits of the logical address are mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIFA moves into the same page in the next bank of the attached device by incrementing the bank address EMA\_BA and resetting the column address. The page in the previous bank is left open until it is necessary to close it. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIFA uses the EMA\_WE\_DQM pins during a WRT command to mask out selected bytes or entire words. The EMA\_WE\_DQM pins are always low during a READ command.

**Table 20-13. Mapping from Logical Address to EMIFA Pins for 16-bit SDRAM**

| IBANK | PAGESIZE | Logical Address |    |             |             |             |             |       |             |           |                |                |                |                |               |               |
|-------|----------|-----------------|----|-------------|-------------|-------------|-------------|-------|-------------|-----------|----------------|----------------|----------------|----------------|---------------|---------------|
|       |          | 31:27           | 26 | 25          | 24          | 23          | 22          | 21:14 | 13          | 12        | 11             | 10             | 9              | 8:1            | 0             |               |
| 0     | 0        | -               |    |             |             |             | Row Address |       |             |           |                |                |                | Col Address    | EMA_WE_DQM[0] |               |
| 1     | 0        | -               |    |             |             |             | Row Address |       |             |           |                |                |                | EMA_BA[0]      | Col Address   | EMA_WE_DQM[0] |
| 2     | 0        | -               |    |             | Row Address |             |             |       |             |           | EMA_BA[1:0]    |                |                | Col Address    | EMA_WE_DQM[0] |               |
| 0     | 1        | -               |    |             |             |             | Row Address |       |             |           |                |                |                | Column Address |               | EMA_WE_DQM[0] |
| 1     | 1        | -               |    |             |             | Row Address |             |       |             |           |                | EMA_BA[0]      | Column Address |                | EMA_WE_DQM[0] |               |
| 2     | 1        | -               |    |             | Row Address |             |             |       |             |           | EMA_BA[1:0]    |                |                | Column Address |               | EMA_WE_DQM[0] |
| 0     | 2        | -               |    |             |             | Row Address |             |       |             |           |                |                | Column Address |                | EMA_WE_DQM[0] |               |
| 1     | 2        | -               |    |             | Row Address |             |             |       |             |           | EMA_BA[0]      | Column Address |                | EMA_WE_DQM[0]  |               |               |
| 2     | 2        | -               |    | Row Address |             |             |             |       | EMA_BA[1:0] |           |                | Column Address |                | EMA_WE_DQM[0]  |               |               |
| 0     | 3        | -               |    |             | Row Address |             |             |       |             |           | Column Address |                | EMA_WE_DQM[0]  |                |               |               |
| 1     | 3        | -               |    |             | Row Address |             |             |       |             | EMA_BA[0] | Column Address |                | EMA_WE_DQM[0]  |                |               |               |
| 2     | 3        | -               |    | Row Address |             |             |             |       | EMA_BA[1:0] |           |                | Column Address |                | EMA_WE_DQM[0]  |               |               |

**NOTE:** The upper bit of the Row Address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

## 20.2.5 Asynchronous Controller and Interface

The EMIFA easily interfaces to a variety of asynchronous devices including NOR Flash, NAND Flash, and SRAM. It can be operated in two major modes (see [Table 20-14](#)):

- Normal Mode
- Select Strobe Mode

**Table 20-14. Normal Mode vs. Select Strobe Mode**

| Mode               | Function of $\overline{\text{EMA\_WE\_DQM}}$ pins | Operation of $\overline{\text{EMA\_CS}}[5:2]$           |
|--------------------|---------------------------------------------------|---------------------------------------------------------|
| Normal Mode        | Byte enables                                      | Active during the entire asynchronous access cycle      |
| Select Strobe Mode | Byte enables                                      | Active only during the strobe period of an access cycle |

The first mode of operation is Normal Mode, in which the  $\overline{\text{EMA\_WE\_DQM}}$  pins of the EMIFA function as byte enables. In this mode, the  $\overline{\text{EMA\_CS}}[5:2]$  pins behave as typical chip select signals, remaining active for the duration of the asynchronous access. See [Section 20.2.5.1](#) for an example interface with multiple 8-bit devices.

The second mode of operation is Select Strobe Mode, in which the  $\overline{\text{EMA\_CS}}[5:2]$  pins act as a strobe, active only during the strobe period of an access. In this mode, the  $\overline{\text{EMA\_WE\_DQM}}$  pins of the EMIFA function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in [Table 20-14](#). Refer to [Section 20.2.5.4](#) for the details of asynchronous operations in Normal Mode, and to [Section 20.2.5.5](#) for the details of asynchronous operations in Select Strobe Mode. The EMIFA hardware defaults to Normal Mode, but can be manually switched to Select Strobe Mode by setting the SS bit in the asynchronous  $m$  ( $m = 1, 2, 3, \text{ or } 4$ ) configuration register (CEnCFG) ( $n = 2, 3, 4, \text{ or } 5$ ). Throughout the chapter,  $m$  can hold the values 1, 2, 3 or 4; and  $n$  can hold the values 2, 3, 4, or 5.

In both Normal Mode and Select Strobe Mode, the EMIFA can be configured to operate in a sub-mode called NAND Flash Mode. In NAND Flash Mode, the EMIFA is able to calculate an error correction code (ECC) for transfers up to 518 bytes.

The EMIFA also provides configurable cycle timing parameters and an Extended Wait Mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

### 20.2.5.1 Interfacing to Asynchronous Memory

[Figure 20-7](#) shows the EMIFA's external pins used in interfacing with an asynchronous device. In  $\overline{\text{EMA\_CS}}[n]$ ,  $n = 2, 3, 4, \text{ or } 5$ .

**Figure 20-7. EMIFA Asynchronous Interface**

Of special note is the connection between the EMIFA and the external device's address bus. The EMIFA address pin EMA\_A[0] always provides the least significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EMA\_BA[1] and EMA\_BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Additionally, when the EMIFA interfaces to a 16-bit asynchronous device, the EMA\_BA[0] pin can serve as the upper address line EMA\_A[22]. Note that the width of the address bus varies with devices; therefore, see your device-specific data manual for the EMA\_A bus width supported. Figure 20-8 and Figure 20-9 show the mapping between the EMIFA and the connected device's data and address pins for various programmed data bus widths. The data bus width may be configured in the asynchronous *n* configuration register (CENCFG).

Figure 20-9 shows a common interface between the EMIFA and external asynchronous memory. Figure 20-9 shows an interface between the EMIFA and an external memory with byte enables. The EMIFA should be operated in either Normal Mode or Select Strobe Mode when using this interface, so that the EMA\_WE\_DQM signals operate as byte enables.

**Figure 20-8. EMIFA to 8-bit/16-bit Memory Interface**

a) EMIF to 8-bit memory interface

b) EMIF to 16-bit memory interface

**Figure 20-9. Common Asynchronous Interface**

### 20.2.5.2 Accessing Larger Asynchronous Memories

The device has a limited number of dedicated EMIFA address pins, enough to interface directly to an SDRAM. If a device such as an asynchronous flash needs to be attached to the EMIFA, then GPIO pins may be used to control the flash device's upper address lines. This is sufficient to boot from the flash. Normally, code stored in flash is copied into SDRAM or internal memory before executing because these memories have much faster access times. For details on which device pins are GPIO capable, see your device-specific data manual.

The ROM bootloader can load a secondary bootloader from an attached asynchronous device. The ROM bootloader assumes that any GPIO pins used to control the upper address lines of the boot flash will be pulled to 0 after reset. This means that normally the GPIO pins selected for this function will be either spare or used as outputs only by the application, and therefore can be pulled to 0 at reset with an external pulldown resistor. The GPIO pins chosen should be tri-stated by default on device reset. For details on which GPIO-capable pins are tri-stated on device reset, see your device-specific data manual.

When booting from flash, the ROM bootloader copies a board-specific secondary bootloader from the lower portion of the flash, so it does not need to manipulate the upper address lines. Only the secondary bootloader, which is board-specific and is stored in the external flash, needs to know which GPIO pins have been assigned to the function of upper address lines. Therefore, the secondary bootloader can perform the task of configuring the selected pins as GPIO and loading the remainder of the code from the upper flash memory.

### 20.2.5.3 Configuring the EMIFA for Asynchronous Accesses

The operation of the EMIFA's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in [Section 20.4](#), but the Boot ROM documentation should be consulted to determine if the fields are programmed during boot. The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers will use the new configuration.

**Table 20-15. Description of the Asynchronous *m* Configuration Register (CE<sub>n</sub>CFG)**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SS              | <b>Select Strobe mode.</b> This bit selects the EMIFA's mode of operation in the following way: <ul style="list-style-type: none"> <li>SS = 0 selects Normal Mode <ul style="list-style-type: none"> <li>EMA_WE_DQM pins function as byte enables</li> <li>EMA_CS[5:2] active for duration of access</li> </ul> </li> <li>SS = 1 selects Select Strobe Mode <ul style="list-style-type: none"> <li>EMA_WE_DQM pins function as byte enables</li> <li>EMA_CS[5:2] acts as a strobe.</li> </ul> </li> </ul>                                                                                                                                                           |
| EW              | <b>Extended Wait Mode enable.</b> <ul style="list-style-type: none"> <li>EW = 0 disables Extended Wait Mode</li> <li>EW = 1 enables Extended Wait Mode</li> </ul> When set to 1, the EMIFA enables its Extended Wait Mode in which the strobe width of an access cycle can be extended in response to the assertion of the EMA_WAIT pin <sup>(1)</sup> . The WP <sub>n</sub> bit in the asynchronous wait cycle configuration register (AWCC) controls to polarity of EMA_WAIT pin. Extended Wait Mode should not be used while in NAND Flash Mode. See <a href="#">Section 20.2.5.7</a> for more details on this mode of operation.                                |
| W_SETUP/R_SETUP | <b>Read/Write setup widths.</b><br>These fields define the number (n) of EMIFA clock cycles of setup time for the address pins (EMA_A and EMA_BA), byte enables (EMA_WE_DQM), and asynchronous chip enable (EMA_CS[5:2]) before the read strobe pin (EMA_OE) or write strobe pin (EMA_WE) falls. This value should be encoded as n - 1, where n is the number of EMIFA clock cycles. For example, when W_SETUP = 2, then write setup width = 3 EMA_CLK cycles. For writes, the W_SETUP field also defines the setup time for the data pins (EMA_D). Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |

<sup>(1)</sup> The EMA\_WAIT pin is not available on all devices; therefore, this field is reserved on those devices.

**Table 20-15. Description of the Asynchronous *m* Configuration Register (CE<sub>n</sub>CFG) (continued)**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| W_STROBE/R_STROBE | <b>Read/Write strobe widths.</b><br>These fields define the number (n) of EMIFA clock cycles between the falling and rising edge of the read strobe pin (EMA_OE) or write strobe pin (EMA_WE). This value should be encoded as n - 1, where n is the number of EMIFA clock cycles. For example, when W_SETUP = 2, then write setup width = 3 EMA_CLK cycles. If Extended Wait Mode is enabled by setting the EW field in the asynchronous <i>n</i> configuration register (CE <sub>n</sub> CFG), these fields must be set to a value greater than zero. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.                                                                                                              |
| W_HOLD/R_HOLD     | <b>Read/Write hold widths.</b> <sup>(2)</sup><br>These fields define the number (n) of EMIFA clock cycles of hold time for the address pins (EMA_A and EMA_BA), byte enables (EMA_WE_DQM), and asynchronous chip enable (EMA_CS[5:2]) after the read strobe pin (EMA_OE) or write strobe pin (EMA_WE) rises. This value should be encoded as n - 1, where n is the number of EMIFA clock cycles. For example, when W_SETUP = 2, then write setup width = 3 EMA_CLK cycles. For writes, the W_HOLD field also defines the hold time for the data pins (EMA_D). Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.                                                                                                        |
| TA                | <b>Minimum turnaround time.</b><br>This field defines the minimum number of EMIFA clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that will be inserted between asynchronous accesses and SDRAM accesses. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. If more turnaround cycles are required than can be programmed into the TA field, additional cycles can be added to the R_HOLD field to compensate.                                                                                                                                                |
| ASIZE             | <b>Asynchronous Device Bus Width.</b><br>This field determines the data bus width of the asynchronous interface in the following way: <ul style="list-style-type: none"> <li>ASIZE = 0 selects an 8-bit bus</li> <li>ASIZE = 1 selects a 16-bit bus</li> </ul> The configuration of ASIZE determines the function of the EMA_A and EMA_BA pins as described in <a href="#">Section 20.2.5.1</a> . This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in <a href="#">Section 20.2.2</a> . For example, a request for a 32-bit word would require four external access when ASIZE = 0. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |

<sup>(2)</sup> When using a 16 bit NAND device with ECC calculation support enabled via the EMIFA controller, the EMIFA ECC engine requires the read data to be stable for 2 clock cycles to calculate ECC. The ECC latches 8 bits of data at a time, therefore it requiring additional 2 clock cycles to complete the calculation for 16-bit data. For reliable 16-Bit NAND operations R\_HOLD must be set to 1 to ensure 2 clock cycles for ECC calculation.

**Table 20-16. Description of the Asynchronous Wait Cycle Configuration Register (AWCC)<sup>(1)</sup>**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WP <sub>n</sub> | <b>EMA_WAIT Polarity.</b> <ul style="list-style-type: none"> <li>WP<sub>n</sub> = 0 selects active-low polarity</li> <li>WP<sub>n</sub> = 1 selects active-high polarity</li> </ul> When set to 1, the EMIFA will wait if the EMA_WAIT pin is high. When cleared to 0, the EMIFA will wait if the EMA_WAIT pin is low. The EMIFA must have the Extended Wait Mode enabled for the EMA_WAIT pin to affect the width of the strobe period. The polarity of the EMA_WAIT signal is not programmable in NAND Flash Mode. |

<sup>(1)</sup> The EMA\_WAIT pin is not available on all devices; therefore, this register is reserved on those devices.

**Table 20-16. Description of the Asynchronous Wait Cycle Configuration Register (AWCC)<sup>(1)</sup>**  
(continued)

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAX_EXT_WAIT | <p><b>Maximum Extended Wait Cycles.</b></p> <p>This field configures the number of EMIFA clock cycles the EMIFA will wait for the EMA_WAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIFA clock cycles it will wait is determined by the following formula:</p> <p>Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16</p> <p>If the EMA_WAIT pin is not deactivated within the time specified by this field, the EMIFA resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if it has been enabled in the EMIFA interrupt mask set register (INTMSKSET). Refer to <a href="#">Section 20.2.8.1</a> for more information about the EMIFA interrupts.</p> <p>Extended Wait Mode should not be used while in NAND Flash Mode.</p> |

**Table 20-17. Description of the EMIFA Interrupt Mask Set Register (INTMSKSET)**

| Parameter   | Description                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WR_MASK_SET | <b>Wait Rise Mask Set.</b><br>Writing a 1 enables an interrupt to be generated when a rising edge on EMA_WAIT <sup>(1)</sup> occurs while in NAND Flash Mode |
| AT_MASK_SET | <b>Asynchronous Timeout Mask Set.</b><br>Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.                   |

<sup>(1)</sup> The EMA\_WAIT pin is not available on all devices; therefore, this field is reserved on those devices.

**Table 20-18. Description of the EMIFA Interrupt Mast Clear Register (INTMSKCLR)**

| Parameter   | Description                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WR_MASK_CLR | <b>Wait Rise Mask Clear.</b><br>Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET). |
| AT_MASK_CLR | <b>Asynchronous Timeout Mask Clear.</b><br>Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.                 |

#### 20.2.5.4 Read and Write Operations in Normal Mode

Normal Mode is the asynchronous interface's default mode of operation. It is selected when the SS bit in the asynchronous *n* configuration register (CENCFG) is cleared to 0. In this mode, the EMA\_WE\_DQM pins operate as byte enables. [Section 20.2.5.4.1](#) and [Section 20.2.5.4.2](#) explain the details of read and write operations while in Normal Mode.

##### 20.2.5.4.1 Asynchronous Read Operations (Normal Mode)

**NOTE:** During the entirety of an asynchronous read operation, the  $\overline{\text{EMA\_WE}}$  pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 20.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once it becomes the EMIFA's highest priority task, according to the priority scheme detailed in [Section 20.2.12](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIFA until the entire request is fulfilled. The details of an asynchronous read operation in Normal Mode are described in [Table 20-19](#). Also, [Figure 20-10](#) shows an example timing diagram of a basic read operation.

**Table 20-19. Asynchronous Read Operation in Normal Mode**

| Time Interval     | Pin Activity in Normal Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turnaround period | Once the read operation becomes the highest priority task for the EMIFA, the EMIFA waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CENCFG). There are two exceptions to this rule: <ul style="list-style-type: none"> <li>If the current read operation was directly proceeded by another read operation to the same chip select, no turnaround cycles are inserted.</li> </ul> After the EMIFA has waited for the turnaround cycles to complete, it again checks to make sure that the read operation is still its highest priority task. If so, the EMIFA proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIFA terminates the operation. |

**Table 20-19. Asynchronous Read Operation in Normal Mode (continued)**

| Time Interval             | Pin Activity in Normal Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in CENCFG.</li> <li>The address pins EMA_A and EMA_BA become valid and carry the values described in <a href="#">Section 20.2.5.1</a>.</li> <li>EMA_CS[5:2] falls to enable the external device (if not already low from a previous operation)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Strobe period             | <p>The following actions occur during the strobe period of a read operation:</p> <ol style="list-style-type: none"> <li>EMA_OE falls at the start of the strobe period</li> <li>On the rising edge of the clock which is concurrent with the end of the strobe period: <ul style="list-style-type: none"> <li>EMA_OE rises</li> <li>The data on the EMA_D bus is sampled by the EMIFA.</li> </ul> </li> </ol> <p>In <a href="#">Figure 20-10</a>, EMA_WAIT is inactive. If EMA_WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. <a href="#">Section 20.2.5.7</a> contains more details on using the EMA_WAIT pin.</p>                                                                                                                                                                                                                         |
| End of the hold period    | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>The address pins EMA_A and EMA_BA become invalid</li> <li>EMA_CS[5:2] rises (if no more operations are required to complete the current request)</li> </ul> <p>EMIFA may be required to issue additional read operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIFA immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIFA returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIFA instead enters directly into the turnaround period for the pending read or write operation.</p> |

**Figure 20-10. Timing Waveform of an Asynchronous Read Cycle in Normal Mode**

### 20.2.5.4.2 Asynchronous Write Operations (Normal Mode)

**NOTE:** During the entirety of an asynchronous write operation, the  $\overline{\text{EMA\_OE}}$  pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 20.2.2](#) request a write to memory in the asynchronous bank of the EMIFA. After the request is received, a write operation is initiated once it becomes the EMIFA's highest priority task, according to the priority scheme detailed in [Section 20.2.12](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIFA until the entire request is fulfilled. The details of an asynchronous write operation in Normal Mode are described in [Table 20-20](#). Also, [Figure 20-11](#) shows an example timing diagram of a basic write operation.

**Table 20-20. Asynchronous Write Operation in Normal Mode**

| Time Interval             | Pin Activity in Normal Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turnaround period         | <p>Once the write operation becomes the highest priority task for the EMIFA, the EMIFA waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. In this case, the EMIFA immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIFA returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIFA instead enters directly into the turnaround period for the pending read or write operation.</p> |

**Figure 20-11. Timing Waveform of an Asynchronous Write Cycle in Normal Mode**

## 20.2.5.5 Read and Write Operation in Select Strobe Mode

Select Strobe Mode is the EMIFA's second mode of operation. It is selected when the SS bit of the asynchronous *n* configuration register (CEnCFG) is set to 1. In this mode, the EMA\_WE\_DQM pins operate as byte enables and the EMA\_CS[n] (n = 2, 3, 4, or 5) pin is only active during the strobe period of an access cycle. [Section 20.2.5.4.1](#) and [Section 20.2.5.4.2](#) explain the details of read and write operations while in Select Strobe Mode.

### 20.2.5.5.1 Asynchronous Read Operations (Select Strobe Mode)

**NOTE:** During the entirety of an asynchronous read operation, the EMA\_WE pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 20.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once it becomes the EMIFA's highest priority task, according to the priority scheme detailed in [Section 20.2.12](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIFA until the entire request is fulfilled. The details of an asynchronous read operation in Select Strobe Mode are described in [Table 20-21](#). Also, [Figure 20-12](#) shows an example timing diagram of a basic read operation.

**Table 20-21. Asynchronous Read Operation in Select Strobe Mode**

| Time Interval             | Pin Activity in Select Strobe Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turnaround period         | <p>Once the read operation becomes the highest priority task for the EMIFA, the EMIFA waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CEnCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> <li>If the current read operation was directly preceded by another read operation to the same chip select, no turn-around cycles are inserted.</li> </ul> <p>After the EMIFA has waited for the turn-around cycles to complete, it again checks to make sure that the read operation is still its highest priority task. If so, the EMIFA proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIFA terminates the operation.</p> |
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in CEnCFG.</li> <li>The address pins EMA_A and EMA_BA become valid and carry the values described in <a href="#">Section 20.2.5.1</a>.</li> <li>The EMA_WE_DQM pins become valid as byte enables.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Strobe period             | <p>The following actions occur during the strobe period of a read operation:</p> <ol style="list-style-type: none"> <li>EMA_CS[n] (n = 2, 3, 4, or 5) and EMA_OE fall at the start of the strobe period</li> <li>On the rising edge of the clock which is concurrent with the end of the strobe period: <ul style="list-style-type: none"> <li>EMA_CS[n] (n = 2, 3, 4, or 5) and EMA_OE rise</li> <li>The data on the EMA_D bus is sampled by the EMIFA.</li> </ul> </li> </ol> <p>In <a href="#">Figure 20-12</a>, EMA_WAIT is inactive. If EMA_WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. <a href="#">Section 20.2.5.7</a> contains more details on using the EMA_WAIT pin.</p>                                                                                                                         |
| End of the hold period    | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>The address pins EMA_A and EMA_BA become invalid</li> <li>The EMA_WE_DQM pins become invalid</li> </ul> <p>The EMIFA may be required to issue additional read operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIFA immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIFA returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIFA instead enters directly into the turnaround period for the pending read or write operation.</p>                   |

### 20.2.5.5.2 Asynchronous Write Operations (Select Strobe Mode)

**NOTE:** During the entirety of an asynchronous write operation, the  $\overline{\text{EMA\_OE}}$  pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 20.2.2](#) request a write to memory in the asynchronous bank of the EMIFA. After the request is received, a write operation is initiated once it becomes the EMIFA's highest priority task, according to the priority scheme detailed in [Section 20.2.12](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIFA until the entire request is fulfilled. The details of an asynchronous write operation in Select Strobe Mode are described in [Table 20-22](#). Also, [Figure 20-13](#) shows an example timing diagram of a basic write operation.

**Table 20-22. Asynchronous Write Operation in Select Strobe Mode**

| Time Interval             | Pin Activity in Select Strobe Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Figure 20-13. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode**

### 20.2.5.6 NAND Flash Mode

NAND Flash Mode is a submode of both Normal Mode and Select Strobe Mode. Chip select  $\overline{\text{EMA\_CS}}[n]$  ( $n = 2, 3, 4, \text{ or } 5$ ) may be placed in NAND Flash mode by setting the  $\text{CSnNAND}$  ( $n = 2, 3, 4, \text{ or } 5$ ) bit in the NAND Flash control register (NANDFCR). [Table 20-23](#) displays the bit fields present in NANDFCR and briefly describes their use.

When a chip select space is configured to operate in NAND Flash mode, the EMIFA hardware can calculate the error correction code (ECC) for each 518 byte data transfer to that chip select space. The EMIFA hardware will not generate the NAND access cycle, which includes the command, address, and data phases, necessary to complete a transfer to NAND Flash. All NAND Flash operations can be divided into single asynchronous cycles, and with the help of software the EMIFA can execute a complete NAND access cycle.

**Table 20-23. Description of the NAND Flash Control Register (NANDFCR)**

| Parameter | Description                                                                                                                                                                                                                                                                               |

#### 20.2.5.6.1 Configuring for NAND Flash Mode

Similar to the asynchronous accesses previously described, the EMIFA's memory-mapped registers must be programmed appropriately to interface to a NAND Flash device. In addition to the fields listed in [Table 20-15](#), the  $\text{CSnNAND}$  ( $n = 2, 3, 4, \text{ or } 5$ ) bit of the NAND Flash control register (NANDFCR) should be set to 1 to enter NAND Flash Mode. Note that the EW bit of  $\text{CEnCFG}$  should be cleared to avoid enabling the wait feature while in NAND Flash Mode.

#### 20.2.5.6.2 Connecting to NAND Flash

[Figure 20-14](#) shows the EMIFA external pins used to interface with a NAND Flash device. EMIFA address lines are used to drive the NAND Flash device's command latch enable (CLE) and address latch enable (ALE) signals. Any EMIFA address lines may be used to drive the CLE and ALE signals of the NAND Flash.

**NOTE:** The EMIFA will not control the NAND Flash device's write protect pin. The write protect pin must be controlled outside of the EMIFA.

**Figure 20-14. EMIFA to NAND Flash Interface**

a) Connection to 8-bit NAND device

b) Connection to 16-bit NAND device

### 20.2.5.6.3 Driving CLE and ALE

As stated in [Section 20.2.5.1](#), the EMIFA always drives the least significant bit of a 32-bit word address on EMA\_A[0]. This functionality must be considered when attempting to drive the offset lines connected to CLE and ALE to the appropriate state.

For example, if using EMA\_A[2] and EMA\_A[1] to connect to CLE and ALE, respectively, the following offsets should be added to EMIFA base address:

- 0000 0000h to drive CLE and ALE low
- 0000 0010h to drive CLE high and ALE low
- 0000 0008h to drive CLE low and ALE high

### 20.2.5.6.4 NAND Read and Program Operations

A NAND Flash access cycle is composed of a command, address, and data phase. The EMIFA will not automatically generate these three phases to complete a NAND access with one transfer request. To complete a NAND access cycle, multiple single asynchronous access cycles must be completed by the EMIFA. Software must be used to request the appropriate asynchronous accesses to complete a NAND Flash access cycle. This software must be developed to the specification of the chosen NAND Flash device.

Since NAND operations are divided into single asynchronous access cycles, the chip select signal will not remain activated for the duration of the NAND operation. Instead, the chip select signal will deactivate between each asynchronous access cycle. For this reason, the EMIFA does not support NAND Flash devices that require the chip select signal to remain low during the  $t_R$  time for a read. See [Section 20.2.5.6.8](#) for workaround.

Care must be taken when performing a NAND read or write operation via the EDMA controller. See [Section 20.2.5.6.5](#) for more details.

---

**NOTE:** The EMIFA does not support NAND Flash devices that require the chip select signal to remain low during the  $t_r$  time for a read. See [Section 20.2.5.6.8](#) for workaround.

---

#### 20.2.5.6.5 NAND Data Read and Write via EDMA Controller

When performing NAND accesses, the EDMA controller is most efficiently used for the data phase of the access. The command and address phases of the NAND access require only a few words of data to be transferred and therefore do not take advantage of the EDMA controller's ability to transfer larger quantities of data with a single request. In this section we will focus on using the EDMA controller for the data phase of a NAND access.

There are two conditions that require care to be taken when performing NAND reads and writes via the EDMA controller. These are:

- The address lines used to drive CLE and ALE signals must be driven low
- The EMIFA does not support constant addressing mode

Since the EMIFA does not support a constant addressing mode, when programming the EDMA, a linear incrementing address mode must be used. When using a linear incrementing address mode, if the CLE and ALE are driven by EMA\_A[2] and EMA\_A[1], respectively, care must be taken not to increase the address into a range that drives CLE and/or ALE high. To prevent the address from incrementing into a range that drives CLE and/or ALE high, the EDMA ACNT, BCNT, SIDX, DIDX, and synchronization type must be programmed appropriately. Following is an example configuration of EDMA controller when EMA\_A[2] is connected to CLE and EMA\_A[1] is connected to ALE.

EDMA setup for a NAND Flash data read:

- $ACNT \leq 8$  bytes (this can also be set to less than or equal to the external data bus width)
- $BCNT = \text{transfer size in bytes}/ACNT$
- $SIDX$  (source index) = 0
- $DIDX$  (destination index) =  $ACNT$
- AB synchronized

EDMA setup for a NAND Flash data write:

- $ACNT \leq 8$  bytes (this can also be set to less than or equal to the external data bus width)
- $BCNT = \text{transfer size in bytes}/ACNT$
- $SIDX$  (source index) =  $ACNT$
- $DIDX$  (destination index) = 0
- AB synchronized

#### 20.2.5.6.6 ECC Generation

##### 20.2.5.6.6.1 1-Bit ECC

If the CSnNAND ( $n = 2, 3, 4$ , or 5) bit in the NAND Flash control register (NANDFCR) is set to 1, the EMIFA supports 1-bit ECC calculation for up to 512 bytes for the corresponding chip select. To perform the ECC calculation, the CSnECC ( $n = 2, 3, 4$ , or 5) bit in NANDFCR must be set to 1. It is the responsibility of the software to start the ECC calculation by writing to the CSnECC ( $n = 2, 3, 4$ , or 5) bit prior to issuing a write or read to NAND Flash. It is also the responsibility of the software to read the calculated ECC from the NAND Flash  $m$  ECC register (NANDFmECC) ( $m = 1, 2, 3$ , or 4) once the transfer to NAND Flash has completed. If the software writes or reads more than 512 bytes, the ECC will be incorrect. Reading the NANDmECC ( $m = 1, 2, 3$ , or 4) clears the CSnECC ( $n = 2, 3, 4$ , or 5) bit in NANDFCR. The NANDFmECC ( $m = 1, 2, 3$ , or 4) is cleared upon writing a 1 to the CSnECC ( $n = 2, 3, 4$ , or 5) bit. [Figure 20-15](#) shows the algorithm used to calculate the ECC value for an 8-bit NAND Flash.

For an 8-bit NAND Flash p10 through p4e are column parities and p8e through p2048o are row parities. Similarly, the algorithm can be extended to a 16-bit NAND Flash. For a 16-bit NAND Flash p10 through p8e are column parities and p16e through p2048o are row parities. The software must ignore the unwanted parity bits if ECC is desired for less than 512 bytes of data. For example, p2048e and p2048o are not required for ECC on 256 bytes of data. Similarly, p1024e, p1024o, p2048e, and p2048o are not required for ECC on 128 bytes of data.

**Figure 20-15. ECC Value for 8-Bit NAND Flash**

#### 20.2.5.6.6.2 4-Bit ECC

The EMIFA supports 4-bit ECC on 8-bit/16-bit NAND Flash. In NAND mode, if the NAND Flash 4-bit ECC start bit (4BITECC\_START) in the in the NAND Flash control register (NANDFCR) is set, the EMIFA calculates 4-bit ECC for the selected chip select. Only one chip select can be selected for the 4-bit ECC calculation at one time. The selection of the chip select is done by programming the 4-bit ECC CS select bit field (4BITECCSEL) in the NAND Flash control register (NANDFCR). The calculated parity (for writes) and syndrome (for reads) can be read from the NAND Flash 4-bit ECC 1-4 registers (NAND4BITECC[4:1]). The 4-bit ECC start bit (4BITECC\_START) is cleared upon reading any of the NAND Flash 4-bit ECC 1-4 registers (NAND4BITECC[4:1]). The NAND Flash 4-bit ECC 1-4 registers are cleared upon writing one to the 4-bit ECC start bit (4BITECC\_START).

The 4-bit ECC algorithm works on a 10-bit data bus, but only the lower eight bits of the data bus actually contain data. When the EMIFA is used in 16-bit mode, the lower and upper 8-bits of the 16-bit data read from the data bus are fed into the ECC engine one at a time, in that order. In all cases, since only 8-bits of data are fed to the ECC engine, the upper two bits of the 10-bit data bus that feeds the ECC engine are always zero. However, the parity and the syndrome value read from the NAND Flash 4-bit ECC 1-4 registers (NAND4BITECC[4:1]) are 10 bits wide. It is the responsibility of software to convert 10-bit parity values to 8 bits before writing to the spare location of the NAND Flash after a write operation. Similarly, it is the responsibility of the software to convert the 8-bit parity values read from the spare location of the NAND Flash after a read operation, to 10 bits before writing the NAND Flash 4-bit ECC load register (NAND4BITECCLOAD).

The 4-bit ECC employed in the EMIFA interface is a Reed-Solomon error correcting code. The symbol size is ten bits (two bits are always zero and eight bits contain data as described above). With eight 10-bit parity words, up to four symbols can be corrected per block read. Though the ECC operation is called 4-bit, it is important to note that correction can actually happen on up to four 10-bit symbols. Only the lower eight bits of each 10-bit symbol actually contain data (see above), so correction can happen on up to four bytes. When bit errors are randomly distributed through the block of data read from the NAND, those errors are not likely to fall into the same bytes of data, so 4-bits of correction is an apt description. Technically speaking, however, more than four bits of error can be corrected if multiple bit errors are confined to four or fewer bytes of the data. If bit errors fall into more than four bytes, the ECC engine will report that there are too many errors to correct.

At the end of the syndrome calculation after read, the error address and the error value can be calculated by setting the address and error value calculation start bit (4BITECC\_ADD\_CALC\_START) in the NAND Flash control register (NANDFCR). The end of address calculation is flagged by the 4-bit ECC correction state field (ECC\_STATE) in the NAND Flash status register (NANDFSR). The number of errors can be read from the 4-bit number of errors field (ECC\_ERRNUM) in the NAND Flash status register (NANDFSR). The error address value can be read from the NAND Flash error address 1-2 registers (NANDERRADD[2:1]). The error value can be read from the NAND Flash error value 1-2 registers (NANDERRVAL[2:1]). The address and error value start bit (4BITECC\_ADD\_CALC\_START) is cleared upon reading any of the NAND Flash error address 1-2 registers (NANDERRADD[2:1]) or the NAND Flash error value 1-2 registers (NANDERRVAL[2:1]). The EMIFA registers the syndrome value internally before the error address and error value calculation. Therefore, a new read operation can be performed simultaneously with the error address calculation.

The EMIFA supports 4-bit ECC calculation up to 518 bytes. The software needs to follow the following procedure for 4-bit ECC calculation:

For writes:

1. Set the 4BITECC\_START bit in the NAND Flash control register (NANDFCR) to 1.
2. Write 518 bytes of data to the NAND Flash.
3. Read the parity from the NAND Flash 4-Bit ECC 1-4 registers (NAND4BITECC[4:1]).
4. Convert the 10-bit parity values to 8-bits. All 10-bit parity values can be concatenated together with ECC value 1 (4BITECCVAL1) as LSB and ECC value 8 (4BITECCVAL8) as MSB. Then the concatenated value can be broken down into ten 8-bit values.
5. Store the parity to spare location in the NAND Flash.

For reads:

1. Set the 4BITECC\_START bit in the NAND Flash control register (NANDFCR) to 1.
2. Read 518 bytes of data from the NAND Flash.
3. Clear the 4BITECC\_START bit in NANDFCR by reading any of the NAND Flash 4-bit ECC registers.
4. Read the parity stored in the spare location in the NAND Flash.
5. Convert the 8-bit parity values to 10-bits. Reverse of the conversion that was done during writes.
6. Write the parity values in the NAND Flash 4-bit ECC load register (NAND4BITECCLOAD). Write each parity value one at a time starting from 4BITECCVAL8 down to 4BITECCVAL1.
7. Perform a dummy read to the NAND Flash status register (NANDFSR). This is only required to ensure time for syndrome calculation after writing the ECC values in step 6.
8. Read the syndrome from the NAND Flash 4-bit ECC 1-4 registers (NAND4BITECC[4:1]). A syndrome value of 0 means no bit errors. If the syndrome is non-zero, continue with step 9.
9. Set the 4BITECC\_ADD\_CALC\_START bit in the NAND Flash control register (NANDFCR) to 1.
10. Perform a dummy read to any EMIFA registers except the NAND Flash error address 1-2 registers (NANDERRADD[2:1]) or the NAND Flash error value 1-2 registers (NANDERRVAL[2:1]).
11. Start another read from NAND, if required (a new thread from step 1).
12. Wait for the 4-bit ECC correction state field (ECC\_STATE) in the NAND Flash status register (NANDFSR) to be equal to 1, 2h, or 3h.
13. The number of errors can be read from the 4-bit number of errors field (ECC\_ERRNUM) in the NAND Flash status register (NANDFSR).
14. Read the error address from the NAND Flash error address 1-2 registers (NANDERRADD[2:1]). Address for the error word is equal to (total\_words\_read + 7 - address\_value). For 518 bytes, the address will be equal to (525 - address\_value).
15. Read the error value from the NAND Flash error value 1-2 registers (NANDERRVAL[2:1]). Errors can be corrected by XORing the error word with the error value from the NAND Flash error value 1-2 registers (NANDERRVAL[2:1]).

#### 20.2.5.6.7 NAND Flash Status Register (NANDFSR)

The NAND Flash status register (NANDFSR) indicates the raw status of the EMA\_WAIT pin while in NAND Flash Mode. The EMA\_WAIT pin should be connected to the NAND Flash device's R/B signal, so that it indicates whether or not the NAND Flash device is busy. During a read, the R/B signal will transition and remain low while the NAND Flash retrieves the data requested. Once the R/B signal transitions high, the requested data is ready and should be read by the EMIFA. During a write/program operation, the R/B signal transitions and remains low while the NAND Flash is programming the Flash with the data it has received from the EMIFA. Once the R/B signal transitions high, the data has been written to the Flash and the next phase of the transaction may be performed. From this explanation, you can see that the NAND Flash status register is useful to the software for indicating the status of the NAND Flash device and determining when to proceed to the next phase of a NAND Flash operation.

When a rising edge occurs on the EMA\_WAIT pin, the EMIFA sets the WR (Wait Rise) bit in the EMIFA interrupt raw register (INTRAW). Therefore, the EMIFA Wait Rise interrupt may be used to indicate the status of the NAND Flash device. The WP<sub>n</sub> bit in the asynchronous wait cycle configuration register (AWCC) does not affect the NAND Flash status register (NANDFSR) or the WR bit in INTRAW. See [Section 20.2.8](#) for more a detailed description of the wait rise interrupt.

#### 20.2.5.6.8 Interfacing to a Non-CE Don't Care NAND Flash

As explained in [Section 20.2.5.6.4](#), the EMIFA does not support NAND Flash devices that require the chip select signal to remain low during the t<sub>rp</sub> time for a read. One way to work around this limitation is to use a GPIO pin to drive the CE signal of the NAND Flash device. If this work around is implemented, software will configure the selected GPIO to be low, then begin the NAND Flash operation, starting with the command phase. Once the NAND Flash operation has completed the software can then configure the selected GPIO to be high.

#### 20.2.5.7 Extended Wait Mode and the EMA\_WAIT Pin

The EMIFA supports the Extend Wait Mode. This is a mode in which the external asynchronous device may assert control over the length of the strobe period. The Extended Wait Mode can be entered by setting the EW bit in the asynchronous *n* configuration register (CEnCFG) (*n* = 2, 3, 4, or 5). When this bit is set, the EMIFA monitors the EMA\_WAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIFA detects that the EMA\_WAIT pin has been asserted, it will begin inserting extra strobe cycles into the operation until the EMA\_WAIT pin is deactivated by the external device. The EMIFA will then return to the last cycle of the programmed strobe period and the operation will proceed as usual from this point. Please refer to the device data manual for details on the timing requirements of the EMA\_WAIT signal.

The EMA\_WAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX\_EXT\_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EMA\_CLK cycles the strobe period may be extended beyond the programmed length. When the counter expires, the EMIFA proceeds to the hold period of the operation regardless of the state of the EMA\_WAIT pin. The EMIFA can also generate an interrupt upon expiration of this counter. See [Section 20.2.8.1](#) for details on enabling this interrupt.

For the EMIFA to function properly in the Extended Wait mode, the WP<sub>n</sub> bit of AWCC must be programmed to match the polarity of the EMA\_WAIT pin. In its reset state of 1, the EMIFA will insert wait cycles when the EMA\_WAIT pin is sampled high. When set to 0, the EMIFA will insert wait cycles only when EMA\_WAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in Extended Wait mode. Specifically, the sum of the W\_SETUP and W\_STROBE fields must be greater than 4, and the sum of the R\_SETUP and R\_STROBE fields must be greater than 4 for the EMIFA to recognize the EMA\_WAIT pin has been asserted. The W\_SETUP, W\_STROBE, R\_SETUP, and R\_STROBE fields are in CEnCFG.

## 20.2.6 Data Bus Parking

The EMIFA always drives the data bus to the previous write data value when it is idle. This feature is called data bus parking. Only when the EMIFA issues a read command to the external memory does it stop driving the data bus. The data bus is released (tri-stated) when the chip enable ( $\overline{\text{EMA\_CS}}[n]$ ) is asserted by EMIFA for the read access. After the read operation is completed, the data bus is driven again by the bus parking feature at the end of the turnaround time. At all other times that the EMIF is enabled but not actively transferring data, the bus parking feature drives the data bus to the last written value.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIFA is in the self-refresh state. In this situation, the read operation is not followed by the EMIFA parking the data bus. Instead, the EMIFA tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIFA is in the self-refresh state, in order to prevent floating inputs on the data bus. External pull-ups, such as 10k $\Omega$  resistors, should be placed on the 16 EMIFA data bus pins (which do not have internal pull-ups) if it is required to perform reads in this situation. The precise resistor value should be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see [Section 20.2.4.7](#).

## 20.2.7 Reset and Initialization Considerations

The EMIFA memory controller has two reset signals,  $\overline{\text{CHIP\_RST}}$  and  $\overline{\text{MOD\_G\_RST}}$ . The  $\overline{\text{CHIP\_RST}}$  is a module-level reset that resets both the state machine as well as the EMIFA memory controller's memory-mapped registers. The  $\overline{\text{MOD\_G\_RST}}$  resets the state machine only. If the EMIFA memory controller is reset independently of other peripherals, the user's software should not perform memory, as well as register accesses, while  $\overline{\text{CHIP\_RST}}$  or  $\overline{\text{MOD\_G\_RST}}$  are asserted. If memory or register accesses are performed while the EMIFA memory controller is in the reset state, other masters may hang. Following the rising edge of  $\overline{\text{CHIP\_RST}}$  or  $\overline{\text{MOD\_G\_RST}}$ , the EMIFA memory controller immediately begins its initialization sequence. Command and data stored in the EMIFA memory controller FIFOs are lost. [Table 20-24](#) describes the different methods for asserting each reset signal. [Figure 20-16](#) shows the EMIFA memory controller reset diagram.

**Table 20-24. Reset Sources**

| Reset Signal                    | Reset Source               |
|---------------------------------|----------------------------|
| $\overline{\text{CHIP\_RST}}$   | Hardware/ Device Reset     |
| $\overline{\text{MOD\_G\_RST}}$ | Power and Sleep Controller |

**Figure 20-16. EMIFA Reset Block Diagram**

The EMIFA and its registers are reset when any of the following events occur:

1. The  $\overline{\text{RESET}}$  pin on the device is asserted
2. An emulator reset is initiated through the Code Composer Studio™ integrated development environment

In the first case, the EMIFA will exit the reset state when  $\overline{\text{RESET}}$  is released and after the PLL controller releases the entire device from reset. In the second case, the EMIFA will exit the reset state immediately after the emulator reset is complete.

In both cases, the EMIFA automatically begins running the SDRAM initialization sequence described in [Section 20.2.4.4](#) after coming out of reset. Even though the initialization procedure is automatic, a special procedure, found in [Section 20.2.4.5](#) must still be followed.

## 20.2.8 Interrupt Support

The EMIFA supports a single interrupt to the CPU. [Section 20.2.8.1](#) details the generation and internal masking of EMIFA interrupts, and [Section 20.2.8.2](#) describes how the EMIFA interrupts are sent to the CPU.

### 20.2.8.1 Interrupt Events

There are three conditions that may cause the EMIFA to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EMA\_WAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EMA\_WAIT signal. This interrupt generation is not affected by the  $\text{WP}_n$  bit in the asynchronous wait cycle configuration register (AWCC). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EMA\_WAIT pin within the number of cycles defined by the MAX\_EXT\_WAIT bit in AWCC (this happens only in extended wait mode). EMIFA supports only linear incrementing and cache line wrap addressing modes. If an access request for an unsupported addressing mode is received, the EMIFA will set the LT bit in the EMIFA interrupt raw register (INTRAW) and treat the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit ( $\text{WR\_MASK\_SET}/\text{AT\_MASK\_SET}/\text{LT\_MASK\_SET}$ ) in the EMIFA interrupt mask set register (INTMSKSET) to 1, will the interrupt be sent to the CPU. Once enabled, the interrupt may be disabled by writing a 1 to the corresponding bit in the EMIFA interrupt mask clear register (INTMSKCLR). The bit fields in both the INTMSKSET and INTMSKCLR may be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INTMSKSET and INTMSKCLR will have a value of 1; when the interrupt is disabled, the corresponding bit field will have a value of 0.

The EMIFA interrupt raw register (INTRAW) and the EMIFA interrupt mask register (INTMSK) indicate the status of each interrupt. The appropriate bit ( $\text{WR}/\text{AT}/\text{LT}$ ) in INTRAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit ( $\text{WR\_MASKED}/\text{AT\_MASKED}/\text{LT\_MASKED}$ ) in INTMSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INTRAW clears the INTRAW bit as well as the corresponding bit in INTMSK. [Table 20-25](#) contains a brief summary of the interrupt status and control bit fields. See [Section 20.4](#) for complete details on the register fields.

**Table 20-25. Interrupt Monitor and Control Bit Fields**

| Register Name                                   | Bit Name    | Description                                                                                                                                                  |
|-------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMIFA interrupt raw register (INTRAW)           | WR          | This bit is set when an rising edge on the EMA_WAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INTMSK.                     |
|                                                 | AT          | This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INTMSK.                                   |
|                                                 | LT          | This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INTMSK.                               |
| EMIFA interrupt mask register (INTMSK)          | WR_MASKED   | This bit is set only when a rising edge on the EMA_WAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INTMSKSET. |
|                                                 | AT_MASKED   | This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INTMSKSET.              |
|                                                 | LT_MASKED   | This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INTMSKSET.                  |
| EMIFA interrupt mask set register (INTMSKSET)   | WR_MASK_SET | Writing a 1 to this bit enables the wait rise interrupt.                                                                                                     |
|                                                 | AT_MASK_SET | Writing a 1 to this bit enables the asynchronous timeout interrupt.                                                                                          |
|                                                 | LT_MASK_SET | Writing a 1 to this bit enables the line trap interrupt.                                                                                                     |
| EMIFA interrupt mask clear register (INTMSKCLR) | WR_MASK_CLR | Writing a 1 to this bit disables the wait rise interrupt.                                                                                                    |
|                                                 | AT_MASK_CLR | Writing a 1 to this bit disables the asynchronous timeout interrupt.                                                                                         |
|                                                 | LT_MASK_CLR | Writing a 1 to this bit disables the line trap interrupt.                                                                                                    |

### 20.2.8.2 Interrupt Multiplexing

For details on EMIFA interrupt multiplexing, see your device-specific data manual.

### 20.2.8.3 Interrupt Processing

For details on EMIFA interrupt processing, see the *DSP Subsystem* chapter and the *ARM Interrupt Controller (AINTC)* chapter.

For more details on the CPU's NMI interrupt, see the *DSP Subsystem* chapter and the *TMS320C674x CPU and Instruction Set Reference Guide* ([SPRUFE8](#)).

## 20.2.9 EDMA Event Support

EMIFA memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests may be made directly, by masters and the DMA.

### 20.2.10 Pin Multiplexing

For details on EMIFA pin multiplexing, see your device-specific data manual.

### 20.2.11 Memory Map

For information describing the device memory-map, see your device-specific data manual.

## 20.2.12 Priority and Arbitration

[Section 20.2.2](#) describes the external prioritization and arbitration among requests from different sources within the SoC. The result of this external arbitration is that only one request is presented to the EMIFA at a time. Once the EMIFA completes a request, the external arbiter then provides the EMIFA with the next pending request.

Internally, the EMIFA undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDCR).

Either of these events will cause the EMIFA to immediately commence its initialization sequence as described in [Section 20.2.4.4](#).

Once the EMIFA has completed its initialization sequence, it performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIFA's backlog refresh counter is at the Refresh Must urgency level, the EMIFA performs multiple SDRAM auto refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIFA performs a read operation.
3. If the EMIFA's backlog refresh counter is at the Refresh Need urgency level, the EMIFA performs an SDRAM auto refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIFA performs a write operation.
5. If the EMIFA's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIFA performs an SDRAM auto refresh cycle.
6. If the value of the SR bit in SDCR has been set to 1, the EMIFA will enter the self-refresh state as described in [Section 20.2.4.7](#).

After taking one of the actions listed above, the EMIFA then returns to the top of the priority list to determine its next action.

Because the EMIFA does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See [Section 20.2.4.7](#) for details on the operation of the EMIFA when in the self-refresh state.

## 20.2.13 System Considerations

This section describes various system considerations to keep in mind when operating the EMIFA.

### 20.2.13.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- $t_{RAS}$  (typically 120  $\mu$ s) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate} \times 11$  (typically 15.7  $\mu$ s  $\times$  11 = 172.7  $\mu$ s) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes will require four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIFA can be sent is 16 words, therefore the maximum number of access cycles per memory request is 64 when the EMIFA is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EMA\_WAIT input signal up to a programmed maximum limit. It is up to the user to make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

### 20.2.13.2 Cache Fill Requests

The CPU can run code from either internal or external memory. When running code from external memory, the CPU's program cache is periodically filled with eight words (32-bytes) through a dedicated port to the EMIFA. Two system level concerns arise when filling the program cache from the EMIFA.

First, the program cache fills have the possibility of being locked out from accessing the EMIFA by a stream of higher priority requests. Therefore, care should be taken when issuing persistent requests to the EMIFA from a source such which is a high priority requester.

Second, requests to the EMIFA from the other sources risk missing their deadlines while a program cache fill from the EMIFA is in progress. This is because all other EMIFA accesses are held pending while the program cache is filled. The worst-case scenario that can arise is when a requester submits a request immediately after a program cache fill request has begun. The system should be analyzed to make sure that this worst-case request delay is acceptable.

## 20.2.14 Power Management

Power dissipation from the EMIFA memory controller may be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIFA memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clocks are turned off outside of the EMIFA memory controller through the use of the Power and Sleep Controller (PSC) and the PLL controller. [Figure 20-17](#) shows the connections between the EMIFA memory controller, PSC, and PLL. Before gating clocks off, the EMIFA memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the clock provided by the PLL must not be turned off because this may result in data corruption. See the following subsections for the proper procedures to follow when stopping the EMIFA memory controller clocks.

**Figure 20-17. EMIFA PSC Block Diagram**

### 20.2.14.1 Power Management Using Self-Refresh Mode

The EMIFA can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to [Section 20.2.4.7](#) for more details on placing the EMIFA into the self-refresh state.

### 20.2.14.2 Power Management Using Power Down Mode

In case of power down, to lower the power consumption, EMIFA drives EMA\_SDCKE low. EMA\_SDCKE goes high when there is a need to send refresh (REFR) commands, after which EMA\_SDCKE is again driven low. EMA\_SDCKE remains low until any request arrives. Refer to [Section 20.2.4.8](#) for more details on placing EMIFA in power down mode.

### 20.2.14.3 Power Management Using Clock Stop

The LPSC of the memory controller can be programmed to be in one of the following states:

- Enable
- Auto Sleep
- Auto Wake
- Sync Reset

After the EMIFA clock is enabled, by default it is in the enable state. EMIFA can be put to auto sleep state, when the clock is to be gated off. Auto Wake brings back EMIFA to the enable state from the auto sleep state.

#### 20.2.14.3.1 Auto Sleep and Auto Wake

To achieve maximum power savings EMIFA core clock should be gated off. EMIFA memory controller can make use of auto sleep and auto wake to achieve clock gating. Following describes the procedure to be followed to put EMIFA memory controller in auto sleep state:

- EMIFA should be put to self-refresh mode before stopping the clock. Refer to [Section 20.2.4.7](#) for details on self-refresh mode. The EMIFA memory controller will complete any outstanding accesses and backlogged refresh cycles and then place the EMIFA memory in self-refresh mode.
- Then, program the LPSC of EMIFA for auto sleep, to gate off the clocks.

Register and memory access requests are honored while EMIFA is in auto sleep state. When EMIFA sees a request while it is in auto sleep state, it automatically returns to enable state, processes the request, and returns back to auto sleep state until further requests come.

On frequent requests, EMIFA switches between auto sleep and enable states. To bring EMIFA back to the enable state, auto wake can be used. Following procedure is followed for performing auto wake.

- Program the LPSC of EMIFA for auto wake.
- Bring EMIFA out of self-refresh. Refer to [Section 20.2.4.7](#) for details on self-refresh mode.

After auto wake, EMIFA is in enable state and clocks run continuously.

#### 20.2.14.3.2 Sync Reset and Enable

Sync reset of EMIFA through the LPSC does not reset the EMIFA registers or memory. Thus EMIFA LPSC sync reset behavior is similar to EMIFA LPSC auto sleep, except that register or memory requests are not honored by EMIFA. Following is the procedure to put EMIFA in sync reset state:

- EMIFA should be put to self-refresh mode before stopping the clock. Refer to [Section 20.2.4.7](#) for details on self-refresh mode. The EMIFA memory controller will complete any outstanding accesses and backlogged refresh cycles and then place the EMIFA memory in self-refresh mode.
- Then, program the LPSC of EMIFA to Sync-Reset state.

On sync reset, requests to EMIFA are not honored. To bring EMIFA back to the enable state, use the following enable procedure:

- Program the LPSC of EMIFA to enter enable state.
- Bring EMIFA out of self-refresh. Refer to [Section 20.2.4.7](#) for details on self-refresh mode.

Now EMIFA memory controller is in the enable state and continues with normal operation.

### 20.2.15 Emulation Considerations

EMIFA memory controller will remain fully functional during emulation halts, to allow emulation access to external memory.

## 20.3 Example Configuration

This section presents an example of interfacing the EMIFA to both an SDR SDRAM device and an asynchronous flash device.

### 20.3.1 Hardware Interface

Figure 20-18 shows the hardware interface between the EMIFA, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and two SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between the EMIFA and the SDRAM is straightforward, but the connection between the EMIFA and the flash deserves a detailed look.

The address inputs for the flash are provided by three sources. The A[12:0] address inputs are provided by a combination of the EMA\_A and EMA\_BA pins according to Section 20.2.5.1. The upper address inputs A[18:13] are provided by GPIO pins. The six GPIO pins are connected to the upper address bits of the flash memory and attached to pulldown resistors so that their value is 0 after reset and before configuring the pins as GPIO. This is necessary if the ROM bootloader is copying the secondary bootloader from the flash. More details on using GPIO pins as upper address pins can be found in Section 20.2.5.2. RD/BY signal from one flash is connected to EMA\_WAIT pin of EMIFA. A GPIO pin can be made use of to receive the RD/BY signal coming from the second flash, as shown in Figure 20-18

Finally, this example configuration connects the  $\overline{\text{EMA\_WE}}$  pin to the  $\overline{\text{WE}}$  input of the flash and operates the EMIFA in Normal Mode.

### 20.3.2 Software Configuration

The following sections describe how to interface the EMIFA to SDRAM, Asynchronous SRAM (ASRAM), or a NAND Flash device.

#### 20.3.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIFA to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of  $f_{\text{EMA\_CLK}} = 100 \text{ MHz}$ . Procedure A described in Section 20.2.4.5 is followed which assumes that the SDRAM power-up timing constraint were met during the SDRAM Auto-Initialization sequence after Reset.

##### 20.3.2.1.1 PLL Programming for the EMIFA to K4S641632H-TC(L)70 Interface

The device PLL Controller should first be programmed to select the desired EMA\_CLK frequency. Before doing this, the SDRAM should be placed in Self-Refresh Mode by setting the SR bit in the SDRAM configuration register (SDCR). The SR bit should be set using a byte-write to the upper byte of the SDCR to avoid triggering the SDRAM Initialization Sequence. The EMA\_CLK frequency can now be adjusted to the desired value by programming the appropriate SYSCLK domain of the PLL Controller. Once the PLL has been reprogrammed, remove the SDRAM from Self-Refresh by clearing the SR bit in SDCR, again with a byte-write.

**Table 20-26. SR Field Value For the EMIFA to K4S641632H-TC(L)70 Interface**

| Field | Value    | Purpose                                        |
|-------|----------|------------------------------------------------|
| SR    | 1 then 0 | To place the EMIFA into the self refresh state |

**Figure 20-18. Example Configuration Interface**

### 20.3.2.1.2 SDRAM Timing Register (SDTIMR) Settings for the EMIFA to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDTIMR) should be programmed first as described in [Table 20-27](#) to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h should be written to SDTIMR. [Figure 20-19](#) shows a graphical description of how SDTIMR should be programmed.

**Table 20-27. SDTIMR Field Calculations for the EMIFA to K4S641632H-TC(L)70 Interface**

| Field Name | Formula                                         | Value from K4S641632H-TC(L)70 Datasheet                        | Value Calculated for Field |
|------------|-------------------------------------------------|----------------------------------------------------------------|----------------------------|
| T_RFC      | $T\_RFC \geq (t_{RFC} \times f_{EMA\_CLK}) - 1$ | $t_{RC} = 68 \text{ ns (min)}$ <sup>(1)</sup>                  | 6                          |
| T_RP       | $T\_RP \geq (t_{RP} \times f_{EMA\_CLK}) - 1$   | $t_{RP} = 20 \text{ ns (min)}$                                 | 1                          |
| T_RCD      | $T\_RCD \geq (t_{RCD} \times f_{EMA\_CLK}) - 1$ | $t_{RCD} = 20 \text{ ns (min)}$                                | 1                          |
| T_WR       | $T\_WR \geq (t_{WR} \times f_{EMA\_CLK}) - 1$   | $t_{RDL} = 2 \text{ CLK} = 20 \text{ ns (min)}$ <sup>(2)</sup> | 1                          |
| T_RAS      | $T\_RAS \geq (t_{RAS} \times f_{EMA\_CLK}) - 1$ | $t_{RAS} = 49 \text{ ns (min)}$                                | 4                          |
| T_RC       | $T\_RC \geq (t_{RC} \times f_{EMA\_CLK}) - 1$   | $t_{RC} = 68 \text{ ns (min)}$                                 | 6                          |
| T_RRD      | $T\_RRD \geq (t_{RRD} \times f_{EMA\_CLK}) - 1$ | $t_{RRD} = 14 \text{ ns (min)}$                                | 1                          |

<sup>(1)</sup> The Samsung datasheet does not specify a  $t_{RFC}$  value. Instead, Samsung specifies  $t_{RC}$  as the minimum auto refresh period.

<sup>(2)</sup> The Samsung datasheet does not specify a  $t_{WR}$  value. Instead, Samsung specifies  $t_{RDL}$  as last data in to row precharge minimum delay.

**Figure 20-19. SDRAM Timing Register (SDTIMR)**

|        |      |      |       |          |      |    |     |    |    |
|--------|------|------|-------|----------|------|----|-----|----|----|
| 31     | 27   | 26   | 24    | 23       | 22   | 20 | 19  | 18 | 16 |

### 20.3.2.1.3 SDRAM Self Refresh Exit Timing Register (SDSRETR) Settings for the EMIFA to K4S641632H-TC(L)70 Interface

The SDRAM self refresh exit timing register (SDSRETR) should be programmed second to satisfy the  $t_{\text{XSR}}$  timing requirement from the K4S641632H-TC(L)70 datasheet. [Table 20-28](#) shows the calculation of the proper value to program into the T\_XS field of this register. Based on this calculation, a value of 6h should be written to SDSRETR. [Figure 20-20](#) shows how SDSRETR should be programmed.

**Table 20-28. RR Calculation for the EMIFA to K4S641632H-TC(L)70 Interface**

| Field Name | Formula                                                      | Value from K4S641632H-TC(L)70 Datasheet     | Value Calculated for Field |
|------------|--------------------------------------------------------------|---------------------------------------------|----------------------------|
| T_XS       | $T\_XS \geq (t_{\text{XSR}} \times f_{\text{EMA\_CLK}}) - 1$ | $t_{\text{RC}} = 68 \text{ ns (min)}^{(1)}$ | 6                          |

<sup>(1)</sup> The Samsung datasheet does not specify a  $t_{\text{XSR}}$  value. Instead, Samsung specifies  $t_{\text{RC}}$  as the minimum required time after CKE going high to complete self refresh exit.

**Figure 20-20. SDRAM Self Refresh Exit Timing Register (SDSRETR)**

### 20.3.2.1.4 SDRAM Refresh Control Register (SDRCR) Settings for the EMIFA to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRCR) should next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. [Table 20-29](#) shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah should be written to SDRCR. [Figure 20-21](#) shows how SDRCR should be programmed.

**Table 20-29. RR Calculation for the EMIFA to K4S641632H-TC(L)70 Interface**

| Field Name | Formula                                                                            | Values                                                                                                                                                   | Value Calculated for Field                      |
|------------|------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| RR         | $RR \leq f_{\text{EMA\_CLK}} \times t_{\text{Refresh Period}} / n_{\text{cycles}}$ | From SDRAM datasheet: $t_{\text{Refresh Period}} = 64 \text{ ms}$ ; $n_{\text{cycles}} = 4096$ EMIFA clock rate: $f_{\text{EMA\_CLK}} = 100 \text{ MHz}$ | $RR = 1562 \text{ cycles} = 61\text{Ah cycles}$ |

**Figure 20-21. SDRAM Refresh Control Register (SDRCR)**

### 20.3.2.1.5 SDRAM Configuration Register (SDCR) Settings for the EMIFA to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDCR) should be programmed as described in [Table 20-30](#) to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h should be written to SDCR. [Figure 20-22](#) shows how SDCR should be programmed. The EMIFA is now ready to perform read and write accesses to the SDRAM.

**Table 20-30. SDCR Field Values For the EMIFA to K4S641632H-TC(L)70 Interface**

| Field       | Value | Purpose                                                |
|-------------|-------|--------------------------------------------------------|
| SR          | 0     | To avoid placing the EMIFA into the self refresh state |
| NM          | 1     | To configure the EMIFA for a 16-bit data bus           |
| CL          | 011b  | To select a CAS latency of 3                           |
| BIT11_9LOCK | 1     | To allow the CL field to be written                    |
| IBANK       | 010b  | To select 4 internal SDRAM banks                       |
| PAGESIZE    | 0     | To select a page size of 256 words                     |

**Figure 20-22. SDRAM Configuration Register (SDCR)**

|          |          |          |          |             |
|----------|----------|----------|----------|-------------|
| 31       | 30       | 29       | 28       | 24          |

### 20.3.2.2 Interfacing to Asynchronous SRAM (ASRAM)

The following example describes how to interface the EMIFA to the Toshiba TC55V16100FT-12 device.

#### 20.3.2.2.1 Meeting AC Timing Requirements for ASRAM

When configuring the EMIFA to interface to ASRAM, you must consider the AC timing requirements of the ASRAM as well as the AC timing requirements of the EMIFA. These can be found in the data sheet for each respective device. The read and write asynchronous cycles are programmed separately in the asynchronous configuration register (CEnCFG).

For a read access, [Table 20-31](#) to [Table 20-33](#) list the AC timing specifications that must be considered.

**Table 20-31. EMIFA Input Timing Requirements**

| Parameter | Description                                    |
|-----------|------------------------------------------------|
| $t_{SU}$  | Data Setup time, data valid before EMA_OE high |
| $t_H$     | Data Hold time, data valid after EMA_OE high   |

**Table 20-32. ASRAM Output Timing Characteristics**

| Parameter | Description                              |
|-----------|------------------------------------------|
| $t_{ACC}$ | Address Access time                      |
| $t_{OH}$  | Output data Hold time for address change |
| $t_{COD}$ | Output Disable time from chip enable     |

**Table 20-33. ASRAM Input Timing Requirement for a Read**

| Parameter | Description     |
|-----------|-----------------|
| $t_{RC}$  | Read Cycle time |

[Figure 20-23](#) shows an asynchronous read access and describes how the EMIFA and ASRAM AC timing requirements work together to define the values for R\_SETUP, R\_STROBE, and R\_HOLD.

From [Figure 20-23](#), the following equations may be derived.  $t_{cyc}$  is the period at which the EMIFA operates. The R\_SETUP, R\_STROBE, and R\_HOLD fields are programmed in terms of EMIFA cycles where as the data sheet specifications are typically given in nanoseconds. This explains the presence of  $t_{cyc}$  in the denominator of the following equations. A minus 1 is included in the equations because each field in CEnCFG is programmed in terms of EMIFA clock cycles, minus 1 cycle. For example, R\_SETUP is equal to R\_SETUP width in EMIFA clock cycles minus 1 cycle.

$$R\_SETUP + R\_STROBE \geq \frac{t_{ACC}(m) + t_{SU}}{t_{cyc}} - 2$$

$$R\_SETUP + R\_STROBE + R\_HOLD \geq \frac{t_{RC}(m)}{t_{cyc}} - 3$$

$$R\_HOLD \geq \frac{(t_H - t_{OH}(m))}{t_{cyc}} - 1$$

The EMIFA offers an additional parameter, TA, that defines the turnaround time between read and write cycles. This parameter protects against the situation when the output turn-off time of the memory is longer than the time it takes to start the next write cycle. If this is the case, the EMIFA will drive data at the same time as the memory, causing contention on the bus. By examining [Figure 20-23](#), the equation for TA can be derived as:

$$TA \geq \frac{t_{\text{COD}}(m)}{t_{\text{cyc}}} - 1$$

**Figure 20-23. Timing Waveform of an ASRAM Read**

For a write access, [Table 20-34](#) lists the AC timing specifications that must be satisfied.

**Table 20-34. ASRAM Input Timing Requirements for a Write**

| Parameter       | Description                   |
|-----------------|-------------------------------|
| t <sub>WP</sub> | Write Pulse width             |
| t <sub>AW</sub> | Address valid to end of Write |
| t <sub>DS</sub> | Data Setup time               |
| t <sub>WR</sub> | Write Recovery time           |
| t <sub>DH</sub> | Data Hold time                |
| t <sub>WC</sub> | Write Cycle time              |

Figure 20-24 shows an asynchronous write access and describes how the EMIFA and ASRAM AC timing requirements work together to define values for W\_SETUP, W\_STROBE, and W\_HOLD.

From Figure 20-24, the following equations may be derived.  $t_{cyc}$  is the period at which the EMIFA operates. The W\_SETUP, W\_STROBE, and W\_HOLD fields are programmed in terms of EMIFA cycles where as the data sheet specifications are typically given in nano seconds. This explains the presence of  $t_{cyc}$  in the denominator of the following equations. A minus 1 is included in the equations because each field in CENCFG is programmed in terms of EMIFA clock cycles, minus 1 cycle. For example, W\_SETUP is equal to W\_SETUP width in EMIFA clock cycles minus 1 cycle.

$$W\_STROBE \geq \frac{t_{WP}(m)}{t_{cyc}} - 1$$

$$W\_SETUP + W\_STROBE \geq \max\left(\frac{t_{AW}(m)}{t_{cyc}}, \frac{t_{DS}(m)}{t_{cyc}}\right) - 2$$

$$W\_HOLD \geq \max\left(\frac{t_{WR}(m)}{t_{cyc}}, \frac{t_{DH}(m)}{t_{cyc}}\right) - 1$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq \frac{t_{WC}(m)}{t_{cyc}} - 3$$

**Figure 20-24. Timing Waveform of an ASRAM Write**

### 20.3.2.2.2 Taking Into Account PCB Delays

The equations described in [Section 20.3.2.2.1](#) are for the ideal case, when board design does not contribute delays. Board characteristics, such as impedance, loading, length, number of nodes, etc., affect how the device driver behaves. Signals driven by the EMIFA will be delayed when they reach the ASRAM and conversely. [Table 20-35](#) lists the delays shown in [Figure 20-25](#) and [Figure 20-26](#) due to PCB affects. The PCB delays are board specific and must be estimated or determined though the use of IBIS modeling. The signals denoted (ASRAM) are the signals seen at the ASRAM. For example,  $\overline{\text{EMA\_CS}}$  represents the signal at the EMIFA and  $\overline{\text{EMA\_CS}}$  (ASRAM) represents the delayed signal seen at the ASRAM.

**Table 20-35. ASRAM Timing Requirements With PCB Delays**

| Parameter           | Description                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------|
| <b>Read Access</b>  |                                                                                                          |
| $t_{\text{EM\_CS}}$ | Delay on $\overline{\text{EMA\_CS}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_CS}}$ is driven by EMIF. |
| $t_{\text{EM\_A}}$  | Delay on EMA_A from EMIFA to ASRAM. EMA_A is driven by EMIF.                                             |
| $t_{\text{EM\_OE}}$ | Delay on $\overline{\text{EMA\_OE}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_OE}}$ is driven by EMIF. |
| $t_{\text{EM\_D}}$  | Delay on EMA_D from ASRAM to EMIFA. EMA_D is driven by ASRAM.                                            |
| <b>Write Access</b> |                                                                                                          |
| $t_{\text{EM\_CS}}$ | Delay on $\overline{\text{EMA\_CS}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_CS}}$ is driven by EMIF. |
| $t_{\text{EM\_A}}$  | Delay on EMA_A from EMIFA to ASRAM. EMA_A is driven by EMIF.                                             |
| $t_{\text{EM\_WE}}$ | Delay on $\overline{\text{EMA\_WE}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_WE}}$ is driven by EMIF. |
| $t_{\text{EM\_D}}$  | Delay on EMA_D from EMIFA to ASRAM. EMA_D is driven by EMIF.                                             |

From [Figure 20-25](#), the following equations may be derived.  $t_{\text{cyc}}$  is the period at which the EMIFA operates. The R\_SETUP, R\_STROBE, and R\_HOLD fields are programmed in terms of EMIFA cycles where as the data sheet specifications are typically given in nano seconds. This explains the presence of  $t_{\text{cyc}}$  in the denominator of the following equations. A minus 1 is included in the equations because each field in CENCFG is programmed in terms of EMIFA clock cycles, minus 1 cycle. For example, R\_SETUP is equal to R\_SETUP width in EMIFA clock cycles minus 1 cycle.

$$\text{R\_SETUP} + \text{R\_STROBE} \geq \frac{(t_{\text{EM\_A}} + t_{\text{ACC}}(m) + t_{\text{SU}} + t_{\text{EM\_D}})}{t_{\text{cyc}}} - 2$$

$$\text{R\_SETUP} + \text{R\_STROBE} + \text{R\_HOLD} \geq \frac{t_{\text{RC}}(m)}{t_{\text{cyc}}} - 3$$

$$\text{R\_HOLD} \geq \frac{(t_{\text{H}} - t_{\text{EM\_D}} - t_{\text{OH}}(m) - t_{\text{EM\_A}})}{t_{\text{cyc}}} - 1$$

$$\text{TA} \geq \frac{(t_{\text{EM\_CS}} + t_{\text{COD}}(m) + t_{\text{EM\_D}})}{t_{\text{cyc}}} - 1$$

**Figure 20-25. Timing Waveform of an ASRAM Read with PCB Delays**

From [Figure 20-26](#), the following equations may be derived.  $t_{cyc}$  is the period at which the EMIFA operates. The  $W\_SETUP$ ,  $W\_STROBE$ , and  $W\_HOLD$  fields are programmed in terms of EMIFA cycles where as the data sheet specifications are typically given in nano seconds. This explains the presence of  $t_{cyc}$  in the denominator of the following equations. A minus 1 is included in the equations because each field in  $CE_nCFG$  is programmed in terms of EMIFA clock cycles, minus 1 cycle. For example,  $W\_SETUP$  is equal to  $W\_SETUP$  width in EMIFA clock cycles minus 1 cycle.

$$W\_STROBE \geq \frac{t_{WP}(m)}{t_{cyc}} - 1$$

$$W\_SETUP + W\_STROBE \geq \max \left( \frac{(t_{EM\_A} + t_{AW}(m) - t_{EM\_WE})}{t_{cyc}}, \frac{(t_{EM\_D} + t_{DS}(m) - t_{EM\_WE})}{t_{cyc}} \right) - 2$$

$$W\_HOLD \geq \max \left( \frac{(t_{EM\_WE} + t_{WR}(m) - t_{EM\_A})}{t_{cyc}}, \frac{(t_{EM\_WE} + t_{DH}(m) - t_{EM\_D})}{t_{cyc}} \right) - 1$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq \frac{t_{WC}(m)}{t_{cyc}} - 3$$

**Figure 20-26. Timing Waveform of an ASRAM Write with PCB Delays**

### 20.3.2.2.3 Example Using TC5516100FT-12

This section takes you through the configuration steps required to implement Toshiba's TC55V1664FT-12 ASRAM with the EMIFA. The following assumptions are made:

- ASRAM is connected to chip select space 3 ( $\overline{\text{EMA\_CS}}[3]$ )
- EMIFA clock speed is 100 MHz ( $t_{\text{cyc}} = 10 \text{ nS}$ )

Table 20-36 lists the data sheet specifications for the EMIFA and Table 20-37 lists the data sheet specifications for the ASRAM.

**Table 20-36. EMIFA Timing Requirements for TC5516100FT-12 Example**

| Parameter       | Description                                                         | Min                   | Max | Units |
|-----------------|---------------------------------------------------------------------|-----------------------|-----|-------|
| $t_{\text{SU}}$ | Data Setup time, data valid before $\overline{\text{EMA\_OE}}$ high | 3 to 7 <sup>(1)</sup> |     | nS    |
| $t_{\text{H}}$  | Data Hold time, data valid after $\overline{\text{EMA\_OE}}$ high   | 0                     |     | nS    |

<sup>(1)</sup> Depending on operating conditions. See your device-specific data manual for the value.

**Table 20-37. ASRAM Timing Requirements for TC5516100FT-12 Example**

| Parameter        | Description                              | Min | Max | Units |
|------------------|------------------------------------------|-----|-----|-------|
| $t_{\text{ACC}}$ | Address Access time                      |     | 12  | nS    |
| $t_{\text{OH}}$  | Output data Hold time for address change | 3   |     | nS    |
| $t_{\text{RC}}$  | Read cycle time                          | 12  |     | nS    |
| $t_{\text{WP}}$  | Write Pulse width                        | 8   |     | nS    |
| $t_{\text{AW}}$  | Address valid to end of Write            | 9   |     | nS    |
| $t_{\text{DS}}$  | Data Setup time                          | 7   |     | nS    |
| $t_{\text{WR}}$  | Write Recovery time                      | 0   |     | nS    |
| $t_{\text{DH}}$  | Data Hold time                           | 0   |     | nS    |
| $t_{\text{WC}}$  | Write Cycle time                         | 12  |     | nS    |
| $t_{\text{COD}}$ | Output Disable time from chip enable     |     | 7   |       |

Table 20-38 lists the values of the PCB board delays. The delays were estimated using the rule that there is 180 pS of delay for every 1 inch of trace.

**Table 20-38. Measured PCB Delays for TC5516100FT-12 Example**

| Parameter           | Description                                                                                              | Delay (ns) |
|---------------------|----------------------------------------------------------------------------------------------------------|------------|
| <b>Read Access</b>  |                                                                                                          |            |
| $t_{\text{EM\_CS}}$ | Delay on $\overline{\text{EMA\_CS}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_CS}}$ is driven by EMIF. | 0.36       |
| $t_{\text{EM\_A}}$  | Delay on $\overline{\text{EMA\_A}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_A}}$ is driven by EMIF.   | 0.27       |
| $t_{\text{EM\_OE}}$ | Delay on $\overline{\text{EMA\_OE}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_OE}}$ is driven by EMIF. | 0.36       |
| $t_{\text{EM\_D}}$  | Delay on $\overline{\text{EMA\_D}}$ from ASRAM to EMIFA. $\overline{\text{EMA\_D}}$ is driven by ASRAM.  | 0.45       |
| <b>Write Access</b> |                                                                                                          |            |
| $t_{\text{EM\_CS}}$ | Delay on $\overline{\text{EMA\_CS}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_CS}}$ is driven by EMIF. | 0.36       |
| $t_{\text{EM\_A}}$  | Delay on $\overline{\text{EMA\_A}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_A}}$ is driven by EMIF.   | 0.27       |
| $t_{\text{EM\_WE}}$ | Delay on $\overline{\text{EMA\_WE}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_WE}}$ is driven by EMIF. | 0.36       |
| $t_{\text{EM\_D}}$  | Delay on $\overline{\text{EMA\_D}}$ from EMIFA to ASRAM. $\overline{\text{EMA\_D}}$ is driven by EMIF.   | 0.45       |

Inserting these values into the equations defined above allows you to determine the values for SETUP, STROBE, HOLD, and TA. For a read:

$$R\_SETUP + R\_STROBE \geq \frac{(t_{EM\_A} + t_{ACC}(m) + t_{SU} + t_{EM\_D})}{t_{cyc}} - 2 \geq \frac{(0.27 + 12 + 5 + 0.45)}{10} - 2 \geq -0.23$$

$$R\_SETUP + R\_STROBE + R\_HOLD \geq \frac{t_{RC}(m)}{t_{cyc}} - 3 \geq \left(\frac{12}{10}\right) - 3 \geq -1.8$$

$$R\_HOLD \geq \frac{(t_H - t_{EM\_D} - t_{OH}(m) - t_{EM\_A})}{t_{cyc}} - 1 \geq \frac{(0 - 0.45 - 3 - 0.27)}{10} - 1 \geq -1.37$$

$$TA \geq \frac{(t_{EM\_CS} + T_{COD}(m) + t_{EM\_D})}{t_{cyc}} - 1 \geq \frac{(0.36 + 7 + 0.45)}{10} - 1 \geq -0.22$$

Therefore if R\_SETUP = 0, then R\_STROBE = 0, R\_HOLD = 0, and TA = 0.

For a write:

$$W\_STROBE \geq \frac{t_{WP}(m)}{t_{cyc}} - 1 \geq \left(\frac{8}{10}\right) - 1 \geq -0.2$$

$$\begin{aligned} W\_SETUP + W\_STROBE &\geq \max\left(\frac{(t_{EM\_A} + t_{AW}(m) - t_{EM\_WE})}{t_{cyc}}, \frac{(t_{EM\_D} + t_{DS}(m) - t_{EM\_WE})}{t_{cyc}}\right) - 2 \\ &\geq \max\left(\frac{(0.36 + 0 - 0.27)}{10}, \frac{(0.36 + 0 - 0.45)}{10}\right) - 2 \geq -2.01 \end{aligned}$$

$$\begin{aligned} W\_HOLD &\geq \max\left(\frac{(t_{EM\_WE} + t_{WR}(m) - t_{EM\_A})}{t_{cyc}}, \frac{(t_{EM\_WE} + t_{DH}(m) - t_{EM\_D})}{t_{cyc}}\right) - 1 \\ &\geq \max\left(\frac{(0.27 + 9 - 0.36)}{10}, \frac{(0.45 + 7 - 0.36)}{10}\right) - 1 \geq -0.1 \end{aligned}$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq \frac{t_{WC}(m)}{t_{cyc}} - 3 \geq \left(\frac{12}{10}\right) - 3 \geq -1.8$$

Therefore, W\_SETUP = 0, W\_STROBE = 0, and W\_HOLD = 0.

Since the value of the W\_SETUP/R\_SETUP, W\_STROBE/R\_STROBE, W\_HOLD/R\_HOLD, and TA fields are equal to EMIFA clock cycles minus 1 cycle, the CE3CFG should be configured as in [Table 20-39](#). In this example, the EMA\_WAIT signal is not implemented; therefore, the asynchronous wait cycle configuration register (AWCC) does not need to be programmed.

**Table 20-39. Configuring CE3CFG for TC5516100FT-12 Example**

| Parameter         | Setting                                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| SS                | <b>Select Strobe mode.</b> <ul style="list-style-type: none"> <li>SS = 0. Places EMIFA in Normal Mode.</li> </ul>                 |
| EW                | <b>Extended Wait mode enable.</b> <ul style="list-style-type: none"> <li>EW = 0. Disabled Extended wait mode.</li> </ul>          |
| W_SETUP/R_SETUP   | <b>Read/Write setup widths.</b> <ul style="list-style-type: none"> <li>W_SETUP = 0</li> <li>R_SETUP = 0</li> </ul>                |
| W_STROBE/R_STROBE | <b>Read/Write strobe widths.</b> <ul style="list-style-type: none"> <li>W_STROBE = 0</li> <li>R_STROBE = 0</li> </ul>             |
| W_HOLD/R_HOLD     | <b>Read/Write hold widths.</b> <ul style="list-style-type: none"> <li>W_HOLD = 0</li> <li>R_HOLD = 0</li> </ul>                   |
| TA                | <b>Minimum turnaround time.</b> <ul style="list-style-type: none"> <li>TA = 0</li> </ul>                                          |
| ASIZE             | <b>Asynchronous Device Bus Width.</b> <ul style="list-style-type: none"> <li>ASIZE = 1, select a 16-bit data bus width</li> </ul> |

### 20.3.2.3 Interfacing to NAND Flash

The following example explains how to interface the EMIFA to the Hynix HY27UA081G1M NAND Flash device.

#### 20.3.2.3.1 Margin Requirements

The Flash interface is typically a low-performance interface compared to synchronous memory interfaces, high-speed asynchronous memory interfaces, and high-speed FIFO interfaces. For this reason, this example gives little attention to minimizing the amount of margin required when programming the asynchronous timing parameters. The approach used requires approximately 10 ns of margin on all parameters, which is not significant for a 100-ns read or write cycle. For additional details on minimizing the amount of margin, see the ASRAM example given in [Section 20.3.2.2](#).

**Table 20-40. Recommended Margins**

| Timing Parameter | Recommended Margin |
|------------------|--------------------|
| Output Setup     | 10 nS              |
| Output Hold      | 10 nS              |
| Input Setup      | 10 nS              |
| Input Hold       | 10 nS              |

### 20.3.2.3.2 Meeting AC Timing Requirements for NAND Flash

When configuring the EMIFA to interface to NAND Flash, you must consider the AC timing requirements of the NAND Flash as well as the AC timing requirements of the EMIFA. These can be found in the data sheet for each respective device. The read and write asynchronous cycles are programmed separately in the asynchronous configuration register (CE<sub>n</sub>CFG).

A NAND Flash access cycle is composed of a command, address, and data phases. The EMIFA will not automatically generate these three phases to complete a NAND access with one transfer request. To complete a NAND access cycle, multiple single asynchronous access cycles must be completed by the EMIFA. The command and address phases of a NAND Flash access cycle are asynchronous writes performed by the EMIFA where as the data phase can be either an asynchronous write or a read depending on whether the NAND Flash is being programmed or read.

Therefore, to determine the required EMIFA configuration to interface to the NAND Flash for a read operation, [Table 20-41](#) and [Table 20-42](#) list the AC timing parameters that must be considered.

**Table 20-41. EMIFA Read Timing Requirements**

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| t <sub>SU</sub> | Data Setup time, data valid before $\overline{\text{EMA\_OE}}$ high |
| t <sub>H</sub>  | Data Hold time, data valid after $\overline{\text{EMA\_OE}}$ high   |

**Table 20-42. NAND Flash Read Timing Requirements**

| Parameter        | Description                          |
|------------------|--------------------------------------|
| t <sub>RP</sub>  | Read Pulse width                     |
| t <sub>REA</sub> | Read Enable Access time              |
| t <sub>CEA</sub> | Chip Enable low to output valid      |
| t <sub>CHZ</sub> | Chip Enable high to output High-Z    |
| t <sub>RC</sub>  | Read Cycle time                      |
| t <sub>RHZ</sub> | Read enable high to output High-Z    |
| t <sub>CLR</sub> | Command Latch low to Read enable low |

[Figure 20-27](#) shows an asynchronous read access and describes how the EMIFA and NAND Flash AC timing requirements work together to define the values for R\_SETUP, R\_STROBE, and R\_HOLD.

From Figure 20-27, the following equations may be derived.  $t_{cyc}$  is the period at which the EMIFA operates. The R\_SETUP, R\_STROBE, and R\_HOLD fields are programmed in terms of EMIFA cycles where as the data sheet specifications are typically given in nano seconds. This explains the presence of  $t_{cyc}$  in the denominator of the following equations. A minus 1 is included in the equations because each field in CEnCFG is programmed in terms of EMIFA clock cycles, minus 1 cycle. For example, R\_SETUP is equal to R\_SETUP width in EMIFA clock cycles minus 1 cycle.

$$R\_SETUP \geq \frac{t_{CLR}(m)}{t_{cyc}} - 1$$

$$R\_STROBE \geq \max\left(\frac{(t_{REA}(m) + t_{SU})}{t_{cyc}}, \frac{t_{RP}(m)}{t_{cyc}}\right) - 1$$

$$R\_SETUP + R\_STROBE \geq \frac{(t_{CEA}(m) + t_{SU})}{t_{cyc}} - 2$$

$$R\_HOLD \geq \frac{(t_H - t_{CHZ}(m))}{t_{cyc}} - 1$$

$$R\_SETUP + R\_STROBE + R\_HOLD \geq \frac{t_{RC}(m)}{t_{cyc}} - 3$$

The EMIFA offers an additional parameter, TA, that defines the turnaround time between read and write cycles. This parameter protects against the situation when the output turn-off time of the memory is longer than the time it takes to start the next write cycle. If this is the case, the EMIFA will drive data at the same time as the memory, causing contention on the bus. By examining Figure 20-27, the equation for TA can be derived as:

$$TA \geq \max\left(\frac{t_{CHZ}(m)}{t_{cyc}}, \frac{t_{RHZ}(m) - (R\_HOLD + 1)t_{cyc}}{t_{cyc}}\right) - 1$$

**Figure 20-27. Timing Waveform of a NAND Flash Read**

To determine the required EMIFA configuration to interface to the NAND Flash for a write operation, [Table 20-43](#) lists the NAND AC timing parameters for a command latch, address latch, and data input latch that must be considered.

**Table 20-43. NAND Flash Write Timing Requirements**

| Parameter | Description                |
|-----------|----------------------------|
| $t_{WP}$  | Write Pulse width          |
| $t_{CLS}$ | CLE Setup time             |
| $t_{ALS}$ | ALE Setup time             |
| $t_{CS}$  | $\overline{CS}$ Setup time |
| $t_{DS}$  | Data Setup time            |
| $t_{CLH}$ | CLE Hold time              |
| $t_{ALH}$ | ALE Hold time              |
| $t_{CH}$  | $\overline{CS}$ Hold time  |
| $t_{DH}$  | Data Hold time             |
| $t_{WC}$  | Write Cycle time           |

[Figure 20-28](#) to [Figure 20-30](#) show the command latch, address latch, and data input latch of the NAND access.

From [Figure 20-28](#) to [Figure 20-30](#), the following equations may be derived.  $t_{cyc}$  is the period at which the EMIFA operates. The W\_SETUP, W\_STROBE, and W\_HOLD fields are programmed in terms of EMIFA cycles where as the data sheet specifications are typically given in nano seconds. This explains the presence of  $t_{cyc}$  in the denominator of the following equations. A minus 1 is included in the equations because each field in CE<sub>n</sub>CFG is programmed in terms of EMIFA clock cycles, minus 1 cycle. For example, W\_SETUP is equal to W\_SETUP width in EMIFA clock cycles minus 1 cycle.

$$W\_SETUP \geq \max\left(\frac{t_{CLS}(m)}{t_{cyc}}, \frac{t_{ALS}(m)}{t_{cyc}}, \frac{t_{CS}(m)}{t_{cyc}}\right) - 1$$

$$W\_STROBE \geq \frac{t_{WP}(m)}{t_{cyc}} - 1$$

$$W\_SETUP + W\_STROBE \geq \frac{t_{DS}(m)}{t_{cyc}} - 2$$

$$W\_HOLD \geq \max\left(\frac{t_{CLH}(m)}{t_{cyc}}, \frac{t_{ALH}(m)}{t_{cyc}}, \frac{t_{CH}(m)}{t_{cyc}}, \frac{t_{DH}(m)}{t_{cyc}}\right) - 1$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq \frac{t_{WC}(m)}{t_{cyc}} - 3$$

### 20.3.2.3.3 Example Using Hynix HY27UA081G1M

This section takes you through the configuration steps required to implement Hynix's HY27UA081G1M NAND Flash with the EMIFA. The following assumptions are made:

- NAND Flash is connected to chip select space 2 ( $\overline{\text{EMA\_CS}}[2]$ )
- EMIFA clock speed is 100 MHz ( $t_{\text{cyc}} = 10 \text{ nS}$ )

Table 20-44 lists the data sheet specifications for the EMIFA and Table 20-45 lists the data sheet specifications for the NAND Flash.

**Table 20-44. EMIFA Timing Requirements for HY27UA081G1M Example**

| Parameter       | Description                                                         | Min                   | Max | Units |
|-----------------|---------------------------------------------------------------------|-----------------------|-----|-------|
| $t_{\text{SU}}$ | Data Setup time, data valid before $\overline{\text{EMA\_OE}}$ high | 3 to 7 <sup>(1)</sup> |     | nS    |
| $t_{\text{H}}$  | Data Hold time, data valid after $\overline{\text{EMA\_OE}}$ high   | 0                     |     | nS    |

<sup>(1)</sup> Depending on operating conditions. See your device-specific data manual for the value.

**Table 20-45. NAND Flash Timing Requirements for HY27UA081G1M Example**

| Parameter        | Description                          | Min | Max | Units |
|------------------|--------------------------------------|-----|-----|-------|
| $t_{\text{RP}}$  | Read Pulse width                     | 60  |     | nS    |
| $t_{\text{REA}}$ | Read Enable Access time              |     | 60  | nS    |
| $t_{\text{CEA}}$ | Chip Enable low to output valid      |     | 75  | nS    |
| $t_{\text{CHZ}}$ | Chip Enable high to output High-Z    |     | 20  | nS    |
| $t_{\text{RC}}$  | Read Cycle time                      | 80  |     | nS    |
| $t_{\text{RHZ}}$ | Read Enable high to output High-Z    |     | 30  | nS    |
| $t_{\text{CLR}}$ | Command Latch low to Read enable low | 10  |     | nS    |
| $t_{\text{WP}}$  | Write Pulse width                    | 60  |     | nS    |
| $t_{\text{CLS}}$ | CLE Setup time                       | 0   |     | nS    |
| $t_{\text{ALS}}$ | ALE Setup time                       | 0   |     | nS    |
| $t_{\text{CS}}$  | $\overline{\text{CS}}$ Setup time    | 0   |     | nS    |
| $t_{\text{DS}}$  | Data Setup time                      | 20  |     | nS    |
| $t_{\text{CLH}}$ | CLE Hold time                        | 10  |     | nS    |
| $t_{\text{ALH}}$ | ALE Hold time                        | 10  |     | nS    |
| $t_{\text{CH}}$  | $\overline{\text{CS}}$ Hold time     | 10  |     | nS    |
| $t_{\text{DH}}$  | Data Hold time                       | 10  |     | nS    |
| $t_{\text{WC}}$  | Write Cycle time                     | 80  |     | nS    |

Inserting these values into the equations defined above allows you to determine the values for SETUP, STROBE, HOLD, and TA. For a read:

$$R\_SETUP \geq \frac{t_{CLR(m)}}{t_{cyc}} - 1 \geq \left(\frac{10}{10}\right) - 1 \geq 0$$

$$R\_STROBE \geq \max\left(\frac{(t_{REA(m)} + t_{SU})}{t_{cyc}}, \frac{t_{RP}}{t_{cyc}}\right) - 1 \geq \left(\frac{65}{10}\right) - 1 \geq 5.5$$

$$R\_SETUP + R\_STROBE \geq \frac{(t_{CEA} + t_{SU})}{t_{cyc}} - 2 \geq \frac{(75 + 5)}{10} - 2 \geq 6$$

$$R\_HOLD \geq \frac{(t_H - t_{CHZ(m)})}{t_{cyc}} - 1 \geq \frac{(0 - 20)}{10} - 1 \geq -3$$

$$R\_SETUP + R\_STROBE + R\_HOLD \geq \frac{t_{RC(m)}}{t_{cyc}} - 3 \geq \left(\frac{80}{10}\right) - 3 \geq 5$$

Therefore with a 10 nS margin added in,  $R\_SETUP \geq 1.0$ ,  $R\_STROBE \geq 6.5$ , and  $R\_HOLD \geq 0$ .

After solving for  $R\_HOLD$ , TA may be calculated:

$$TA \geq \max\left(\frac{t_{CHZ(m)}}{t_{cyc}}, \frac{t_{RHZ(m)} - (R\_HOLD + 1)t_{cyc}}{t_{cyc}}\right) - 1 \geq \left(\frac{20}{10}\right) - 1 \geq 1$$

Adding a 10 ns margin,  $TA \geq 2$ .

For a write:

$$W\_STROBE \geq \frac{t_{WP(m)}}{t_{cyc}} - 1 \geq \left(\frac{60}{10}\right) - 1 \geq 5$$

$$W\_SETUP \geq \max\left(\frac{t_{CLS(m)}}{t_{cyc}}, \frac{t_{ALS(m)}}{t_{cyc}}, \frac{t_{CS(m)}}{t_{cyc}}\right) - 1 \geq \left(\frac{0}{10}\right) - 1 \geq -1$$

$$W\_SETUP + W\_STROBE \geq \frac{t_{DS(m)}}{t_{cyc}} - 2 \geq \frac{20}{10} - 2 \geq 0$$

$$W\_HOLD \geq \max\left(\frac{t_{CLH(m)}}{t_{cyc}}, \frac{t_{ALH(m)}}{t_{cyc}}, \frac{t_{CH(m)}}{t_{cyc}}, \frac{t_{DH(m)}}{t_{cyc}}\right) - 1 \geq \left(\frac{10}{10}\right) - 1 \geq 0$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq \frac{t_{WC(m)}}{t_{cyc}} - 3 \geq \left(\frac{80}{10}\right) - 3 \geq 5$$

Therefore with a 10 nS margin added in,  $W\_SETUP \geq 0$ ,  $W\_STROBE \geq 6$ , and  $W\_HOLD \geq 1$ .

Since the value of the W\_SETUP/R\_SETUP, W\_STROBE/R\_STROBE, W\_HOLD/R\_HOLD, and TA fields are equal to EMIFA clock cycles minus 1 cycle, the CE2CFG should be configured as in [Table 20-46](#). In this example, although the EMA\_WAIT signal is connected to the R/B signal of the NAND Flash the Extended Wait mode of the EMIFA is not used, therefore the asynchronous wait cycle configuration register (AWCC) does not need to be programmed.

**Table 20-46. Configuring CE2CFG for HY27UA081G1M Example**

| Parameter         | Setting                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| SS                | <b>Select Strobe mode.</b> <ul style="list-style-type: none"> <li>SS = 0. Places EMIFA in Normal Mode.</li> </ul>                  |
| EW                | <b>Extended Wait mode enable.</b> <ul style="list-style-type: none"> <li>EW = 0. Disabled Extended wait mode.</li> </ul>           |
| W_SETUP/R_SETUP   | <b>Read/Write setup widths.</b> <ul style="list-style-type: none"> <li>W_SETUP = 0</li> <li>R_SETUP = 2</li> </ul>                 |
| W_STROBE/R_STROBE | <b>Read/Write strobe widths.</b> <ul style="list-style-type: none"> <li>W_STROBE = 6</li> <li>R_STROBE = 7</li> </ul>              |
| W_HOLD/R_HOLD     | <b>Read/Write hold widths.</b> <ul style="list-style-type: none"> <li>W_HOLD = 1</li> <li>R_HOLD = 0</li> </ul>                    |
| TA                | <b>Minimum turnaround time.</b> <ul style="list-style-type: none"> <li>TA = 2</li> </ul>                                           |
| ASIZE             | <b>Asynchronous device bus width.</b> <ul style="list-style-type: none"> <li>ASIZE = 0, select an 8-bit data bus width.</li> </ul> |

Since this is a NAND Flash example, the EMIFA must be configured for NAND Flash mode. This is accomplished by configuring the NAND Flash control register (NANDFCR) as in [Table 20-47](#). In NANDFCR, chip select space 2 must be configured with NAND Flash mode enabled.

**Table 20-47. Configuring NANDFCR for HY27UA081G1M Example**

| Parameter | Setting                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CS5ECC    | <b>NAND Flash ECC start for chip select 5.</b> <ul style="list-style-type: none"> <li>CS5ECC = 0. Not set during configuration. Only set just prior to reading or writing data.</li> </ul> |
| CS4ECC    | <b>NAND Flash ECC start for chip select 4.</b> <ul style="list-style-type: none"> <li>CS4ECC = 0. Not set during configuration. Only set just prior to reading or writing data.</li> </ul> |
| CS3ECC    | <b>NAND Flash ECC start for chip select 3.</b> <ul style="list-style-type: none"> <li>CS3ECC = 0. Not set during configuration. Only set just prior to reading or writing data.</li> </ul> |
| CS2ECC    | <b>NAND Flash ECC start for chip select 2.</b> <ul style="list-style-type: none"> <li>CS2ECC = 0. Not set during configuration. Only set just prior to reading or writing data.</li> </ul> |
| CS5NAND   | <b>NAND Flash mode for chip select 5.</b> <ul style="list-style-type: none"> <li>CS5NAND = 0. NAND Flash mode is disabled.</li> </ul>                                                      |
| CS4NAND   | <b>NAND Flash mode for chip select 4.</b> <ul style="list-style-type: none"> <li>CS4NAND = 0. NAND Flash mode is disabled.</li> </ul>                                                      |
| CS3NAND   | <b>NAND Flash mode for chip select 3.</b> <ul style="list-style-type: none"> <li>CS3NAND = 0. NAND Flash mode is disabled.</li> </ul>                                                      |
| CS2NAND   | <b>NAND Flash mode for chip select 2.</b> <ul style="list-style-type: none"> <li>CS5NAND = 1. NAND Flash mode is enabled.</li> </ul>                                                       |

## 20.4 Registers

The external memory interface (EMIFA) is controlled by programming its internal memory-mapped registers (MMRs). [Table 20-48](#) lists the memory-mapped registers for the EMIFA.

**NOTE:** All EMIFA MMRs, except SDCR, support only word (32-bit) accesses. Performing a byte (8-bit) or halfword (16-bit) write to these registers results in undefined behavior. The SDCR is byte writable to allow the setting of the SR, PD and PDWR bits without triggering the SDRAM initialization sequence.

The EMIFA registers must always be accessed using 32-bit accesses (unless otherwise specified in this chapter). For the base address of the memory-mapped registers of EMIFA, see your device-specific data manual.

**Table 20-48. External Memory Interface (EMIFA) Registers**

| Offset | Acronym         | Register Description                           | Section                         |

### 20.4.1 Module ID Register (MIDR)

This is a read-only register indicating the module ID of the EMIFA. The MIDR is shown in [Figure 20-31](#) and described in [Table 20-49](#).

**Figure 20-31. Module ID Register (MIDR)**

LEGEND: R = Read only; -n = value after reset

**Table 20-49. Module ID Register (MIDR) Field Descriptions**

| Bit  | Field | Value      | Description         |
|------|-------|------------|---------------------|
| 31-0 | REV   | 4000 0205h | Module ID of EMIFA. |

### 20.4.2 Asynchronous Wait Cycle Configuration Register (AWCC)

The asynchronous wait cycle configuration register (AWCC) is used to configure the parameters for extended wait cycles. Both the polarity of the EMA\_WAIT pin(s) and the maximum allowable number of extended wait cycles can be configured. The AWCC is shown in [Figure 20-32](#) and described in [Table 20-50](#). Not all devices support both EMA\_WAIT[1] and EMA\_WAIT[0], see the device-specific data manual to determine support on each device.

**NOTE:** The EW bit in the asynchronous *n* configuration register (CE<sub>n</sub>CFG) must be set to allow for the insertion of extended wait cycles.

**Figure 20-32. Asynchronous Wait Cycle Configuration Register (AWCCR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 20-50. Asynchronous Wait Cycle Configuration Register (AWCCR) Field Descriptions**

| Bit   | Field        | Value                    | Description                                                                                                                                                                                                                                                                               |

| 15-8  | Reserved     | 0                        | Reserved                                                                                                                                                                                                                                                                                  |
| 7-0   | MAX_EXT_WAIT | 0-FFh                    | Maximum extended wait cycles. The EMIFA will wait for a maximum of (MAX_EXT_WAIT + 1) × 16 clock cycles before it stops inserting asynchronous wait cycles and proceeds to the hold period of the access.                                                                                 |

### 20.4.3 SDRAM Configuration Register (SDCR)

The SDRAM configuration register (SDCR) is used to configure various parameters of the SDRAM controller such as the number of internal banks, the internal page size, and the CAS latency to match those of the attached SDRAM device. In addition, this register is used to put the attached SDRAM device into Self-Refresh mode. The SDCR is shown in [Figure 20-33](#) and described in [Table 20-51](#).

**NOTE:** Writing to the lower three bytes of this register will cause the EMIFA to start the SDRAM initialization sequence described in [Section 20.2.4.4](#).

**Figure 20-33. SDRAM Configuration Register (SDCR)**

A. The NM bit must be set to 1 if the EMIFA on your device only has 16 data bus pins.

**Table 20-51. SDRAM Configuration Register (SDCR) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | SR       | 0<br>1 | Self-Refresh mode bit. This bit controls entering and exiting of the Self-Refresh mode described in <a href="#">Section 20.2.4.7</a> . The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence.<br>Writing a 0 to this bit will cause connected SDRAM devices and the EMIFA to exit the Self-Refresh mode.<br>Writing a 1 to this bit will cause connected SDRAM devices and the EMIFA to enter the Self-Refresh mode.          |
| 30    | PD       | 0<br>1 | Power Down bit. This bit controls entering and exiting of the power-down mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. If both SR and PD bits are set, the EMIFA will go into Self Refresh.<br>Writing a 0 to this bit will cause connected SDRAM devices and the EMIFA to exit the power-down mode.<br>Writing a 1 to this bit will cause connected SDRAM devices and the EMIFA to enter the power-down mode. |
| 29    | PDWR     |        | Perform refreshes during power down. Writing a 1 to this bit will cause EMIFA to exit power-down state and issue and AUTO REFRESH command every time Refresh May level is set.                                                                                                                                                                                                                                                                                                                         |
| 28-15 | Reserved | 0      | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                                                                                                                |
| 14    | NM       | 0<br>1 | Narrow mode bit. This bit defines whether a 16- or 32-bit-wide SDRAM is connected to the EMIFA. This bit field must always be set to 1. Writing to this field triggers the SDRAM initialization sequence.<br>32-bit SDRAM data bus is used.<br>16-bit SDRAM data bus is used.                                                                                                                                                                                                                          |
| 13-12 | Reserved | 0      | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                                                                                                                |

**Table 20-51. SDRAM Configuration Register (SDCR) Field Descriptions (continued)**

| Bit  | Field       | Value  | Description                                                                                                                                                                                                                                                                                  |
|------|-------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11-9 | CL          | 0-7h   | CAS Latency. This field defines the CAS latency to be used when accessing connected SDRAM devices. A 1 must be simultaneously written to the BIT11_9LOCK bit field of this register in order to write to the CL bit field. Writing to this field triggers the SDRAM initialization sequence. |
|      |             | 0-1h   | Reserved                                                                                                                                                                                                                                                                                     |
|      |             | 2h     | CAS latency = 2 EMA_CLK cycles                                                                                                                                                                                                                                                               |

### 20.4.4 SDRAM Refresh Control Register (SDRCR)

The SDRAM refresh control register (SDRCR) is used to configure the rate at which connected SDRAM devices will be automatically refreshed by the EMIFA. Refer to [Section 20.2.4.6](#) on the refresh controller for more details. The SDRCR is shown in [Figure 20-34](#) and described in [Table 20-52](#).

**Figure 20-34. SDRAM Refresh Control Register (SDRCR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 20-52. SDRAM Refresh Control Register (SDRCR) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                           |
|-------|----------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                               |
| 12-0  | RR       | 0-1FFFh | Refresh Rate. This field is used to define the SDRAM refresh period in terms of EMA_CLK cycles. Writing a value < 0x0020 to this field will cause it to be loaded with (2 × T_RFC) + 1 value from the SDRAM timing register (SDTIMR). |

## 20.4.5 Asynchronous *n* Configuration Registers (CE2CFG-CE5CFG)

The asynchronous *n* configuration registers (CE2CFG, CE3CFG, CE4CFG, and CE5CFG) are used to configure the shaping of the address and control signals during an access to asynchronous memory connected to CS2, CS3, CS4, and CS5, respectively. It is also used to program the width of asynchronous interface and to select from various modes of operation. This register can be written prior to any transfer, and any asynchronous transfer following the write will use the new configuration. The CEnCFG is shown in Figure 20-35 and described in Table 20-53.

**Figure 20-35. Asynchronous *n* Configuration Register (CEnCFG)**

|                         |                         |         |        |                         |       |
|-------------------------|-------------------------|---------|--------|-------------------------|-------|

| R/W-Fh                  | R/W-3Fh                 |         | R/W-7h | R/W-3h                  | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

A. The EW bit must be cleared to 0 when operating in NAND Flash mode.

B. This bit field must be cleared to 0 if the EMIFA on your device does not have an EMA\_WAIT pin.

**Table 20-53. Asynchronous *n* Configuration Register (CEnCFG) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | SS       | 0<br>1 | Select Strobe bit. This bit defines whether the asynchronous interface operates in Normal Mode or Select Strobe Mode. See <a href="#">Section 20.2.5</a> for details on the two modes of operation.<br>Normal Mode enabled.<br>Select Strobe Mode enabled.                                                                                                                                                                                                                                                          |
| 30    | EW       | 0<br>1 | Extend Wait bit. This bit defines whether extended wait cycles will be enabled. See <a href="#">Section 20.2.5.7</a> on extended wait cycles for details. This bit field must be cleared to 0, if the EMIFA on your device does not have an EMA_WAIT pin. The CS <sub><i>n</i></sub> _WAIT bit in the asynchronous wait cycle configuration register (AWCC) must also be configured to determine which EMA_WAIT pin is used for memory accesses.<br>Extended wait cycles disabled.<br>Extended wait cycles enabled. |
| 29-26 | W_SETUP  | 0-Fh   | Write setup width in the format <i>n</i> - 1, where <i>n</i> = number of EMA_CLK cycles. **Table 20-53. Asynchronous  $n$  Configuration Register (CE $n$ CFG) Field Descriptions (continued)**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12-7 | R_STROBE | 0-3Fh | Read strobe width in the format $n - 1$ , where $n$ = number of EMA_CLK cycles. See <a href="#">Section 20.2.5.3</a> for details.<br>0h = Divide-by-1<br>1h = Divide-by-2<br>...<br>2h – 3Fh = Divide-by-3 to Divide-by-64 |
| 6-4  | R_HOLD   | 0-7h  | Read hold width in the format $n - 1$ , where $n$ = number of EMA_CLK cycles. See <a href="#">Section 20.2.5.3</a> for details.<br>0h = Divide-by-1<br>1h = Divide-by-2<br>...<br>2h – 7h = Divide-by-3 to Divide-by-8     |
| 3-2  | TA       | 0-3h  | Minimum Turn-Around time. This field defines the minimum number of EMA_CLK cycles between reads and writes, minus one cycle. See <a href="#">Section 20.2.5.3</a> for details.                                             |
| 1-0  | ASIZE    | 0-3h  | Asynchronous Data Bus Width. This field defines the width of the asynchronous device's data bus.                                                                                                                           |
|      |          | 0     | 8-bit data bus                                                                                                                                                                                                             |
|      |          | 1h    | 16-bit data bus                                                                                                                                                                                                            |
|      |          | 2h-3h | Reserved                                                                                                                                                                                                                   |

## 20.4.6 SDRAM Timing Register (SDTIMR)

The SDRAM timing register (SDTIMR) is used to program many of the SDRAM timing parameters. Consult the SDRAM datasheet for information on the appropriate values to program into each field. The SDTIMR is shown in [Figure 20-36](#) and described in [Table 20-54](#).

**Figure 20-36. SDRAM Timing Register (SDTIMR)**

|        |    |    |        |    |      |        |    |          |        |

**Table 20-54. SDRAM Timing Register (SDTIMR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                 |
|-------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | T_RFC    | 0-1Fh | Specifies the Trfc value of the SDRAM. This defines the minimum number of EMA_CLK cycles from Refresh (REFR) to Refresh (REFR), minus 1:<br>$T\_RFC = (Trfc/t_{EMA\_CLK}) - 1$                              |
| 26-24 | T_RP     | 0-7h  | Specifies the Trp value of the SDRAM. This defines the minimum number of EMA_CLK cycles from Precharge (PRE) to Activate (ACTV) or Refresh (REFR) command, minus 1:<br>$T\_RP = (Trp/t_{EMA\_CLK}) - 1$     |
| 23    | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                     |
| 22-20 | T_RCD    | 0-7h  | Specifies the Trcd value of the SDRAM. This defines the minimum number of EMA_CLK cycles from Active (ACTV) to Read (READ) or Write (WRT), minus 1:<br>$T\_RCD = (Trcd/t_{EMA\_CLK}) - 1$                   |
| 19    | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                     |
| 18-16 | T_WR     | 0-7h  | Specifies the Twr value of the SDRAM. This defines the minimum number of EMA_CLK cycles from last Write (WRT) to Precharge (PRE), minus 1:<br>$T\_WR = (Twr/t_{EMA\_CLK}) - 1$                              |
| 15-12 | T_RAS    | 0-Fh  | Specifies the Tras value of the SDRAM. This defines the minimum number of EMA_CLK clock cycles from Activate (ACTV) to Precharge (PRE), minus 1:<br>$T\_RAS = (Tras/t_{EMA\_CLK}) - 1$                      |
| 11-8  | T_RC     | 0-Fh  | Specifies the Trc value of the SDRAM. This defines the minimum number of EMA_CLK clock cycles from Activate (ACTV) to Activate (ACTV), minus 1:<br>$T\_RC = (Trc/t_{EMA\_CLK}) - 1$                         |
| 7     | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                     |
| 6-4   | T_RRD    | 0-7h  | Specifies the Trrd value of the SDRAM. This defines the minimum number of EMA_CLK clock cycles from Activate (ACTV) to Activate (ACTV) for a different bank, minus 1:<br>$T\_RRD = (Trrd/t_{EMA\_CLK}) - 1$ |
| 3-0   | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                     |

### 20.4.7 SDRAM Self Refresh Exit Timing Register (SDSRETR)

The SDRAM self refresh exit timing register (SDSRETR) is used to program the amount of time between when the SDRAM exits Self-Refresh mode and when the EMIFA issues another command. The SDSRETR is shown in [Figure 20-37](#) and described in [Table 20-55](#).

**Figure 20-37. SDRAM Self Refresh Exit Timing Register (SDSRETR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 20-55. SDRAM Self Refresh Exit Timing Register (SDSRETR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5 | Reserved | 0     | Reserved. The reserved bit location is always read as 0.                                                                                            |
| 4-0  | T_XS     | 0-1Fh | This field specifies the minimum number of ECLKOUT cycles from Self-Refresh exit to any command, minus one.<br>$T\_XS = T_{Xsr} / t_{EMA\_CLK} - 1$ |

### 20.4.8 EMIFA Interrupt Raw Register (INTRAW)

The EMIFA interrupt raw register (INTRAW) is used to monitor and clear the EMIFA's hardware-generated Asynchronous Timeout Interrupt. The AT bit in this register will be set when an Asynchronous Timeout occurs regardless of the status of the EMIFA interrupt mask set register (INTMSKSET) and EMIFA interrupt mask clear register (INTMSKCLR). Writing a 1 to this bit will clear it. The EMIFA on some devices does not have the EMA\_WAIT pin; therefore, these registers and fields are reserved on those devices. The INTRAW is shown in [Figure 20-38](#) and described in [Table 20-56](#).

**Figure 20-38. EMIFA Interrupt Raw Register (INTRAW)**

|     |          |  |  |  |  |  |         |   |         |   |         |  |   |
|-----|----------|--|--|--|--|--|---------|---|---------|---|---------|--|---|
| 31  | Reserved |  |  |  |  |  |         |   |         |   |         |  | 8 |
| R-0 |          |  |  |  |  |  |         |   |         |   |         |  |   |
| 7   | Reserved |  |  |  |  |  | 3       | 2 | 1       | 0 |         |  |   |
| R-0 |          |  |  |  |  |  | WR      |   | LT      |   | AT      |  |   |
| R-0 |          |  |  |  |  |  | R/W1C-0 |   | R/W1C-0 |   | R/W1C-0 |  |   |

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing 0 has no effect); -n = value after reset

**Table 20-56. EMIFA Interrupt Raw Register (INTRAW) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                   |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                       |
| 2    | WR       | 0     | Wait Rise. This bit is set to 1 by hardware to indicate that a rising edge on the EMA_WAIT pin has occurred.                                                                                                                                                                                  |
|      |          | 0     | Indicates that a rising edge has not occurred on the EMA_WAIT pin. Writing a 0 has no effect.                                                                                                                                                                                                 |
|      |          | 1     | Indicates that a rising edge has occurred on the EMA_WAIT pin. Writing a 1 will clear this bit and the WR_MASKED bit in the EMIFA interrupt masked register (INTMSK).                                                                                                                         |
| 1    | LT       | 0     | Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size.                                                                                                                                                                                            |
|      |          | 0     | Writing a 0 has no effect.                                                                                                                                                                                                                                                                    |
|      |          | 1     | Indicates that a line trap has occurred. Writing a 1 will clear this bit as well as the LT_MASKED bit in the EMIFA interrupt masked register (INTMSK).                                                                                                                                        |
| 0    | AT       | 0     | Asynchronous Timeout. This bit is set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMA_WAIT pin did not go inactive within the number of cycles defined by the MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC). |
|      |          | 0     | Indicates that an Asynchronous Timeout has not occurred. Writing a 0 has no effect.                                                                                                                                                                                                           |
|      |          | 1     | Indicates that an Asynchronous Timeout has occurred. Writing a 1 will clear this bit as well as the AT_MASKED bit in the EMIFA interrupt masked register (INTMSK).                                                                                                                            |

### 20.4.9 EMIFA Interrupt Masked Register (INTMSK)

Like the EMIFA interrupt raw register (INTRAW), the EMIFA interrupt masked register (INTMSK) is used to monitor and clear the status of the EMIFA's hardware-generated Asynchronous Timeout Interrupt. The main difference between the two registers is that when the AT\_MASKED bit in this register is set, an active-high pulse will be sent to the CPU interrupt controller. Also, the AT\_MASKED bit field in INTMSK is only set to 1 if the associated interrupt has been enabled in the EMIFA interrupt mask set register (INTMSKSET). The EMIFA on some devices does not have the EMA\_WAIT pin, therefore, these registers and fields are reserved on those devices. The INTMSK is shown in [Figure 20-39](#) and described in [Table 20-57](#).

**Figure 20-39. EMIFA Interrupt Mask Register (INTMSK)**

**Table 20-57. EMIFA Interrupt Mask Register (INTMSK) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|------|-----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved  | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                  |
| 2    | WR_MASKED | 0     | Wait Rise Masked. This bit is set to 1 by hardware to indicate a rising edge has occurred on the EMA_WAIT pin, provided that the WR_MASK_SET bit is set to 1 in the EMIFA interrupt mask set register (INTMSKSET).                                                                                                                                                                                       |
|      |           | 1     | Indicates that a wait rise interrupt has not been generated. Writing a 0 has no effect.                                                                                                                                                                                                                                                                                                                  |
|      |           | 1     | Indicates that a wait rise interrupt has been generated. Writing a 1 will clear this bit and the WR bit in the EMIFA interrupt raw register (INTRAW).                                                                                                                                                                                                                                                    |
| 1    | LT_MASKED | 0     | Masked Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size, only if the LT_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET) is set to 1.                                                                                                                                                                                                  |
|      |           | 1     | Writing a 0 has no effect.                                                                                                                                                                                                                                                                                                                                                                               |
|      |           | 1     | Writing a 1 will clear this bit as well as the LT bit in the EMIFA interrupt raw register (INTRAW).                                                                                                                                                                                                                                                                                                      |
| 0    | AT_MASKED | 0     | Asynchronous Timeout Masked. This bit is set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMA_WAIT pin did not go inactive within the number of cycles defined by the MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC), provided that the AT_MASK_SET bit is set to 1 in the EMIFA interrupt mask set register (INTMSKSET). |
|      |           | 1     | Indicates that an Asynchronous Timeout Interrupt has not been generated. Writing a 0 has no effect.                                                                                                                                                                                                                                                                                                      |
|      |           | 1     | Indicates that an Asynchronous Timeout Interrupt has been generated. Writing a 1 will clear this bit as well as the AT bit in the EMIFA interrupt raw register (INTRAW).                                                                                                                                                                                                                                 |

## 20.4.10 EMIFA Interrupt Mask Set Register (INTMSKSET)

The EMIFA interrupt mask set register (INTMSKSET) is used to enable the Asynchronous Timeout Interrupt. If read as 1, the AT\_MASKED bit in the EMIFA interrupt masked register (INTMSK) will be set and an interrupt will be generated when an Asynchronous Timeout occurs. If read as 0, the AT\_MASKED bit will always read 0 and no interrupt will be generated when an Asynchronous Timeout occurs. Writing a 1 to the AT\_MASK\_SET bit enables the Asynchronous Timeout Interrupt. The EMIFA on some devices does not have the EMA\_WAIT pin; therefore, these registers and fields are reserved on those devices. The INTMSKSET is shown in [Figure 20-40](#) and described in [Table 20-58](#).

**Figure 20-40. EMIFA Interrupt Mask Set Register (INTMSKSET)**

| 31-3 | Reserved    | 0      | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2    | WR_MASK_SET | 0<br>1 | Wait Rise Mask Set. This bit determines whether or not the wait rise Interrupt is enabled. Writing a 1 to this bit sets this bit, sets the WR_MASK_CLR bit in the EMIFA interrupt mask clear register (INTMSKCLR), and enables the wait rise interrupt. To clear this bit, a 1 must be written to the WR_MASK_CLR bit in INTMSKCLR.<br><br>0 Indicates that the wait rise interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the wait rise interrupt is enabled. Writing a 1 sets this bit and the WR_MASK_CLR bit in the EMIFA interrupt mask clear register (INTMSKCLR).                                                                                                  |
| 1    | LT_MASK_SET | 0<br>1 | Mask set for LT_MASKED bit in the EMIFA interrupt mask register (INTMSK).<br><br>0 Indicates that the line trap interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the line trap interrupt is enabled. Writing a 1 sets this bit and the LT_MASK_CLR bit in the EMIFA interrupt mask clear register (INTMSKCLR).                                                                                                                                                                                                                                                                                                                                                            |
| 0    | AT_MASK_SET | 0<br>1 | Asynchronous Timeout Mask Set. This bit determines whether or not the Asynchronous Timeout Interrupt is enabled. Writing a 1 to this bit sets this bit, sets the AT_MASK_CLR bit in the EMIFA interrupt mask clear register (INTMSKCLR), and enables the Asynchronous Timeout Interrupt. To clear this bit, a 1 must be written to the AT_MASK_CLR bit of the EMIFA interrupt mask clear register (INTMSKCLR).<br><br>0 Indicates that the Asynchronous Timeout Interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the Asynchronous Timeout Interrupt is enabled. Writing a 1 sets this bit and the AT_MASK_CLR bit in the EMIFA interrupt mask clear register (INTMSKCLR). |

### 20.4.11 EMIFA Interrupt Mask Clear Register (INTMSKCLR)

The EMIFA interrupt mask clear register (INTMSKCLR) is used to disable the Asynchronous Timeout Interrupt. If read as 1, the AT\_MASKED bit in the EMIFA interrupt masked register (INTMSK) will be set and an interrupt will be generated when an Asynchronous Timeout occurs. If read as 0, the AT\_MASKED bit will always read 0 and no interrupt will be generated when an Asynchronous Timeout occurs. Writing a 1 to the AT\_MASK\_CLR bit disables the Asynchronous Timeout Interrupt. The EMIFA on some devices does not have the EMA\_WAIT pin, therefore, these registers and fields are reserved on those devices. The INTMSKCLR is shown in [Figure 20-41](#) and described in [Table 20-59](#).

**Table 20-59. EMIFA Interrupt Mask Clear Register (INTMSKCLR) Field Descriptions**

| Bit  | Field       | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved    | 0      | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2    | WR_MASK_CLR | 0<br>1 | Wait Rise Mask Clear. This bit determines whether or not the wait rise interrupt is enabled. Writing a 1 to this bit clears this bit, clears the WR_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET), and disables the wait rise interrupt. To set this bit, a 1 must be written to the WR_MASK_SET bit in INTMSKSET.<br><br>0 Indicates that the wait rise interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the wait rise interrupt is enabled. Writing a 1 clears this bit and the WR_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET).                                                                                                |
| 1    | LT_MASK_CLR | 0<br>1 | Line trap Mask Clear. This bit determines whether or not the line trap interrupt is enabled. Writing a 1 to this bit clears this bit, clears the LT_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET), and disables the line trap interrupt. To set this bit, a 1 must be written to the LT_MASK_SET bit in INTMSKSET.<br><br>0 Indicates that the line trap interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the line trap interrupt is enabled. Writing a 1 clears this bit and the LT_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET).                                                                                                |
| 0    | AT_MASK_CLR | 0<br>1 | Asynchronous Timeout Mask Clear. This bit determines whether or not the Asynchronous Timeout Interrupt is enabled. Writing a 1 to this bit clears this bit, clears the AT_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET), and disables the Asynchronous Timeout Interrupt. To set this bit, a 1 must be written to the AT_MASK_SET bit of the EMIFA interrupt mask set register (INTMSKSET).<br><br>0 Indicates that the Asynchronous Timeout Interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the Asynchronous Timeout Interrupt is enabled. Writing a 1 clears this bit and the AT_MASK_SET bit in the EMIFA interrupt mask set register (INTMSKSET). |

## 20.4.12 NAND Flash Control Register (NANDFCR)

The NAND Flash control register (NANDFCR) is shown in [Figure 20-42](#) and described in [Table 20-60](#).

**Figure 20-42. NAND Flash Control Register (NANDFCR)**

**Table 20-60. NAND Flash Control Register (NANDFCR) Field Descriptions**

| Bit   | Field                  | Value | Description                                                                                                                                                                                                                                                                  |
|-------|------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-14 | Reserved               | 0     | Reserved                                                                                                                                                                                                                                                                     |
| 13    | 4BITECC_ADD_CALC_START | 1     | NAND Flash 4-bit ECC address and error value calculation Start. Set to 1 to start 4_bit ECC error address and error value calculation on read syndrome. This bit is cleared when any of the NAND Flash error address registers or NAND Flash error value registers are read. |
| 12    | 4BITECC_START          | 1     | start 4_bit ECC error address and error value calculation on read syndrome.                                                                                                                                                                                                  |
| 12    | 4BITECC_START          | 1     | Nand Flash 4-bit ECC start for the selected chip select. Set to 1 to start 4_bit ECC calculation on data for NAND Flash on chip select selected by bit 4BITECCSEL. This bit is cleared when ay of the NAND Flash 4_bit ECC registers are read.                               |
| 12    | 4BITECC_START          | 1     | start 4_bit ECC calculation on data for NAND Flash on chip select selected by bit 4BITECCSEL.                                                                                                                                                                                |
| 11    | CS5ECC                 | 0     | NAND Flash ECC start for chip select 5. Set to 1 to start 1_bit ECC calculation on data for NAND Flash for this chip select. This bit is cleared when CS5 1_bit ECC register is read.                                                                                        |
| 11    | CS5ECC                 | 0     | Do not start ECC calculation.                                                                                                                                                                                                                                                |
| 11    | CS5ECC                 | 1     | Start ECC calculation on data for NAND Flash on $\overline{\text{EMA\_CS5}}$ .                                                                                                                                                                                               |
| 10    | CS4ECC                 | 0     | NAND Flash ECC start for chip select 4. Set to 1 to start 1_bit ECC calculation on data for NAND Flash for this chip select. This bit is cleared when CS4 1_bit ECC register is read.                                                                                        |
| 10    | CS4ECC                 | 0     | Do not start ECC calculation.                                                                                                                                                                                                                                                |
| 10    | CS4ECC                 | 1     | Start ECC calculation on data for NAND Flash on $\overline{\text{EMA\_CS4}}$ .                                                                                                                                                                                               |
| 9     | CS3ECC                 | 0     | NAND Flash ECC start for chip select 3. Set to 1 to start 1_bit ECC calculation on data for NAND Flash for this chip select. This bit is cleared when CS3 1_bit ECC register is read.                                                                                        |
| 9     | CS3ECC                 | 0     | Do not start ECC calculation.                                                                                                                                                                                                                                                |
| 9     | CS3ECC                 | 1     | Start ECC calculation on data for NAND Flash on $\overline{\text{EMA\_CS3}}$ .                                                                                                                                                                                               |
| 8     | CS2ECC                 | 0     | NAND Flash ECC start for chip select 2. This bit is cleared when CS2 1_bit ECC register is read.                                                                                                                                                                             |

Not all devices support both EMA_WAIT[1] and EMA_WAIT[0], see the device-specific data manual to determine support on each device. The WPn bit in the asynchronous wait cycle configuration register (AWCC) has no effect on WAITST.<br>EMA_WAIT[n] pin is low.<br>EMA_WAIT[n] pin is high.                                                              |

### 20.4.14 NAND Flash $n$ ECC Registers (NANDF1ECC-NANDF4ECC)

The NAND Flash  $n$  ECC register (NANDF $n$ ECC) is shown in Figure 20-44 and described in Table 20-62. For 8-bit NAND Flash, the P1 to P4 bits are column parities; the P8 to P2048 bits are row parities. For 16-bit NAND Flash, the P1 to P8 bits are column parities; the P16 to P2048 bits are row parities.

## ***General-Purpose Input/Output (GPIO)***

---

---

The GPIO peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, you can write to an internal register to control the state driven on the output pin. When configured as an input, you can detect the state of the input by reading the state of an internal register. This chapter describes the GPIO.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>21.1 Introduction .....</b> | <b>939</b>  |
| <b>21.2 Architecture .....</b> | <b>940</b>  |
| <b>21.3 Registers .....</b>    | <b>948</b>  |

## 21.1 Introduction

### 21.1.1 Purpose of the Peripheral

Most system-on-chip (SoC) devices require some general-purpose input/output (GPIO) functionality in order to interact with other components in the system using low-speed interface pins. The control and use of the GPIO capability on this device is grouped together in the GPIO peripheral and is described in the following sections.

### 21.1.2 Features

The GPIO peripheral consists of the following features.

- Output set/clear functionality through separate data set and clear registers allows multiple software processes to control GPIO signals without critical section protection.
- Set/clear functionality through writing to a single output data register is also supported.
- Separate input/output registers
  - Output register can be read to reflect output drive status.
  - Input register can be read to reflect pin status.
- All GPIO signals can be used as interrupt sources with configurable edge detection.
- All GPIO signals can be used to generate events to the EDMA.

### 21.1.3 Functional Block Diagram

[Figure 21-1](#) shows a block diagram of the GPIO peripheral.

### 21.1.4 Industry Standard(s) Compliance Statement

The GPIO peripheral connects to external devices. While it is possible that the software implements some standard connectivity protocol over GPIO, the GPIO peripheral itself is not compliant with any such standards.

**Figure 21-1. GPIO Block Diagram**

## 21.2 Architecture

The following sections describe the GPIO peripheral.

### 21.2.1 Clock Control

The input clock to the GPIO peripheral is indicated in the device datasheet. The maximum operating speed of the GPIO peripheral is limited by system-level latencies. More specifically, how quickly the GPIO registers can be written to or read from.

### 21.2.2 Signal Descriptions

The number of GPIO signals supported will vary between devices. For information on the number of signals supported and the package pinout of each GPIO signal, see your device-specific data manual.

### 21.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. Refer to the device-specific data manual to determine how pin multiplexing affects the GPIO module.

### 21.2.4 Endianness Considerations

The GPIO operation is independent of endianness; therefore, there are no endianness considerations for the GPIO module.

## 21.2.5 GPIO Register Structure

The GPIO signals are grouped by banks of 16 signals per bank. Each bank of GPIO signals has several registers with various control fields for each GPIO signal. Each 32-bit GPIO control register controls a pair of GPIO banks.

The register names for each bank of control registers (or pair of banks of GPIO bits) are all of the form *register\_nameXY*, where *X* and *Y* are the two banks of GPIO bits controlled, such as 01, 23, 45, etc. The register fields associated with each GPIO are all of the form *BkPj*, where *k* is the GPIO bank and *j* is the pin number within the GPIO bank. For example, for GP2[5], which is located in GPIO bank 2, the control register names are of the form *register\_name23*, and the register field associated with GP2[5] is GP2P5.

Table 21-1 shows the banks and register control bit information associated with each GPIO pin for up to 144 supportable pins. The table is not indicative of how many GPIO pins are supported on a device; it is only a reference for what register and field mappings look like for the first 144 supportable GPIO pins. For devices with less than 144 GPIO pins, assume that the extraneous fields and registers listed in the table are Reserved with no function. For devices with more than 144 GPIO pins, additional control registers and fields should be appended using the same numbering scheme in the table. Detailed information regarding the specific register names for each bank and the contents and function of these registers is presented in Section 21.3.

**Table 21-1. GPIO Register Bits and Banks Associated With GPIO Signals**

| GPIO Pin Number | GPIO Signal Name | Bank Number | Control Registers      | Register Bit | Register Field |
|-----------------|------------------|-------------|------------------------|--------------|----------------|
| 1               | GP0[0]           | 0           | <i>register_name01</i> | Bit 0        | GP0P0          |
| 2               | GP0[1]           | 0           | <i>register_name01</i> | Bit 1        | GP0P1          |
| 3               | GP0[2]           | 0           | <i>register_name01</i> | Bit 2        | GP0P2          |
| 4               | GP0[3]           | 0           | <i>register_name01</i> | Bit 3        | GP0P3          |
| 5               | GP0[4]           | 0           | <i>register_name01</i> | Bit 4        | GP0P4          |
| 6               | GP0[5]           | 0           | <i>register_name01</i> | Bit 5        | GP0P5          |
| 7               | GP0[6]           | 0           | <i>register_name01</i> | Bit 6        | GP0P6          |
| 8               | GP0[7]           | 0           | <i>register_name01</i> | Bit 7        | GP0P7          |
| 9               | GP0[8]           | 0           | <i>register_name01</i> | Bit 8        | GP0P8          |
| 10              | GP0[9]           | 0           | <i>register_name01</i> | Bit 9        | GP0P9          |
| 11              | GP0[10]          | 0           | <i>register_name01</i> | Bit 10       | GP0P10         |
| 12              | GP0[11]          | 0           | <i>register_name01</i> | Bit 11       | GP0P11         |
| 13              | GP0[12]          | 0           | <i>register_name01</i> | Bit 12       | GP0P12         |
| 14              | GP0[13]          | 0           | <i>register_name01</i> | Bit 13       | GP0P13         |
| 15              | GP0[14]          | 0           | <i>register_name01</i> | Bit 14       | GP0P14         |
| 16              | GP0[15]          | 0           | <i>register_name01</i> | Bit 15       | GP0P15         |
| 17              | GP1[0]           | 1           | <i>register_name01</i> | Bit 16       | GP1P0          |

| 144             | GP8[15]          | 8           | <i>register_name8</i>  | Bit 15       | GP8P15         |

## 21.2.6 Using a GPIO Signal as an Output

GPIO signals are configured to operate as inputs or outputs by writing the appropriate value to the GPIO direction register (DIR). This section describes using the GPIO signal as an output signal.

### 21.2.6.1 Configuring a GPIO Output Signal

To configure a given GPIO signal as an output, clear the bit in DIR that is associated with the desired GPIO signal. For detailed information on DIR, see [Section 21.3](#).

### 21.2.6.2 Controlling the GPIO Output Signal State

There are three registers that control the output state driven on a GPIO signal configured as an output:

1. GPIO set data register (SET\_DATA) controls driving GPIO signals high.
2. GPIO clear data register (CLR\_DATA) controls driving GPIO signals low.
3. GPIO output data register (OUT\_DATA) contains the current state of the output signals.

Reading SET\_DATA, CLR\_DATA, and OUT\_DATA returns the output state, not necessarily the actual signal state (since some signals may be configured as inputs). The actual signal state is read using the GPIO input data register (IN\_DATA) associated with the desired GPIO signal. IN\_DATA contains the actual logic state on the external signal.

For detailed information on these registers, see [Section 21.3](#).

#### 21.2.6.2.1 Driving a GPIO Output Signal High

To drive a GPIO signal high, use one of the following methods:

- Write a logic 1 to the bit in SET\_DATA associated with the desired GPIO signal(s) to be driven high. Bit positions in SET\_DATA containing logic 0 do not affect the state of the associated output signals.
- Modify the bit in OUT\_DATA associated with the desired GPIO signal by using a read-modify-write operation. The logic states driven on the GPIO output signals match the logic values written to all bits in OUT\_DATA.

For GPIO signals configured as inputs, the values written to the associated SET\_DATA, CLR\_DATA, and OUT\_DATA bits have no effect.

#### 21.2.6.2.2 Driving a GPIO Output Signal Low

To drive a GPIO signal low, use one of the following methods:

- Write a logic 1 to the bit in CLR\_DATA associated with the desired GPIO signal(s) to be driven low. Bit positions in CLR\_DATA containing logic 0 do not affect the state of the associated output signals.
- Modify the bit in OUT\_DATA associated with the desired GPIO signal by using a read-modify-write operation. The logic states driven on the GPIO output signals match the logic values written to all bits in OUT\_DATA.

For GPIO signals configured as inputs, the values written to the associated SET\_DATA, CLR\_DATA, and OUT\_DATA bits have no effect.

### 21.2.7 Using a GPIO Signal as an Input

GPIO signals are configured to operate as inputs or outputs by writing the appropriate value to the GPIO direction register (DIR). This section describes using the GPIO signal as an input signal.

#### 21.2.7.1 Configuring a GPIO Input Signal

To configure a given GPIO signal as an input, set the bit in DIR that is associated with the desired GPIO signal. For detailed information on DIR, see [Section 21.3](#).

#### 21.2.7.2 Reading a GPIO Input Signal

The current state of the GPIO signals is read using the GPIO input data register (IN\_DATA).

- For GPIO signals configured as inputs, reading IN\_DATA returns the state of the input signal synchronized to the GPIO peripheral clock.
- For GPIO signals configured as outputs, reading IN\_DATA returns the output value being driven by the device.

Some signals may utilize open-drain output buffers for wired-logic operations. For open-drain GPIO signals, reading IN\_DATA returns the wired-logic value on the signal (which will not be driven by the device alone). Information on any signals using open-drain outputs is available in your device-specific data manual.

To use GPIO input signals as interrupt sources, see [Section 21.2.10](#).

### 21.2.8 Reset Considerations

The GPIO peripheral has two reset sources: software reset and hardware reset.

#### 21.2.8.1 Software Reset Considerations

A software reset (such as a reset initiated through the emulator) does not modify the configuration and state of the GPIO signals. A reset invoked via the Power and Sleep Controller (PSC) (GPIO clock disable, PSC reset, followed by GPIO clock enable) will result in the default configuration register settings. For details on the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 21.2.8.2 Hardware Reset Considerations

A hardware reset does reset the GPIO configuration and data registers to their default states; therefore, affecting the configuration and state of the GPIO signals.

### 21.2.9 Initialization

The following steps are required to configure the GPIO module after a hardware reset:

1. Perform the necessary device pin multiplexing setup (see your device-specific data manual).
2. Program the Power and Sleep Controller (PSC) to enable the GPIO module. For details on the PSC, see the *Power and Sleep Controller (PSC)* chapter.
3. Program the direction, data, and interrupt control registers to set the configuration of the desired GPIO pins (described in this chapter).

The GPIO module is now ready to perform data transactions.

### 21.2.10 Interrupt Support

The GPIO peripheral can send an interrupt event to the CPU.

#### 21.2.10.1 Interrupt Events and Requests

All GPIO signals can be configured to generate interrupts. The device supports interrupts from single GPIO signals, interrupts from banks of GPIO signals, or both.

Note that the GPIO interrupts may also be used to provide synchronization events to the DMA controller.

#### 21.2.10.2 Enabling GPIO Interrupt Events

GPIO interrupt events are enabled in banks of 16 by setting the appropriate bit(s) in the GPIO interrupt per-bank enable register (BINTEN). For example, to enable bank 0 interrupts (events from GP0[15-0]), set bit 0 in BINTEN; to enable bank 3 interrupts (events from GP3[15-0]), set bit 3 in BINTEN.

For detailed information on BINTEN, see [Section 21.3](#).

#### 21.2.10.3 Configuring GPIO Interrupt Edge Triggering

Each GPIO interrupt source can be configured to generate an interrupt on the GPIO signal rising edge, falling edge, both edges, or neither edge (no event). The edge detection is synchronized to the GPIO peripheral module clock.

The following four registers control the configuration of the GPIO interrupt edge detection:

1. The GPIO set rising edge interrupt register (SET\_RIS\_TRIG) enables GPIO interrupts on the occurrence of a rising edge on the GPIO signal.
2. The GPIO clear rising edge interrupt register (CLR\_RIS\_TRIG) disables GPIO interrupts on the occurrence of a rising edge on the GPIO signal.
3. The GPIO set falling edge interrupt register (SET\_FAL\_TRIG) enables GPIO interrupts on the occurrence of a falling edge on the GPIO signal.
4. The GPIO clear falling edge interrupt register (CLR\_FAL\_TRIG) disables GPIO interrupts on the occurrence of a falling edge on the GPIO signal.

To configure a GPIO interrupt to occur only on rising edges of the GPIO signal:

- Write a logic 1 to the associated bit in SET\_RIS\_TRIG.
- Write a logic 1 to the associated bit in CLR\_FAL\_TRIG.

To configure a GPIO interrupt to occur only on falling edges of the GPIO signal:

- Write a logic 1 to the associated bit in SET\_FAL\_TRIG.
- Write a logic 1 to the associated bit in CLR\_RIS\_TRIG.

To configure a GPIO interrupt to occur on both the rising and falling edges of the GPIO signal:

- Write a logic 1 to the associated bit in SET\_RIS\_TRIG.
- Write a logic 1 to the associated bit in SET\_FAL\_TRIG.

To disable a specific GPIO interrupt:

- Write a logic 1 to the associated bit in CLR\_RIS\_TRIG.
- Write a logic 1 to the associated bit in CLR\_FAL\_TRIG.

For detailed information on these registers, see [Section 21.3](#).

Note that the direction of the GPIO signal does not have to be an input for the interrupt event generation to work. When a GPIO signal is configured as an output, the software can change the GPIO signal state and, in turn, generate an interrupt. This can be useful for debugging interrupt signal connectivity.

#### 21.2.10.4 GPIO Interrupt Status

The status of GPIO interrupt events can be monitored by reading the GPIO interrupt status register (INTSTAT). Pending GPIO interrupts are indicated with a logic 1 in the associated bit position; interrupts that are not pending are indicated with a logic 0.

For individual GPIO interrupts that are directly routed to the DSP subsystem, the interrupt status can be read by reading the associated interrupt flag in the CPU. For the GPIO bank interrupts, INTSTAT can be used to determine which GPIO interrupt occurred. It is the responsibility of software to ensure that all pending GPIO interrupts are appropriately serviced.

Pending GPIO interrupt flags can be cleared by writing a logic 1 to the associated bit position in INTSTAT.

For detailed information on INTSTAT, see [Section 21.3](#).

#### 21.2.10.5 Interrupt Multiplexing

GPIO interrupts may be multiplexed with other interrupt functions on the device.

#### 21.2.11 EDMA Event Support

The GPIO peripheral may provide synchronization events to the DMA controller.

#### 21.2.12 Power Management

The GPIO peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the GPIO peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

When the GPIO peripheral is placed in a low-power state by the PSC, the interrupt generation capability is suspended until the GPIO peripheral is removed from the low-power state. While in the low-power state, the GPIO signals configured as outputs are maintained at their state prior to the GPIO peripheral entering the low-power state.

#### 21.2.13 Emulation Considerations

The GPIO peripheral is not affected by emulation suspend events (such as halts and breakpoints).

## 21.3 Registers

**Table 21-2** lists the memory-mapped registers for the general-purpose input/output (GPIO). The table enumerates the registers required to support 144 GPIO pins, however not all devices will support 144 GPIO pins. For devices with less than 144 GPIO pins, assume that the extraneous fields and registers are Reserved and serve no function. For devices with more than 144 GPIO pins, append registers and fields as necessary using the address offset scheme in the table. See your device-specific data manual for the number of GPIO pins supported and the base memory address for these registers.

**Table 21-2. GPIO Registers**

| Offset                    | Acronym        | Register Description                                     | Section                         |

### 21.3.1 Revision ID Register (REVID)

The revision ID register (REVID) contains the peripheral version information. REVID is shown in [Figure 21-2](#) and described in [Table 21-3](#).

**Figure 21-2. Revision ID Register (REVID)**

LEGEND: R = Read only; -n = value after reset

**Table 21-3. Revision ID Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description         |
|------|-------|------------|---------------------|
| 31-0 | REV   | 4483 0105h | Peripheral Revision |

### 21.3.2 GPIO Interrupt Per-Bank Enable Register (BINTEN)

The GPIO interrupt per-bank enable register (BINTEN) is shown in [Figure 21-3](#) and described in [Table 21-4](#). For information on which GPIO signals are associated with each bank, see [Table 21-1](#). Note that the bits in BINTEN control both the interrupt and EDMA events.

**Figure 21-3. GPIO Interrupt Per-Bank Enable Register (BINTEN)**

### 21.3.3 GPIO Direction Registers (DIRn)

The GPIO direction register (DIR $n$ ) determines if GPIO pin  $j$  in GPIO bank  $k$  is an input or an output. Each of the GPIO banks may have up to 16 GPIO pins. By default, all the GPIO pins are configured as inputs (bit value = 1). The GPIO direction register (DIR01) is shown in Figure 21-4, DIR23 is shown in Figure 21-5, DIR45 is shown in Figure 21-6, DIR67 is shown in Figure 21-7, DIR8 is shown in Figure 21-8, and described in Table 21-5. See Table 21-1 to determine the DIR $n$  bit associated with each GPIO bank and pin number.

**Figure 21-4. GPIO Banks 0 and 1 Direction Register (DIR01)**

### 21.3.4 GPIO Output Data Registers (OUT\_DATA<sub>n</sub>)

The GPIO output data register (OUT\_DATA<sub>n</sub>) determines the value driven on the corresponding GPIO pin *j* in GPIO bank *k*, if the pin is configured as an output (DIR<sub>n</sub> = 0). Writes do not affect pins not configured as GPIO outputs. The bits in OUT\_DATA<sub>n</sub> are set or cleared by writing directly to this register. A read of OUT\_DATA<sub>n</sub> returns the value of the register not the value at the pin (that might be configured as an input). The GPIO output data register (OUT\_DATA01) is shown in [Figure 21-9](#), OUT\_DATA23 is shown in [Figure 21-10](#), OUT\_DATA45 is shown in [Figure 21-11](#), OUT\_DATA67 is shown in [Figure 21-12](#), OUT\_DATA8 is shown in [Figure 21-13](#), and described in [Table 21-6](#). See [Table 21-1](#) to determine the OUT\_DATA<sub>n</sub> bit associated with each GPIO bank and pin number.

| Bit  | Field | Value | Description                                                                                                                                                                         |
|------|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPkPj |       | Output drive state of GPk[j]. The GPkPj bit is used to drive the output (low = 0, high = 1) of pin j in GPIO bankk. The GPkPj bit is ignored when GPk[j] is configured as an input. |
|      |       | 0     | GPk[j] is driven low.                                                                                                                                                               |
|      |       | 1     | GPk[j] is driven high.                                                                                                                                                              |

### 21.3.5 GPIO Set Data Registers (SET\_DATA<sub>n</sub>)

The GPIO set data register (SET\_DATA<sub>n</sub>) controls driving high of the corresponding GPIO pin *j* in GPIO bank *k*, if the pin is configured as an output (DIR<sub>n</sub> = 0). Writes do not affect pins not configured as GPIO outputs. Writing a 1 to a specific bit in SET\_DATA<sub>n</sub> sets the corresponding GPIO pin *j* in GPIO bank *k*. A read of the BkPj bit returns the output drive state of the corresponding pin GPIOk[j]. The GPIO set data register (SET\_DATA01) is shown in Figure 21-14, SET\_DATA23 is shown in Figure 21-15, SET\_DATA45 is shown in Figure 21-16, SET\_DATA67 is shown in Figure 21-17, SET\_DATA8 is shown in Figure 21-18, and described in Table 21-7. See Table 21-1 to determine the SET\_DATA<sub>n</sub> bit associated with each GPIO bank and pin number.

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPkPj |       | Set the output drive state of GPk[j] to logic high. The GPkPj bit is used to drive the output high on pin j in GPIO bankk. The GPkPj bit is ignored when GPk[j] is configured as an input. Reading the GPkPj bit returns the output drive state of GPk[j]. |
|      |       | 0     | No effect.                                                                                                                                                                                                                                                 |
|      |       | 1     | GPk[j] is set to output logic high.                                                                                                                                                                                                                        |

### 21.3.6 GPIO Clear Data Registers (CLR\_DATAn)

The GPIO clear data register (CLR\_DATAn) controls clearing low of the corresponding GPIO pin *j* in GPIO bank *k*, if the pin is configured as an output (DIRn = 0). Writes do not affect pins not configured as GPIO outputs. Writing a 1 to a specific bit in CLR\_DATAn resets the corresponding GPIO pin *j* in GPIO bank *k*. A read of the BkPj bit returns the output drive state of the corresponding pin GPIOk[j]. The GPIO clear data register (CLR\_DATA01) is shown in [Figure 21-19](#), CLR\_DATA23 is shown in [Figure 21-20](#), CLR\_DATA45 is shown in [Figure 21-21](#), CLR\_DATA67 is shown in [Figure 21-22](#), CLR\_DATA8 is shown in [Figure 21-23](#), and described in [Table 21-8](#). See [Table 21-1](#) to determine the CLR\_DATAn bit associated with each GPIO bank and pin number.

### 21.3.7 GPIO Input Data Registers (IN\_DATA<sub>n</sub>)

The current state of the GPIO signals is read using the GPIO input data register (IN\_DATA<sub>n</sub>).

- For GPIO signals configured as inputs, reading IN\_DATA<sub>n</sub> returns the state of the input signal synchronized to the GPIO peripheral clock.
- For GPIO signals configured as outputs, reading IN\_DATA<sub>n</sub> returns the output value being driven by the device.

The GPIO input data register (IN\_DATA01) is shown in [Figure 21-24](#), IN\_DATA23 is shown in [Figure 21-25](#), IN\_DATA45 is shown in [Figure 21-26](#), IN\_DATA67 is shown in [Figure 21-27](#), IN\_DATA8 is shown in [Figure 21-28](#), and described in [Table 21-9](#). See [Table 21-1](#) to determine the IN\_DATA<sub>n</sub> bit associated with each GPIO bank and pin number.

|      |       | 1     | GPk[j] is logic low.                                                                   |
|      |       |       | GPk[j] is logic high.                                                                  |

### 21.3.8 GPIO Set Rising Edge Interrupt Registers (SET\_RIS\_TRIG<sub>n</sub>)

The GPIO set rising edge trigger interrupt register (SET\_RIS\_TRIG<sub>n</sub>) enables a rising edge trigger on the GPIO pin to generate a GPIO interrupt. The GPIO set rising edge interrupt register (SET\_RIS\_TRIG01) is shown in [Figure 21-29](#), SET\_RIS\_TRIG23 is shown in [Figure 21-30](#), SET\_RIS\_TRIG45 is shown in [Figure 21-31](#), SET\_RIS\_TRIG67 is shown in [Figure 21-32](#), SET\_RIS\_TRIG8 is shown in [Figure 21-33](#), and described in [Table 21-10](#). See [Table 21-1](#) to determine the SET\_RIS\_TRIG<sub>n</sub> bit associated with each GPIO bank and pin number.

|------|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPjPk |       | Enable rising edge trigger interrupt detection on GPk[j]. Reading the GPkPj bit in either SET_RIS_TRIG <sub>n</sub> or CLR_RIS_TRIG <sub>n</sub> always returns an indication of whether the rising edge interrupt generation function is enabled for pin GPk[j]. Therefore, this bit will be one in both registers if the function is enabled, and zero in both registers if the function is disabled. |
|      |       | 0     | No effect.                                                                                                                                                                                                                                                                                                                                                                                              |
|      |       | 1     | Interrupt is caused by a low-to-high transition on GPk[j].                                                                                                                                                                                                                                                                                                                                              |

### 21.3.9 GPIO Clear Rising Edge Interrupt Registers (CLR\_RIS\_TRIG<sub>n</sub>)

The GPIO clear rising edge trigger interrupt register (CLR\_RIS\_TRIG<sub>n</sub>) disables the rising edge trigger on the GPIO pin to generate a GPIO interrupt. The GPIO clear rising edge interrupt register (CLR\_RIS\_TRIG01) is shown in [Figure 21-34](#), CLR\_RIS\_TRIG23 is shown in [Figure 21-35](#), CLR\_RIS\_TRIG45 is shown in [Figure 21-36](#), CLR\_RIS\_TRIG67 is shown in [Figure 21-37](#), and described in [Table 21-11](#). See [Table 21-1](#) to determine the CLR\_RIS\_TRIG<sub>n</sub> bit associated with each GPIO bank and pin number.

**Table 21-11. GPIO Clear Rising Edge Interrupt Register (CLR\_RIS\_TRIG<sub>n</sub>) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|------|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPkPj |       | Disable rising edge interrupt detection on GPk[j]. Reading the GPkPj bit in either SET_RIS_TRIG <sub>n</sub> or CLR_RIS_TRIG <sub>n</sub> always returns an indication of whether the rising edge interrupt generation function is enabled for GPk[j]. Therefore, this bit will be one in both registers if the function is enabled, and zero in both registers if the function is disabled. |
|      |       | 0     | No effect.                                                                                                                                                                                                                                                                                                                                                                                   |
|      |       | 1     | No interrupt is caused by a low-to-high transition on GPk[j].                                                                                                                                                                                                                                                                                                                                |

### 21.3.10 GPIO Set Falling Edge Interrupt Registers (SET\_FAL\_TRIGn)

The GPIO set falling edge trigger interrupt register (SET\_FAL\_TRIGn) enables a falling edge trigger on the GPIO pin to generate a GPIO interrupt. The GPIO set falling edge interrupt register (SET\_FAL\_TRIG01) is shown in [Figure 21-39](#), SET\_FAL\_TRIG23 is shown in [Figure 21-40](#), SET\_FAL\_TRIG45 is shown in [Figure 21-41](#), SET\_FAL\_TRIG67 is shown in [Figure 21-42](#), SET\_FAL\_TRIG8 is shown in [Figure 21-43](#), and described in [Table 21-1](#) to determine the SET\_FAL\_TRIGn bit associated with each GPIO bank and pin number.

|------|-------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPkPj |       | Enable falling edge trigger interrupt detection on GPk[j]. Reading the GPkPj bit in either SET_FAL_TRIG <sub>n</sub> or CLR_FAL_TRIG <sub>n</sub> always returns an indication of whether the falling edge interrupt generation function is enabled for pin GPk[j]. Therefore, this bit will be one in both registers if the function is enabled, and zero in both registers if the function is disabled. |
|      |       | 0     | No effect.                                                                                                                                                                                                                                                                                                                                                                                                |
|      |       | 1     | Interrupt is caused by a high-to-low transition on GPk[j].                                                                                                                                                                                                                                                                                                                                                |

### 21.3.11 GPIO Clear Falling Edge Interrupt Registers (CLR\_FAL\_TRIGn)

The GPIO clear falling edge trigger interrupt register (CLR\_FAL\_TRIGn) disables the falling edge trigger on the GPIO pin to generate a GPIO interrupt. The GPIO clear falling edge interrupt register (CLR\_FAL\_TRIG01) is shown in [Figure 21-44](#), CLR\_FAL\_TRIG23 is shown in [Figure 21-45](#), CLR\_FAL\_TRIG45 is shown in [Figure 21-46](#), CLR\_FAL\_TRIG67 is shown in [Figure 21-47](#), CLR\_FAL\_TRIG8 is shown in [Figure 21-48](#), and described in [Table 21-13](#). See [Table 21-1](#) to determine the CLR\_FAL\_TRIGn bit associated with each GPIO bank and pin number.

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPkPj |       | Disable falling edge interrupt detection on GPk[j]. Reading the GPkPj bit in either SET_FAL_TRIG <sub>n</sub> or CLR_FAL_TRIG <sub>n</sub> always returns an indication of whether the falling edge interrupt generation function is enabled for GPk[j]. Therefore, this bit will be one in both registers if the function is enabled, and zero in both registers if the function is disabled. |
|      |       | 0     | No effect.                                                                                                                                                                                                                                                                                                                                                                                     |
|      |       | 1     | No interrupt is caused by a high-to-low transition on GPk[j].                                                                                                                                                                                                                                                                                                                                  |

### 21.3.12 GPIO Interrupt Status Registers (INTSTATn)

The status of GPIO interrupt events can be monitored by reading the GPIO interrupt status register (INTSTATn). In the associated bit position, pending GPIO interrupts are indicated with a logic 1 and GPIO interrupts that are not pending are indicated with a logic 0. The GPIO interrupt status register (INTSTAT01) is shown in [Figure 21-49](#), INTSTAT23 is shown in [Figure 21-50](#), INTSTAT45 is shown in [Figure 21-51](#), INTSTAT67 is shown in [Figure 21-52](#), INTSTAT8 is shown in [Figure 21-53](#), and described in [Table 21-14](#). See [Table 21-1](#) to determine the INTSTATn bit associated with each GPIO bank and pin number.

| Bit  | Field | Value | Description                                                                                                                                                                                   |
|------|-------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | GPkPj |       | Interrupt status of GPk[j]. The GPkPj bit is used to monitor pending GPIO interrupts on pin j of GPIO bank k. Write a 1 to the GPkPj bit to clear the status bit; a write of 0 has no effect. |
|      |       | 0     | No pending interrupt on GPk[j].                                                                                                                                                               |
|      |       | 1     | Pending interrupt on GPk[j].                                                                                                                                                                  |

## Host Port Interface (HPI)

This chapter describes the host port interface (HPI).

| Topic                          | Page       |
|--------------------------------|------------|
| <b>22.1 Introduction .....</b> | <b>972</b> |
| <b>22.2 Architecture .....</b> | <b>975</b> |
| <b>22.3 Registers .....</b>    | <b>995</b> |

## 22.1 Introduction

The host port interface (HPI) provides a parallel port interface through which an external host processor can directly access the processor's resources (configuration and program/data memories). The external host device is asynchronous to the CPU clock and functions as a master to the HPI interface. The HPI enables a host device and the processor to exchange information via internal or external memory. Dedicated address (HPIA) and data (HPID) registers within the HPI provide the data path between the external host interface and the processor resources. An HPI control register (HPIC) is available to the host and the CPU for various configuration and interrupt functions.

### 22.1.1 Purpose of the Peripheral

The HPI enables an external host processor (host) to directly access program/data memory on the processor using a parallel interface. The primary purpose is to provide a mechanism to move data to and from the processor. In addition to data transfer, the host can also use the HPI to bootstrap the processor by downloading program and data information to the processor's memory after power-up.

### 22.1.2 Features

The HPI supports the following features:

- Multiplexed address/data
- Dual 16-bit halfword cycle access (internal data word is 32-bits wide)
- 16-bit-wide host data bus interface
- Internal data bursting using 8-word read and write first-in, first-out (FIFO) buffers
- HPI control register (HPIC) accessible by both the DSP CPU and the external host
- HPI address register (HPIA) accessible by both the DSP CPU and the external host
- Separate HPI address registers for read (HPIAR) and write (HPIAW) with configurable option for operating as a single HPI address register
- HPI data register (HPID)/FIFOs providing data-path between external host interface and CPU resources
- Multiple strobes and control signals to allow flexible host connection
- Asynchronous UHPI\_HRDY output to allow the HPI to insert wait states to the host
- Software control of data prefetching to the HPID/FIFOs
- Processor-to-Host interrupt output signal controlled by HPIC accesses
- Host-to-Processor interrupt controlled by HPIC accesses
- Register controlled HPIA and HPIC ownership and FIFO timeout
- Memory-mapped peripheral identification register (PID)
- Bus holders on host data and address buses (these are actually external to HPI module)

### 22.1.4 Industry Standard(s) Compliance Statement

The HPI is not an industry standard interface that is developed and monitored by an international organization. It is a generic parallel interface that can be configured to gluelessly interface to a variety of parallel devices.

### 22.1.5 Terminology Used in This Document

The following is a brief explanation of some terms used in this document:

| Term          | Meaning                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU           | DSP CPU                                                                                                                                                  |
| host          | External host device                                                                                                                                     |
| HPI DMA logic | Logic used to communicate between the HPI and the DMA system that moves data to and from memory. This is independent of the EDMA system on the processor |
| processor     | Entire system-on-chip                                                                                                                                    |

## 22.2 Architecture

### 22.2.1 Clock Control

For detailed information on the PLLs and clock distribution on the processor, see the *Phase-Locked Loop Controller (PLLC)* chapter.

### 22.2.2 Memory Map

The HPI can be used by the host to access on-chip device memory, peripheral, and memory-mapped registers. See your device-specific data manual for more detailed information.

### 22.2.3 Signal Descriptions

Table 22-1 shows the a description of the HPI signals.

**Table 22-1. HPI Pins**

| Pin                                                               | Type  | Host Connection                                          | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------|-------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UHPI_HCNTL[1:0]                                                   | I     | Address or control pins                                  | <b>HPI access control inputs.</b> The HPI latches the logic levels of these pins on the falling edge of internal $\overline{\text{HSTRB}}$ (for details about internal $\overline{\text{HSTRB}}$ , see <a href="#">Section 22.2.6.4</a> ). The four binary states of these pins determine the access type of the current transfer (HPIC, HPIA, HPID with and without autoincrementing).                                                                                                                                                                                                         |
| $\overline{\text{UHPI\_HCS}}$                                     | I     | Chip select pin                                          | <b>HPI chip select.</b> $\overline{\text{UHPI\_HCS}}$ must be low for the HPI to be selected by the host. $\overline{\text{UHPI\_HCS}}$ can be kept low between accesses. $\overline{\text{UHPI\_HCS}}$ normally precedes an active $\overline{\text{UHPI\_HDS}}$ (data strobe) signal, but can be connected to a $\overline{\text{UHPI\_HDS}}$ pin for simultaneous select and strobe activity.                                                                                                                                                                                                |
| UHPI_HR/ $\overline{\text{W}}$                                    | I     | R/W strobe pin                                           | <b>HPI read/write.</b> On the falling edge of internal $\overline{\text{HSTRB}}$ , UHPI_HR/ $\overline{\text{W}}$ indicates whether the current access is to be a read or write operation. Driving UHPI_HR/ $\overline{\text{W}}$ high indicates the transfer is a read from the HPI, while driving UHPI_HR/ $\overline{\text{W}}$ low indicates a write to the HPI.                                                                                                                                                                                                                            |
| UHPI_HHWIL                                                        | I     | Address or control pins                                  | <b>Halfword identification line.</b> The host uses UHPI_HHWIL to identify the first and second halfwords of the host cycle. UHPI_HHWIL must be driven low for the first halfword and high for the second halfword.                                                                                                                                                                                                                                                                                                                                                                              |
| $\overline{\text{UHPI\_HAS}}$                                     | I     | None                                                     | <b>Address strobe.</b> Connect to logic high.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| $\overline{\text{UHPI\_HINT}}$                                    | O/Z   | Interrupt pin                                            | <b>Host interrupt.</b> The CPU can interrupt the host processor by writing a 1 to the HINT bit of HPIC. Before subsequent $\overline{\text{UHPI\_HINT}}$ interrupts can occur, the host must acknowledge interrupts by writing a 1 to the HINT bit. This pin is active-low (that is, when an interrupt is asserted from the host, the state of this signal is low) and inverted from the HINT bit value in HPIC.                                                                                                                                                                                |
| $\overline{\text{UHPI\_HDS1}}$ and $\overline{\text{UHPI\_HDS2}}$ | I     | Read strobe and write strobe pins or any data strobe pin | <b>HPI data strobe pins.</b> These pins are used for strobing data in and out of the HPI (for data strobing details, see <a href="#">Section 22.2.6.4</a> ). The direction of the data transfer depends on the logic level of the UHPI_HR/ $\overline{\text{W}}$ signal. The $\overline{\text{UHPI\_HDS}}$ signals are also used to latch control information on the falling edge. During an HPID write access, data is latched into the HPID register on the rising edge of $\overline{\text{UHPI\_HDS}}$ . During read operations, these pins act as output-enable pins of the host data bus. |
| UHPI_HD[15:0]                                                     | I/O/Z | Data bus                                                 | <b>HPI data bus.</b> The HPI data bus carries the address and data to/from the HPI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| $\overline{\text{UHPI\_HRDY}}$                                    | O/Z   | Asynchronous ready pin                                   | <b>HPI-ready signal.</b> When the HPI drives $\overline{\text{UHPI\_HRDY}}$ low, the host has permission to complete the current host cycle. When the HPI drives $\overline{\text{UHPI\_HRDY}}$ high, the HPI is not ready for the current host cycle to complete.                                                                                                                                                                                                                                                                                                                              |

## 22.2.4 Pin Multiplexing and General-Purpose I/O Control Blocks

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. See your device-specific data manual to determine how pin multiplexing affects the HPI.

The HPI supports general-purpose I/O (GPIO) capability on all pins. All HPI pins may be enabled for GPIO mode when the HPI is disabled via the HPIENA bit in the chip configuration 1 register (CFGCHIP1) in the *System Configuration (SYSCFG) Module* chapter.

When the HPI is enabled, the pins not being used for host accesses may be configured as general-purpose I/O.

### 22.2.4.1 Treatment of Optional Pins when Configured as General-Purpose I/O

Certain pins are optional, but if used to interface to the external hosts, the pins are inputs to the HPI. For the purpose of host accesses, the HPI treats these pins as if they were driven to the values listed in [Table 22-2](#).

**Table 22-2. Value on Optional Pins when Configured as General-Purpose I/O**

| Pin           | GPIO Enable Bit(s) | When Enabled as GPIO,<br>Treated as Driven: |
|---------------|--------------------|---------------------------------------------|
| UHPI_HD[15:8] | GPIOEN8            | 0                                           |
| UHPI_HD[7:0]  | GPIOEN7            | 0                                           |
| UHPI_HCNTL0   | GPIOEN1            | 1                                           |
| UHPI_HCNTL1   | GPIOEN1            | 1                                           |
| UHPI_HAS      | GPIOEN2            | 1                                           |

### 22.2.4.2 General-Purpose I/O Programmer's Model

For each HPI pin, there are three bits that control this pin as general-purpose I/O (GPIO):

- Enable: GPIO\_EN.GPIOEN[xx]
- Direction: GPIO\_DIRn.DIR[yy]
- Data: GPIO\_DATn.DIR[yy]

For example, the  $\overline{\text{UHPI\_HAS}}$  pin is enabled with the GPIO\_EN.GPIOEN2 bit. In the default setting, the GPIO\_EN.GPIOEN2 bit is cleared to 0; therefore, the  $\overline{\text{UHPI\_HAS}}$  pin functions as the host address strobe.

Enabling this pin for GPIO, by setting the GPIO\_EN.GPIOEN2 bit to 1 does two things:

- Transfers control of the  $\overline{\text{UHPI\_HAS}}$  pin to GPIO direction and data bits.
- Drives a 1 into the  $\overline{\text{UHPI\_HAS}}$  pin input of the external host interface block (regardless of the actual pin value).

Once enabled as GPIO, the direction of the  $\overline{\text{UHPI\_HAS}}$  pin is controlled by the GPIO\_DIR2.HASZ bit. If this bit is set to 1, the pin will be driven as an output; if this bit is cleared to 0, the pin will be an input.

Once the direction of the  $\overline{\text{UHPI\_HAS}}$  pin is set, the data value is either written to or read from the GPIO\_DAT2.HASZ bit. If the pin was configured as an output, then writing to this bit determines the value to drive out the pin. Reading from this bit will return the value written.

When the GPIO\_DIR2.HASZ bit is cleared to 0, configuring the  $\overline{\text{UHPI\_HAS}}$  pin as an input, writing to the GPIO\_DAT2.HASZ bit has no effect. Reading from this bit will return the value on the  $\overline{\text{UHPI\_HAS}}$  pin.

**NOTE:** Note that you cannot preload a value into the DAT field before configuring the pin as an output. This means that when switching the pin from input to output, the pin will initially drive the last value input back out on the pin. Then the DAT bit can be written to change the value on the pin. If the intermediate value between writing to DIR and writing to DAT will cause a problem at the system level, it is suggested to use another general-purpose I/O pin on the device.

## 22.2.5 Protocol Description

The HPI does not conform to any industry standard protocol.

## 22.2.6 Operation

### 22.2.6.1 Using the Address Registers

The HPI contains two 32-bit address registers: one for read operations (HPIAR) and one for write operations (HPIAW). These roles are unchanging from the viewpoint of the HPI logic. The HPI DMA logic gets the address from HPIAR when reading from processor resources (see [Section 22.2.2](#)) and gets the address from HPIAW when writing to processor resources (see [Section 22.2.2](#)).

However, unlike the HPI logic, the host can choose how to interact with the two HPI address registers. Using the DUALHPIA bit in the HPI control register (HPIC), the host determines whether HPIAR and HPIAW act as a single 32-bit register (single-HPIA mode) or as two independent 32-bit registers (dual-HPIA mode).

Note that the addresses loaded into the HPI address registers must be byte addresses, and must be 32-bit word aligned (with the least-significant two bits equal to zero), for use in addressing memory space within the DSP.

#### 22.2.6.1.1 Single-HPIA Mode

When DUALHPIA = 0 in HPIC, HPIAR and HPIAW become a single HPI address register (HPIA) from the perspective of the host. In this mode:

- A host HPIA write cycle (UHPI\_HCNTL[1:0] = 10b, UHPI\_HR/ $\overline{W}$  = 0) updates HPIAR and HPIAW with the same value.
- Both HPI address registers are incremented during autoincrement read/write cycles (UHPI\_HCNTL[1:0] = 01b).
- An HPIA read cycle (UHPI\_HCNTL[1:0] = 10b, UHPI\_HR/ $\overline{W}$  = 1) returns the content of HPIAR, which should be identical to the content of HPIAW.

To maintain consistency between the contents of HPIAR and HPIAW, the host should always reinitialize the HPI address registers after changing the state of the DUALHPIA bit. In addition, when DUALHPIA = 0, the host must always reinitialize the HPI address registers when it changes the data direction (from an HPID read cycle to an HPID write cycle, or conversely). Otherwise, the memory location accessed by the HPI DMA logic might not be the location intended by the host.

### 22.2.6.1.2 Dual-HPIA Mode

When DUALHPIA = 1 in HPIC, HPIAR and HPIAW are two independent HPI address registers from the perspective of the host. In this mode:

- A host HPIA access (UHPI\_HCNTL[1:0] = 10b) reads/updates either HPIAR or HPIAW, depending on the value of the HPIA read/write select (HPIASEL) bit in HPIC. This bit is programmed by the host. While HPIASEL = 1, only HPIAR is read or updated by the host. While HPIASEL = 0, only HPIAW is read or updated by the host. The HPIASEL bit is only meaningful in the dual-HPIA mode.

**NOTE:** The HPIASEL bit does not affect the HPI DMA logic. Regardless of the value of HPIASEL, the HPI DMA logic uses HPIAR when reading from memory and HPIAW when writing to memory.

- A host HPID access with autoincrementing (UHPI\_HCNTL[1:0] = 01b) causes only the relevant HPIA value to be incremented to the next consecutive memory address. In an autoincrement read cycle, HPIAR is incremented after it has been used to perform the current read from memory. In an autoincrement write cycle, HPIAW is incremented after it has been used for the write operation.

### 22.2.6.2 Host-HPI Signal Connections

Figure 22-2 shows an example of a signal connection between the HPI and a host.

**Figure 22-2. Example of Host-Processor Signal Connections**

A Data strobing options are given in [Section 22.2.6.4](#)

### 22.2.6.3 HPI Configuration and Data Flow

The host accomplishes a multiplexed access in the following manner:

1. The host writes to the HPI control register (HPIC) to properly configure the HPI. Typically, this means programming the halfword order bit (HWOB) and the HPIA-related bits (DUALHPIA and HPIASEL). This step is normally performed once before the initial data access.
2. The host writes the desired internal processor memory address to an address register (HPIAR and/or HPIAW). For an introduction to the two HPI address registers and the two ways the host can interact with them, see [Section 22.2.6.1](#).
3. The host reads from or writes to the data register (HPID). Data transfers between HPID and the internal memory of the processor are handled by the HPI DMA logic and are transparent to the CPU.

Each step of the access uses the same bus. Therefore, the host must drive the appropriate levels on the UHPI\_HCNTL1 and UHPI\_HCNTL0 signals to indicate which register is to be accessed. The host must also drive the appropriate level on the UHPI\_HR $\overline{W}$  signal to indicate the data direction (read or write) and must drive other control signals as appropriate. When HPI resources are temporarily busy or unavailable, the HPI can communicate this to the host by deasserting the HPI-ready (UHPI\_HRDY) output signal.

When performing an access, the HPI first latches the levels on UHPI\_HCNTL[1:0], UHPI\_HR $\overline{W}$ , and other control signals. This latching can occur on the falling edge of the internal strobe signal (for details, see [Section 22.2.6.4](#)). After the control information is latched, the HPI initiates an access based on the control signals.

If the host wants to read data from processor resources (see [Section 22.2.2](#)), the HPI DMA logic reads the resource address from HPIAR and retrieves the data from the addressed memory location. When the data has been placed in HPID, the HPI drives the data onto its UHPI\_HD bus. The UHPI\_HRDY signal informs the host whether the data on the UHPI\_HD bus is valid (UHPI\_HRDY low) or not valid yet (UHPI\_HRDY high). When the data is valid, the host should latch the data and drive the connected data strobe (UHPI\_HDS1 or UHPI\_HDS2) inactive, which, in turn, will cause the internal strobe (internal HSTRB) signal to transition from low to high.

If the host wants to write data to processor resources (see [Section 22.2.2](#)), the operation is similar. After the host determines that the HPI is ready to latch the data (UHPI\_HRDY is low), it must cause internal HSTRB to transition from low to high, which causes the data to be latched into HPID. Once the data is in HPID, the HPI DMA logic reads the memory address from HPIAW and transfers the data from HPID to the addressed memory location.

#### 22.2.6.4 UHPI\_HDS2, UHPI\_HDS1, and UHPI\_HCS: Data Strobing and Chip Selection

As shown in Figure 22-3, the strobing logic is a function of three key inputs: the chip select pin (UHPI\_HCS) and two data strobe signals (UHPI\_HDS1 and UHPI\_HDS2). The internal strobe signal, which is referred to as internal HSTRB throughout this document, functions as the actual strobe signal inside the HPI. UHPI\_HCS must be low (HPI selected) during strobe activity on the UHPI\_HDS pins. If UHPI\_HCS remains high (HPI not selected), activity on the UHPI\_HDS pins is ignored.

**Figure 22-3. HPI Strobe and Select Logic**

Strobe connections between the host and the HPI depend in part on the number and types of strobe pins available on the host. Table 22-3 describes some options for connecting to the UHPI\_HDS pins.

Notice in Figure 22-3 that UHPI\_HRDY is also gated by UHPI\_HCS. If UHPI\_HCS goes high (HPI not selected), UHPI\_HRDY goes low, regardless of whether the current internal transfer is completed in the processor.

**NOTE:** The UHPI\_HCS input and one UHPI\_HDS strobe input can be tied together and driven with a single strobe signal from the host. This technique selects the HPI and provides the strobe, simultaneously. When using this method, be aware that UHPI\_HRDY is gated by UHPI\_HCS as previously described.

It is not recommended to tie both UHPI\_HDS1 and UHPI\_HDS2 to static logic levels and use UHPI\_HCS as a strobe.

**Table 22-3. Options for Connecting Host and HPI Data Strobe Pins**

| Available Host Data Strobe Pins                                | Connections to HPI Data Strobe Pins                                                                                                                                                                                                                                          |
|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host has separate read and write strobe pins, both active-low  | Connect one strobe pin to UHPI_HDS1 and the other to UHPI_HDS2 <sup>(1)</sup> . Since such a host might not provide a R/W line, take care to satisfy UHPI_HR/W timings as stated in your device-specific data manual. This could possibly be done using a host address line. |
| Host has separate read and write strobe pins, both active-high | Connect one strobe pin to UHPI_HDS1 and the other to UHPI_HDS2 <sup>(1)</sup> . Since such a host might not provide a R/W line, take care to satisfy UHPI_HR/W timings as stated in your device-specific data manual. This could possibly be done using a host address line. |
| Host has one active-low strobe pin                             | Connect the strobe pin to UHPI_HDS1 or UHPI_HDS2, and connect the other pin to logic-level 1.                                                                                                                                                                                |
| Host has one active-high strobe pin                            | Connect the strobe pin to UHPI_HDS1 or UHPI_HDS2, and connect the other strobe pin to logic-level 0.                                                                                                                                                                         |

<sup>(1)</sup> The UHPI\_HR/W signal could be driven by a host address line in this case.

### 22.2.6.5 UHPI\_HCNTL[1:0] and UHPI\_HR $\overline{W}$ : Indicating the Cycle Type

The cycle type consists of:

- The access type that the host selects by driving the appropriate levels on the UHPI\_HCNTL[1:0] pins of the HPI. [Table 22-4](#) describes the four available access types.
- The transfer direction that the host selects with the UHPI\_HR $\overline{W}$  pin. The host must drive the UHPI\_HR $\overline{W}$  signal high (read) or low (write).

A summary of cycle types is in [Table 22-5](#). The HPI samples the UHPI\_HCNTL levels at the falling edge of the internal strobe signal  $\overline{HSTRB}$ .

**Table 22-4. Access Types Selectable With the UHPI\_HCNTL Signals**

| UHPI_HCNTL1 | UHPI_HCNTL0 | Access Type                                                                                                                                                                                                               |
|-------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | 0           | <b>HPIC access.</b> The host requests to access the HPI control register (HPIC).                                                                                                                                          |
| 0           | 1           | <b>HPID access with autoincrementing.</b> The host requests to access the HPI data register (HPID) and to have the appropriate HPI address register (HPIAR and/or HPIAW) automatically incremented by 1 after the access. |
| 1           | 0           | <b>HPIA access.</b> The host requests to access the appropriate HPI address register (HPIAR and/or HPIAW).                                                                                                                |
| 1           | 1           | <b>HPID access without autoincrementing.</b> The host requests to access the HPI data register (HPID) but requests no automatic post-increment of the HPI address register.                                               |

| 1           | 1           | 1                      | HPID read cycle without autoincrementing  |

### 22.2.6.6 UHPI\_HHWIL: Identifying the First and Second Halfwords in Multiplexed Mode Transfers

Each host cycle consists of two consecutive halfword transfers. For each transfer, the host must specify the cycle type with UHPI\_HCNTL[1:0] and UHPI\_HR $\overline{W}$ , and the host must use UHPI\_HHWIL to indicate whether the first or second halfword is being transferred. For HPID and HPIA accesses, UHPI\_HHWIL must always be driven low for the first halfword transfer and high for the second halfword transfer. Results are undefined if the sequence is broken. For examples of using UHPI\_HHWIL, see [Section 22.2.6.7](#).

When the host sends the two halfwords of a 32-bit word in this manner, the host can send the most-significant and the least-significant halfwords of the word in either order (most-significant halfword first or most-significant halfword second). However, the host must inform the HPI of the selected order before beginning the host cycle. This is done by programming the halfword order (HWOB) bit in HPIC. Although HWOB is written at bit 0 in HPIC, its current value is readable at both bit 0 and bit 8 (HWOBSTAT). Thus, the host can determine the current halfword order configuration by checking the least-significant bit of either half of HPIC.

There is one case when the HPI does not require a dual halfword access with UHPI\_HHWIL low for the first halfword and UHPI\_HHWIL high for the second halfword. This is the case when accessing the HPIC register. When accessing HPIC, the state of UHPI\_HHWIL is ignored and the same 16-bit HPIC register is accessed regardless of whether the host performs a single or dual access. For an example timing diagram of this case, see [Section 22.2.6.8](#).

### 22.2.6.7 Performing a Multiplexed Access

[Figure 22-2](#) shows an example of signal connections for multiplexed transfers. [Figure 22-4](#) and [Figure 22-5](#) show typical HPI signal activity when performing a read and write transfer, respectively. In these cases, the falling edge of internal  $\overline{\text{HSTRB}}$  is used to latch the UHPI\_HCNTL[1:0], UHPI\_HR/W, and UHPI\_HHWIL states into the HPI. Internal  $\overline{\text{HSTRB}}$  is derived from  $\overline{\text{UHPI\_HCS}}$ ,  $\overline{\text{UHPI\_HDS1}}$ , and  $\overline{\text{UHPI\_HDS2}}$  as described in [Section 22.2.6.4](#).

NOTE: Depending on the type of write operation (HPID without autoincrementing, HPIA, HPIC, or HPID with autoincrementing) and the state of the FIFO, transitions on UHPI\_HRDY may or may not occur. For more information, see [Section 22.2.6.9](#).

**Figure 22-5. Multiplexed-Mode Host Write Cycle**

NOTE: Depending on the type of write operation (HPID without autoincrementing, HPIA, HPIC, or HPID with autoincrementing) and the state of the FIFO, transitions on  $\overline{\text{UHPI\_HRDY}}$  may or may not occur. For more information, see [Section 22.2.6.9](#).

### 22.2.6.8 Single-Halfword HPIC Cycle

Figure 22-6 shows the special case (see Section 22.2.6.6) when the host performs a single-halfword cycle to access the HPIC. The state of UHPI\_HHWIL is ignored and if a dual-halfword access is performed, then the same HPIC register is accessed twice.

**Figure 22-6. Multiplexed-Mode Single-Halfword HPIC Cycle (Read or Write)**

### 22.2.6.9 Hardware Handshaking Using the HPI-Ready ( $\overline{\text{UHPI\_HRDY}}$ ) Signal

The HPI uses its ready signal,  $\overline{\text{UHPI\_HRDY}}$ , to tell the host whether it is ready to complete an access. During a read cycle, the HPI is ready ( $\overline{\text{UHPI\_HRDY}}$  is low) when it has data available for the host. During a write cycle, the HPI is ready ( $\overline{\text{UHPI\_HRDY}}$  is low) when it is ready to latch data from the host. If the HPI is not ready, it can drive  $\overline{\text{UHPI\_HRDY}}$  high to insert wait states. These wait states indicate to the host that read data is not yet valid (read cycle) or that the HPI is not ready to latch write data (write cycle). The number of wait states that must be inserted by the HPI is dependent upon the state of the resource that is being accessed.

When the HPI is not ready to complete the current cycle ( $\overline{\text{UHPI\_HRDY}}$  is high), the host can begin a new host cycle by forcing the HPI to latch new control information. However, once the cycle has been initiated, the host must wait until  $\overline{\text{UHPI\_HRDY}}$  goes low before causing a rising edge on the internal strobe signal (internal  $\overline{\text{HSTRB}}$ ) to complete the cycle. If internal  $\overline{\text{HSTRB}}$  goes high when the HPI is not ready, the cycle will be terminated with invalid data being returned (read cycle) or written (write cycle).

One reason the HPI may drive  $\overline{\text{UHPI\_HRDY}}$  high is a not-ready condition in one of its first-in, first-out buffers (FIFOs). For example, any HPID access that occurs while the write FIFO is full or the read FIFO is empty may result in some number of wait states being inserted by the HPI. The FIFOs are explained in Section 22.2.6.10.

The following sections describe the behavior of  $\overline{\text{UHPI\_HRDY}}$  during HPI register accesses. In all cases, the chip select signal,  $\overline{\text{UHPI\_HCS}}$ , must be asserted for  $\overline{\text{UHPI\_HRDY}}$  to go low.

### 22.2.6.9.1 $\overline{\text{UHPI\_HRDY}}$ Behavior During Multiplexed-Mode Read Operations

Figure 22-7 shows an HPIC ( $\text{UHPI\_HCNTL}[1:0] = 00\text{b}$ ) or HPIA ( $\text{UHPI\_HCNTL}[1:0] = 10\text{b}$ ) read cycle. Neither an HPIC read cycle nor an HPIA read cycle causes  $\overline{\text{UHPI\_HRDY}}$  to go high. For this type of access, the state of  $\text{UHPI\_HHWIL}$  is ignored, so if a dual halfword access is performed, the same register will be accessed twice.

**Figure 22-7.  $\overline{\text{UHPI\_HRDY}}$  Behavior During an HPIC or HPIA Read Cycle in the Multiplexed Mode**

Figure 22-8 includes an HPID read cycle without autoincrementing. The host writes the memory address during the HPIA ( $\text{UHPI\_HCNTL}[1:0] = 10\text{b}$ ) write cycle, and the host reads the data during the HPID ( $\text{UHPI\_HCNTL}[1:0] = 11\text{b}$ ) read cycle.  $\overline{\text{UHPI\_HRDY}}$  goes high for each HPIA halfword access, but  $\overline{\text{UHPI\_HRDY}}$  goes high for only the first halfword access in each HPID read cycle.

**Figure 22-8.  $\overline{\text{UHPI\_HRDY}}$  Behavior During a Data Read Operation in the Multiplexed Mode (Case 1: HPIA Write Cycle Followed by Nonautoincrement HPID Read Cycle)**

Figure 22-9 includes an autoincrement HPID read cycle. The host writes the memory address while asserting  $\text{UHPI\_HCNTL}[1:0] = 10\text{b}$  and reads the data while asserting  $\text{UHPI\_HCNTL}[1:0] = 01\text{b}$ . During the first HPID read cycle,  $\overline{\text{UHPI\_HRDY}}$  goes high for only the first halfword access, and subsequent HPID read cycles do not cause  $\overline{\text{UHPI\_HRDY}}$  to go high.

**Figure 22-9.  $\overline{\text{UHPI\_HRDY}}$  Behavior During a Data Read Operation in the Multiplexed Mode (Case 2: HPIA Write Cycle Followed by Autoincrement HPID Read Cycles)**

### 22.2.6.9.2 $\overline{\text{UHPI\_HRDY}}$ Behavior During Multiplexed-Mode Write Operations

Figure 22-10 shows an HPIC ( $\text{UHPI\_HCNTL}[1:0] = 00\text{b}$ ) write cycle operation. An HPIC write cycle does not cause  $\overline{\text{UHPI\_HRDY}}$  to go high and the state of  $\text{UHPI\_HHWIL}$  is ignored. Firmware is not required to perform a dual access to access HPIC.

**Figure 22-10.  $\overline{\text{UHPI\_HRDY}}$  Behavior During an HPIC Write Cycle in the Multiplexed Mode**

Figure 22-11 includes a HPID write cycle without autoincrementing. The host writes the memory address while  $\text{UHPI\_HCNTL}[1:0] = 10\text{b}$  and writes the data while  $\text{UHPI\_HCNTL}[1:0] = 11\text{b}$ . During the HPID write cycle,  $\overline{\text{UHPI\_HRDY}}$  goes high only for the second halfword access.

**Figure 22-11.  $\overline{\text{UHPI\_HRDY}}$  Behavior During a Data Write Operation in the Multiplexed Mode (Case 1: No Autoincrementing)**

Figure 22-12 shows autoincrement HPID write cycles when the write FIFO is empty prior to the HPIA write. The host writes the memory address while  $\text{UHPI\_HCNTL}[1:0] = 10\text{b}$  and writes the data while  $\text{UHPI\_HCNTL}[1:0] = 01\text{b}$ .  $\overline{\text{UHPI\_HRDY}}$  does not go high during any of the HPID write cycles until the FIFO is full.

**Figure 22-12.  $\overline{\text{UHPI\_HRDY}}$  Behavior During a Data Write Operation in the Multiplexed Mode (Case 2: Autoincrementing Selected, FIFO Empty Before Write)**

Figure 22-13 shows a case similar to that of Figure 22-12. However, in the case of Figure 22-13, the write FIFO is not empty when the HPIA access is made.  $\overline{\text{UHPI\_HRDY}}$  goes high twice for the first halfword access of the HPIA write cycle. The first  $\overline{\text{UHPI\_HRDY}}$  high period is due to the nonempty FIFO. The data currently in the FIFO must first be written to the memory. This results in  $\overline{\text{UHPI\_HRDY}}$  going high immediately after the falling edge of the data strobe ( $\text{HSTRB}$ ). The second and third  $\overline{\text{UHPI\_HRDY}}$  high periods occur for the writes to the HPIA.  $\overline{\text{UHPI\_HRDY}}$  remains low for the HPID accesses.

**Figure 22-13.  $\overline{\text{UHPI\_HRDY}}$  Behavior During a Data Write Operation in the Multiplexed Mode (Case 3: Autoincrementing Selected, FIFO Not Empty Before Write)**

### 22.2.6.10 FIFOs and Bursting

The HPI data register (HPID) is a port through which the host accesses two first-in, first-out buffers (FIFOs). As shown in [Figure 22-14](#), a read FIFO supports host read cycles, and a write FIFO supports host write cycles. Both read and write FIFOs are 8-words deep (each word is 32 bits). If the host is performing multiple reads or writes to consecutive memory addresses (autoincrement HPID cycles), the FIFOs are used for bursting. The HPI DMA logic reads or writes a burst of four words at a time when accessing one of the FIFOs.

Bursting is essentially invisible to the host because the host interface signaling is not affected. Its benefit to the host is that the `UHPI_HRDY` signal is deasserted less often when there are multiple reads or writes to consecutive addresses.

**Figure 22-14. FIFOs in the HPI**

### 22.2.6.10.1 Read Bursting

When the host writes to the read address register (HPIAR), the read FIFO is flushed. Any host read data that was in the read FIFO is discarded (the read FIFO pointers are reset). If an HPI DMA write to the read FIFO is in progress at the time of a flush request, the HPI allows this write to complete and then performs the flush.

Read bursting can begin in one of two ways: the host initiates an HPID read cycle with autoincrementing, or the host initiates issues a FETCH command (writes 1 to the FETCH bit in HPIC).

If the host initiates an HPID read cycle with autoincrementing, the HPI DMA logic performs two 4-word burst operations to fill the read FIFO. The host is initially held off by the deassertion of the  $\overline{\text{UHPI\_HRDY}}$  signal until data is available to be read from the read FIFO. Once data is available in the read FIFO, the host can read data from the read FIFO by performing subsequent reads of HPID with autoincrementing. Once the initial read has been performed, the HPI DMA logic continues to perform 4-word burst operations to consecutive memory addresses every time there are four empty word locations in the read FIFO. The HPI DMA logic continues to prefetch data to keep the read FIFO full, until the occurrence of an event that causes a read FIFO flush (see [Section 22.2.6.10.3](#)).

As mentioned, the second way that read bursting may begin is with a FETCH command. The host should always precede the FETCH command with the initialization of the HPIAR register or a nonautoincrement access, so that the read FIFO is flushed beforehand. When the host initiates a FETCH command, the HPI DMA logic begins to prefetch data to keep the read FIFO full, as described in the previous paragraph. The FETCH bit in HPIC does not actually store the value that is written to it; rather, the decoding of a host write of 1 to this bit is considered a FETCH command.

The FETCH command can be helpful if the host wants to minimize a stall condition on the interface. The host can initiate prefetching by writing 1 to the FETCH bit and later perform a read. The host can make use of the time it takes to load the read FIFO with read data, during which the HPI was not ready, by using the CPU to service other tasks.

Both types of continuous or burst reads described in the previous paragraphs begin with a write to the HPI address register, which causes a read FIFO flush. This is the typical way of initiating read cycles, because the initial read address needs to be specified.

---

**NOTE:** An HPID read cycle without autoincrementing does not initiate any prefetching activity. Instead, it causes the read FIFO to be flushed and causes the HPI DMA logic to perform a single-word read from the processor memory. As soon as the host activates a read cycle without autoincrementing, prefetching activity ceases until the occurrence of a FETCH command or an autoincrement read cycle.

---

### 22.2.6.10.2 Write Bursting

A write to the write address register (HPIAW) causes the write FIFO to be flushed. This means that any write data in the write FIFO is forced to its destination in the processor memory (the HPI DMA logic performs burst operations until the write FIFO is empty). When the FIFO has been flushed, the only action that will cause the HPI DMA logic to perform burst writes is a host write to HPID with autoincrementing. The initial host-write data is stored in the write FIFO. An HPI DMA write is not requested until there are four words in the write FIFO. As soon as four words have been written to the FIFO via HPID write cycles with autoincrementing, the HPI DMA logic performs a 4-word burst operation to the processor memory. The burst operations continue as long as there are at least four words in the FIFO. If the FIFO becomes full (eight words are waiting in the FIFO), the HPI holds off the host by deasserting  $\overline{\text{UHPI\_HRDY}}$  until at least one empty word location is available in the FIFO.

Because excessive time might pass between consecutive burst operations, the HPI has a time-out counter. If there are fewer than four words in the write FIFO and the time-out counter expires, the HPI DMA logic empties the FIFO immediately by performing a 2-word or 3-word burst, or a single-word write, as necessary. Every time new data is written to the write FIFO, the time-out counter is automatically reset to begin its count again. The time-out period is set to a value of 160. For more detailed information about the time-out period, see your device-specific data manual.

---

**NOTE:** An HPID write cycle without autoincrementing does not initiate any bursting activity. Instead, it causes the write FIFO to be flushed and causes the HPI DMA logic to perform a single-word write to the processor memory. As soon as the host activates a write cycle without autoincrementing, bursting activity ceases until the occurrence of an autoincrement write cycle. A nonautoincrement write cycle always should be preceded by the initialization of HPIAW or by another nonautoincrement access, so that the write FIFO is flushed beforehand.

---

### 22.2.6.10.3 FIFO Flush Conditions

When specific conditions occur within the HPI, the read or write FIFO must be flushed to prevent the reading of stale data from the FIFOs. When a read FIFO flush condition occurs, all current host accesses and direct memory accesses (DMAs) to the read FIFO are allowed to complete. This includes DMAs that have been requested but not yet initiated. The read FIFO pointers are then reset, causing any read data to be discarded.

Similarly, when a write FIFO flush condition occurs, all current host accesses and DMAs to the write FIFO are allowed to complete. This includes DMAs that have been requested but not yet initiated. All posted writes in the FIFO are then forced to completion with a final burst or single-word write, as necessary.

If the host initiates an HPID host cycle during a FIFO flush, the cycle is held off with the deassertion of `UHPI_HRDY` until the flush is complete and the FIFO is ready to be accessed.

The following conditions cause the read and write FIFOs to be flushed:

- Read FIFO flush conditions:
  - A value from the host is written to the read address register (HPIAR).
  - The host performs an HPID read cycle without autoincrementing.
- Write FIFO flush conditions:
  - A value from the host is written to the write address register (HPIAW).
  - The host performs an HPID write cycle without autoincrementing.
  - The write-burst time-out counter expires.

When operating with `DUALHPIA = 0`, any read or write flush condition causes both read and write FIFOs to be flushed. In addition, the following scenarios cause both FIFOs to be flushed when `DUALHPIA = 0`:

- The host performs a write to the HPIA register.
- The host performs an HPID write cycle with autoincrementing while the read FIFO is not empty (the read FIFO still contains data from prefetching or an HPID read cycle with autoincrementing).
- The host performs an HPID read cycle with autoincrementing while the write FIFO is not empty (there is still posted write data in the write FIFO).

This is useful in providing protection against reading stale data by reading a memory address when a previous write cycle has not been completed at the same address. Similarly, this protects against overwriting data at a memory address when a previous read cycle has not been completed at the same address.

When operating with `DUALHPIA = 1` (HPIAR and HPIAW are independent), there is no such protection. However, when `DUALHPIA = 1`, data flow can occur in both directions without flushing both FIFOs simultaneously, thereby improving HPI bandwidth.

### 22.2.6.10.4 FIFO Behavior When a Hardware Reset or Software Reset Occurs

A hardware reset (RESET pin driven low) or an HPI software reset causes the FIFOs to be reset. The FIFO pointers are cleared, so that all data in the FIFOs are discarded. In addition, all associated FIFO logic is reset.

If a host cycle is active when a hardware or HPI software reset occurs, the `UHPI_HRDY` signal is asserted (driven low), allowing the host to complete the cycle. When the cycle is complete, `UHPI_HRDY` is deasserted (driven high). Any access interrupted by a reset may result in corrupted read data or a lost write data (if the write does not actually update the intended memory or register). Although data may be lost, the host interface protocol is not violated. While either of reset condition is true, and the host is idle (internal `HSTRB` is held high), the FIFOs are held in reset, and host transactions are held off with an inactive `UHPI_HRDY` signal.

## 22.2.7 Reset Considerations

The HPI has two reset sources: software reset and hardware reset.

### 22.2.7.1 Software Reset Considerations

The HPI is not affected by a software reset issued by the emulator.

### 22.2.7.2 Hardware Reset Considerations

When the entire processor is reset with the RESET pin:

- If the internal strobe signal, internal  $\overline{\text{HSTRB}}$ , is high (host is inactive),  $\overline{\text{UHPI\_HRDY}}$  is driven low and remains low until the reset condition is over.
- If internal  $\overline{\text{HSTRB}}$  is low (host cycle is active),  $\overline{\text{UHPI\_HRDY}}$  is driven high, allowing the host to complete the cycle. When internal  $\overline{\text{HSTRB}}$  goes high (cycle is complete),  $\overline{\text{UHPI\_HRDY}}$  is driven low and remains low until the reset condition is over. If the active cycle was a write cycle, the memory or register may not have been correctly updated. If the active cycle was a read cycle, the fetched value may not be valid.
- The HPI registers are reset to their default values (see [Section 22.3](#)).
- The read and write FIFOs and the associated FIFO logic are reset (this includes a flush of the FIFOs).
- Host-to-CPU and CPU-to-host interrupts are cleared.

## 22.2.8 Initialization

The following steps are required to configure the HPI after a hardware reset:

1. Perform the necessary device pin multiplexing setup (see your device-specific data manual).
2. Configure the HPIENA and HPIBYTEAD bits in the chip configuration 1 register (CFGCHIP1) in the *System Configuration (SYSCFG) Module* chapter.
3. Choose how HPIAR and HPIAW will be controlled by configuring the DUALHPIA bit in HPIC.
4. Choose how halfword ordering will be handled by configuring the HWOB bit in HPIC.
5. Choose how the HPI will respond to emulation suspend events by configuring the FREE and SOFT bits in PWREMU\_MGMT.
6. Choose the desired initial addresses and write the addresses to HPIAW and HPIAR, appropriately.
7. Release the HPI logic from reset by clearing the HPIRST bit in HPIC.

The HPI is now ready to perform data transactions.

## 22.2.9 Interrupt Support

The host can interrupt the CPU via the DSPINT bit in HPIC, as described in [Section 22.2.9.1](#). The CPU can send an interrupt to the host by using the HINT bit in HPIC, as described in [Section 22.2.9.2](#).

### 22.2.9.1 DSPINT Bit: Host-to-CPU Interrupts

The DSPINT bit in HPIC allows the host to send an interrupt request to the CPU. The use of the DSPINT bit is summarized in [Figure 22-15](#).

**Figure 22-15. Host-to-CPU Interrupt State Diagram**

- A When the DSPINT bit transitions from 0 to 1, an interrupt is generated to the CPU. No new interrupt can be generated until the CPU has cleared the bit (DSPINT = 0).

To interrupt the CPU, the host must:

1. Drive both UHPI\_HCNTL1 and UHPI\_HCNTL0 low to request a write to HPIC.
2. Write 1 to the DSPINT bit in HPIC.

When the host sets the DSPINT bit, the HPI generates an interrupt pulse to the CPU. If this maskable interrupt is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (ISR).

Before the host can use DSPINT to generate a subsequent interrupt to the CPU, the CPU must acknowledge the current interrupt by writing a 1 to the DSPINT bit. When the CPU writes 1, DSPINT is forced to 0. The host should verify that DSPINT = 0 before generating subsequent interrupts. While DSPINT = 1, host writes to the DSPINT bit do not generate an interrupt pulse.

Writes of 0 have no effect. A hardware reset immediately clears DSPINT and thus clears an active host-to-CPU interrupt.

### 22.2.9.2 HINT Bit: CPU-to-Host Interrupts

The HINT bit in HPIC allows the CPU to send an interrupt request to the host. The use of the HINT bit is summarized in [Figure 22-16](#).

**Figure 22-16. CPU-to-Host Interrupt State Diagram**

If the CPU writes 1 to the HINT bit of HPIC, the HPI drives the  $\overline{\text{UHPI\_HINT}}$  signal low, indicating an interrupt condition to the host. Before the CPU can use the HINT bit generate a subsequent interrupt to host, the host must acknowledge the current interrupt by writing 1 to the HINT bit. When the host does this, the HPI clears the HINT bit (HINT = 0), and this drives the  $\overline{\text{UHPI\_HINT}}$  signal high. The CPU should read HPIC and make sure HINT = 0 before generating subsequent interrupts.

Writes of 0 have no effect. A hardware reset immediately clears the HINT bit and thus clears an active CPU-to-host interrupt.

### 22.2.10 EDMA Event Support

The HPI does not provide synchronization events to the EDMA system. Memory accesses from the HPI are handled automatically, independent of the EDMA controller. The HPI controller has its own dedicated DMA and its operation and configuration are transparent.

### 22.2.11 Power Management

The HPI peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the HPI peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

## 22.2.12 Emulation Considerations

The FREE and SOFT bits in the power and emulation management register (PWREMU\_MGMT) determine the response of the HPI to an emulation suspend condition. If FREE = 1, the HPI is not affected, and the SOFT bit has no effect. If FREE = 0 and SOFT = 0, the HPI is not affected. If FREE = 0 and SOFT = 1:

- The HPI DMA logic halts after the current host and HPI DMA operations are completed.
- The external host interface functions as normal throughout the emulation suspend condition. The host may access the control register (HPIC). The host may also access the HPIA registers and may perform data reads until the read FIFO is empty or data writes until the write FIFO is full. As in normal operation,  $\overline{\text{UHPI\_HRDY}}$  is driven low during a host cycle that cannot be completed due to the write FIFO being full or the read FIFO being empty. If this occurs,  $\overline{\text{UHPI\_HRDY}}$  continues to be driven low, holding off the host, until the emulation suspend condition is over, and the FIFOs are serviced by the HPI DMA logic, allowing the host cycle to complete.
- When the emulation suspend condition is over, the appropriate requests by the HPI DMA logic are made to process any posted host writes in the write FIFO or to fill the read FIFO as necessary. HPI operation then continues as normal.

## 22.3 Registers

Table 22-6 lists the memory-mapped registers for the HPI. See your device-specific data manual for the memory addresses of these registers.

**Table 22-6. HPI Registers**

### 22.3.4 GPIO Direction 1 Register (GPIO\_DIR1)

The GPIO direction 1 register (GPIO\_DIR1) determines if the UHPI\_HD $n$  pin is an input or an output. GPIO\_DIR1 is shown in [Figure 22-20](#) and described in [Table 22-10](#).

**Figure 22-20. GPIO Direction 1 Register (GPIO\_DIR1)**

### 22.3.5 GPIO Data 1 Register (GPIO\_DAT1)

The GPIO data 1 register (GPIO\_DAT1) determines the value driven on the corresponding UHPI\_HD $n$  pin, if the pin is configured as an output (GPIO\_DIR1.HD $n$  = 1). Writes do not affect pins not configured as GPIO outputs. The bits in GPIO\_DAT1 are set or cleared by writing directly to this register. A read of GPIO\_DAT1 returns the value of the register bit (HD $n$ ) not the value at the UHPI\_HD $n$  pin (that might be configured as an input). GPIO\_DAT1 is shown in [Figure 22-21](#) and described in [Table 22-11](#).

**Figure 22-21. GPIO Data 1 Register (GPIO\_DAT1)**

|                                          |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

### 22.3.7 GPIO Data 2 Register (GPIO\_DAT2)

The GPIO data 2 register (GPIO\_DAT2) determines the value driven on the corresponding HPI pin, if the pin is configured as an output (GPIO\_DIR2 bit = 1). Writes do not affect pins not configured as GPIO outputs. The bits in GPIO\_DAT2 are set or cleared by writing directly to this register. A read of GPIO\_DAT2 returns the value of the register bit not the value at the HPI pin (that might be configured as an input). GPIO\_DAT2 is shown in [Figure 22-23](#) and described in [Table 22-13](#).

**Figure 22-23. GPIO Data 2 Register (GPIO\_DAT2)**

### 22.3.8 Host Port Interface Control Register (HPIC)

The host port interface control register (HPIC) stores configuration and control information for the HPI. As shown in [Figure 22-24](#) and [Figure 22-25](#) and described in [Table 22-14](#), the host and CPU do not have the same access permissions. The host has full read/write access; the CPU has primarily read-only access, but with the exception that the CPU can write 1 to the HINT bit to generate an interrupt to the host.

**Figure 22-24. Host Port Interface Control Register (HPIC)–Host Access Permissions**

### 22.3.9 Host Port Interface Write Address Register (HPIAW)

The HPI contains two 32-bit address registers: one for read operations (HPIAR) and one for write operations (HPIAW). The host port interface write address register (HPIAW) is shown in [Figure 22-26](#) and described in [Table 22-15](#). The HPI can be configured such that HPIAR and HPIAW act as a single 32-bit HPIA (single-HPIA mode) or as two separate 32-bit HPIAs (dual-HPIA mode) from the perspective of the host. For details about these HPIA modes, see [Section 22.2.6.1](#).

Note that the addresses loaded into the HPI address registers can be configured by the HPIBYTEAD bit in the chip configuration 1 register (CFGCHIP1) of the system configuration module. If byte address is selected (HPIBYTEAD = 1), the address must be 32-bit word aligned (with the least-significant two bits equal to zero).

**Figure 22-26. Host Port Interface Write Address Register (HPIAW)**

### 22.3.10 Host Port Interface Read Address Register (HPIAR)

The HPI contains two 32-bit address registers: one for read operations (HPIAR) and one for write operations (HPIAW). The host port interface read address register (HPIAR) is shown in [Figure 22-27](#) and described in [Table 22-16](#). The HPI can be configured such that HPIAR and HPIAW act as a single 32-bit HPIA (single-HPIA mode) or as two separate 32-bit HPIAs (dual-HPIA mode) from the perspective of the host. For details about these HPIA modes, see [Section 22.2.6.1](#).

Note that the addresses loaded into the HPI address registers can be configured by the HPIBYTEAD bit in the chip configuration 1 register (CFGCHIP1) of the system configuration module. If byte address is selected (HPIBYTEAD = 1), the address must be 32-bit word aligned (with the least-significant two bits equal to zero).

## ***Inter-Integrated Circuit (I2C) Module***

---

---

This chapter describes the inter-integrated circuit (I2C) peripheral. The scope of this chapter assumes that you are familiar with the Philips Semiconductors Inter-IC bus (I2C-bus) specification version 2.1.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>23.1 Introduction .....</b> | <b>1005</b> |
| <b>23.2 Architecture .....</b> | <b>1007</b> |
| <b>23.3 Registers .....</b>    | <b>1019</b> |

## 23.1 Introduction

### 23.1.1 Purpose of the Peripheral

The I2C peripheral provides an interface between the SoC and other devices that are compliant with the I2C-bus specification and connected by way of an I2C-bus. External components that are attached to this two-wire serial bus can transmit and receive data that is up to eight bits wide both to and from the SoC through the I2C peripheral.

### 23.1.2 Features

The I2C peripheral has the following features:

- Compliance with the Philips Semiconductors I2C-bus specification (version 2.1):
  - Support for byte format transfer
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers mode
  - Support for multiple slave-transmitters and master-receivers mode
  - Combined master transmit/receive and receive/transmit mode
  - I2C data transfer rate of from 10 kbps up to 400 kbps (Philips I2C rate)
- 2-bit to 8-bit format transfer
- Free data format mode
- One read DMA event and one write DMA event that the DMA can use
- Seven interrupts that the CPU can use
- Peripheral enable/disable capability

#### 23.1.2.1 Features Not Supported

- High-speed mode
- CBUS-compatibility mode
- The combined format in 10-bit addressing mode (the I2C sends the slave address the second byte every time it sends the slave address the first byte).

### 23.1.3 Functional Block Diagram

A block diagram of the I2C peripheral is shown in [Figure 25-1](#). Refer to [Section 23.2](#) for detailed information about the architecture of the I2C peripheral.

**Figure 23-1. I2C Peripheral Block Diagram**

### 23.1.4 Industry Standard(s) Compliance Statement

The I2C peripheral is compliant with the Philips Semiconductors Inter-IC bus (I2C-bus) specification version 2.1.

## 23.2 Architecture

The I2C peripheral consists of the following primary blocks:

- A serial interface: one data pin (I2Cx\_SDA) and one clock pin (I2Cx\_SCL)
- Data registers to temporarily hold receive data and transmit data traveling between the I2Cx\_SDA pin and the CPU or the EDMA controller
- Control and status registers
- A peripheral data bus interface to enable the CPU and the EDMA controller to access the I2C peripheral registers
- A clock synchronizer to synchronize the I2C input clock (from the processor clock generator) and the clock on the I2Cx\_SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C peripheral
- A noise filter on each of the two pins, I2Cx\_SDA and I2Cx\_SCL
- An arbitrator to handle arbitration between the I2C peripheral (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- EDMA event generation logic, so that activity in the EDMA controller can be synchronized to data reception and data transmission in the I2C peripheral

Figure 25-1 shows the four registers used for transmission and reception. The CPU or the EDMA controller writes data for transmission to ICDXR and reads received data from ICDRR. When the I2C peripheral is configured as a transmitter, data written to ICDXR is copied to ICXSR and shifted out on the I2Cx\_SDA pin one bit at a time. When the I2C peripheral is configured as a receiver, received data is shifted into ICRSR and then copied to ICDRR.

### 23.2.1 Bus Structure

Figure 25-1 shows how the I2C peripheral is connected to the I2C bus. The I2C bus is a multi-master bus that supports a multi-master mode. This allows more than one device capable of controlling the bus that is connected to it. A unique address recognizes each I2C device. Each I2C device can operate as either transmitter or receiver, depending on the function of the device. Devices that are connected to the I2C bus can be considered a master or slave when performing data transfers, in addition to being a transmitter or receiver.

**NOTE:** A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. Any device that is addressed by this master is considered a slave during this transfer.

An example of multiple I2C modules that are connected for a two-way transfer from one device to other devices is shown in Figure 23-2.

**Figure 23-2. Multiple I2C Modules Connected**

### 23.2.2 Clock Generation

As shown in Figure 23-3, I2C input clock is fed to the I2C module. A programmable prescaler (IPSC bit in ICPSC) in the I2C module divides down the I2C input clock to produce a prescaled module clock. The prescaled module clock must be operated within the range of 6.7 to 13.3 MHz. The I2C clock dividers divide-down the high (ICCH bit in ICCLKH) and low portions (ICCL bit in ICCLKL) of the prescaled module clock signal to produce the I2C serial clock, which appears on the I2Cx\_SCL pin when the I2C module is configured to be a master on the I2C bus.

The prescaler (IPSC bit in ICPSC) must only be initialized while the I2C module is in the reset state (IRS = 0 in ICMR). The prescaled frequency only takes effect when the IRS bit in ICMR is changed to 1. Changing the IPSC bit in ICPSC while IRS = 1 in ICMR has no effect. Likewise, you must configure the I2C clock dividers (ICCH bit in ICCLKH and ICCL bit in ICCLKL) while the I2C module is still in reset (IRS = 0 in ICMR).

**Figure 23-3. Clocking Diagram for the I2C Peripheral**

#### CAUTION

**Prescaled Module Clock Frequency Range:**

The I2C module must be operated with a prescaled module clock frequency of 6.7 to 13.3 MHz. The I2C prescaler register (ICPSC) must be configured to this frequency range.

### 23.2.3 Clock Synchronization

Only one master device generates the clock signal (I2Cx\_SCL) under normal conditions. However, there are two or more masters during the arbitration procedure; and, you must synchronize the clock so that you can compare the data output. Figure 23-4 illustrates the clock synchronization. The wired-AND property of I2Cx\_SCL means that a device that first generates a low period on I2Cx\_SCL (device #1) overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The I2Cx\_SCL is held low by the device with the longest low period. The other devices that finish their low periods must wait for I2Cx\_SCL to be released before starting their high periods. A synchronized signal on I2Cx\_SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. This way, a slave slows down a fast master and the slow device creates enough time to store a received data word or to prepare a data word that you are going to transmit.

**Figure 23-4. Synchronization of Two I2C Clock Generators During Arbitration**

### 23.2.4 Signal Descriptions

The I2C peripheral has a serial data pin (I2Cx\_SDA) and a serial clock pin (I2Cx\_SCL) for data communication, as shown in Figure 25-1. These two pins carry information between the device and other devices that are connected to the I2C-bus. The I2Cx\_SDA and I2Cx\_SCL pins both are bi-directional. They each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

See your device-specific data manual for additional timing and electrical specifications for these pins.

#### 23.2.4.1 Input and Output Voltage Levels

The master device generates one clock pulse for each data bit that is transferred. Due to a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated power supply level. See your device-specific data manual for more information.

### 23.2.4.2 Data Validity

The data on I2Cx\_SDA must be stable during the high period of the clock (see Figure 23-5). The high or low state of the data line, I2Cx\_SDA, can change only when the clock signal on I2Cx\_SCL is low.

**Figure 23-5. Bit Transfer on the I2C-Bus**

### 23.2.5 START and STOP Conditions

The I2C peripheral can generate START and STOP conditions when the peripheral is configured to be a master on the I2C-bus, as shown in Figure 23-6:

- The START condition is defined as a high-to-low transition on the I2Cx\_SDA line while I2Cx\_SCL is high. A master drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the I2Cx\_SDA line while I2Cx\_SCL is high. A master drives this condition to indicate the end of a data transfer.

The I2C-bus is considered busy after a START condition and before a subsequent STOP condition. The bus busy (BB) bit of ICSTR is 1. The bus is considered free between a STOP condition and the next START condition. The BB is 0.

The master mode (MST) bit and the START condition (STT) bit in ICMDR must both be 1 for the I2C peripheral to start a data transfer with a START condition. The STOP condition (STP) bit must be set to 1 for the I2C peripheral to end a data transfer with a STOP condition. A repeated START condition generates when BB is set to 1 and STT is also set to 1. See Section 23.3.9 for a description of ICMDR (including the MST, STT, and STP bits).

**Figure 23-6. I2C Peripheral START and STOP Conditions**

## 23.2.6 Serial Data Formats

Figure 23-7 shows an example of a data transfer on the I2C-bus. The I2C peripheral supports 1-bit to 8-bit data values. Figure 23-7 is shown in an 8-bit data format (BC = 000 in ICM DR). Each bit put on the I2Cx\_SDA line is equivalent to one pulse on the I2Cx\_SCL line. The data is always transferred with the most-significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted; however, the transmitters and receivers must agree on the number of data values being transferred.

The I2C peripheral supports the following data formats:

- 7-bit addressing mode
- 10-bit addressing mode
- Free data format mode

Figure 23-7. I2C Peripheral Data Transfer

### 23.2.6.1 7-Bit Addressing Format

In the 7-bit addressing format (Figure 23-8), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/W bit. The R/W bit determines the direction of the data.

- $R/\overline{W} = 0$ : The master writes (transmits) data to the addressed slave.
- $R/\overline{W} = 1$ : The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after the  $R/\overline{W}$  bit. If the slave inserts the ACK bit,  $n$  bits of data from the transmitter (master or slave, depending on the  $R/\overline{W}$  bit) follow it.  $n$  is a number from 1 to 8 that the bit count (BC) bits of ICM DR determine. The receiver inserts an ACK bit after the data bits have been transferred.

Write a 0 to the expanded address enable (XA) bit of ICM DR to select the 7-bit addressing format.

Figure 23-8. I2C Peripheral 7-Bit Addressing Format (FDF = 0, XA = 0 in ICM DR)

$n$  = The number of data bits (from 1 to 8) specified by the bit count (BC) field of ICM DR.

### 23.2.6.2 10-Bit Addressing Format

The 10-bit addressing format (Figure 23-9) is like the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and  $R/\overline{W} = 0$  (write). The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment (ACK) after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. (For more information about using 10-bit addressing, see the Philips Semiconductors I2C-bus specification.)

Write 1 to the XA bit of ICMDR to select the 10-bit addressing format.

**Figure 23-9. I2C Peripheral 10-Bit Addressing Format With Master-Transmitter Writing to Slave-Receiver (FDF = 0, XA = 1 in ICMDR)**

n = The number of data bits (from 1 to 8) specified by the bit count (BC) field of ICMDR.

### 23.2.6.3 Free Data Format

In the free data format (Figure 23-10), the first bits after a START condition (S) are a data word. An ACK bit is inserted after each data word. The data word can be from 1 to 8 bits, depending on the bit count (BC) bits of ICMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

To select the free data format, write 1 to the free data format (FDF) bit of ICMDR.

**Figure 23-10. I2C Peripheral Free Data Format (FDF = 1 in ICMDR)**

n = The number of data bits (from 1 to 8) specified by the bit count (BC) field of ICMDR.

### 23.2.6.4 Using a Repeated START Condition

The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, and free data formats. The 7-bit addressing format using a repeated START condition (S) is shown in Figure 23-11. At the end of each data word, the master can drive another START condition. Using this capability, a master can transmit/receive any number of data words before driving a STOP condition. The length of a data word can be from 1 to 8 bits and is selected with the bit count (BC) bits of ICMDR.

**Figure 23-11. I2C Peripheral 7-Bit Addressing Format With Repeated START Condition (FDF = 0, XA = 0 in ICMDR)**

n = The number of data bits (from 1 to 8) specified by the bit count (BC) field of ICMDR.

### 23.2.7 Operating Modes

The I2C peripheral has four basic operating modes to support data transfers as a master and as a slave. See [Table 23-1](#) for the names and descriptions of the modes.

If the I2C peripheral is a master, it begins as a master-transmitter and, typically, transmits an address for a particular slave. When giving data to the slave, the I2C peripheral must remain a master-transmitter. In order to receive data from a slave, the I2C peripheral must be changed to the master-receiver mode.

If the I2C peripheral is a slave, it begins as a slave-receiver and, typically, sends acknowledgment when it recognizes its slave address from a master. If the master will be sending data to the I2C peripheral, the peripheral must remain a slave-receiver. If the master has requested data from the I2C peripheral, the peripheral must be changed to the slave-transmitter mode.

**Table 23-1. Operating Modes of the I2C Peripheral**

| Operating Mode          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slave-receiver mode     | The I2C peripheral is a slave and receives data from a master. All slave modules begin in this mode. In this mode, serial data bits received on I2Cx_SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C peripheral does not generate the clock signal, but it can hold I2Cx_SCL low while the intervention of the processor is required (RSFULL = 1 in ICSTR) after data has been received.                                                                                                                                                                                                                                                                                                                                                        |
| Slave-transmitter mode  | The I2C peripheral is a slave and transmits data to a master. This mode can only be entered from the slave-receiver mode; the I2C peripheral must first receive a command from the master. When you are using any of the 7-bit/10-bit addressing formats, the I2C peripheral enters its slave-transmitter mode if the slave address is the same as its own address (in ICOAR) and the master has transmitted $R/\overline{W} = 1$ . As a slave-transmitter, the I2C peripheral then shifts the serial data out on I2Cx_SDA with the clock pulses that are generated by the master. While a slave, the I2C peripheral does not generate the clock signal, but it can hold I2Cx_SCL low while the intervention of the processor is required (XSMT = 0 in ICSTR) after data has been transmitted. |
| Master-receiver mode    | The I2C peripheral is a master and receives data from a slave. This mode can only be entered from the master-transmitter mode; the I2C peripheral must first transmit a command to the slave. When you are using any of the 7-bit/10-bit addressing formats, the I2C peripheral enters its master-receiver mode after transmitting the slave address and $R/\overline{W} = 1$ . Serial data bits on I2Cx_SDA are shifted into the I2C peripheral with the clock pulses generated by the I2C peripheral on I2Cx_SCL. The clock pulses are inhibited and I2Cx_SCL is held low when the intervention of the processor is required (RSFULL = 1 in ICSTR) after data has been received.                                                                                                             |
| Master-transmitter mode | The I2C peripheral is a master and transmits control information and data to a slave. All master modules begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on I2Cx_SDA. The bit shifting is synchronized with the clock pulses generated by the I2C peripheral on I2Cx_SCL. The clock pulses are inhibited and I2Cx_SCL is held low when the intervention of the processor is required (XSMT = 0 in ICSTR) after data has been transmitted.                                                                                                                                                                                                                                                                                        |

### 23.2.8 NACK Bit Generation

When the I2C peripheral is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C peripheral must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. [Table 23-2](#) summarizes the various ways the I2C peripheral sends a NACK bit.

**Table 23-2. Ways to Generate a NACK Bit**

| I2C Peripheral Condition                                           | NACK Bit Generation                                                                                                                                                                                                                                                     |                                                                                                 |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
|                                                                    | Basic                                                                                                                                                                                                                                                                   | Optional                                                                                        |
| Slave-receiver mode                                                | <ul style="list-style-type: none"> <li>Disable data transfers (STT = 0 in ICSTR).</li> <li>Allow an overrun condition (RSFULL = 1 in ICSTR).</li> <li>Reset the peripheral (IRS = 0 in ICMDR)</li> </ul>                                                                | Set the NACKMOD bit of ICMDR before the rising edge of the last data bit you intend to receive. |
| Master-receiver mode<br>AND<br>Repeat mode<br>(RM = 1 in ICMDR)    | <ul style="list-style-type: none"> <li>Generate a STOP condition (STOP = 1 in ICMDR).</li> <li>Reset the peripheral (IRS = 0 in ICMDR).</li> </ul>                                                                                                                      | Set the NACKMOD bit of ICMDR before the rising edge of the last data bit you intend to receive. |
| Master-receiver mode<br>AND<br>Nonrepeat mode<br>(RM = 0 in ICMDR) | <ul style="list-style-type: none"> <li>If STP = 1 in ICMDR, allow the internal data counter to count down to 0 and force a STOP condition.</li> <li>If STP = 0, make STP = 1 to generate a STOP condition.</li> <li>Reset the peripheral (IRS = 0 in ICMDR).</li> </ul> | Set the NACKMOD bit of ICMDR before the rising edge of the last data bit you intend to receive. |

### 23.2.9 Arbitration

If two or more master-transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (I2Cx\_SDA) by the competing transmitters. [Figure 23-12](#) illustrates the arbitration procedure between two devices. The first master-transmitter, which drives I2Cx\_SDA high, is overruled by another master-transmitter that drives I2Cx\_SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C peripheral is the losing master, it switches to the slave-receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to I2Cx\_SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

**Figure 23-12. Arbitration Procedure Between Two Master-Transmitters**

### 23.2.10 Reset Considerations

The I2C peripheral has two reset sources: software reset and hardware reset.

#### 23.2.10.1 Software Reset Considerations

To reset the I2C peripheral, write 0 to the I2C reset (IRS) bit in the I2C mode register (ICMDR). All status bits in the I2C interrupt status register (ICSTR) are forced to their default values, and the I2C peripheral remains disabled until IRS is changed to 1. The I2Cx\_SDA and I2Cx\_SCL pins are in the high-impedance state.

---

**NOTE:** If the IRS bit is cleared to 0 during a transfer, this can cause the I2C bus to hang (I2Cx\_SDA and I2Cx\_SCL are in the high-impedance state).

---

#### 23.2.10.2 Hardware Reset Considerations

When a hardware reset occurs, all the registers of the I2C peripheral are set to their default values and the I2C peripheral remains disabled until the I2C reset (IRS) bit in the I2C mode register (ICMDR) is changed to 1.

---

**NOTE:** The IRS bit must be cleared to 0 while you configure/reconfigure the I2C peripheral. Forcing IRS to 0 can be used to save power and to clear error conditions.

---

### 23.2.11 Initialization

Proper I2C initialization is required prior to starting communication with other I2C device(s). Unless a fully fledged driver is in place, you need to determine the required I2C configuration needed (for example, Master Receiver, etc.) and configure the I2C controller with the desired settings. Enabling the I2C clock should be the first task. Then the I2C controller is placed in reset. You now are ready to configure the I2C controller. Once configuration is done, you need to enable the I2C controller by releasing the controller from reset. Prior to starting communication, you need to make sure that all status bits are cleared and no pending interrupts exist. Once the bus is determined to be available (the bus is not busy), the I2C is ready to proceed with the desired communication.

### 23.2.11.1 Configuring the I2C in Master Receiver Mode and Servicing Receive Data via CPU

The following initialization procedure is for the I2C controller configured in Master Receiver mode. The CPU is used to move data from the I2C receive register to CPU memory (memory accessible by the CPU).

1. Enable I2C clock from the Power and Sleep Controller, if it is driven by the Power and Sleep Controller (see the *Power and Sleep Controller (PSC)* chapter).
2. Place I2C in reset (clear IRS = 0 in ICMDR).
3. Configure ICMDR:
  - Configure I2C as Master (MST = 1).
  - Indicate the I2C configuration to be used; for example, Data Receiver (TRX = 0)
  - Indicate 7-bit addressing is to be used (XA = 0).
  - Disable repeat mode (RM = 0).
  - Disable loopback mode (DLB = 0).
  - Disable free data format (FDF = 0).
  - Optional: Disable start byte mode if addressing a fully fledged I2C device (STB = 0).
  - Set number of bits to transfer to be 8 bits (BC = 0).
4. Configure Slave Address: the I2C device this I2C master would be addressing (ICSAR = 7BIT ADDRESS).
5. Configure the peripheral clock operation frequency (ICPSC). This value should be selected in such a way that the frequency is between 6.7 and 13.3 MHz.
6. Configure I2C master clock frequency:
  - Configure the low-time divider value (ICCLKL).
  - Configure the high-time divider value (ICCLKH).
7. Make sure the interrupt status register (ICSTR) is cleared:
  - Read ICSTR and write it back (write 1 to clear) ICSTR = ICSTR
  - Read ICIVR until it is 0.
8. Take I2C controller out of reset: enable I2C controller (set IRS bit = 1 in ICMDR).
9. Wait until bus busy bit is cleared (BB = 0 in ICSTR).
10. Generate a START event, followed by Slave Address, etc. (set STT = 1 in ICMDR).
11. Wait until data is received (ICRRDY = 1 in ICSTR).
12. Read data:
  - If ICRRDY = 1 in ICSTR, then read ICDRR.
  - Perform the previous two steps until receiving one byte short of the entire byte expecting to receive.
13. Configure the I2C controller not to generate an ACK on the next/final byte reception: set NACKMOD bit for the I2C to generate a NACK on the last byte received (set NACKMOD = 1 in ICMDR).
14. End transfer/release bus when transfer is done. Generate a STOP event (set STP = 1 in ICMDR).

### 23.2.12 Interrupt Support

The I2C peripheral is capable of interrupting the CPU. The CPU can determine which I2C events caused the interrupt by reading the I2C interrupt vector register (ICIVR). ICIVR contains a binary-coded interrupt vector type to indicate which interrupt has occurred. Reading ICIVR clears the interrupt flag; if other interrupts are pending, a new interrupt is generated. If there is more than one pending interrupt flag, reading ICIVR clears the highest-priority interrupt flag.

### 23.2.12.1 Interrupt Events and Requests

The I2C peripheral can generate the interrupts described in [Table 23-3](#). Each interrupt has a flag bit in the I2C interrupt status register (ICSTR) and a mask bit in the interrupt mask register (ICIMR). When one of the specified events occurs, its flag bit is set. If the corresponding mask bit is 0, the interrupt request is blocked; if the mask bit is 1, the request is forwarded to the CPU as an I2C interrupt.

**Table 23-3. Descriptions of the I2C Interrupt Events**

| I2C Interrupt                                 | Initiating Event                                                                                                                                                                                                                                       |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arbitration-lost interrupt (AL)               | Generated when the I2C arbitration procedure is lost or illegal START/STOP conditions occur                                                                                                                                                            |
| No-acknowledge interrupt (NACK)               | Generated when the master I2C does not receive any acknowledge from the receiver                                                                                                                                                                       |
| Registers-ready-for-access interrupt (ARDY)   | Generated by the I2C when the previously programmed address, data and command have been performed and the status bits have been updated. This interrupt is used to let the controlling processor know that the I2C registers are ready to be accessed. |
| Receive interrupt/status (ICRINT and ICRRDY)  | Generated when the received data in the receive-shift register (ICRSR) has been copied into the ICDRR. The ICRRDY bit can also be polled by the CPU to read the received data in the ICDRR.                                                            |
| Transmit interrupt/status (ICXINT and ICXRDY) | Generated when the transmitted data has been copied from ICDXR to the transmit-shift register (ICXSR) and shifted out on the I2Cx_SDA pin. This bit can also be polled by the CPU to write the next transmitted data into the ICDXR.                   |
| Stop-Condition-Detection interrupt (SCD)      | Generated when a STOP condition has been detected                                                                                                                                                                                                      |
| Address-as-Slave interrupt (AAS)              | Generated when the I2C has recognized its own slave address or an address of all (8) zeros.                                                                                                                                                            |

### 23.2.13 DMA Events Generated by the I2C Peripheral

For the EDMA controller to handle transmit and receive data, the I2C peripheral generates the following two EDMA events. Activity in EDMA channels can be synchronized to these events.

- **Receive event (ICREVT):** When receive data has been copied from the receive shift register (ICRSR) to the data receive register (ICDRR), the I2C peripheral sends an REVT signal to the EDMA controller. In response, the EDMA controller can read the data from ICDRR.
- **Transmit event (ICXEVT):** When transmit data has been copied from the data transmit register (ICDXR) to the transmit shift register (ICXSR), the I2C peripheral sends an XEVT signal to the EDMA controller. In response, the EDMA controller can write the next transmit data value to ICDXR.

### 23.2.14 Power Management

The I2C peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the I2C peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

### 23.2.15 Emulation Considerations

The response of the I2C events to emulation suspend events (such as halts and breakpoints) is controlled by the FREE bit in the I2C mode register (ICMDR). The I2C peripheral either stops exchanging data (FREE = 0) or continues to run (FREE = 1) when an emulation suspend event occurs. How the I2C peripheral terminates data transactions is affected by whether the I2C peripheral is acting as a master or a slave. For more information, see the description of the FREE bit in ICMDR (see [Section 23.3.9](#)).

## 23.3 Registers

[Table 30-8](#) lists the memory-mapped registers for the inter-integrated circuit (I2C) peripheral. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in [Table 30-8](#) should be considered as reserved locations and the register contents should not be modified.

**Table 23-4. Inter-Integrated Circuit (I2C) Registers**

| Offset | Acronym | Register Description                   | Section                         |
|--------|---------|----------------------------------------|---------------------------------|
| 0h     | ICOAR   | I2C Own Address Register               | <a href="#">Section 23.3.1</a>  |

### 23.3.1 I2C Own Address Register (ICOAR)

The I2C own address register (ICOAR) is used to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in ICMDR), only bits 6-0 are used; bits 9-7 are ignored. ICOAR is shown in [Figure 23-13](#) and described in [Table 23-5](#).

**Figure 23-13. I2C Own Address Register (ICOAR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-5. I2C Own Address Register (ICOAR) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                               |
|-------|----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-10 | Reserved | 0      | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                       |
| 9-0   | OADDR    | 0-3FFh | Own slave address. Provides the slave address of the I2C.<br>In 7-bit addressing mode (XA = 0 in ICMDR): bits 6-0 provide the 7-bit slave address of the I2C. Bits 9-7 are ignored.<br>In 10-bit addressing mode (XA = 1 in ICMDR): bits 9-0 provide the 10-bit slave address of the I2C. |

### 23.3.2 I2C Interrupt Mask Register (ICIMR)

The I2C interrupt mask register (ICIMR) is used to individually enable or disable I2C interrupt requests. ICIMR is shown in [Figure 23-14](#) and described [Table 23-6](#).

**Figure 23-14. I2C Interrupt Mask Register (ICIMR)**

|          |  |       |       |        |        |       |       |       |
|----------|--|-------|-------|--------|--------|-------|-------|-------|

### 23.3.3 I2C Interrupt Status Register (ICSTR)

The I2C interrupt status register (ICSTR) is used to determine which interrupt has occurred and to read status information. ICSTR is shown in [Figure 23-15](#) and described in [Table 23-7](#).

**Figure 23-15. I2C Interrupt Status Register (ICSTR)**

|          |         |         |         |         |         |         |         |
|----------|---------|---------|---------|---------|---------|---------|---------|
| Reserved |         |         |         |         |         |         |         |
| R-0      |         |         |         |         |         |         |         |

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing 0 has no effect); -n = value after reset

**Table 23-7. I2C Interrupt Status Register (ICSTR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-15 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 14    | SDIR     | 0     | Slave direction bit. In digital-loopback mode (DLB), the SDIR bit is cleared to 0.<br>I2C is acting as a master-transmitter/receiver or a slave-receiver. SDIR is cleared by one of the following events:<br><ul style="list-style-type: none"> <li>A STOP or a START condition.</li> <li>SDIR is manually cleared. To clear this bit, write a 1 to it.</li> </ul>                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | I2C is acting as a slave-transmitter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 13    | NACKSNT  | 0     | No-acknowledgment sent bit. NACKSNT bit is used when the I2C is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in <a href="#">Section 23.3.9</a> ).<br>NACK is not sent. NACKSNT is cleared by one of the following events:<br><ul style="list-style-type: none"> <li>It is manually cleared. To clear this bit, write a 1 to it.</li> <li>The I2C is reset (either when 0 is written to the IRS bit of ICMDR or when the processor is reset).</li> </ul>                                                                                                                                 |
|       |          | 1     | NACK is sent. A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 12    | BB       | 0     | Bus busy bit. BB bit indicates whether the I2C-bus is busy or is free for another data transfer. In the master mode, BB is controlled by the software.<br>Bus is free. BB is cleared by one of the following events:<br><ul style="list-style-type: none"> <li>The I2C receives or transmits a STOP bit (bus free).</li> <li>BB is manually cleared. To clear this bit, write a 1 to it.</li> <li>The I2C is reset (either when 0 is written to the IRS bit of ICMDR or when the processor is reset).</li> </ul>                                                                                                                                                          |
|       |          | 1     | Bus is busy. When the STT bit in ICMDR is set to 1, a restart condition is generated. BB is set by one of the following events:<br><ul style="list-style-type: none"> <li>The I2C has received or transmitted a START bit on the bus.</li> <li>I2Cx_SCL is in a low state and the IRS bit in ICMDR is 0.</li> </ul>                                                                                                                                                                                                                                                                                                                                                       |
| 11    | RSFULL   | 0     | Receive shift register full bit. RSFULL indicates an overrun condition during reception. Overrun occurs when the receive shift register (ICRSR) is full with new data but the previous data has not been read from the data receive register (ICDRR). The new data will not be copied to ICDRR until the previous data is read. As new bits arrive from the I2Cx_SDA pin, they overwrite the bits in ICRSR.<br>No overrun is detected. RSFULL is cleared by one of the following events:<br><ul style="list-style-type: none"> <li>ICDRR is read.</li> <li>The I2C is reset (either when 0 is written to the IRS bit of ICMDR or when the processor is reset).</li> </ul> |
|       |          | 1     | Overrun is detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 23-7. I2C Interrupt Status Register (ICSTR) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | XSMT     | 0<br>1 | Transmit shift register empty bit. XSMT indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (ICXSR) is empty but the data transmit register (ICDXR) has not been loaded since the last ICDXR-to-ICXSR transfer. The next ICDXR-to-ICXSR transfer will not occur until new data is in ICDXR. If new data is not transferred in time, the previous data may be re-transmitted on the I2Cx_SDA pin.<br><br>Underflow is detected.<br><br>No underflow is detected. XSMT is set by one of the following events: <ul style="list-style-type: none"><li>• Data is written to ICDXR.</li><li>• The I2C is reset (either when 0 is written to the IRS bit of ICMR or when the processor is reset).</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 9   | AAS      | 0<br>1 | Addressed-as-slave bit.<br><br>The AAS bit has been cleared by a repeated START condition or by a STOP condition.<br><br>AAS is set by one of the following events: <ul style="list-style-type: none"><li>• I2C has recognized its own slave address or an address of all zeros (general call).</li><li>• The first data word has been received in the free data format (FDF = 1 in ICMR).</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 7-6 | Reserved | 0      | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 5   | SCD      | 0<br>1 | Stop condition detected bit. SCD indicates when a STOP condition has been detected on the I2C bus. The STOP condition could be generated by the I2C or by another I2C device connected to the bus.<br><br>No STOP condition has been detected. SCD is cleared by one of the following events: <ul style="list-style-type: none"><li>• By reading the INTCODE bits in ICIVR as 110b.</li><li>• SCD is manually cleared. To clear this bit, write a 1 to it.</li></ul><br>A STOP condition has been detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4   | ICXRDY   | 0<br>1 | Transmit-data-ready interrupt flag bit. ICXRDY indicates that the data transmit register (ICDXR) is ready to accept new data because the previous data has been copied from ICDXR to the transmit shift register (ICXSR). The CPU can poll ICXRDY or use the XRDY interrupt request.<br><br>ICDXR is not ready. ICXRDY is cleared by one of the following events: <ul style="list-style-type: none"><li>• Data is written to ICDXR.</li><li>• ICXRDY is manually cleared. To clear this bit, write a 1 to it.</li></ul><br>ICDXR is ready. Data has been copied from ICDXR to ICXSR. ICXRDY is forced to 1 when the I2C is reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3   | ICRRDY   | 0<br>1 | Receive-data-ready interrupt flag bit. ICRRDY indicates that the data receive register (ICDRR) is ready to be read because data has been copied from the receive shift register (ICRSR) to ICDRR. The CPU can poll ICRRDY or use the RRDY interrupt request.<br><br>ICDRR is not ready. ICRRDY is cleared by one of the following events: <ul style="list-style-type: none"><li>• ICDRR is read.</li><li>• ICRRDY is manually cleared. To clear this bit, write a 1 to it.</li><li>• The I2C is reset (either when 0 is written to the IRS bit of ICMR or when the processor is reset).</li></ul><br>ICDRR is ready. Data has been copied from ICRSR to ICDRR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2   | ARDY     | 0<br>1 | Register-access-ready interrupt flag bit (only applicable when the I2C is in the master mode). ARDY indicates that the I2C registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request.<br><br>The registers are not ready to be accessed. ARDY is cleared by one of the following events: <ul style="list-style-type: none"><li>• The I2C starts using the current register contents.</li><li>• ARDY is manually cleared. To clear this bit, write a 1 to it.</li><li>• The I2C is reset (either when 0 is written to the IRS bit of ICMR or when the processor is reset).</li></ul><br>The registers are ready to be accessed. This bit is set after the slave address appears on the I2C bus. <ul style="list-style-type: none"><li>• In the nonrepeat mode (RM = 0 in ICMR): If STP = 0 in ICMR, ARDY is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C generates a STOP condition when the counter reaches 0).</li><li>• In the repeat mode (RM = 1): ARDY is set at the end of each data word transmitted from ICDXR.</li></ul> |

**Table 23-7. I2C Interrupt Status Register (ICSTR) Field Descriptions (continued)**

| Bit | Field | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|-------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | NACK  | <p>0</p> <p>1</p> | <p>No-acknowledgment interrupt flag bit. NACK applies when the I2C is a transmitter (master or slave). NACK indicates whether the I2C has detected an acknowledge bit (ACK) or a no-acknowledge bit (NACK) from the receiver. The CPU can poll NACK or use the NACK interrupt request.</p> <p>ACK received/NACK is not received. NACK is cleared by one of the following events:</p> <ul style="list-style-type: none"> <li>An acknowledge bit (ACK) has been sent by the receiver.</li> <li>NACK is manually cleared. To clear this bit, write a 1 to it.</li> <li>The CPU reads the interrupt vector register (ICIVR) when the register contains the code for a NACK interrupt.</li> <li>The I2C is reset (either when 0 is written to the IRS bit of ICMDR or when the processor is reset).</li> </ul> <p>NACK bit is received. The hardware detects that a no-acknowledge (NACK) bit has been received.<br/> <b>Note:</b> While the I2C performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment.</p>                                                                                                                      |
| 0   | AL    | <p>0</p> <p>1</p> | <p>Arbitration-lost interrupt flag bit (only applicable when the I2C is a master-transmitter). AL primarily indicates when the I2C has lost an arbitration contest with another master-transmitter. The CPU can poll AL or use the AL interrupt request.</p> <p>Arbitration is not lost. AL is cleared by one of the following events:</p> <ul style="list-style-type: none"> <li>AL is manually cleared. To clear this bit, write a 1 to it.</li> <li>The CPU reads the interrupt vector register (ICIVR) when the register contains the code for an AL interrupt.</li> <li>The I2C is reset (either when 0 is written to the IRS bit of ICMDR or when the processor is reset).</li> </ul> <p>Arbitration is lost. AL is set by one of the following events:</p> <ul style="list-style-type: none"> <li>The I2C senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously.</li> <li>The I2C attempts to start a transfer while the BB (bus busy) bit is set to 1.</li> </ul> <p>When AL is set to 1, the MST and STP bits of ICMDR are cleared, and the I2C becomes a slave-receiver.</p> |

### 23.3.4 I2C Clock Divider Registers (ICCLKL and ICCLKH)

When the I2C is a master, the prescaled module clock is divided down for use as the I2C serial clock on the I2Cx\_SCL pin. The shape of the I2C serial clock depends on two divide-down values, ICCL and ICCH. For detailed information on how these values are programmed, see [Section 23.2.2](#).

#### 23.3.4.1 I2C Clock Low-Time Divider Register (ICCLKL)

For each I2C serial clock cycle, ICCL in the I2C clock low-time divider register (ICCLKL) determines the amount of time the signal is low. ICCLKL must be configured while the I2C is still in reset (IRS = 0 in ICMR). ICCLKL is shown in [Figure 23-16](#) and described in [Table 23-8](#).

**Figure 23-16. I2C Clock Low-Time Divider Register (ICCLKL)**

|    |          |    |
|----|----------|----|
| 31 | Reserved | 16 |
|    | R-0      |    |
| 15 | ICCL     | 0  |
|    | R/W-0    |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-8. I2C Clock Low-Time Divider Register (ICCLKL) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                     |
|-------|----------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                             |
| 15-0  | ICCL     | 0-FFFFh | Clock low-time divide-down value of 1-65536. The period of the module clock is multiplied by (ICCL + d) to produce the low-time duration of the I2C serial on the I2Cx_SCL pin. |

#### 23.3.4.2 I2C Clock High-Time Divider Register (ICCLKH)

For each I2C serial clock cycle, ICCH in the I2C clock high-time divider register (ICCLKH) determines the amount of time the signal is high. ICCLKH must be configured while the I2C is still in reset (IRS = 0 in ICMR). ICCLKH is shown in [Figure 23-17](#) and described in [Table 23-9](#).

**Figure 23-17. I2C Clock High-Time Divider Register (ICCLKH)**

|    |          |    |

|    | R-0      |    |
| 15 | ICCH     | 0  |
|    | R/W-0    |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-9. I2C Clock High-Time Divider Register (ICCLKH) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                       |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                               |
| 15-0  | ICCH     | 0-FFFFh | Clock high-time divide-down value of 1-65536. The period of the module clock is multiplied by (ICCH + d) to produce the high-time duration of the I2C serial on the I2Cx_SCL pin. |

### 23.3.5 I2C Data Count Register (ICCNT)

The I2C data count register (ICCNT) is used to indicate how many data words to transfer when the I2C is configured as a master-transmitter-receiver (MST = 1 and TRX = 1/0 in ICMR) and the repeat mode is off (RM = 0 in ICMR). In the repeat mode (RM = 1), ICCNT is not used.

The value written to ICCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each data word transferred (ICCNT remains unchanged). If a STOP condition is requested (STP = 1 in ICMR), the I2C terminates the transfer with a STOP condition when the countdown is complete (that is, when the last data word has been transferred).

ICCNT is shown in [Figure 23-18](#) and described in [Table 23-10](#).

**Figure 23-18. I2C Data Count Register (ICCNT)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-10. I2C Data Count Register (ICCNT) Field Descriptions**

| Bit   | Field    | Value    | Description                                                                                                                                                                                                                                                                   |
|-------|----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0        | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                           |
| 15-0  | ICDC     | 0-FFFFh  | Data count value. When RM = 0 in ICMR, ICDC indicates the number of data words to transfer in the nonrepeat mode. When RM = 1 in ICMR, the value in ICCNT is a don't care. If STP = 1 in ICMR, a STOP condition is generated when the internal data counter counts down to 0. |
|       |          | 0        | The start value loaded to the internal data counter is 65536.                                                                                                                                                                                                                 |
|       |          | 1h-FFFFh | The start value loaded to internal data counter is 1-65535.                                                                                                                                                                                                                   |

### 23.3.6 I2C Data Receive Register (ICDRR)

The I2C data receive register (ICDRR) is used to read the receive data. The ICDRR can receive a data value of up to 8 bits; data values with fewer than 8 bits are right-aligned in the D bits and the remaining D bits are undefined. The number of data bits is selected by the bit count bits (BC) of ICMDR. The I2C receive shift register (ICRSR) shifts in the received data from the I2Cx\_SDA pin. Once data is complete, the I2C copies the contents of ICRSR into ICDRR. The CPU and the EDMA controller cannot access ICRSR.

ICDRR is shown in [Figure 23-19](#) and described in [Table 23-11](#).

**Figure 23-19. I2C Data Receive Register (ICDRR)**

LEGEND: R = Read only; -n = value after reset

**Table 23-11. I2C Data Receive Register (ICDRR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect. |
| 7-0  | D        | 0-FFh | Receive data.                                                                                       |

### 23.3.7 I2C Slave Address Register (ICSAR)

The I2C slave address register (ICSAR) contains a 7-bit or 10-bit slave address. When the I2C is not using the free data format (FDF = 0 in ICMDR), it uses this address to initiate data transfers with a slave or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in ICMDR), only bits 6-0 of ICSAR are used; bits 9-7 are ignored.

ICSAR is shown in [Figure 23-20](#) and described in [Table 23-12](#).

**Figure 23-20. I2C Slave Address Register (ICSAR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-12. I2C Slave Address Register (ICSAR) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-10 | Reserved | 0      | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                                                               |
| 9-0   | SADDR    | 0-3FFh | Slave address. Provides the slave address of the I2C.<br>In 7-bit addressing mode (XA = 0 in ICMDR): bits 6-0 provide the 7-bit slave address that the I2C transmits when it is in the master-transmitter mode. Bits 9-7 are ignored.<br>In 10-bit addressing mode (XA = 1 in ICMDR): Bits 9-0 provide the 10-bit slave address that the I2C transmits when it is in the master-transmitter mode. |

### 23.3.8 I2C Data Transmit Register (ICDXR)

The CPU or EDMA writes transmit data to the I2C data transmit register (ICDXR). The ICDXR can accept a data value of up to 8 bits. When writing a data value with fewer than 8 bits, the written data must be right-aligned in the D bits. The number of data bits is selected by the bit count bits (BC) of ICMDR. Once data is written to ICDXR, the I2C copies the contents of ICDXR into the I2C transmit shift register (ICXSR). The ICXSR shifts out the transmit data from the I2Cx\_SDA pin. The CPU and the EDMA controller cannot access ICXSR.

ICDXR is shown in [Figure 23-21](#) and described in [Table 23-13](#).

**Figure 23-21. I2C Data Transmit Register (ICDXR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-13. I2C Data Transmit Register (ICDXR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect. |
| 7-0  | D        | 0-FFh | Transmit data.                                                                                      |

### 23.3.9 I2C Mode Register (ICMDR)

The I2C mode register (ICMDR) contains the control bits of the I2C. ICMDR is shown in Figure 23-22 and described in Table 23-14.

**Figure 23-22. I2C Mode Register (ICMDR)**

**Table 23-14. I2C Mode Register (ICMDR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15    | NACKMOD  | 0     | No-acknowledge (NACK) mode bit (only applicable when the I2C is a receiver).<br>In slave-receiver mode: The I2C sends an acknowledge (ACK) bit to the transmitter during the each acknowledge cycle on the bus. The I2C only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit.<br>In master-receiver mode: The I2C sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. When the counter reaches 0, the I2C sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit. |
|       |          | 1     | In either slave-receiver or master-receiver mode: The I2C sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared.<br>To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.                                                                                                                                                                                                                                                 |
| 14    | FREE     | 0     | This emulation mode bit is used to determine the state of the I2C when a breakpoint is encountered in the high-level language debugger.<br>When I2C is master: If I2Cx_SCL is low when the breakpoint occurs, the I2C stops immediately and keeps driving I2Cx_SCL low, whether the I2C is the transmitter or the receiver. If I2Cx_SCL is high, the I2C waits until I2Cx_SCL becomes low and then stops.<br>When I2C is slave: A breakpoint forces the I2C to stop when the current transmission/reception is complete.                                                |
|       |          | 1     | The I2C runs free; that is, it continues to operate when a breakpoint occurs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 13    | STT      | 0     | START condition bit (only applicable when the I2C is a master). The RM, STT, and STP bits determine when the I2C starts and stops data transmissions (see Table 23-15). Note that the STT and STP bits can be used to terminate the repeat mode.<br>In master mode, STT is automatically cleared after the START condition has been generated.<br>In slave mode, if STT is 0, the I2C does not monitor the bus for commands from a master. As a result, the I2C performs no data transfers.                                                                             |
|       |          | 1     | In master mode, setting STT to 1 causes the I2C to generate a START condition on the I2C-bus.<br>In slave mode, if STT is 1, the I2C monitors the bus and transmits/receives data in response to commands from a master.                                                                                                                                                                                                                                                                                                                                                |
| 12    | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 11    | STP      | 0     | STOP condition bit (only applicable when the I2C is a master). The RM, STT, and STP bits determine when the I2C starts and stops data transmissions (see Table 23-15). Note that the STT and STP bits can be used to terminate the repeat mode.<br>STP is automatically cleared after the STOP condition has been generated.                                                                                                                                                                                                                                            |
|       |          | 1     | STP has been set to generate a STOP condition when the internal data counter of the I2C counts down to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 23-14. I2C Mode Register (ICMDR) Field Descriptions (continued)**

| Bit | Field | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|-------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | MST   | 0<br>1 | Master mode bit. MST determines whether the I2C is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I2C master generates a STOP condition. See <a href="#">Table 23-16</a> .<br>Slave mode. The I2C is a slave and receives the serial clock from the master.<br>Master mode. The I2C is a master and generates the serial clock on the I2Cx_SCL pin.                                                                                                                                                                                                                                                                                                                                                                          |
| 9   | TRX   | 0<br>1 | Transmitter mode bit. When relevant, TRX selects whether the I2C is in the transmitter mode or the receiver mode. <a href="#">Table 23-16</a> summarizes when TRX is used and when it is a don't care.<br>Receiver mode. The I2C is a receiver and receives data on the I2Cx_SDA pin.<br>Transmitter mode. The I2C is a transmitter and transmits data on the I2Cx_SDA pin.                                                                                                                                                                                                                                                                                                                                                                                           |
| 8   | XA    | 0<br>1 | Expanded address enable bit.<br>7-bit addressing mode (normal address mode). The I2C transmits 7-bit slave addresses (from bits 6-0 of ICSAR), and its own slave address has 7 bits (bits 6-0 of ICOAR).<br>10-bit addressing mode (expanded address mode). The I2C transmits 10-bit slave addresses (from bits 9-0 of ICSAR), and its own slave address has 10 bits (bits 9-0 of ICOAR).                                                                                                                                                                                                                                                                                                                                                                             |
| 7   | RM    | 0<br>1 | Repeat mode bit (only applicable when the I2C is a master). The RM, STT, and STP bits determine when the I2C starts and stops data transmissions (see <a href="#">Table 23-15</a> ). If the I2C is configured in slave mode, the RM bit is don't care.<br>Nonrepeat mode. The value in the data count register (ICCNT) determines how many data words are received/transmitted by the I2C.<br>Repeat mode. Data words are continuously received/transmitted by the I2C until the STP bit is manually set to 1, regardless of the value in ICCNT.                                                                                                                                                                                                                      |
| 6   | DLB   | 0<br>1 | Digital loopback mode bit (only applicable when the I2C is a master-transmitter). This bit disables or enables the digital loopback mode of the I2C. The effects of this bit are shown in <a href="#">Figure 23-23</a> . Note that DLB mode in the free data format mode (DLB = 1 and FDF = 1) is not supported.<br>Digital loopback mode is disabled.<br>Digital loopback mode is enabled. In this mode, the MST bit must be set to 1 and data transmitted out of ICDXR is received in ICDRR after n clock cycles by an internal path, where:<br>$n = ((\text{I2C input clock frequency} / \text{prescaled module clock frequency}) \times 8)$<br>The transmit clock is also the receive clock. The address transmitted on the I2Cx_SDA pin is the address in ICOAR. |
| 5   | IRS   | 0<br>1 | I2C reset bit. Note that if IRS is reset during a transfer, it can cause the I2C bus to hang (I2Cx_SDA and I2Cx_SCL are in a high-impedance state).<br>The I2C is in reset/disabled. When this bit is cleared to 0, all status bits (in ICSTR) are set to their default values.<br>The I2C is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 4   | STB   | 0<br>1 | START byte mode bit (only applicable when the I2C is a master). As described in version 2.1 of the Philips I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C is a slave, the I2C ignores a START byte from a master, regardless of the value of the STB bit.<br>The I2C is not in the START byte mode.<br>The I2C is in the START byte mode. When you set the START condition bit (STT), the I2C begins the transfer with more than just a START condition. Specifically, it generates:<br>1. A START condition<br>2. A START byte (0000 0001b)<br>3. A dummy acknowledge clock pulse<br>4. A repeated START condition<br>The I2C sends the slave address that is in ICSAR.           |
| 3   | FDF   | 0<br>1 | Free data format mode bit. Note that DLB mode in the free data format mode (DLB = 1 and FDF = 1) is not supported. See <a href="#">Table 23-16</a> .<br>Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit.<br>Free data format mode is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 23-14. I2C Mode Register (ICMDR) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2-0 | BC    | 0-7h  | Bit count bits. BC defines the number of bits (1 to 8) in the next data word that is to be received or transmitted by the I2C. The number of bits selected with BC must match the data size of the other device. Note that when BC = 0, a data word has 8 bits.<br><br>If the bit count is less than 8, receive data is right aligned in the D bits of ICDRR and the remaining D bits are undefined. Also, transmit data written to ICDXR must be right aligned. |
|     |       | 0     | 8 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 1h    | 1 bit per data word                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|     |       | 2h    | 2 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 3h    | 3 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 4h    | 4 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 5h    | 5 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 6h    | 6 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 7h    | 7 bits per data word                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 23-15. Master-Transmitter/Receiver Bus Activity Defined by RM, STT, and STP Bits**

| ICMDR Bit |     |     |                             |                                                                                                                              |
|-----------|-----|-----|-----------------------------|------------------------------------------------------------------------------------------------------------------------------|

### 23.3.10 I2C Interrupt Vector Register (ICIVR)

The I2C interrupt vector register (ICIVR) is used by the CPU to determine which event generated the I2C interrupt. Reading ICIVR clears the interrupt flag; if other interrupts are pending, a new interrupt is generated. If there are more than one interrupt flag, reading ICIVR clears the highest priority interrupt flag. Note that you must read (clear) ICIVR before doing another start; otherwise, ICIVR could contain an incorrect (old interrupt flags) value.

ICIVR is shown in [Figure 23-24](#) and described in [Table 23-17](#).

**Figure 23-24. I2C Interrupt Vector Register (ICIVR)**

LEGEND: R= Read only; -n = value after reset

**Table 23-17. I2C Interrupt Vector Register (ICIVR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect. |
| 2-0  | INTCODE  | 0-7h  | Interrupt code bits. The binary code in INTCODE indicates which event generated an I2C interrupt.   |
|      |          | 0     | None                                                                                                |
|      |          | 1h    | Arbitration-lost interrupt (AL). Highest priority if multiple I2C interrupts are pending.           |
|      |          | 2h    | No-acknowledgment interrupt (NACK)                                                                  |
|      |          | 3h    | Register-access-ready interrupt (ARDY)                                                              |
|      |          | 4h    | Receive-data-ready interrupt (ICRRDY)                                                               |
|      |          | 5h    | Transmit-data-ready interrupt (ICXRDY)                                                              |
|      |          | 6h    | Stop condition detected interrupt (SCD)                                                             |
|      |          | 7h    | Address-as-slave interrupt (AAS). Lowest priority if multiple I2C interrupts are pending.           |

### 23.3.11 I2C Extended Mode Register (ICEMDR)

The I2C extended mode register (ICEMDR) is used to indicate which condition generates a transmit data ready interrupt. ICEMDR is shown in [Figure 23-25](#) and described in [Table 23-18](#).

**Figure 23-25. I2C Extended Mode Register (ICEMDR)**

|     |          |  |  |  |  |  |  |        |       |   |    |
|-----|----------|--|--|--|--|--|--|--------|-------|---|----|
| 31  | Reserved |  |  |  |  |  |  |        |       |   | 16 |
| R-0 |          |  |  |  |  |  |  |        |       |   |    |
| 15  | Reserved |  |  |  |  |  |  |        | 1     | 0 |    |
| R-0 |          |  |  |  |  |  |  | IGNACK | BCM   |   |    |
| R-0 |          |  |  |  |  |  |  | R/W-0  | R/W-1 |   |    |

LEGEND: R/W = Read/Write; R= Read only; -n = value after reset

**Table 23-18. I2C Extended Mode Register (ICEMDR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                            |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                    |
| 1    | IGNACK   | 0     | Ignore NACK mode.<br>Master transmitter operates normally, that is, it discontinues the data transfer and sets the ARDY and NACK bits in ICSTR when receiving a NACK from the slave.                                                                                                                                                                   |
|      |          | 1     | Master transmitter ignores a NACK from the slave.                                                                                                                                                                                                                                                                                                      |
| 0    | BCM      | 0     | Backward compatibility mode bit. Determines which condition generates a transmit data ready interrupt. The BCM bit only has an effect when the I2C is operating as a slave-transmitter.<br>The transmit data ready interrupt is generated when the master requests more data by sending an acknowledge signal after the transmission of the last data. |
|      |          | 1     | The transmit data ready interrupt is generated when the data in ICDXR is copied to ICXSR.                                                                                                                                                                                                                                                              |

### 23.3.12 I2C Prescaler Register (ICPSC)

The I2C prescaler register (ICPSC) is used for dividing down the I2C input clock to obtain the desired prescaled module clock for the operation of the I2C. The IPSC bits must be initialized while the I2C is in reset (IRS = 0 in ICMDR). The prescaled frequency takes effect only when the IRS bit is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

ICPSC is shown in [Figure 23-26](#) and described in [Table 23-19](#).

**Figure 23-26. I2C Prescaler Register (ICPSC)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-19. I2C Prescaler Register (ICPSC) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                           |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                   |
| 7-0  | IPSC     | 0-FFh | <p>I2C prescaler divide-down value. IPSC determines how much the I2C input clock is divided to create the I2C prescaled module clock:</p> <p><math>I2C \text{ clock frequency} = I2C \text{ input clock frequency} / (IPSC + 1)</math></p> <p><b>Note:</b> IPSC must be initialized while the I2C is in reset (IRS = 0 in ICMDR).</p> |

### 23.3.13 I2C Revision Identification Register (REVID1)

The I2C revision identification register (REVID1) contains identification data for the peripheral. REVID1 is shown in [Figure 23-27](#) and described in [Table 23-20](#).

**Figure 23-27. I2C Revision Identification Register 1 (REVID1)**

LEGEND: R = Read only; -n = value after reset

**Table 23-20. I2C Revision Identification Register 1 (REVID1) Field Descriptions**

| Bit  | Field  | Value | Description                      |
|------|--------|-------|----------------------------------|
| 31-0 | REVID1 | 4415h | Peripheral Identification Number |

### 23.3.14 I2C Revision Identification Register (REVID2)

The I2C revision identification register (REVID2) contains identification data for the peripheral. REVID2 is shown in [Figure 23-28](#) and described in [Table 23-21](#).

**Figure 23-28. I2C Revision Identification Register 2 (REVID2)**

LEGEND: R = Read only; -n = value after reset

**Table 23-21. I2C Revision Identification Register 2 (REVID2) Field Descriptions**

| Bit  | Field  | Value | Description                      |
|------|--------|-------|----------------------------------|
| 31-0 | REVID2 | 6h    | Peripheral Identification Number |

### 23.3.15 I2C DMA Control Register (ICDMAC)

The I2C DMA control register (ICDMAC) is used to control the transmit DMA event and receive DMA event pin to the system . ICDMAC is shown in [Figure 23-29](#) and described in [Table 23-22](#).

**Figure 23-29. I2C DMA Control Register (ICDMAC)**

LEGEND: R/W = Read/Write; R= Read only; -n = value after reset

**Table 23-22. I2C DMA Control Register (ICDMAC) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                     |
|------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0      | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                             |
| 1    | TXDMAEN  | 0<br>1 | Transmit DMA enable. This bit controls the transmit DMA event pin to the system. Always set this bit to 1.<br>DMA transmit event is disabled.<br>DMA transmit event is enabled. |
| 0    | RXDMAEN  | 0<br>1 | Receive DMA enable . This bit controls the receive DMA event pin to the system. Always set this bit to 1.<br>DMA receive event is disabled.<br>DMA receive event is enabled.    |

### 23.3.16 I2C Pin Function Register (ICPFUNC)

The I2C pin function register (ICPFUNC) is used to configure the external I2C pins (I2Cx\_SDA and I2Cx\_SCL) as a I2C peripheral pin or a GPIO pin. ICPFUNC is shown in [Figure 23-30](#) and described in [Table 23-23](#).

**Figure 23-30. I2C Pin Function Register (ICPFUNC)**

|          |          |  |  |  |  |  |  |  |  |  |  |  |  |        |    |   |
|----------|----------|--|--|--|--|--|--|--|--|--|--|--|--|--------|----|---|
| 31       | Reserved |  |  |  |  |  |  |  |  |  |  |  |  |        | 16 |   |

| 31-1 | Reserved | 0     | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                                                                                                                                                                                                                                                                                                                                                                                       |
| 0    | PFUNC0   | 0     | Controls the function of the I2Cx_SCL and I2Cx_SDA pins.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|      |          | 0     | Pins function as I2Cx_SCL and I2Cx_SDA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|      |          | 1     | Pins function as GPIO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|      |          |       | Note: No hardware protection is required to disable the I2C function when the PFUNC0 bit and the IRS bit in the I2C mode register (ICMDR) are both set to 1. When PFUNC0 = 1 (GPIO mode), the sub-module that controls the I2C function receives the value 1 for I2Cx_SCL and I2Cx_SDA. The IRS bit can be set to 1 regardless of PFUNC0, and the I2C function works whenever the IRS bit is 1. You are expected to hold I2C in reset via the IRS bit when changing to/from GPIO mode via the PFUNC0 bit. |

### 23.3.17 I2C Pin Direction Register (ICPDIR)

The I2C pin direction register (ICPDIR) is used to configure each GPIO pin as either an input or an output. ICPDIR is shown in [Figure 23-31](#) and described in [Table 23-24](#).

**Figure 23-31. I2C Pin Direction Register (ICPDIR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-24. I2C Pin Direction Register (ICPDIR) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                  |
|------|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0      | These reserved bit locations are always read as zeros. A value written to this field has no effect.                                          |
| 1    | PDIR1    | 0<br>1 | Controls the direction of the I2Cx_SDA pin when configured as GPIO.<br>I2Cx_SDA pin functions as input.<br>I2Cx_SDA pin functions as output. |
| 0    | PDIR0    | 0<br>1 | Controls the direction of the I2Cx_SCL pin when configured as GPIO.<br>I2Cx_SCL pin functions as input.<br>I2Cx_SCL pin functions as output. |

### 23.3.18 I2C Pin Data In Register (ICPDIN)

The I2C pin data in register (ICPDIN) holds the I/O state of each of the I2C pins (I2Cx\_SDA and I2Cx\_SCL); and should return the value from the pin's input buffer (with appropriate synchronization/DFT considerations). However, this register allows the actual value of the pin to be read regardless of the state of PFUNC or PDIR bits . ICPDIN is shown in [Figure 23-32](#) and described in [Table 23-25](#).

**Figure 23-32. I2C Pin Data In Register (ICPDIN)**

|     |          |  |  |  |  |  |  |  |  |  |       |       |   |  |    |
|-----|----------|--|--|--|--|--|--|--|--|--|-------|-------|---|--|----|

### 23.3.19 I2C Pin Data Out Register (ICPDOUT)

The I2C pin data out register (ICPDOUT) has one bit for each of the GPIO pins. This bit holds a value for data out at all times, and may be read back at all times. The value held by this register is not affected by writing to the PDIR and PFUNC bits. However, the data value in this register is driven out onto the GPIO pin only if the PFUNC0 bit in ICPFUNC is set to 1 (I2Cx\_SDA and I2Cx\_SCL function as GPIO) and also the corresponding bit in ICPDIR is set to 1 (output).

ICPDOUT is shown in [Figure 23-33](#) and described in [Table 23-26](#).

**Figure 23-33. I2C Pin Data Out Register (ICPDOUT)**

|     |          |  |  |  |  |  |  |  |  |  |        |   |        |  |  |    |

### 23.3.20 I2C Pin Data Set Register (ICPDSET)

The I2C pin data set register (ICPDSET) is an alias of the I2C pin data out register (ICPDOUT). Writing a 1 to a bit in ICPDSET sets the corresponding bit in ICPDOUT to a 1, while writing a 0 keeps the bit unchanged. ICPDSET is shown in [Figure 23-34](#) and described in [Table 23-27](#).

**Figure 23-34. I2C Pin Data Set Register (ICPDSET)**

|          |  |  |  |  |  |  |  |  |  |  |  |  |  |        |        |    |   |
|----------|--|--|--|--|--|--|--|--|--|--|--|--|--|--------|--------|----|---|

| 0    | PDSET0   |       | Used to set the PDOUT0 bit in the I2C pin data out register (ICPDOUT) that corresponds to the I2Cx_SCL GPIO pin.<br><b>During reads:</b> Reads return indeterminate values. |
|      |          | 0     | No effect                                                                                                                                                                   |
|      |          | 1     | PDOUT0 bit is set to logic high.                                                                                                                                            |

### 23.3.21 I2C Pin Data Clear Register (ICPDCLR)

The I2C pin data clear register (ICPDCLR) is an alias of the I2C pin data out register (ICPDOUT). Writing a 1 to a bit in ICPDCLR clears the corresponding bit in ICPDOUT to a 0, while writing a 0 keeps the bit unchanged. ICPDCLR is shown in [Figure 23-35](#) and described in [Table 23-28](#).

**Figure 23-35. I2C Pin Data Clear Register (ICPDCLR)**

|     |          |  |  |  |  |  |  |  |  |  |        |   |        |  |    |

|      |          |       | <b>During writes:</b>                                                                                              |
|      |          | 0     | No effect                                                                                                          |
|      |          | 1     | PDOUT0 bit is cleared to logic low.                                                                                |

## ***Liquid Crystal Display Controller (LCDC)***

---

---

The liquid crystal display controller (LCDC) is capable of supporting an asynchronous (memory-mapped) LCD interface and a synchronous (raster-type) LCD interface. This chapter describes the LCDC.

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|

## 24.1 Introduction

### 24.1.1 Purpose of the Peripheral

The LCD controller consists of two independent controllers, the Raster Controller and the LCD Interface Display Driver (LIDD) controller. Each controller operates independently from the other and only one of them is active at any given time.

- The Raster Controller handles the synchronous LCD interface. It provides timing and data for constant graphics refresh to a passive display. It supports a wide variety of monochrome and full-color display types and sizes by use of programmable timing controls, a built-in palette, and a gray-scale/serializer. Graphics data is processed and stored in frame buffers. A frame buffer is a contiguous memory block in the system. A built-in DMA engine supplies the graphics data to the Raster engine which, in turn, outputs to the external LCD device.
- The LIDD Controller supports the asynchronous LCD interface. It provides full-timing programmability of control signals and output data.

Figure 24-1 shows the LCD controller details. The raster and LIDD Controllers are responsible for generating the correct external timing. The DMA engine provides a constant flow of data from the frame buffer(s) to the external LCD panel via the Raster and LIDD Controllers. In addition, CPU access is provided to read and write registers.

The solid, thick lines in Figure 24-1 indicate the data path. The Raster Controller's data path is fairly complicated, for a thorough description of the Raster Controller data path, see Section 24.2.5.

**Figure 24-1. LCD Controller**

### 24.1.2 Features

See your device-specific data manual to check the features supported by the LCD controller.

### 24.1.3 Terminology

| Term                 | Meaning                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Passive (STN) device | Refers to the Super-Twisted Nematic (STN) display device.                                                                        |
| Active (TFT) device  | Refers to the Thin-Film Transistor (TFT) display device.                                                                         |
| BPP                  | Bits per pixel; that is, the number of bits used for each pixel. In some documentation, this is also referred to as color depth. |
| RGB                  | Red, Green, Blue                                                                                                                 |

## 24.2 Architecture

### 24.2.1 Clocking

This section details the various clocks and signals. [Figure 24-2](#) shows input and output LCD controller clocks.

**Figure 24-2. Input and Output Clocks**

#### 24.2.1.1 Pixel Clock

The pixel clock (LCD\_PCLK) frequency is derived from LCD\_CLK, the reference clock to this LCD module (see [Figure 24-2](#)). The pixel clock is used by the LCD display to clock the pixel data into the line shift register.

$$\text{LCD\_PCLK} = \frac{\text{LCD\_CLK}}{\text{CLKDIV}}$$

where CLKDIV is a field in the LCD\_CTRL register and should not be 0 or 1.

- **Passive (STN) mode.** LCD\_PCLK only transitions when valid data is available for output. It does not transition when the horizontal clock is asserted or during wait state insertion.
- **Active (TFT) mode.** LCD\_PCLK continuously toggles as long as the Raster Controller is enabled.

#### 24.2.1.2 Horizontal Clock (LCD\_HSYNC)

LCD\_HSYNC toggles after all pixels in a horizontal line have been transmitted to the LCD and a programmable number of pixel clock wait states has elapsed both at the beginning and end of each line.

The RASTER\_TIMING\_0 register fully defines the behavior of this signal.

LCD\_HSYNC can be programmed to be synchronized with the rising or falling edge of LCD\_PCLK. The configuration field is bits 24 and 25 in the RASTER\_TIMING\_2 register.

- **Active (TFT) mode.** The horizontal clock or the line clock is also used by TFT displays as the horizontal synchronization signal (LCD\_HSYNC).

The timings of the horizontal clock(line clock) pins are programmable to support:

- Delay insertion both at the beginning and end of each line
- Line clock polarity.
- Line clock pulse width, driven on rising or falling edge of pixel clock.

#### 24.2.1.3 Vertical Clock (LCD\_VSYNC)

LCD\_VSYNC toggles after all lines in a frame have been transmitted to the LCD and a programmable number of line clock cycles has elapsed both at the beginning and end of each frame.

The RASTER\_TIMING\_1 register fully defines the behavior of this signal.

LCD\_VSYNC can be programmed to be synchronized with the rising or falling edge of LCD\_PCLK. The configuration field is bits 24 and 25 in the RASTER\_TIMING\_2 register.

- **Passive (STN) mode.** The vertical clock; that is, the frame clock, toggles during the first line of the screen.
- **Active (TFT) mode.** The vertical clock, that is, the frame clock, is also used by TFT displays as the vertical synchronization signal (LCD\_VSYNC).

The timings of the vertical clock pins are programmable to support:

- Delay insertion both at the beginning and end of each frame
- Frame clock polarity

#### 24.2.1.4 LCD\_AC\_ENB\_CS

- **Passive (STN) mode.** To prevent a dc charge within the screen pixels, the power and ground supplies of the display are periodically switched. The Raster Controller signals the LCD to switch the polarity by toggling this pin (LCD\_AC\_ENB\_CS).
- **Active (TFT) mode.** This signal acts as an output enable (OE) signal. It is used to signal the external LCD that the data is valid on the data bus (LCD\_D[15:0]).

## 24.2.2 LCD External I/O Signals

Table 24-1 shows the details of the LCD controller external signals.

**Table 24-1. LCD External I/O Signals**

| Signal        | Type                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LCD_VSYNC     | OUT                                    | <p>Raster controller: Frame clock the LCD uses to signal the start of a new frame of pixels. | LCD_MCLK      | OUT                                    | <p>Raster controller: not used.</p> <p>LIDD character: Secondary enable strobe</p> <p>LIDD graphics: Chip select 1 (<math>\overline{CS1}</math>)</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| LCD_D[15:0]   | <p>Raster: OUT</p> <p>LIDD: OUT/IN</p> | <p>LCD data bus, providing a 4-, 8-, or 16-bit data path.</p> <p>Raster controller: For monochrome displays, each signal represents a pixel; for passive color displays, groupings of three signals represent one pixel (red, green, and blue). LCD_D[3:0] is used for monochrome displays of 2, 4, and 8 BPP; LCD_D[7:0] is used for color STN displays and LCD_D[15:0] is used for active (TFT) mode.</p> <p>LIDD character: Read and write the command and data registers.</p> <p>LIDD graphics: Read and write the command and data registers.</p> |

### 24.2.3 DMA Engine

The DMA engine provides the capability to output graphics data to constantly refresh LCDs, without burdening the CPU, via interrupts or a firmware timer. It operates on one or two frame buffers, which are set up during initialization. Using two frame buffers (ping-pong buffers) enables the simultaneous operation of outputting the current video frame to the external display and updating the next video frame. The ping-pong buffering approach is preferred in most applications.

When the Raster Controller is used, the DMA engine reads data from a frame buffer and writes it to the input FIFO (as shown in [Figure 24-1](#)). The Raster Controller requests data from the FIFO for frame refresh; as a result, the DMA's job is to ensure that the FIFO is always kept full.

When the LIDD Controller is used, the DMA engine accesses the LIDD Controller's address and/or data registers.

To program DMA engine, configure the following registers, as shown in [Table 24-2](#).

**Table 24-2. Register Configuration for DMA Engine Programming**

| Register           | Configuration                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------|
| LCDDMA_CTRL        | Configure DMA data format                                                                           |
| LCDDMA_FB0_BASE    | Configure frame buffer 0                                                                            |
| LCDDMA_FB0_CEILING |                                                                                                     |
| LCDDMA_FB1_BASE    | Configure frame buffer 1. (If only one frame buffer is used, these two registers will not be used.) |
| LCDDMA_FB1_CEILING |                                                                                                     |

In addition, the LIDD\_CTRL register (for LIDD Controller) or the RASTER\_CTRL register (for Raster Controller) should also be configured appropriately, along with all the timing registers.

To enable DMA transfers, the LIDD\_DMA\_EN bit (in the LIDD\_CTRL register) or the LCDEN bit (in the RASTER\_CTRL register) should be written with 1.

---

**NOTE:** If the data left in the frame buffer is smaller than the DMA burst size, the DMA by default transfers 1 word (4 bytes) at a time until the entire frame buffer is transferred. This sometimes causes an input FIFO underflow, which can only be recovered through a Power and Sleep Controller (PSC) reset. Thus, it is recommended that the size of the frame buffer be divisible by the chosen burst size.

---

#### 24.2.3.1 Interrupts

Interrupts in this LCD module are related to DMA engine operation. Three registers are closely related to this subject:

- The LIDD\_CTRL and RASTER\_CTRL registers enable or disable each individual interrupt sources.
- The LCD\_STAT register collects all the interrupt status information.

##### 24.2.3.1.1 LIDD Mode

When operating in LIDD mode, the DMA engine generates one interrupt signal every time the specified frame buffer has been transferred completely.

- The DONE\_INT\_EN bit in the LIDD\_CTRL register specifies if the interrupt signal is delivered to the system interrupt controller, which in turn may or may not generate an interrupt to CPU.
- The EOF1, EOF0, and DONE bits in the LCD\_STAT register reflect the interrupt signal, regardless of being delivered to the system interrupt controller or not.

### 24.2.3.1.2 Raster Mode

When operating in Raster mode, the DMA engine can generate the interrupts in the following scenarios:

1. **Output FIFO under-run.** This occurs when the DMA engine cannot keep up with the data rate consumed by the LCD (which is determined by the LCD\_PCLK.) This is likely due to a system memory throughput issue or an incorrect LCD\_PCLK setting. The FUF bit in LCD\_STAT is set when this error occurs. This bit is cleared by disabling the Raster Controller (i.e., clearing the LCDEN bit in RASTER\_CTRL).
2. **Frame synchronization lost.** This error happens when the DMA engine attempts to read what it believes to be the first word of the video buffer but it cannot be recognized as such. This could be caused by an invalid frame buffer address or an invalid BPP value (for more details, see [Section 24.2.5.2](#)). The SYNC bit in the LCD\_STAT register is set when such an error is detected. This field is cleared by disabling the Raster Controller (clearing the LCDEN bit in the RASTER\_CTRL register).
3. **Palette loaded.** This interrupt can be generated when the palette is loaded into the memory by the DMA engine. At the same time, the PL bit in the LCD\_STAT register is set. In data-only (PLM = 2h) and palette-plus-data (PLM = 00) modes, writing 0 to this bit clears the interrupt. In the palette-only (PLM = 1) mode, this bit is cleared by disabling the Raster Controller (clearing the LCDEN bit in the RASTER\_CTRL register).
4. **AC bias transition.** If the ACB\_I bit in the RASTER\_TIMING\_2 register is programmed with a non-zero value, an internal counter will be loaded with this value and starts to decrement each time LCD\_AC\_ENB\_CS (AC-bias signal) switches its state. When the counter reaches zero, the ABC bit in the LCD\_STAT register is set, which will deliver an interrupt signal to the system interrupt controller (if the interrupt is enabled.) The counter reloads the value in field ACB\_I, but does not start to decrement until the ABC bit is cleared by writing 0 to this bit.
5. **Frame transfer completed.** When one frame of data is transferred completely, the DONE bit in the LCD\_STAT register is set. This bit is cleared by disabling the Raster Controller (i.e., clearing the LCDEN bit in the RASTER\_CTRL register). Note that the EOF0 and EOF1 bits in the LCD\_STAT register will be set accordingly.

Note that the interrupt enable bits are in the RASTER\_CTRL register. The corresponding enable bit must be set in order to generate an interrupt to the CPU. However, the LCD\_STAT register reflects the interrupt signal regardless of the interrupt enable bits settings.

### 24.2.3.1.3 Interrupt Handling

See your device-specific data manual for information about the LCD interrupt number to the CPU. The interrupt service routine needs to determine the interrupt source by examining the LCD\_STAT register and clearing the interrupt properly.

## 24.2.4 LIDD Controller

The LIDD Controller is designed to support LCD panels with a memory-mapped interface. The types of displays range from low-end character monochrome LCD panels to high-end TFT smart LCD panels.

LIDD mode (and the use of this logic) is enabled by clearing the MODESEL bit in the LCD control register (LCD\_CTRL).

LIDD Controller operation is summarized as follows:

- During initialization, the LCD LIDD CS0/CS1 configuration registers (LIDD\_CS0\_CONF and LIDD\_CS1\_CONF) are configured to match the requirements of the LCD panel being used.
- During normal operation, the CPU writes display data to the LCD data registers (LIDD\_CS0\_DATA and LIDD\_CS1\_DATA). The LIDD interface converts the CPU write into the proper signal transition sequence for the display, as programmed earlier. Note that the first CPU write should send the beginning address of the update to the LCD panel and the subsequent writes update data at display locations starting from the first address and continuing sequentially. Note that DMA may be used instead of CPU.
- The LIDD Controller is also capable of reading back status or data from the LCD panel, if the latter has this capability. This is set up and activated in a similar manner to the write function described above.

**NOTE:** If an LCD panel is not used, this interface can be used to control any MCU-like peripheral.

See your device-specific data manual to check the LIDD features supported by the LCD controller.

Table 24-3 describes how the signals are used to interface external LCD modules, which are configured by the LIDD\_CTRL register.

**Table 24-3. LIDD I/O Name Map**

| Display Type                    | Interface Type | Data Bits | LIDD_CTRL [2:0] | I/O Name                      | Display I/O Name                       | Comment                                         |
|---------------------------------|----------------|-----------|-----------------|-------------------------------|----------------------------------------|-------------------------------------------------|
| Character Display               | HD44780 Type   | 4         | 100             | LCD_D[7:4]                    | DATA[7:4]                              | Data Bus (length defined by Instruction)        |

|                                 |                |           |                 | $\overline{LCD\_AC\_ENB\_CS}$ | $\overline{CS}$ (or $\overline{CS0}$ ) | Chip Select (first display)                     |
|                                 |                |           |                 | LCD_MCLK                      | $\overline{CS1}$                       | Chip Select (second display optional)           |
|                                 |                |           | 010             | LCD_MCLK                      | None                                   | Synchronous Clock (optional)                    |

The timing parameters are defined by the LIDD\_CS0\_CONF and LIDD\_CS1\_CONF registers, which are described in [Section 24.3.5](#).

The timing configuration is based on an internal reference clock, MCLK. The MCLK is generated out of LCD\_CLK, which is determined by the CLKDIV bit in the LCD\_CTRL register:

$$\text{MCLK} = \text{LCD\_CLK} \text{ when } \text{CLKDIV} = 0.$$

$$\text{MCLK} = \frac{\text{LCD\_CLK}}{\text{CLKDIV}} \text{ when } \text{CLKDIV} \neq 0.$$

See your device-specific data manual for the timing configurations supported by the LCD controller.

### 24.2.5 Raster Controller

Raster mode (and the use of this logic) is enabled by setting the MODESEL bit in the LCD control register (LCD\_CTRL). [Table 24-4](#) shows the active external signals when this mode is active.

**Table 24-4. Operation Modes Supported by Raster Controller**

| Interface                   | Data Bus Width | Register Bits<br>RASTER_CTRL[9, 7, 1] | Signal Name                          | Description                  |
|-----------------------------|----------------|---------------------------------------|--------------------------------------|------------------------------|
| Passive (STN) Mono<br>4-bit | 4              | 001                                   | LCD_D[3:0]                           | Data bus                     |
|                             |                |                                       | LCD_PCLK                             | Pixel clock                  |

|                             |                |                                       | LCD_VSYNC                            | Vertical clock (Frame Clock) |
|                             |                |                                       | $\overline{\text{LCD\_AC\_ENB\_CS}}$ | Output enable                |
|                             |                |                                       | LCD_MCLK                             | Not used                     |

### 24.2.5.1 Logical Data Path

The block diagram of the Raster Controller is shown in [Figure 24-1](#). [Figure 24-3](#) illustrates its logical data path for various operation modes (passive (STN) versus active (TFT), various BPP size).

[Figure 24-3](#) shows that:

- The gray-scaler/serializer and output FIFO blocks are bypassed in active (TFT) modes.
- The palette is bypassed in both 12- and 16-BPP modes.

**Figure 24-3. Logical Data Path for Raster Controller**

In summary:

- The display image is stored in frame buffers.
- The built-in DMA engine constantly transfers the data stored in the frame buffers to the Input FIFO.
- The Raster Controller relays data to the external pins according to the specified format.

The remainder of this section describes the functioning blocks in [Figure 24-3](#), including frame buffers, palette, and gray-scaler/serializer. Their operation and programming techniques are covered in detail. The output format is also described in [Section 24.2.5.5](#).

## 24.2.5.2 Frame Buffer

A frame buffer is a contiguous memory block, storing enough data to fill a full LCD screen. For this device, external memory needs to be used for the frame buffer. For specific details on which external memory interface (EMIF) controller can be accessed by the LCD controller, see your device-specific data manual. The data in the frame buffer consists of pixel values as well as a look-up palette. [Figure 24-4](#) shows the frame buffer structure.

**Figure 24-4. Frame Buffer Structure**

### 1, 2, 4, 12, 16 BPP Modes

### 8 BPP Mode

#### NOTE:

- 8-BPP mode uses the first 512 bytes in the frame buffer as the palette while the other modes use 32 bytes.
- 12- and 16-BPP modes do not need a palette; i.e., the pixel data is the desired RGB value. However, the first 32 bytes are still considered a palette. The first entry should be 4000h (bit 14 is 1) while the remaining entries must be filled with 0. (For details, see [Table 24-5](#).)
- Each entry in a palette occupies 2 bytes. As a result, 8-BPP mode palette has 256 color entries while the other palettes have up to 16 color entries.
- 4-BPP mode uses up the all the 16 entries in a palette.
- 1-BPP mode uses the first 2 entries in a palette while 2-BPP mode uses the first 4 entries. The remaining entries are not used and must be filled with 0.
- In 12- and 16-BPP modes, pixel data is RGB data. For all the other modes, pixel data is actually an index of the palette entry.

**Table 24-5. Bits-Per-Pixel Encoding for Palette Entry 0 Buffer**

| Bit   | Name | Value | Description <sup>(1) (2)</sup>                                      |
|-------|------|-------|---------------------------------------------------------------------|
| 14-12 | BPP  |       | Bits-per-pixel.                                                     |
|       |      | 000   | 1 BPP                                                               |
|       |      | 001   | 2 BPP                                                               |
|       |      | 010   | 4 BPP                                                               |
|       |      | 011   | 8 BPP                                                               |
|       |      | 1xx   | 12 BPP in passive mode (TFT_STN = 0 and STN_565 = 0 in RASTER_CTRL) |
|       |      |       | 16 BPP in passive mode (TFT_STN = 0 and STN_565 = 1 in RASTER_CTRL) |
|       |      |       | 16 BPP in active mode (TFT_STN = 1 in RASTER_CTRL)                  |

<sup>(1)</sup> Eight 1-bit pixels, four 2-bit pixels, and two 4-bit pixels are packed into each byte, and 12-bit pixels are right justified on (16-bit) word boundaries (in the same format as palette entry).

<sup>(2)</sup> For STN565, see the 16 BPP STN mode bit ([Section 24.3.8.8](#)).

The equations shown in [Table 24-6](#) are used to calculate the total frame buffer size (in bytes) based on varying pixel size encoding and screen sizes.

[Figure 24-5](#) and [Figure 24-6](#) show more detail of the palette entry organization.

**Table 24-6. Frame Buffer Size According to BPP**

| BPP   | Frame Buffer Size                                    |
|-------|------------------------------------------------------|
| 1     | $32 + (\text{Lines} \times \text{Columns})/8$        |
| 2     | $32 + (\text{Lines} \times \text{Columns})/4$        |
| 4     | $32 + (\text{Lines} \times \text{Columns})/2$        |
| 8     | $512 + (\text{Lines} \times \text{Columns})$         |
| 12/16 | $32 + 2 \times (\text{Lines} \times \text{Columns})$ |

**Figure 24-5. 16-Entry Palette/Buffer Format (1, 2, 4, 12, 16 BPP)**

A. Bits-per-pixels (BPP) is only contained within the first palette entry (palette entry 0).

**Figure 24-6. 256-Entry Palette/Buffer Format (8 BPP)**

A. Bits-per-pixels (BPP) is only contained within the first palette entry (palette entry 0).

Bits 12, 13, and 14 of the first palette entry select the number of bits-per-pixel to be used in the following frame and thus the number of palette RAM entries. The palette entry is used by the Raster Controller to correctly unpack pixel data.

The following figures show the memory organization within the frame buffer for each pixel encoding size.

**Figure 24-7. 16-BPP Data Memory Organization (TFT Mode Only)—Little Endian**

**Figure 24-8. 12-BPP Data Memory Organization—Little Endian**

Unused [15-12] bits are filled with zeroes in TFT mode.

**Figure 24-9. 8-BPP Data Memory Organization**

**Figure 24-10. 4-BPP Data Memory Organization**

**Figure 24-11. 2-BPP Data Memory Organization**

| Bit      | 7       | 6 | 5       | 4 | 3        | 2 | 1        | 0 |
|----------|---------|---|---------|---|----------|---|----------|---|
| Base     | Pixel 0 |   | Pixel 1 |   | Pixel 2  |   | Pixel 3  |   |
| Base + 1 | Pixel 4 |   | Pixel 5 |   | Pixel 6  |   | Pixel 7  |   |
| Base + 2 | Pixel 8 |   | Pixel 9 |   | Pixel 10 |   | Pixel 11 |   |

**Figure 24-12. 1-BPP Data Memory Organization**

| Bit      | 7  | 6  | 5   | 4   | 3   | 2   | 1   | 0   |
|----------|----|----|-----|-----|-----|-----|-----|-----|
| Base     | P0 | P1 | P2  | P3  | P4  | P5  | P6  | P7  |
| Base + 1 | P8 | P9 | P10 | P11 | P12 | P13 | P14 | P15 |

### 24.2.5.3 Palette

As explained in the previous section, the pixel data is an index of palette entry (when palette is used). The number of colors supported is given by  $2^{\text{number of BPP}}$ . However, due to a limitation of the gray-scaler/serializer block, fewer grayscales or colors may be supported.

The PLM field (in RASTER\_CTRL) affects the palette loading:

- If PLM is 00b (palette-plus-data mode) or 01b (palette-only mode), the palette is loaded by the DMA engine at the very beginning, which is followed by the loading of pixel data.
- If PLM is 10b (data-only mode), the palette is not loaded. Instead, the DMA engine loads the pixel data immediately.

### 24.2.5.4 Gray-Scaler/Serializer

#### 24.2.5.4.1 Passive (STN) Mode

Once a palette entry is selected from the look-up palette by the pixel data, its content is sent to the gray-scaler/serializer. If it is monochrome data, it is encoded as 4 bits. If it is color data, it is encoded as 4 bits (Red), 4 bits (Green), and 4 bits (Blue).

These 4-bit values are used to select one of the 16 intensity levels, as shown in [Table 24-7](#). A patented algorithm is used during this processing to provide an optimized intensity value that matches the eye's visual perception of color/gray gradations.

#### 24.2.5.4.2 Active (TFT) Mode

The gray-scaler/serializer is bypassed.

**Table 24-7. Color/Grayscale Intensities and Modulation Rates**

| Dither Value<br>(4-Bit Value from Palette) | Intensity<br>(0% is White) | Modulation Rate<br>(Ratio of ON to ON+OFF Pixels) |
|--------------------------------------------|----------------------------|---------------------------------------------------|
| 0000                                       | 0.0%                       | 0                                                 |
| 0001                                       | 11.1%                      | 1/9                                               |
| 0010                                       | 20.0%                      | 1/5                                               |
| 0011                                       | 26.7%                      | 4/15                                              |
| 0100                                       | 33.3%                      | 3/9                                               |
| 0101                                       | 40.0%                      | 2/5                                               |

#### 24.2.5.4.3 Summary of Color Depth

**Table 24-8. Number of Colors/Shades of Gray Available on Screen**

| Number of<br>BPP | Passive Mode (TFT_STN = 0)                                                                                         |                                                             | Active Mode (TFT_STN = 1)                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|--------------------------------------------------------------|
|                  | Monochrome (MONO_COLOR = 1)                                                                                        | Color (MONO_COLOR = 0)                                      | Color Only (MONO_COLOR = 0)                                  |
| 1                | 2 palette entries to select within<br>15 grayscales                                                                | 2 palette entries to select within<br>3375 possible colors  | 2 palette entries to select within<br>4096 possible colors   |
| 2                | 4 palette entries to select within<br>15 grayscales                                                                | 4 palette entries to select within<br>3375 possible colors  | 4 palette entries to select within<br>4096 possible colors   |
| 4                | 16 palette entries to select within<br>15 grayscales                                                               | 16 palette entries to select within<br>3375 possible colors | 16 palette entries to select within<br>4096 possible colors  |
| 8                | Not relevant since it would consist in<br>256 palette entries to select within<br>15 grayscales, but exists anyway | 256 palette entries to select<br>3375 possible colors       | 256 palette entries to select within<br>4096 possible colors |
| 12               | x                                                                                                                  | 3375 possible colors                                        | 4096 possible colors                                         |
| 16               | x                                                                                                                  | 3375 possible colors (STN_565 = 1)                          | Up to 65536 possible colors                                  |

## 24.2.5.5 Output Format

### 24.2.5.5.1 Passive (STN) Mode

As shown in Figure 24-3, the pixel data stored in frame buffers go through palette (if applicable) and gray-scaler/serializer before reaching the Output FIFO. As a result, it is likely that the data fed to the Output FIFO is numerically different from the data in the frame buffers. (However, they represent the same color or grayscale.)

The output FIFO formats the received data according to display modes (see Table 24-4). Figure 24-13 shows the actual data output on the external pins.

### 24.2.5.5.2 Active (TFT) Mode

As shown in Figure 24-3, the gray-scaler/serializer and output FIFO are bypassed in active (TFT) mode. Namely, at each pixel clock, one pixel data (16 bits) is output to the external LCD.

**Figure 24-13. Monochrome and Color Output**

### 24.2.5.6 Subpanel Feature

In some applications, it is desired to display only the first or last few lines of the LCD panel (see [Figure 24-14](#)). This is mainly used for power saving.

This is supported by the Raster Controller via its subpanel feature. The RASTER\_SUBPANEL register fully defines its behavior, that is, the following parameters are defined:

- Whether the first or last few lines will be refreshed.
- A line number, which is the last (or first) line to be refreshed.
- The pixel data to be loaded to the refresh area.

Note that there is only one pixel value for all the pixels in the refresh area. As a result, frame buffers and DMA engine are not used in this case, which leads to power saving.

**Figure 24-14. Raster Mode Display Format**

## 24.3 Registers

Table 24-9 lists the memory-mapped registers for the LCD module.

**Table 24-9. LCD Controller (LDC) Registers**

| Address Offset | Acronym            | Register Description                            | Section                         |

### 24.3.1 LCD Revision Identification Register (REVID)

The LCD revision identification register (REVID) is shown in [Figure 24-15](#) and described in [Table 24-10](#).

**Figure 24-15. LCD Revision Identification Register (REVID)**

|              |   |
|--------------|---|
| 31           | 0 |
| REV          |   |
| R-4C10 0100h |   |

LEGEND: R = Read only; -n = value after reset

**Table 24-10. LCD Revision Identification Register (REVID) Field Descriptions**

| Bit  | Field | Value      | Description                      |
|------|-------|------------|----------------------------------|
| 31-0 | REV   | 4C10 0100h | Peripheral Identification Number |

### 24.3.2 LCD Control Register (LCD\_CTRL)

The LCD control register (LCD\_CTRL) contains the fundamental mode select bit for the LCD controller. The LCD\_CTRL is shown in [Figure 24-16](#) and described in [Table 24-11](#).

**Figure 24-16. LCD Control Register (LCD\_CTRL)**

| 0     | MODESEL  | 0<br>1 | LCD Mode Select<br>LCD Controller in LIDD mode<br>LCD Controller in Raster mode                                                                                                                                                                                                                                                                                    |

The 8-bit clock divider (CLKDIV) field is used to select the frequency of the pixel clock. CLKDIV can generate a range of pixel clock frequencies from LCD\_CLK/2 to LCD\_CLK/255. The pixel clock frequency must be adjusted to meet the required screen refresh rate.

The refresh rate depends on:

- The number of pixels for the target display.
- Whether monochrome or color mode is selected.
- The number of pixel clock delays programmed at the beginning and end of each line.
- The number of line clocks inserted at the beginning and end of each frame.
- The width of the frame clock (LCD\_VSYNC) signal in active mode or VSW line clocks inserted in passive mode.
- The width of the line clock (LCD\_HSYNC) signal.

All of these factors alter the time duration from one frame transmission to the next. Different display manufacturers require different frame refresh rates, depending on the physical characteristics of the display. CLKDIV is used to alter the pixel clock frequency in order to meet these requirements. Pixel clock is used to synchronously signal the device to drive data to the LCD data pins, and to signal the output FIFO to latch the data from the pins. The frequency of the pixel clock for a set CLKDIV value or the required CLKDIV value to yield a target pixel clock frequency can be calculated using the following equation:

$$\text{LCD\_PCLK} = \frac{\text{LCD\_CLK}}{\text{CLKDIV}}$$

The pixel clock frequency is programmed taking into account the limitations shown in [Table 24-12](#).

If CLKDIV equals 0 or 1, the effect is undefined. Dividing the pixel clock frequency by an odd number distorts the duty cycle.

**Table 24-12. Pixel Clock Frequency Programming Limitations**

| Type of Screen                            | Output (In Bits) | Minimum Pixel Clock Divider |
|-------------------------------------------|------------------|-----------------------------|
| TFT 1,2,4,8 BPP                           | 12 ( 1 pixel)    | 2                           |
| TFT 16 BPP                                | 16 (1 pixel)     | 2                           |
| STN monochrome(4 output lines per panel ) | 4 (4 pixel)      | 4                           |
| STN monochrome(8 output lines per panel)  | 8 (8 pixel)      | 8                           |
| STN color                                 | 8 (2 2/3 pixel)  | 3                           |

### 24.3.3 LCD Status Register (LCD\_STAT)

The LCD status register (LCD\_STAT) contains bits that signal status and error conditions to the processor. Each of the LCD status bits signals an interrupt request as long as the bit is set AND the interrupt enable for that bit is also set (see the LCD raster control and LCD DMA control registers for these enables). Writing a 1 to each bit clears it; once the bit is cleared, the interrupt is cleared. The LCD\_STAT is shown in [Figure 24-17](#) and described in [Table 24-13](#).

**Figure 24-17. LCD Status Register (LCD\_STAT)**

| 0     | DONE     | 0<br>1 | Raster or LIDD Frame Done (shared; depends on whether Raster or LIDD mode enabled)<br>Raster or DMA_to_LIDD engine is enabled<br>Raster or DMA_to_LIDD disabled and the active frame has just completed                                                                                                                                           |

#### 24.3.3.1 Frame Done (DONE)

When the LCD is disabled by clearing the LCD Raster Control enable bit (RASTER\_EN = 0) in the LCD Raster Control Register, the LCD allows the current frame to complete before it is disabled. After the last set of pixels is clocked out onto the LCD data pins by the pixel clock, the LCD is disabled and DONE is set.

- DONE = 1 when the frame is complete.
- DONE = 0 as long as the frame is not complete.

The frame done (DONE) bit signals the frame is complete. It is cleared when the RASTER\_EN bit is set to 1 (turned ON).

#### 24.3.3.2 Frame Synchronization Lost (SYNC)

The frame synchronization lost (SYNC) bit is set if the LCD controller detects a frame synchronization error. A frame synchronization error can occur for one of two reasons:

- when the LCD controller attempts to read what it believes to be the first word of the video buffer but cannot be recognized as such
- if the LCD controller is starved of data, which can happen due to insufficient bandwidth from the source of LCD data through the system interconnect to the LCD controller

To alleviate data bandwidth bottleneck issues to the LCD controller, the following configuration settings can be experimented with:

- Increase DDR2/mobile DDR (mDDR) memory controller (if used) Command Re-Ordering (PBBPR) setting from default to a value such as 10h to 20h
- Increase LCD FIFO threshold
- Increase priority for LCD controller DMA
- Increase burst size setting for LCD controller DMA
- Run the DDR2/mobile DDR (mDDR) memory controller (if used) at maximum clock speed

This bit is cleared by disabling the LCD controller (RASTER\_EN = 0). This also resets the input FIFO in the DMA controller.

- SYNC = 1 when a frame synchronization lost occurred.
- SYNC = 0 as long as no frame synchronization error occurs.

#### 24.3.3.3 AC-Bias Count Status (ABC)

The ac-bias count status (ABC) bit is set each time the ac-bias line transitions a particular number of times as specified by the ac-bias line transitions per interrupt (ACB\_I) field in LCD Raster Timing Register 2. If ACB\_I is programmed with a non-zero value, a counter is loaded with the value in ACB\_I and is decremented each time the ac-bias line reverses state. When the counter reaches zero, the ABC bit is set that signals an interrupt request to the interrupt controller. The counter reloads using the value in ACB\_I, but does not start to decrement again until you clear ABC by writing 0 to the LCD status register.

- ABC = 1 when the ac-bias transition counter ACB\_I has decremented to 0
- ABC = 0 as long as ACB\_I has not decremented to 0

#### 24.3.3.4 FIFO Underflow Status (FUF)

The FIFO underflow status (FUF) bit is set when the input FIFO is completely empty and the LCD data pins driver logic attempts to fetch data from the FIFO. This bit is cleared by disabling the LCD controller (RASTER\_EN = 0). To recover from this condition and restart normal function of the LCDC, the peripheral needs to be reset through the Power and Sleep Controller (PSC).

- FUF = 1 when the dithering logic is not supplying data to the FIFO at a sufficient rate.
- FUF = 0 as long as FIFO has not underrun.

#### 24.3.3.5 Loaded Palette (PL)

The loaded palette (PL) bit is a read-only bit that is set after the LCD finished loading the palette into memory.

- PL = 1 when the palette is loaded.
- PL = 0 as long as the palette is not loaded.

In data-only (PL = 10) and palette-plus-data (PL = 00) modes, write 0 to clear the interrupt. However, in the palette only (PL = 01) mode, LCD must be turned off in order to reset/clear the interrupt. But in this particular mode, make sure not to turn off the LCD before getting the loading interrupt.

#### 24.3.4 LCD LIDD Control Register (LIDD CTRL)

The LCD LIDD control register (LIDD\_CTRL) contains the polarity controls for LIDD output signals (to account for variety in the external LCD display/peripheral signal requirements), and the LIDD type select bits. These bits are not valid in Raster mode (when LCD control register bit 0 = 1). The LIDD\_CTRL is shown in [Figure 24-18](#) and described in [Table 24-14](#).

**NOTE:** To activate DMA to drive LIDD interface, all other control bit-fields must be programmed before setting LIDD\_DMA\_EN = 1 and must also disable LIDD\_DMA\_EN bit when changing the state of any control bit within the LCD controller.

**Figure 24-18. LCD LIDD Control Register (LIDD\_CTRL)**

### 24.3.5 LCD LIDD CS<sub>n</sub> Configuration Registers (LIDD\_CS0\_CONF and LIDD\_CS1\_CONF)

The LCD LIDD CS<sub>n</sub> configuration registers (LIDD\_CS<sub>n</sub>\_CONF) provides the capability to configure Write and Read Strobe timing parameters to meet a variety of interface timing requirements for the Chip Select 0 (Primary) device and Chip Select 1(Secondary) device, respectively. These values are in MCLK cycles; MCLK is divided down from LCD\_CLK as defined by the CLKDIV field in the LCD control register. The LIDD\_CS<sub>n</sub>\_CONF is shown in [Figure 24-19](#) and described in [Table 24-15](#).

**Figure 24-19. LCD LIDD CS<sub>n</sub> Configuration Register (LIDD\_CS<sub>n</sub>\_CONF)**

**Table 24-15. LCD LIDD CS<sub>n</sub> Configuration Register (LIDD\_CS<sub>n</sub>\_CONF) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                       |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | W_SU     | 0-1Fh | Write Strobe Set-Up cycles. Field value defines number of MCLK cycles after Data Bus/Pad Output Enable, ALE, Direction bit and Chip Select 0 have been set up before the Write Strobe is asserted when performing a write access.                 |
| 26-21 | W_STROBE | 1-3Fh | Write Strobe Duration cycles. Field value defines number of MCLK cycles that the Write Strobe is held active when performing a write access.                                                                                                      |
| 20-17 | W_HOLD   | 1-Fh  | Write Strobe Hold cycles. Field value defines number of MCLK cycles that the Data Bus/Pad Output Enable, ALE, Direction bit, and Chip Select 0 are held after the Write Strobe is deasserted when performing a write access.                      |
| 16-12 | R_SU     | 0-1Fh | Read Strobe Set-Up cycles. Field value defines number of MCLK cycles after Data Bus/Pad Output Enable, ALE, Direction bit and Chip Select 0 have been set up before the Read Strobe is asserted when performing a read access.                    |
| 11-6  | R_STROBE | 1-3Fh | Read Strobe Duration cycles. Field value defines number of MCLK cycles that the Read Strobe is held active when performing a read access.                                                                                                         |
| 5-2   | R_HOLD   | 1-Fh  | Read Strobe Hold cycles. Field value defines number of MCLK cycles that the Data Bus/Pad Output Enable, ALE, Direction bit, and Chip Select 0 are held after the Read Strobe is deasserted when performing a read access.                         |
| 1-0   | TA       | 0-3h  | Field value defines number of MCLK cycles between the end of one CS0 device access and the start of another CS0 device access unless the two accesses are both reads, in which case this delay is not incurred. CS_DELAY = ROUNDUP(7/CLKDIV) + TA |

### 24.3.6 LCD LIDD CS<sub>n</sub> Address Read/Write Registers (LIDD\_CS0\_ADDR and LIDD\_CS1\_ADDR)

The LCD LIDD CS<sub>0</sub> address read/write registers (LIDD\_CS<sub>n</sub>\_ADDR) are accessed by the processor to perform the address/index read or write operations on the CS<sub>0</sub> and CS<sub>1</sub> device respectively. Writing to LIDD\_CS<sub>0</sub>\_ADDR asserts CS<sub>0</sub> and Address Latch Enable, which loads the ADR\_IND<sub>X</sub> field of this register into the address generator of the peripheral device. Likewise, reading from LIDD\_CS<sub>0</sub>\_ADDR asserts CS<sub>0</sub> and Address Latch Enable, which loads status information from the peripheral device into the ADR\_IND<sub>X</sub> field of this register. Similarly writing to LIDD\_CS<sub>1</sub>\_ADDR asserts CS<sub>1</sub> and Address Latch Enable, which loads the ADR\_IND<sub>X</sub> field of this register into the address generator of the peripheral device. Likewise, reading from LIDD\_CS<sub>1</sub>\_ADDR asserts CS<sub>1</sub> and Address Latch Enable, which loads status information from the peripheral device into the ADR\_IND<sub>X</sub> field of this register. The LIDD\_CS<sub>n</sub>\_ADDR is shown in [Figure 24-20](#) and described in [Table 24-16](#).

| 31-16 | Reserved             | 0       | Reserved                                                                                                                                                                                                           |
| 15-0  | ADR_IND <sub>X</sub> | 0-FFFFh | Peripheral Device Address/Index value. On writes this field is loaded into the CS <sub>0</sub> peripheral device's address generator. On reads this field contains the CS <sub>0</sub> peripheral device's status. |

### 24.3.7 LCD LIDD CS<sub>n</sub> Data Read/Write Registers (LIDD\_CS0\_DATA and LIDD\_CS1\_DATA)

The LCD LIDD CS<sub>0</sub> data read/write registers (LIDD\_CS<sub>n</sub>\_DATA) are accessed by the processor to perform the data read or write operations on the CS<sub>0</sub> and CS<sub>1</sub> device respectively. Writing to LIDD\_CS<sub>0</sub>\_DATA asserts CS<sub>0</sub> and deasserts Address Latch Enable, which loads the DATA field of this register into the peripheral device. Likewise, reading from this register asserts CS<sub>0</sub> and deasserts Address Latch Enable, which loads data from the peripheral device into the DATA field of this register. Similarly writing to LIDD\_CS<sub>1</sub>\_DATA asserts CS<sub>1</sub> and deasserts Address Latch Enable, which loads the DATA field of this register into the peripheral device. Likewise, reading from LIDD\_CS<sub>1</sub>\_DATA asserts CS<sub>1</sub> and deasserts Address Latch Enable, which loads data from the peripheral device into the DATA field of this register. The LIDD\_CS<sub>n</sub>\_DATA is shown in [Figure 24-21](#) and described in [Table 24-17](#).

| 15-0  | DATA     | 0-FFFFh | Peripheral Device Data value. On writes this field is loaded into the CS <sub>0</sub> peripheral device On reads this field contains the CS <sub>0</sub> peripheral device's data. |

### 24.3.8 LCD Raster Control Register (RASTER\_CTRL)

The LCD raster control register (RASTER\_CTRL) contains bit-fields that are used to control various functions within the Raster controller sub-module. The RASTER\_CTRL is shown in [Figure 24-22](#) and described in [Table 24-18](#).

**Figure 24-22. LCD Raster Control Register (RASTER\_CTRL)**

### 24.3.8.1 LCD Raster Controller Enable (RASTER\_EN)

**NOTE:** All other control bit-fields must be programmed before setting RASTER\_EN = 1 and must also disable the LCD controller when changing the state of any control bit within the LCD controller.

The LCD Raster Controller enable (RASTER\_EN) bit is used to enable and disable all LCD controller operation.

- When RASTER\_EN = 0, the LCD controller is disabled.
- When RASTER\_EN = 1, the LCD controller is enabled.

You can program the LCD control register (LcdControl) last, and configure all twenty-five bit fields at the same time via a word32 write to the register. If you clear RASTER\_EN bit while the LCD controller is enabled, you can complete transmission of the current frame before being disabled. Completion of the current frame is signaled by the LCD controller to the DMA by setting the frame done (Done) bit within the LCD controller status register (see LCD Controller Status Register), which generates an interrupt request. If the LCD controller is disabled, the signals on pixel data [15:0] pins are set to 0 and the pixel clock, frame clock(vertical clock), line clock (horizontal clock), and ac-bias signals are set to their inactive state. This can be 0 or 1, depending on the inversions programmed in the LCD Raster Timing 2 register.

### 24.3.8.2 LCD Monochrome (MONO\_COLOR)

The color/monochrome select (LcdBW) bit is used to determine whether the LCD controller operates in color or monochrome mode.

- When MONO\_COLOR = 0:
  - Color mode is selected.
  - Palette entries are 12 bits wide, providing up to 4096 colors in active (TFT) mode and up to 3375 colors in passive (STN) color mode.
  - All three dither blocks are used (in passive mode only: TFT\_STN = 0), one for each color component (R, G, B).
- When MONO\_COLOR = 1:
  - Monochrome mode is selected.
  - Palette entries are 4 bits wide effective (15 levels of grayscale).
  - 4 or 8 data lines are enabled, according to the mono 8-bit mode (MONO8B).

**Table 24-19. LCD Controller Data Pin Utilization for Mono/Color Passive/Active Panels**

| Color/Mono BPP                    | Passive/Active Panel | Pins                                                                                                               |
|-----------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------|
| Mono 1,2,4                        | Passive              | Pixel data[3:0]                                                                                                    |
| Mono 8                            | Passive              | Pixel data[7:0]                                                                                                    |
| Color 1,2,4,8,12,16 (STN_565 = 1) | Passive              | Pixel data[7:0]                                                                                                    |
| Color 1,2,4,8,12                  | Active               | Pixel data[11:0] or Pixel data[15:0] according to TFT_ALT_MAP bit in the LCD Raster Control Register (RASTER_CTRL) |
| Color 16                          | Active               | Pixel data[15:0]                                                                                                   |

### 24.3.8.3 TFT\_STN (TFT\_STN)

The TFT\_STN (TFT\_STN) bit selects whether the LCD controller operates in passive (STN) or active (TFT) display control mode. When TFT\_STN = 0, passive or STN mode is selected. LCD data flows from the frame buffer memory, via the LCD dedicated DMA channel, to the palette (the palette is bypassed for the 12 and 16 BPP modes), to the dithering logic and the output FIFO before being output on the LCD data pins. The clock and data pin behaviors is shown for the monochrome passive mode (Figure 24-23) and for the color passive mode (Figure 24-24).

**Figure 24-23. Monochrome Passive Mode Pixel Clock and Data Pin Timing**

**Figure 24-24. Color Passive Mode Pixel Clock and Data Pin Timing**

When TFT\_STN = 1, active or TFT mode is selected. Video data is transferred via the DMA from memory to the input FIFO, then is unpacked and used to select an entry from the palette (for 1, 2, 4, and 8 bits per pixel modes), just as in passive mode. The value read from the palette; however, bypasses both the LCD dither logic and the output FIFO to be output on the LCD data pins in TFT mode. The pixel size within the frame buffer is increased to 16 bits when 12- or 16-bit pixel encoding mode is enabled (BPP = 1xx). In TFT mode for 12 and 16 bits per pixel, palette entry is not selected. The clock and data pin behaviors is shown in Figure 24-25.

**Figure 24-25. Active Mode Pixel Clock and Data Pin Timing**

describes the clocks and data pin behaviors in active mode. The size of the pixel encoding is increased in TFT mode because the LCD dither logic is bypassed (the dither logic only supports 4 bits to encode each color component R, G, B that limits the pixel encoding size in passive mode). Increasing the size of the pixel representation allows a total of 64K colors to be addressed using an off-chip palette in conjunction with the LCD controller.

#### 24.3.8.4 Mono 8 Bit Mode (MONO8B)

**NOTE:** MONO8B does not affect any of the color modes or TFT.

The mono 8-bit mode (MONO8B) bit selects whether four or eight data lines are used to output pixel data to the LCD screen.

- When MONO8B = 0, pixel data [3:0] is used to output four pixel values to the LCD panel at each pixel clock transition.
- When MONO8B = 1, pixel data [7:0] is used to output eight pixel values to the LCD panel at each pixel clock transition

#### 24.3.8.5 FIFO DMA Request Delay (FIFO\_DMA\_DELAY)

The 8-bit FIFO DMA request delay (FIFO\_DMA\_DELAY) field is used to select the minimum number of LCD\_CLK cycles to wait between the servicing of each DMA request issued by the LCD controller, sending an address to the input FIFO. The goal is to ensure enough bandwidth to other system accesses. A delay of FIFO\_DMA\_DELAY cycles is inserted every 16 words read from the input FIFO. This function is a concern only in 8 BPP mode, where the palette is 256 words. The FIFO\_DMA\_DELAY field needs to be set properly to avoid FIFO underflow during palette loading phase. When FDD = 00h, the FIFO DMA request delay function is disabled. This function is only used for palette loading.

### 24.3.8.6 Palette Loading (PLM)

The 2-bit palette loading field describes how the palette loading behaves when each new frame is loaded from memory.

- When PLM = 0, the data in the frame buffer represents the palette data and the picture data. Both palette and picture data are loaded.
- When PLM = 1 (palette-only mode), the data in the frame buffer just represents a new palette to be loaded. This data is loaded and placed into the palette. But be sure to turn off the LCD after getting the loading interrupt, or the LCD behavior would be unpredictable.
- When PLM = 2h (data loading mode), the data in the frame buffer only represents the picture data (data-only). This data is then used as an index (in the palette) or sent directly out. This mode assumes the palette was previously loaded. There is no need to keep loading the palette if it is not changing. As a matter of fact, in data-only mode, the BPP is fixed and can not change on the fly since the palette is not loaded at every frame.
- PLM = 3h is reserved.

### 24.3.8.7 TFT Alternate Signal Mapping (TFT\_ALT\_MAP)

This bit is relevant only if TFT\_ALT\_MAP = 1.

This bit field controls how the TFT pixel data is output. Via this feature, 12-BPP data can be output to all 16-bit LCD pins (this also applies to 1-, 2-, 4-, and 8- BPP). This feature allows you to switch BPP modes on the fly, duplicating the 12-bit output data across the 16 data lines if they are already hardwired to the 16 data lines.

Figure 24-26 shows how the four red, four green, and four blue bits are mapped to all pixel data [15-0] output pins when TFT\_ALT\_MAP = 1.

**Figure 24-26. TFT Alternate Signal Mapping Output**

| Pins | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Data | R3 | R2 | R1 | R0 | R3 | G3 | G2 | G1 | G0 | G3 | G2 | B3 | B2 | B1 | B0 | B3 |

When TFT\_ALT\_MAP = 0, the four red, four green, and four blue data are right-aligned on pixel data [11-0]. The upper pixel data [15-12] are cleared to 0. There is no duplication.

### 24.3.8.8 16 BPP STN Mode (STN\_565)

The STN\_565 bit is relevant only if TFT\_STN = 0, but has no effect in 1-, 2-, 4- and 8-BPP modes. If STN\_565 = 0, the frame buffer organization is in 12 BPP mode. In this mode, each color component is encoded in 4 bits, as shown in [Figure 24-27](#).

**Figure 24-27. 12-Bit STN Data in Frame Buffer**

| Pins | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Data | Data Ignored |    |    |    | R3 | R2 | R1 | R0 | G3 | G2 | G1 | G0 | B3 | B2 | B1 | B0 |

If STN\_565 = 1, the 16-bit STN mode is selected. The only difference from the 12 BPP mode is how the pixel data is organized in the frame buffer and which bits are sent to the dither logic. The 16-bit STN mode appears in frame buffer memory as shown in [Figure 24-28](#).

**Figure 24-28. 16-Bit STN Data in Frame Buffer**

| Pins | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Data | R4 | R3 | R2 | R1 | R0 | G5 | G4 | G3 | G2 | G1 | G0 | B4 | B3 | B2 | B1 | B0 |

The 16-bit STN mode only sends 12 bits to the dithering logic as well as the 12-BPP STN mode. The LSB bit of the red component (bit 11), the two LSBs of green (bits 6 and 5), and the LSB of blue (bit 0) are not sent to the dithering logic, as shown in [Figure 24-29](#).

**Figure 24-29. 16-BPP STN Mode**

**Note:**

Red bit 11, green bits 6, 5 and blue bit 0 are not used as image data and are ignored. The 16-bit STN resolution is equal to the 12-bit STN resolution (3375 colors)

### 24.3.9 LCD Raster Timing Register 0 (RASTER\_TIMING\_0)

The LCD raster timing 0 register (RASTER\_TIMING\_0) contains four bit-fields that are used as modulus values for a collection of down counters, each of which performs a different function to control the timing of several of the LCD's pins. The RASTER\_TIMING\_0 is shown in Figure 24-30 and described in Table 24-20.

**Figure 24-30. LCD Raster Timing Register 0 (RASTER\_TIMING\_0)**

|       |    |       |          |
|-------|----|-------|----------|
| 31    | 24 | 23    | 16       |
| HBP   |    | HFP   |          |
| R/W-0 |    | R/W-0 |          |
| 15    | 10 | 9     | 0        |

**Table 24-20. LCD Raster Timing Register 0 (RASTER\_TIMING\_0) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                         |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | HBP      | 0-FFh | Horizontal Back Porch. Encoded value (HBP + 1) is used to specify number of LCD_PCLKs to add to the beginning of a line transmission before the first set of pixels is output to the display (program to value minus one). Note that pixel clock is held in its inactive state during the beginning of line wait period in STN mode while it is active in TFT mode. |
| 23-16 | HFP      | 0-FFh | Horizontal Front Porch. Encoded value (HFP + 1) is used to specify number of LCD_PCLKs to add to the end of a line transmission before line clock is asserted (program to value minus one). Note that pixel clock is held in its inactive state during the end of line wait period in STN mode while it is active in TFT mode.                                      |
| 15-10 | HSW      | 0-3Fh | Horizontal Sync Pulse Width. Encoded value (HSW + 1) is used to specify number of LCD_PCLKs to pulse the line clock at the end of each line (program to value minus one). Note that pixel clock is held in its inactive state during the generation of the line clock in STN mode while it is active in TFT mode.                                                   |
| 9-4   | PPL      | 0-3Fh | Pixels per Line. This value specifies the number of pixel transmissions per line . Number of pixels per Line = (PPL + 1) × 16                                                                                                                                                                                                                                       |
| 3-0   | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                            |

#### 24.3.9.1 Pixels-Per-Line (PPL)

**NOTE:** PPL must be programmed to the value required minus 1 (for example, for a 640-pixel-per-line LCD panel,  $PPL = (640/16) - 1 = 40 - 1 = 39 = 27h$ ).

The pixels-per-line (PPL) bit-field is used to specify the number of pixels in each line on the screen. The number of pixels per line =  $(PPL + 1) \times 16$ , represents the screen width. PPL is a 6-bit value. Taking into account that the bottom 4 bits of this register are reserved, it is possible to support displays where the number of pixels-per-line ranges from 16-1024. PPL is used to count the correct number of pixel clocks that must occur before the line clock can be pulsed.

### 24.3.9.2 Horizontal Synchronization Pulse Width (HSW)

---

**NOTE:** The pixel clock does not transition during the line clock pulse in passive display mode, but it transitions in active display mode.

---

The 6-bit horizontal synchronization pulse width (HSW) field is used to specify the pulse width of the line clock in passive mode, or horizontal synchronization pulse in active mode. The line clock (or LCD\_HSYNC) is asserted each time a line or row of pixels is output to the display and a programmable number of pixel clock delays have elapsed. When line clock is asserted, the value in HSW is transferred to a 6-bit down counter that uses the programmed pixel clock frequency to decrement. When the counter reaches zero, the line clock is negated. HSW can be programmed to generate a line clock pulse width ranging from 1–64 pixel clock periods (program to value required minus 1).

### 24.3.9.3 Horizontal Front Porch (HFP)

---

**NOTE:** The pixel clock does not transition during these dummy pixel clock cycles in passive display mode, but it transitions continuously in active display mode.

---

The 8-bit horizontal front porch (HFP) field is used to specify the number of dummy pixel clocks to insert at the end of each line or row of pixels before pulsing the line clock(or LCD\_HSYNC) pin. Once a complete line of pixels is transmitted to the LCD driver, the value in HFP is used to count the number of pixel clocks to wait before pulsing the line clock. HFP generates a wait period ranging from 1–256 pixel clock cycles (program to value required minus 1).

### 24.3.9.4 Horizontal Back Porch (HBP)

---

**NOTE:** The pixel clock does not transition during these dummy pixel clock cycles in passive display mode, but it transitions continuously in active display mode.

---

The 8-bit horizontal back porch (HBP) field is used to specify the number of dummy pixel clocks to insert at the beginning of each line or row of pixels. After the line clock(or LCD\_HSYNC) for the previous line has been negated, the value in HBP is used to count the number of pixel clocks to wait before starting to output the first set of pixels in the next line. HBP generates a wait period ranging from 1–256 pixel clock cycles (program to value required minus 1).

### 24.3.10 LCD Raster Timing Register 1 (RASTER\_TIMING\_1)

The LCD raster timing 1 register (RASTER\_TIMING\_1) contains four bit-fields that are used as modulus values for a collection of down counters, each of which performs a different function to control the timing of several of the LCD's pins. The (RASTER\_TIMING\_1 is shown in [Figure 24-31](#) and described in [Table 24-21](#).

**Figure 24-31. LCD Raster Timing Register 1 (RASTER\_TIMING\_1)**

LEGEND: R = Read only; -n = value after reset

**Table 24-21. LCD Raster Timing Register 1 (RASTER\_TIMING\_1) Field Descriptions**

| Bit   | Field | Value  | Description                                                                                                                                                                                                                                                                                                                                               |
|-------|-------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | VBP   | 0-FFh  | Vertical Back Porch. Encoded value (VBP) used to specify number of line clock (LCD_HSYNC) periods to add to the beginning of a frame before the first set of pixels is output to the display. Note that line clock transitions during the insertion of the extra line clock periods.                                                                      |
| 23-16 | VFP   | 0-FFh  | Vertical Front Porch. Encoded value (VFP) used to specify number of line clock (LCD_HSYNC) periods to add to the end of each frame. Note that the line clock transitions during the insertion of the extra line clock periods.                                                                                                                            |
| 15-10 | VSW   | 0-3Fh  | Vertical Synchronization Pulse Width.<br>In TFT mode, encoded value (VSW + 1) defines the number of line clock (LCD_HSYNC) cycles to hold the frame clock (LCD_VSYNC) active.<br>In STN mode, encoded value (VSW + 1) specifies the number of extra line clock (LCD_HSYNC) cycles to be inserted after the vertical front porch (VFP) period has elapsed. |
| 9-0   | LPP   | 0-3FFh | Lines per Panel. Encoded value (LPP + 1) used to specify number of lines per panel. It represents the total number of lines on the LCD.                                                                                                                                                                                                                   |

#### 24.3.10.1 Lines Per Panel (LPP)

**NOTE:** LPP must be programmed to the value required minus 1 (C7h for 200 lines per panel).

The lines per panel (LPP) bit-field is used to specify the number of lines or rows per LCD panel being controlled. It represents the total number of lines for the entire LCD display (the screen height). LPP is a 10-bit value, which represents between 1–1024 lines per panel. LPP is used to count the correct number of line clocks that must occur before the frame clock can be pulsed.

### 24.3.10.2 Vertical Synchronization Pulse Width (VSW)

The 6-bit vertical synchronization pulse width (VSW) field is used to specify the pulse width of the vertical synchronization pulse in active mode or is used to add extra dummy line clock cycles between the vertical front porch and vertical back porch in passive mode.

#### 24.3.10.2.1 Active Mode

**NOTE:** Remember that most of the parameters (HSW, HFP, PPL, HBP) must be programmed to value required minus 1.

In active mode (TFT\_STN = 1), VSYNC is asserted each time the last line or row of pixels from the previous frame is output to the display and a programmable number of line clock delays (VFP) has elapsed. When the frame clock (LCD\_VSYNC) is asserted, the value in VSW is transferred to a 6-bit down counter that uses the line clock frequency to decrement. When the counter reaches zero, the frame clock (LCD\_VSYNC) is negated. VSW can be programmed to generate a vertical synchronization pulse width ranging from 1–64 line clock periods (program to value required minus 1—see Figure 24-32). The following frame starts after LCD\_VSYNC is deasserted and a programmable number of line clock delays (VBP) has elapsed.

**Figure 24-32. Vertical Synchronization Pulse Width (VSW) - Active Mode**

#### 24.3.10.2.2 Passive Mode

**NOTE:** The pixel clock does not transition during the whole dummy line clock periods that are inserted in passive mode before the frame pulse. The line clock does transition during the insertion of the dummy line clock cycles. VSW must be long enough to load the palette.

In passive mode (TFT\_STN = 0), VSW does not affect the timing of the frame clock, but instead can be used to add extra line clock cycles between the end and beginning of frame line clock cycle counts. The total number of line clock cycles that are inserted between each frame is equal to the sum of the values in VFP, VSW and VBP. A counter is used to insert dummy line clock cycles between frames by first using the value in VFP, then VSW, then VBP. You must ensure that the sum of the values in the three fields is equal to the total number of line clock cycles that are needed between frames. The LCD controller frame clock pin is asserted on the rising-edge of the first pixel clock for each frame. The frame clock remains asserted for the remainder of the first line as pixels are output to the display, also during the assertion of the first line clock for the frame, and then negated on the rising-edge of the first pixel clock of the second line of each frame.

### 24.3.10.3 Vertical Front Porch (VFP)

**NOTE:** Remember that VSW must be programmed to value required minus 1.

The 8-bit vertical front porch (VFP) field is used to specify the number of line clocks to insert at the end of each frame. Once a complete frame of pixels is transmitted to the LCD display, the value in VFP is used to count the number of line clock periods to wait. After the count has elapsed the LCD\_VSYNC signal is pulsed in active mode or extra line clocks are inserted as specified by the VSW bit-field in passive mode. VFP generates from 0–255 line clock cycles (see [Figure 24-33](#)).

**Figure 24-33. Vertical Front Porch (VFP)**

#### 24.3.10.4 Vertical Back Porch (VBP)

**NOTE:** The line clock transitions during the generation of the VBP line clock wait periods. Note also that you must adjust the value of VBP appropriately such that enough line clock cycles are permitted to elapse; this allows the palette to be completely filled via the DMA, and allows a sufficient number of encoded pixel values to be input from the frame buffer, processed by the dither logic, then placed in the output FIFO, ready to be output to the LCD data lines.

The 8-bit vertical back porch (VBP) field is used to specify the number of line clocks (or LCD\_HSYNC) to insert at the beginning of each frame. The VBP count starts just after the LCD\_VSYNC signal for the previous frame has been negated for active mode, or the extra line clocks have been inserted as specified by the VSW bit-field in passive mode. After this has occurred, the value in VBP is used to count the number of line clock periods to insert before starting to output pixels in the next frame. VBP generates from 0–255 extra line clock cycles (see [Figure 24-34](#)).

**Figure 24-34. Vertical Back Porch (VBP)**

### 24.3.11 LCD Raster Timing Register 2 (RASTER\_TIMING\_2)

LCD raster timing 2 register (RASTER\_TIMING\_2) contains bit-fields that are used to control various functions associated with the timing of the LCD controller. The RASTER\_TIMING\_2 is shown in Figure 24-35 and described in Table 24-22.

**Figure 24-35. LCD Raster Timing Register 2 (RASTER\_TIMING\_2)**

This output may be used to periodically invert the polarity of the power supply in order to prevent a display DC charge build-up on the LCD panel.<br>AC Bias Time Period = $[2 \times ((\text{Line Clock}) \times (\text{ACB}))]$ |
| 7-0  | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                     |

#### 24.3.11.1 AC-Bias Pin Frequency (ACB)

**NOTE:** The 8-bit ac-bias frequency (ACB) field has no effect in active mode. This is due to the fact that the pixel clock transitions continuously in active mode ; the ac-bias line is used as an output enable signal. The ac-bias is asserted by the LCD controller in active mode; this occurs whenever pixel data is driven out to the data pins to signal to the display when it can latch pixels using the pixel clock.

The 8-bit ac-bias frequency (ACB) field is used to specify the number of line clock periods to count between each toggle of the ac-bias pin. After the LCD controller is enabled, the value in ACB is loaded to an 8-bit down counter, and the counter begins to decrement using the line clock. When the counter reaches zero it stops, the state of ac-bias pin is reversed, and the whole procedure starts again. The number of line clocks between each ac-bias pin transition ranges from 1–256 (program to value required minus 1). This line is used by the LCD display to periodically reverse the polarity of the power supplied to the screen to eliminate DC offset.

#### 24.3.11.2 AC-Bias Line Transitions Per Interrupt (ACB\_I)

The 4-bit ac-bias line transitions per interrupt (ACB\_I) field is used to specify the number of line transitions to count before setting the ac-bias count status (ABC) bit in the LCD controller status register that signals an interrupt request. After the LCD controller is enabled, the value in ACB\_I is loaded to a 4-bit down counter, and the counter decrements each time the ac-bias line state is inverted. When the counter reaches zero it stops, the ac-bias count (ABC) bit is set in the status register. Once ABC is set, the 4-bit down counter is reloaded with the value in ACB\_I and is disabled until ABC is cleared. Once ABC is cleared by the CPU, the down counter is enabled, and again decrements each time the ac-bias line is flipped. The number of ac-bias line transitions between each interrupt request ranges from 0 to 15. Programming ACB\_I = 0000 disables the ac-bias line transitions per interrupt function.

#### 24.3.11.3 Invert VSYNC (IVS)

The invert VSYNC(IVS) bit is used to invert the polarity of the frame clock (VSYNC).

- When IVS = 1, the frame clock (VSYNC) is active low.
- When IVS = 0, it is active high.

#### 24.3.11.4 Invert HSYNC (IHS)

The invert HSYNC(IHS) bit is used to invert the polarity of the line clock (HSYNC).

- When IHS = 1, the line clock (HSYNC) is active low.
- When IHS = 0, it is active high.

#### 24.3.11.5 Invert Pixel Clock (IPC)

The invert pixel clock (IPC) bit is used to select the edge of the pixel clock that drives pixel data out onto the LCD data lines.

- When IPC = 1, data is driven onto the LCD data lines on the falling edge of the pixel clock.
- When IPC = 0, data is driven onto the LCD data lines on the rising edge of the pixel clock.

### 24.3.11.6 Invert Output Enable (BIAS)

**NOTE:** BIAS does not affect the ac-bias pin in passive display mode.

The invert output enable (BIAS) bit is used to select the active or inactive state of the output enable signal in active display mode. In this mode, the ac-bias pin is used as an enable that signals the device when data is actively being driven out using the pixel clock.

- When BIAS = 1, the ac-bias pin is active low. In active display mode, data is driven onto the LCD data lines on the programmed edge of the pixel clock when ac-bias pin is in its active state.
- When BIAS = 0, the ac-bias pin is active high.

### 24.3.11.7 Horizontal and Vertical Sync Edge (SYNC\_EDGE)

This bit determines whether the HSYNC/VSNC is driven on the rising or falling edge of the pixel clock (see the SYNC\_CTRL bit; SYNC\_CTRL must be turned on first). By default, the LCD\_HSYNC and LCD\_VSYNC signals are driven on the falling edge of the pixel clock, and the pixel data is driven on the rising edge of pixel clock. However, if the invert pixel clock (IPC) bit is set to 1, then the LCD\_HSYNC and LCD\_VSYNC signals are driven on rising edge of pixel clock and pixel data is driven on falling edge. By setting the SYNC\_EDGE bit and enabling it (SYNC\_CTRL = 1), you can control on which edge the signals are driven.

In [Figure 24-36](#):

- IPC = 1, pixel data is driven onto the LCD data lines on the falling edge of the pixel clock.
- SYNC\_CTRL = 0, LCD\_HSYNC and LCD\_VSYNC signals are driven on opposite edges of the pixel clock from pixel data ( $\Rightarrow$  rising edge). The rising edge or falling edge is determined by the IPC bit.

**Figure 24-36. SYNC\_CTRL = 0, IPC = 1 in TFT Mode**

In [Figure 24-37](#):

- IPC = 1, pixel data is driven on the falling edge of the pixel clock.
- SYNC\_CTRL = 1, LCD\_HSYNC and LCD\_VSYNC signals are driven according to the SYNC\_EDGE bit.
- SYNC\_EDGE = 0, LCD\_HSYNC and LCD\_VSYNC signals are driven on the falling edge of the pixel clock.

**Figure 24-37. SYNC\_CTRL = 1, SYNC\_EDGE = 0, and IPC = 1**

#### 24.3.11.8 Horizontal and Vertical Sync Control (SYNC\_CTRL)

This bit enables/disables the possibility to make HSYNC and VSYNC programmable.

- When SYNC\_CTRL = 1, HSYNC and VSYNC are driven according to the SYNC\_EDGE bit.
- When SYNC\_CTRL = 0, HSYNC and VSYNC are driven on opposite edges of the pixel clock from pixel data.

### 24.3.12 LCD Raster Subpanel Display Register (RASTER\_SUBPANEL)

LCD raster subpanel display register (RASTER\_SUBPANEL) displays only the first or last  $n$  lines of the panel and sends a fixed content for the others is supported with the LCD raster subpanel display register. For these others, there is no access to the frame buffer because the value stored in Default Pixel Data will be used. The RASTER\_SUBPANEL is shown in [Figure 24-38](#) and described in [Table 24-23](#).

If LPPT is greater than the number of lines per panel then:

- If HOLS = 1: normal panel
- If HOLS = 0: panel with default data

LPPT has a minimum value = 2. DPD, LPPT, HOLS, and SPEN bit fields and bits are not considered if SPEN = 0.

**Figure 24-38. LCD Raster Subpanel Display Register (RASTER\_SUBPANEL)**

|       |      |       |          |    |          |    |

| 29    | HOLS     | 0<br>1 | High or Low Signal. The field indicates the position of subpanel compared to the LPPT value.<br>Low, below<br>High, above                            |
| 28-26 | Reserved | 0      | Reserved                                                                                                                                             |
| 25-16 | LPPT     | 0-3FFh | Line Per Panel Threshold. This field defines the number of lines to be refreshed (1 to 1024).                                                        |
| 15-4  | DPD      | 0-FFFh | Default Pixel Data. DPD defines the default value of the pixel data sent to the panel for the lines until LPPT is reached or after passing the LPPT. |
| 3-0   | Reserved | 0      | Reserved                                                                                                                                             |

#### 24.3.12.1 Default Pixel Data (DPD)

The default pixel data (DPD) defines a default value, which is sent to the display in either the top or bottom region of the screen delimited by the LPPT threshold.

#### 24.3.12.2 Line-per-Panel Threshold (LPPT)

The line-per-panel threshold bit-field delimits the screen portion filled with data fetched from the frame buffer (the subpanel) and the rest of the screen filled with default pixel data (DPD). Note that the LPPT line number points on a line filled with a DPD value when HOLS = 1, but on one filled with video data when HOLS = 0 (see [Figure 24-39](#) and [Figure 24-40](#)).

### 24.3.12.3 High Or Low Signal (HOLS)

The HOLs bit indicates the position of the subpanel compared to the LPPT value. When HOLs = 1, the image from system memory is displayed above the threshold value. The threshold value is the line number where the DPD value begins to be displayed. The rest of the screen is filled with DPD value.

**Figure 24-39. Subpanel Display: SPEN = 1, HOLs = 1**

When HOLs = 0, the beginning of the screen is filled with DPD value until the LPPT excluded. From the LPPT line number, the rest of the screen (below LPPT) displays the image from system memory.

**Figure 24-40. Subpanel Display: SPEN = 1, HOLs = 0**

The bottom of the panel is line 0, and top line of the panel is Line N (where N is the number of lines-per-panel). For example, if you want to display four lines of video data at the bottom of the panel, the correct settings are HOLs = 0 and LPPT = 3. Here, the amount of video data to be transferred from the DMA\_LCD channel is only four lines.

If the LPPT is above the number of LPP, then:

- When HOLs = 1: panel with default data (whole panel is filled with DPD value).
- When HOLs = 0: normal panel (whole panel is filled with video data from the frame buffer).

### 24.3.13 LCD DMA Control Register (LCDDMA\_CTRL)

The LCD DMA control register (LCDDMA\_CTRL) contains bits that control the LCD channel operation. The LCDDMA\_CTRL is shown in [Figure 24-41](#) and described in [Table 24-24](#).

**Figure 24-41. LCD DMA Control Register (LCDDMA\_CTRL)**

|     |          |       |  |   |            |  |  |     |   |          |       |       |               |       |   |    |   |

## ***Multichannel Audio Serial Port (McASP)***

---

---

This chapter describes the multichannel audio serial port (McASP). See your device-specific data manual to determine how many McASPs are available on your device.

| Topic                       | Page        |
|-----------------------------|-------------|
| <b>25.1 Registers .....</b> | <b>1151</b> |

## Introduction

### Purpose of the Peripheral

The multichannel audio serial port (McASP) functions as a general-purpose audio serial port optimized for the needs of multichannel audio applications. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols, and intercomponent digital audio interface transmission (DIT).

The McASP consists of transmit and receive sections that may operate synchronized, or completely independently with separate master clocks, bit clocks, and frame syncs, and using different transmit modes with different bit-stream formats. The McASP module also includes up to 16 serializers that can be individually enabled to either transmit or receive. In addition, all of the McASP pins can be configured as general-purpose input/output (GPIO) pins.

### 25.0.16 Features

Features of the McASP include:

- Two independent clock generator modules for transmit and receive
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator
  - TDM streams from 2 to 32, and 384 time slots
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits
  - Data formatter for bit manipulation
- Up to 16 individually assignable serial data pins:
  - McASP0 can have up to 16 serial data pins
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components
- Wide variety of Inter-IC Sound (I2S) and similar bit-stream formats
- 384-slot TDM with external digital audio interface receiver (DIR) device
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Extensive error checking and recovery:
  - Transmit underruns and receiver overruns due to the system not meeting real-time requirements
  - Early or late frame sync in TDM mode
  - Out-of-range high-frequency master clock for both transmit and receive
  - External error signal coming into the AMUTEIN input
  - DMA error due to incorrect programming
- McASP Audio FIFO (AFIFO):
  - Provides additional data buffering
  - Provides added tolerance to variations in host/DMA controller response times
  - May be used as a DMA event pacer
  - Independent Read FIFO and Write FIFO
  - 256 bytes of RAM for each FIFO (read and write)
    - 256 bytes = four 32-bit words per serializer in the case of 16 data pins
    - 256 bytes = 64 32-bit words in the case of one data pin
  - Option to bypass Write FIFO and/or Read FIFO independently

### **25.0.17 Protocols Supported**

The McASP supports a wide variety of protocols.

- Transmit section supports
  - Wide variety of I2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots
  - S/PDIF, IEC60958-1, AES-3 formats
- Receive section supports
  - Wide variety of I2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe)

The transmit and receive sections may each be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0, 1, 2 bit clocks
- Left/right alignment of word inside slot
- Bit order: MSB first or LSB first
- Bit mask/pad/rotate function
  - Automatically aligns data for DSP internally in either Q31 or integer formats
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

## 25.0.18 Functional Block Diagram

A block diagram of the McASP is shown in Figure 25-1. The McASP has independent receive/transmit clock generators and frame sync generators.

Figure 25-1. McASP Block Diagram

- A McASP0 has up to 16 serial data pins,  $n = 15$
- B One of the DSP's external pins, see your device-specific data manual.

### 25.0.18.1 System Level Connections

Figure 25-2 through Figure 25-5 show examples of McASP usage in digital audio encoder/decoder systems.

**Figure 25-2. McASP to Parallel 2-Channel DACs**

## Industry Standard Compliance Statement

The McASP supports the following industry standard interfaces.

### 25.0.18.1 TDM Format

The McASP transmitter and receiver support the multichannel, synchronous time-division-multiplexed (TDM) format via the TDM transfer mode. Within this transfer mode, a wide variety of serial data formats are supported, including formats compatible with devices using the Inter-IC Sound (I2S) protocol. This section briefly discusses the TDM format and the I2S protocol.

#### 25.0.18.1.1 TDM Format

The TDM format is typically used when communicating between integrated circuit devices on the same printed circuit board or on another printed circuit board within the same piece of equipment. For example, the TDM format is used to transfer data between the DSP and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices.

The TDM format consists of three components in a basic synchronous serial transfer: the clock, the data, and the frame sync. In a TDM transfer, all data bits (AXR[n]) are synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (as defined in [Section 25.0.19](#)). The "slots" are also commonly referred to as "time slots" or "channels" in TDM terminology. A frame consists of multiple slots (or channels). Each TDM frame is defined by the frame sync signal (AFSX or AFSR). Data transfer is continuous and periodic, since the TDM format is most commonly used to communicate with data converters that operate at a fixed sample rate.

There are no delays between slots. The last bit of slot N is followed immediately on the next serial clock cycle with the first bit of slot N + 1, and the last bit of the last slot is followed immediately on the next serial clock cycle with the first bit of the first slot. However, the frame sync may be offset from the first bit of the first slot with a 0, 1, or 2-cycle delay.

It is required that the transmitter and receiver in the system agree on the number of bits per slot, since the determination of a slot boundary is not made by the frame sync signal (although the frame sync marks the beginning of slot 0 and the beginning of a new frame).

[Figure 25-6](#) shows the TDM format. [Figure 25-7](#) shows the different bit delays from the frame sync.

**Figure 25-6. TDM Format–6 Channel TDM Example**

A FS duration of slot is shown. FS duration of single bit is also supported.

**Figure 25-7. TDM Format Bit Delays from Frame Sync**

In a typical audio system, one frame of data is transferred during each data converter sample period  $f_s$ . To support multiple channels, the choices are to either include more time slots per frame (thus operating with a higher bit clock rate), or to use additional data pins to transfer the same number of channels (thus operating with a slower bit clock rate).

For example, a particular six channel DAC may be designed to transfer over a single serial data pin AXR[n] as shown in Figure 25-6. In this case the serial clock must run fast enough to transfer a total of 6 channels within each frame period. Alternatively, a similar six channel DAC may be designed to use three serial data pins AXR[0,1,2], transferring two channels of data on each pin during each sample period (Figure 25-8). In the latter case, if the sample period remains the same, the serial clock can run three times slower than the former case. The McASP is flexible enough to support either type of DAC.

#### 25.0.18.1.2 Inter-IC Sound (I2S) Format

The Inter-IC Sound (I2S) format is used extensively in audio interfaces. The TDM transfer mode of the McASP supports the I2S format when configured to 2 slots per frame.

I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXR[n]. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format is the same as the slot size. The frame signal is also referred to as "word select" in the I2S format. Figure 25-8 shows the I2S protocol.

The McASP supports transfer of multiple stereo channels over multiple AXR[n] pins.

**Figure 25-8. Inter-IC Sound (I2S) Format**

## 25.0.18.2 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphasemark encoded output. The S/PDIF format is supported by the digital audio interface transmit (DIT) transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

### 25.0.18.2.1 Biphasemark Code (BMC)

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). The clock, frame, and data are embedded in only one signal—the data pin AXR[n]. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals to the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 25-9 and Table 25-1 show how data is encoded to the BMC format.

As shown in Figure 25-9, the frequency of the clock is twice the unencoded data bit rate. In addition, the clock is always programmed to  $128 \times f_s$ , where  $f_s$  is the sample rate (see Section 25.0.18.2.3 for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

**Table 25-1. Biphasemark Encoder**

| Data (Unencoded) | Previous State at Pin AXR[n] | BMC-Encoded Cell Output at AXR[n] |
|------------------|------------------------------|-----------------------------------|
| 0                | 0                            | 11                                |
| 0                | 1                            | 00                                |
| 1                | 0                            | 10                                |
| 1                | 1                            | 01                                |

### 25.0.18.2.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered from 0 to 31. [Figure 25-10](#) shows a subframe.

- **Time intervals 0-3** carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is *not* encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See [Table 25-2](#).
- **Time intervals 4-27** carry the audio sample word in linear 2s-complement representation. The most-significant bit (MSB) is carried by time interval 27. When a 24-bit coding range is used, the least-significant bit (LSB) is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4-7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (either 20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field may carry any other information.
- **Time interval 28** carries the validity bit (V) associated with the main data field in the subframe.
- **Time interval 29** carries the user data channel (U) associated with the main data field in the subframe.
- **Time interval 30** carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- **Time interval 31** carries a parity bit (P) such that time intervals 4-31 carry an even number of 1s and an even number of 0s (even parity). As shown in [Table 25-2](#), the preambles (time intervals 0-3) are also defined with even parity.

**Figure 25-10. S/PDIF Subframe Format**

**Table 25-2. Preamble Codes**

| Preamble Code <sup>(1)</sup> | Previous Logical State | Logical States on pin AXR[n] <sup>(2)</sup> | Description                     |
|------------------------------|------------------------|---------------------------------------------|---------------------------------|
| B (or Z)                     | 0                      | 1110 1000                                   | Start of a block and subframe 1 |
| M (or X)                     | 0                      | 1110 0010                                   | Subframe 1                      |
| W (or Y)                     | 0                      | 1110 0100                                   | Subframe 2                      |

<sup>(1)</sup> Historically, preamble codes are referred to as B, M, W. For use in professional applications, preambles are referred to as Z, X, Y, respectively.

<sup>(2)</sup> The preamble is not BMC encoded. Each logical state is synchronized to the serial clock. These 8 logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

As shown in [Table 25-2](#), the McASP DIT only generates one polarity of preambles and it assumes the previous logical state to be 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXR[n] pin before continuing with the next transmission.

### 25.0.18.2.3 Frame Format

An S/PDIF frame is composed of two subframes (Figure 25-11). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency  $f_s$ . The S/PDIF format clock rate is therefore  $128 \times f_s$  ( $128 = 32 \text{ cells/subframe} \times 2 \text{ clocks/cell} \times 2 \text{ subframes/sample}$ ). For example, for an S/PDIF stream at a 192 kHz sampling frequency, the serial clock is  $128 \times 192 \text{ kHz} = 24.58 \text{ MHz}$ .

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (**left** or **A** channel in stereophonic operation and **primary** channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (**right** or **B** channel in stereophonic operation and **secondary** channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, time slot 28 (validity bit) is set to logical 1.

**Figure 25-11. S/PDIF Frame Format**

## 25.0.19 Definition of Terms

The serial bit stream transmitted or received by the McASP is a long sequence of 1s and 0s, either output or input on one of the audio transmit/receive pins (AXR[n]). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 25-12](#) shows two of the three basic components—the clock (ACLK) and the data (AXR[n]).

[Figure 25-12](#) does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses ACLKX as the serial clock, and the receiver uses ACLKR as the serial clock. Optionally, the receiver can use ACLKX as the serial clock when the transmitter and receiver of the McASP are configured to operate synchronously.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Bit</b>  | A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the AXR[n] pin for the entire duration of the bit. A 0 is represented by a logic low on the AXR[n] pin for the entire duration of the bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Word</b> | A word is a group of bits that make up the data being transferred between the DSP and the external device. <a href="#">Figure 25-12</a> shows an 8-bit word.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Slot</b> | A slot consists of the bits that make up the word, and may consist of additional bits used to pad the word to a convenient number of bits for the interface between the DSP and the external device. In <a href="#">Figure 25-12</a> , the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with 4 zeros (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits may be shifted in/out of the McASP on the AXR[n] pin either MSB or LSB first. When the word size is smaller than the slot size, the word may be aligned to the left (beginning) of the slot or to the right (end) of the slot. The additional bits in the slot not belonging to the word may be padded with 0, 1, or with one of the bits (the MSB or the LSB typically) from the data word. These options are shown in <a href="#">Figure 25-13</a> . |

**Figure 25-12. Definition of Bit, Word, and Slot**

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the four pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left aligned.

**Figure 25-13. Bit Order and Word Alignment Within a Slot Examples**

- (a) 87h as 8-bit word, 12-bit slot, left align, MSB first, pad zeros
- (b) 87h as 8-bit word, 12-bit slot, right align, MSB first, pad zeros
- (c) 87h as 8-bit word, 12-bit slot, left align, LSB first, pad zeros
- (d) 87h as 8-bit word, 12-bit slot, right align, LSB first, pad zeros
- (e) 87h as 8-bit word, 12-bit slot, left align, MSB first, pad with bit 7
- (f) 87h as 8-bit word, 12-bit slot, right align, MSB first, pad with bit 4
- (g) 87h as 8-bit word, 12-bit slot, left align, LSB first, pad with bit 7
- (h) 87h as 8-bit word, 12-bit slot, right align, LSB first, pad with bit 4
- (i) 07h as 8-bit word, 12-bit slot, left align, LSB first, pad with bit 7
- (j) 86h as 8-bit word, 12-bit slot, right align, LSB first, pad with bit 4

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter.

**Frame** A frame contains one or multiple slots, as determined by the desired protocol. [Figure 25-14](#) shows an example frame of data and the frame definitions. [Figure 25-14](#) does not specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses AFSX and the receiver uses AFSR. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously.

This section only shows the generic definition of the frame sync. See [Section 25.0.18.1](#), [Section 25.0.18.2](#), and [Section 25.0.21.2.1](#) for details on the frame sync formats required for the different transfer modes and protocols (burst mode, TDM mode and I2S format, DIT mode and S/PDIF format).

**Figure 25-14. Definition of Frame and Frame Sync Width**

(1) In this example, there are two slots in a frame, and FS duration of slot length is shown.

Other terms used throughout this chapter:

**TDM** Time-division multiplexed. See [Section 25.0.18.1](#) for details on the TDM protocol.

**DIR** Digital audio interface receive. The McASP does not natively support receiving in the S/PDIF format. The McASP supports I2S format output by an external DIR device.

**DIT** Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on up to all data pins configured as outputs.

**I2S** Inter-IC Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).

**Slot or Time Slot** For TDM format, the term time slot is interchangeable with the term slot defined in this section. For DIT format, a McASP time slot corresponds to a DIT subframe.

## Architecture

### 25.0.20 Overview

Figure 25-1 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators, error-checking logic, and up to 16 serial data pins. See your device-specific data manual for the number of data pins available on your device.

All the McASP pins on the device may be individually programmed as general-purpose I/O (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializers
  - Data pins AXR[n]: Up to sixteen per McASP
- Transmit clock generator:
  - AHCLKX: McASP transmit high-frequency master clock
  - ACLKX: McASP transmit bit clock
- Transmit Frame Sync Generator
  - AFSX: McASP transmit frame sync or left/right clock (LRCLK)
- Receive clock generator:
  - AHCLKR: McASP receive high-frequency master clock
  - ACLKR: McASP receive bit clock
- Receive Frame Sync Generator
  - AFSR: McASP receive frame sync or left/right clock (LRCLK)
- Mute in/out:
  - AMUTEIN: McASP mute input (from external device)
  - AMUTE: McASP mute output
  - Data pins AXR[n]

### 25.0.21 Clock and Frame Sync Generators

The McASP clock generators are able to produce two independent clock zones: transmit and receive clock zones. The serial clock generators may be programmed independently for the transmit section and the receive section, and may be completely asynchronous to each other. The serial clock (clock at the bit rate) may be sourced:

- **Internally** - by passing through two clock dividers off the internal clock source (AUXCLK)
- **Externally** - directly from ACLKR/X pin
- **Mixed** - an external high-frequency clock is input to the McASP on either the AHCLKX or AHCLKR pins, and divided down to produce the bit rate clock

In the internal/mixed cases, the bit rate clock is generated internally and should be driven out on the ACLKX (for transmit) or ACLKR (for receive) pins. In the internal case, an internally-generated high-frequency clock may be driven out onto the AHCLKX or AHCLKR pins to serve as a reference clock for other components in the system.

The McASP requires a minimum of a bit clock and a frame sync to operate, and provides the capability to reference these clocks from an external high-frequency master clock. In DIT mode, it is possible to use only internally-generated clocks and frame syncs.

### 25.0.21.1 Transmit Clock

The transmit bit clock, ACLKX, (Figure 25-15) may be either externally sourced from the ACLKX pin or internally generated, as selected by the CLKXM bit. If internally generated (CLKXM = 1), the clock is divided down by a programmable bit clock divider (CLKXDIV) from the transmit high-frequency master clock (AHCLKX).

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock, XCLK, (Figure 25-15). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If CLKXP = 0, the CLKXP mux directly passes ACLKX to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

The transmit high-frequency master clock, AHCLKX, may be either externally sourced from the AHCLKX pin or internally generated, as selected by the HCLKXM bit. If internally generated (HCLKXM = 1), the clock is divided down by a programmable high clock divider (HCLKXDIV) from McASP internal clock source AUXCLK. The transmit high-frequency master clock may be (but is not required to be) output on the AHCLKX pin where it is available to other devices in the system.

The transmit clock configuration is controlled by the following registers:

- ACLKXCTL
- AHCLKXCTL

**Figure 25-15. Transmit Clock Generator Block Diagram**

## 25.0.21.2 Receive Clock

The receiver has a clock generation circuit identical to (but independent of) that of the transmitter. The receive bit clock, ACLKR, (Figure 25-16) may be either externally sourced from the ACLKR pin or internally generated, as selected by the CLKRM bit. If internally generated (CLKRM = 1), the clock is divided down by a programmable divider (CLKRDIV) from the receive high-frequency master clock (AHCLKR). Regardless if ACLKR is either internally generated or externally sourced, polarity of the clock may be programmed (CLKRP) to be either rising or falling edge.

The receive high-frequency master clock, AHCLKR, may be either externally sourced from the AHCLKR pin or internally generated, as selected by the HCLKRM bit. If internally generated (HCLKRM = 1), the clock is divided down by a programmable divider (HCLKRDIV) from AUXCLK. The receive high-frequency master clock may be (but is not required to be) output on the AHCLKR pin where it is available to other devices in the system. Regardless if AHCLKR is either internally generated or externally sourced, polarity of the high-frequency clock may be programmed (HCLKRP) to be either rising or falling edge.

The receiver also has the option to operate synchronously from the ACLKX and AFSX signals. This is achieved when the ASYNC bit in the transmit clock control register (ACLKXCTL) is cleared to 0. See Section 25.0.21.1.5 for details on McASP operation when ACLKXCTL.ASYNC = 0.

The receive clock configuration is controlled by the following registers:

- ACLKRCTL
- AHCLKRCTL

Figure 25-16. Receive Clock Generator Block Diagram

### 25.0.21.3 Frame Sync Generator

There are two different modes for frame sync: burst and TDM. A block diagram of the frame sync generator is shown in Figure 25-17. The frame sync options are programmed by the receive and transmit frame sync control registers (AFSRCTL and AFSXCTL). The options are:

- Internally-generated or externally-generated
- Frame sync polarity: rising edge or falling edge
- Frame sync width: single bit or single word
- Bit delay: 0, 1, or 2 cycles before the first data bit

The transmit frame sync pin is AFSX and the receive frame sync pin is AFSR. A typical usage for these pins is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

Regardless if the AFSX/AFSR is internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

**Figure 25-17. Frame Sync Generator Block Diagram**

#### 25.0.21.4 Clocking Examples

Some examples of processes using the McASP clocking and frame flexibility are:

- Receive data from a DVD at 48 kHz, but output up-sampled or decoded audio at 96 kHz or 192 kHz. This could be accomplished by inputting a high-frequency master clock (for example,  $512 \times$  receive FS), receiving with an internally-generated bit clock ratio of divide-by-8, and transmitting with an internally-generated bit clock ratio of divide-by-4 or divide-by-2.
- Transmit/receive data based on one sample rate (for example, 44.1 kHz), and transmit/receive data at a different sample rate (for example, 48 kHz).

### General Architecture

#### 25.0.21.1 Serializers

The serializers take care of shifting serial data in and out of the McASP. Each serializer consists of a shift register (XRSR), a data buffer (XRBUF), a control register (SRCTL), and logic to support the data alignment options of the McASP. For each serializer, there is a dedicated serial data pin (AXR[n]) and a dedicated control register (SRCTL[n]). The control register allows the serializer to be configured as a transmitter, receiver, or as inactive. When configured as a transmitter the serializer shifts out data to the serial data pin AXR[n]. When configured as a receiver, the serializer shifts in data from the AXR[n] pin. The serializer is clocked from the transmit/receive section clock (ACLKX/ACLKR) if configured to transmit/receive respectively.

All serializers that are configured to transmit operate in lock-step. Similarly, all serializers that are configured to receive also operate in lock-step. This means that at most there are two zones per McASP, one for transmit and one for receive.

Figure 25-18 shows the block diagram of the serializer and its interface to other units within the McASP.

**Figure 25-18. Individual Serializer and Connections Within McASP**

For receive, data is shifted in through the AXR[n] pin to the shift register XRSR. Once the entire slot of data is collected in the XRSR, the data is copied to the data buffer XRBUF. The data is now ready to be read by the DSP through the RBUF register, which is an alias of the XRBUF for receive. When the DSP reads from the RBUF, the McASP passes the data from RBUF through the receive format unit and returns the formatted data to the DSP.

For transmit, the DSP services the McASP by writing data into the XBUF register, which is an alias of the XRBUF for transmit. The data automatically passes through the transmit format unit before actually reaching the XRBUF in the serializer. The data is then copied from XRBUF to XRSR, and shifted out from the AXR[n] synchronously to the serial clock.

In DIT mode, in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.).

The serializer configuration is controlled by SRCTL[n].

### 25.0.21.2 Format Unit

The McASP has two data formatting units, one for transmit and one for receive. These units automatically remap the data bits within the transmitted and received words between a natural format for the DSP (such as a Q31 representation) and the required format for the external serial device (such as "I2S format"). During the remapping process, the format unit also can mask off certain bits or perform sign extension.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP will not transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers. However, the McASP can transmit in one format while receiving in a completely different format.

This formatting unit consists of three stages:

- Bit mask and pad (masks off bits, performs sign extension)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 25-19 shows a block diagram of the receive formatting unit, and Figure 25-20 shows the transmit formatting unit. Note that the order in which data flows through the three stages is different between the transmit and receive formatting units.

**Figure 25-20. Transmit Format Unit**

The bit mask and pad stage includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits.

The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the (R/X)FMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation.

The bit reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order.

Finally, note that the (R/X)DATDLY bits in (R/X)FMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, (R/X)DATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay.

The combination of all the options in (R/X)FMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the internal DSP representation.

[Section 25.0.21.4](#) provides more detail and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

### 25.0.21.3 State Machine

The receive and transmit sections have independent state machines. Each state machine controls the interactions between the various units in the respective section. In addition, the state machine keeps track of error conditions and serial port status.

No serial transfers can occur until the respective state machine is released from reset. See initialization sequence for details ([Section 25.0.21.1](#)).

The receive state machine is controlled by the RFMT register, and it reports the McASP status and error conditions in the RSTAT register. Similarly, the transmit state machine is controlled by the XFMT register, and it reports the McASP status and error conditions in the XSTAT register.

#### 25.0.21.4 TDM Sequencer

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of (R/X)TDM and determines if the McASP should receive/transmit in that time slot.

If the McASP should participate (transmit/receive bit is active) in the time slot, the McASP functions normally. If the McASP should not participate (transmit/receive bit is inactive) in the time slot, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot. In addition, the serializers programmed as transmitters place their data output pins in a predetermined state (logic low, high, or high impedance) as programmed by each serializer control register (SRCTL). Refer also to [Section 25.0.21.2.2](#) for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

The receive TDM sequencer is controlled by register RTDM and reports current receive slot to RSLOT. The transmit TDM sequencer is controlled by register XTDM and reports current transmit slot to XSLOT.

#### 25.0.21.5 Clock Check Circuit

A common source of error in audio systems is a serial clock failure due to instabilities in the off-chip DIR circuit. To detect a clock error quickly, a clock-check circuit is included in the McASP for both transmit and receive clocks, since both may be sourced from off chip.

The clock check circuit can detect and recover from transmit and receive clock failures. See [Section 25.0.21.6.6](#) for implementation and programming details.

#### 25.0.21.6 Pin Function Control

All McASP pins except AMUTEIN are bidirectional input/output pins. In addition, these bidirectional pins function either as McASP or general-purpose I/O (GPIO) pins. The following registers control the pin functions:

- Pin function register (PFUNC): selects pin to function as McASP or GPIO
- Pin direction register (PDIR): selects pin to be input or output
- Pin data input register (PDIN): shows data input at the pin
- Pin data output register (PDOUT): data to be output at the pin if the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1). Not applicable when the pin is configured as McASP pin (PFUNC[n] = 0).
- Pin data set register (PDSET): alias of PDOUT. Writing a 1 to PDSET[n] sets the respective PDOUT[n] to 1. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).
- Pin data clear register (PDCLR): alias of PDOUT. Writing a 1 to PDCLR[n] clears the respective PDOUT[n] to 0. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).

See the register descriptions in [Section 25.1](#) for details on the mapping of each McASP pin to the register bits. [Figure 25-21](#) shows the pin control block diagram.

##### 25.0.21.6.1 McASP Pin Control-Transmit and Receive

You must correctly set the McASP GPIO registers PFUNC and PDIR, even when McASP pins are used for their serial port (non-GPIO) function.

Serial port functions include:

- Clock pins (ACLKX, ACLKR, AHCLKX, AHCLKR, AFSX, AFSR) used as clock inputs and outputs
- Serializer data pins (AXR[n]) used to transmit or receive
- AMUTE used as a mute output signal

When using these pins in their serial port function, you must clear PFUNC[n] to 0 for each pin, as opposed to PFUNC[n] = 1, which makes the pin a GPIO.

Also, certain outputs require  $\text{PDIR}[n] = 1$ , such as clock pins used as clock outputs, serializer data pins used to transmit, and AMUTE used as mute output.

Clock inputs and serializers configured to receive must have  $\text{PDIR}[n] = 0$ .

PFUNC and PDIR do not control the AMUTEIN device pin, it is usually tied to a device pin (see your device-specific data manual). If used as a mute input, this pin needs to be configured as an input in the appropriate peripheral.

Finally, there is an important advantage to having separate control of pin direction (by PDIR), and the choice of internal versus external clocking (by CLKRM/CLKXM). Depending on the specific device and usage, you might select an external clock ( $\text{CLKRM} = 0$ ), while enabling the internal clock divider, and the clock pin as an output in the PDIR register ( $\text{PDIR}[\text{ACLKR}] = 1$ ). In this case, the bit clock is an output ( $\text{PDIR}[\text{ACLKR}] = 1$ ) and, therefore, routed to the ACLKR pin. However, because  $\text{CLKRM} = 0$ , the bit clock is then routed back to the McASP module as an "external" clock source. This may result in less skew between the clock inside the McASP and the clock in the external device, thus producing more balanced setup and hold times for a particular system. As a result, this may allow a higher serial clock rate interface.

#### 25.0.21.6.2 GPIO Pin Control

For GPIO operation, you must set the desired  $\text{PFUNC}[n]$  to 1 to indicate GPIO function.  $\text{PDIR}[n]$  must be configured to the desired direction. PDOUT, PDSET, PDCLR control the output value on the pin. PDIN always reflects the state at the pin, regardless of the PDIR and PFUNC setting.

Figure 25-21 and Figure 25-22 display the pin descriptions. The examples that follow (Example 25-1 through Example 25-4) show how the pins can be used as general-purpose input or output pins.

**Figure 25-21. McASP I/O Pin Control Block Diagram**

**Figure 25-22. McASP I/O Pin to Control Register Mapping**

|          |        |       |       |        |       |       |          |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Example 25-1. General-Purpose Input Pin

Because the PDIN register always reflects the state at the pin, you can read the PDIN register to obtain the pin input state. To explicitly set the pin as a general-purpose input pin, you can set the registers as follows:

- PDIR[n] = 0 (input)
- PFUNC[n] = 1 (GPIO function)

### Example 25-2. General-Purpose Output Pin—Initialization Using PDOUT

All pins default as inputs. To initialize a pin as output, you should follow this sequence:

1. PDIR[n] = 0 (default as input)
2. PFUNC[n] = 1 (GPIO function)
3. PDOUT[n] = desired output value
4. PDIR[n] = 1 (change to output after desired value is configured in PDOUT[n])

### Example 25-3. General-Purpose Output Pin—Change Data from 0 to 1 Using PDSET

If the pin is already configured as a general-purpose output pin driving a 0, and you want to change the output from 0 to 1, the recommended method is to use the PDSET register instead of the PDOUT register. This is because writing to the PDSET register only affects pin(s) in concern. To change a pin from 0 to 1:

- Set PDSET[n]. This sets the respective PDOUT[n].

### Example 25-4. General-Purpose Output Pin—Change Data from 1 to 0 Using PDCLR

If the pin is already configured as a general-purpose output pin driving a 1, and you want to change the output from 1 to 0, the recommended method is to use the PDCLR register instead of the PDOUT register. This is because writing to the PDCLR register only affects pin(s) in concern. To change a pin from 1 to 0:

- Set PDCLR[n]. This clears the respective PDOUT[n].

## McASP Audio FIFO (AFIFO)

The McASP Audio FIFO (AFIFO) provides additional data buffering for the McASP. The time it takes the host CPU or DMA controller to respond to DMA requests from the McASP may vary; the additional buffering provided by the AFIFO allows greater tolerance to such variations.

For convenience, the AFIFO is treated here as a block between McASP and the host/DMA controller (see [Figure 25-1](#)). Details on configuration of the AFIFO are provided in [McASP Audio FIFO \(AFIFO\)](#).

## Operation

This section discusses the operation of the McASP.

### 25.0.21.1 Setup and Initialization

This section discusses steps necessary to use the McASP module.

#### 25.0.21.1.1 Considerations When Using a McASP

The following is a list of things to be considered for systems using a McASP:

##### 25.0.21.1.1.1 Clocks

For each receive and transmit section:

- External or internal generated bit clock and high frequency clock?
- If internally generated, what is the bit clock speed and the high frequency clock speed?
- Clock polarity?
- External or internal generated frame sync?
- If internally generated, what is frame sync speed?
- Frame sync polarity?
- Frame sync width?
- Transmit and receive sync or asynchronous?

##### 25.0.21.1.1.2 Data Pins

For each pin of each McASP:

- McASP or GPIO?
- Input or output?

##### 25.0.21.1.1.3 Data Format

For each transmit and receive data:

- Internal numeric representation (integer, Q31 fraction)?
- I2S or DIT (transmit only)?
- Time slot delay (0, 1, or 2 bit)?
- Alignment (left or right)?
- Order (MSB first, LSB first)?
- Pad (if yes, pad with what value)?
- Slot size?
- Rotate?
- Mask?

#### 25.0.21.1.1.4 Data Transfers

- Internal: DMA or CPU?
- External: TDM or burst?
- Bus: peripheral configuration bus or DMA bus?

#### 25.0.21.1.2 Transmit/Receive Section Initialization

You must follow the following steps to properly configure the McASP. If external clocks are used, they should be present prior to the following initialization steps.

1. Reset McASP to default values by setting GBLCTL = 0.
2. Configure McASP Audio FIFO. Recall that the Write FIFO and Read FIFO are enabled/disabled independently.
  - (a) Write FIFO:
    - If the Write FIFO will not be enabled, verify that WFIFOCTL.WENA is cleared to 0 (the default value).
    - If the Write FIFO will be enabled, configure WFIFOCTL. Note that WFIFOCTL.WENA should not be set to 1 (enabled) until the other bitfields in this register are configured.
  - (b) Read FIFO:
    - If the Read FIFO will not be enabled, verify that RFIFOCTL.RENA is cleared to 0 (the default value).
    - If the Read FIFO will be enabled, configure RFIFOCTL. Note that RFIFOCTL.RENA should not be set to 1 (enabled) until the other bitfields in this register are configured.
3. Configure all McASP registers except GBLCTL in the following order:
  - (a) Receive registers: RMASK, RFMT, AFSRCTL, ACLKRCTL, AHCLKRCTL, RTDM, RINTCTL, RCLKCHK. If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the GBLCTL register.
  - (b) Transmit registers: XMASK, XFMT, AFSXCTL, ACLKXCTL, AHCLKXCTL, XTDM, XINTCTL, XCLKCHK. If external clocks AHCLKX and/or ACLKX are used, they must be running already for proper synchronization of the GBLCTL register.
  - (c) Serializer registers: SRCTL[n].
  - (d) Global registers: Registers PFUNC, PDIR, DITCTL, DLBCTL, AMUTE. Note that PDIR should only be programmed after the clocks and frames are set up in the steps above. This is because the moment a clock pin is configured as an output in PDIR, the clock pin starts toggling at the rate defined in the corresponding clock control register. Therefore you must ensure that the clock control register is configured appropriately before you set the pin to be an output. A similar argument applies to the frame sync pins.
  - (e) DIT registers: For DIT mode operation, set up registers DITCSRA[n], DITCSRB[n], DITUDRA[n], and DITUDRB[n].
4. Start the respective high-frequency serial clocks AHCLKX and/or AHCLKR. This step is necessary even if external high-frequency serial clocks are used:
  - (a) Take the respective internal high-frequency serial clock divider(s) out of reset by setting the RHCLKRST bit for the receiver and/or the XHCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be held at 0.
  - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

5. Start the respective serial clocks ACLKX and/or ACLKR. This step can be skipped if external serial clocks are used and they are running:
  - (a) Take the respective internal serial clock divider(s) out of reset by setting the RCLKRST bit for the receiver and/or the XCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
  - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
6. Setup data acquisition as required:
  - (a) If DMA is used to service the McASP, set up data acquisition as desired and start the DMA in this step, before the McASP is taken out of reset.
  - (b) If CPU interrupt is used to service the McASP, enable the transmit and/ or receive interrupt as required.
  - (c) If CPU polling is used to service the McASP, no action is required in this step.
7. Activate serializers.
  - (a) Before starting, clear the respective transmitter and receiver status registers by writing XSTAT = FFFFh and RSTAT = FFFFh.
  - (b) Take the respective serializers out of reset by setting the RSRCLR bit for the receiver and/or the XSRCLR bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
  - (c) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
8. Verify that all transmit buffers are serviced. Skip this step if the transmitter is not used. Also, skip this step if time slot 0 is selected as inactive (special cases, see [Figure 25-24](#), second waveform). As soon as the transmit serializer is taken out of reset, XDATA in the XSTAT register is set, indicating that XBUF is empty and ready to be serviced. The XDATA status causes a DMA event AXEVT to be generated, and can cause an interrupt AXINT to be generated if it is enabled in the XINTCTL register.
  - (a) If DMA is used to service the McASP, the DMA automatically services the McASP upon receiving AXEVT. Before proceeding in this step, you should verify that the XDATA bit in the XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the DMA.
  - (b) If CPU interrupt is used to service the McASP, interrupt service routine is entered upon the AXINT interrupt. The interrupt service routine should service the XBUF registers. Before proceeding in this step, you should verify that the XDATA bit in XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the CPU.
  - (c) If CPU polling is used to service the McASP, the XBUF registers should be written to in this step.

#### **CAUTION**

The DSP does not support the emulation suspend signal. Therefore, if a data window is open in the Code Composer Studio™ integrated development environment to observe the XRBUF locations, the emulation read from the XRBUF locations causes an undesirable side effect of clearing the RDATA bit in RSTAT. Furthermore, if you write to the XRBUF through the Code Composer Studio™ integrated development environment, the emulation write to the XRBUF locations causes the XDATA bit in XSTAT to be cleared.

9. Release state machines from reset.
  - (a) Take the respective state machine(s) out of reset by setting the RSMRST bit for the receiver and/or the XSMRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
  - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

10. Release frame sync generators from reset. Note that it is necessary to release the internal frame sync generators from reset, even if an external frame sync is being used, because the frame sync error detection logic is built into the frame sync generator.
  - (a) Take the respective frame sync generator(s) out of reset by setting the RFRST bit for the receiver, and/or the XFRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
  - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
11. Upon the first frame sync signal, McASP transfers begin. The McASP synchronizes to an edge on the frame sync pin, not the level on the frame sync pin. This makes it easy to release the state machine and frame sync generators from reset.
  - (a) For example, if you configure the McASP for a rising edge transmit frame sync, then you do not need to wait for a low level on the frame sync pin before releasing the McASP transmitter state machine and frame sync generators from reset.

#### **25.0.21.1.3 Separate Transmit and Receive Initialization**

In many cases, it is desirable to separately initialize the McASP transmitter and receiver. For example, you may delay the initialization of the transmitter until the type of data coming in on the receiver is recognized. Or a change in the incoming data stream on the receiver may necessitate a reinitialization of the transmitter.

In this case, you may still follow the sequence outlined in [Section 25.0.21.1.2](#), but use it for each section (transmit, receive) individually. The GBLCTL register is aliased to RGBLCTL and XGBLCTL to facilitate separate initialization of transmit and receive sections.

Also, make sure that the initialization or reinitialization sequence follows the guidelines in [Bits With Restrictions on When They May be Changed](#).

#### **25.0.21.1.4 Importance of Reading Back GBLCTL**

In [Section 25.0.21.1.2](#), steps 4b, 5b, 7c, 9b, and 10b state that GBLCTL should be read back until the bits that were written are successfully latched. This is important, because the transmitter and receiver state machines run off of the respective bit clocks, which are typically about tens to hundreds of times slower than the DSP's internal bus clock. Therefore, it takes many cycles between when the DSP writes to GBLCTL (or RGBLCTL and XGBLCTL), and when the McASP actually recognizes the write operation. If you skip this step, then the McASP may never see the reset bits in the global control registers get asserted and deasserted; resulting in an uninitialized McASP.

Therefore, the logic in McASP has been implemented such that once the DSP writes GBLCTL, RGBLCTL, or XGBLCTL, the resulting write is not visible by reading back GBLCTL until the McASP has recognized the change. This typically requires two bit clocks plus two DSP bus clocks to occur.

Also, if the bit clocks can be completely stopped, any software that polls GBLCTL should be implemented with a time-out. If GBLCTL does not have a time-out, and the bit clock stops, the changes written to GBLCTL will not be reflected until the bit clock restarts.

Finally, please note that while RGBLCTL and XGBLCTL allow separate changing of the receive and transmit halves of GBLCTL, they also immediately reflect the updated value (useful for debug purposes). Only GBLCTL can be used for the read back step.

#### **25.0.21.1.5 Synchronous Transmit and Receive Operation (ASYNC = 0)**

When ASYNC = 0 in ACLKXCTL, the transmit and receive sections operate synchronously from the transmit section clock and transmit frame sync signals ([Figure 25-15](#)). The receive section may have a different (but compatible in terms of slot size) data format. Note that when ASYNC = 0, XCLK is automatically inverted to produce RCLK (note the inversion on the ASYNC multiplexer as shown in [Figure 25-16](#)).

When  $ASYNC = 0$ , the transmit and receive sections must share some common settings, since they both use the same clock and frame sync signals:

- $DITEN = 0$  in  $DITCTL$  (TDM mode is enabled)
- The total number of bits per frame must be the same (that is,  $RSSZ \times RMOD$  must equal  $XSSZ \times XMOD$ )
- Both transmit and receive should either be specified as burst or TDM mode, but not mixed
- The settings in  $ACLKCTL$  are irrelevant
- $RCLK$  is an inverted version of  $XCLK$  (note the inversion on the multiplexer labeled “ASYNC” shown in [Figure 25-16](#))
- $FSXM$  must match  $FSRM$
- $FXWID$  must match  $FRWID$

For all other settings, the transmit and receive sections may be programmed independently.

#### 25.0.21.1.6 Asynchronous Transmit and Receive Operation ( $ASYNC = 1$ )

When  $ASYNC = 1$  in  $ACLKXCTL$ , the transmit and receive sections operate completely independently and have separate clock and frame sync signals ([Figure 25-15](#), [Figure 25-16](#), and [Figure 25-17](#)). The events generated by each section come asynchronously.

### 25.0.21.2 Transfer Modes

#### 25.0.21.2.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two DSPs. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode ([Figure 25-23](#)), as specified for transmit ( $XMOD = 0$  in  $AFSXCTL$ ) and receive ( $RMOD = 0$  in  $AFSRCTL$ ), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration ( $FRWID = 0$  in  $AFSRCTL$ ,  $FXWID = 0$  in  $AFSXCTL$ ).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the  $XBUF_n$  (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the  $RBUF_n$  (for every serializer set to operate as a receiver) has been read.

**Figure 25-23. Burst Frame Sync Mode**

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in [Section 25.0.21.1.2](#) to configure this register.
- AMUTE: Not applicable. Leave at default.
- DLBCTL: If loopback mode is desired, configure this register according to [Section 25.0.21.7](#), otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to [Section 25.0.21.2](#) and [Section 25.0.21.4](#).
- RFMT/XFMT: Program all fields according to data format desired. See [Section 25.0.21.4](#).
- AFSRCTL/AFSXCTL: Clear **RMOD/XMOD** bits to 0 to indicate burst mode. Clear **FRWID/FXWID** bits to 0 for single bit frame sync duration. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See [Section 25.0.21](#).
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See [Section 25.0.21](#).
- RTDM/XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Not applicable. Leave at default.
- SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

### 25.0.21.2.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in [Section 25.0.18.1](#).

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXR[n], whose serializers have been configured to transmit

The transmitter has the option to receive the ACLKX bit clock as an input, or to generate the ACLKX bit clock by dividing down the AHCLKX high-frequency master clock. The transmitter can either generate AHCLKX internally or receive AHCLKX as an input. See [Section 25.0.21.1](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXR[n], whose serializers have been configured to receive

The receiver has the option to receive the ACLKR bit clock as an input or to generate the ACLKR bit clock by dividing down the AHCLKR high-frequency master clock. The receiver can either generate AHCLKR internally or receive AHCLKR as an input. See [Section 25.0.21.2](#) and [Section 25.0.21.3](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in [Section 25.0.21.1.2](#) to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: If loopback mode is desired, configure this register according to [Section 25.0.21.7](#), otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select TDM mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to [Section 25.0.21.2](#) and [Section 25.0.21.4](#).
- RFMT/XFMT: Program all fields according to data format desired. See [Section 25.0.21.4](#).
- AFSRCTL/AFSXCTL: Set **RMOD/XMOD** bits to 2-32 for TDM mode. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See [Section 25.0.21](#).
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See [Section 25.0.21](#).
- RTDM/XTDM: Program all fields according to the time slot characteristics desired.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Program all fields according to serializer operation desired.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

#### 25.0.21.2.2.1 TDM Time Slots

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring XTDM and/or RTDM (this allows multiple DSPs to communicate on the same TDM serial bus).

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either XTDM or RTDM to determine if the McASP should transmit/receive in that time slot.

If the transmit/receive bit is active, the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. Transmit pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bit DISMOD in SRCTL[n].

Figure 25-24 shows when the transmit DMA event AXEVT is generated. See Section 25.0.21.3.1 for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless if the previous time slot (slot N - 1) is active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUF[n] to XRSR[n] generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA request generation does not need this capability, since the receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

**Figure 25-24. Transmit DMA Event (AXEVT) Generation in TDM Time Slots**

A See Section 25.0.21.1.2, step 7a.

### 25.0.21.2.2.2 Special 384 Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF, AES-3, IEC-60958 receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The advantage to using the 384 time slot TDM mode is that interrupts may be generated synchronous to the S/PDIF, AES-3, IEC-60958, such as the last slot interrupt.

The receive TDM time slot register (RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).

To receive data in the DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock). In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK.
- One or more serial data pins, AXR[n], whose serializers have been configured to receive.

For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in AFSRCTL to 384 to receive 384 time slots.

### 25.0.21.2.3 Digital Audio Interface Transmit (DIT) Transfer Mode

In addition to the TDM and burst transfer modes, which are suitable for transmitting audio data between ICs inside the same system, the digital audio interface transmit (DIT) transfer mode of the McASP also supports transmission of audio data in the S/PDIF, AES-3, or IEC-60958 format. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode only applies to serializers configured as transmitters, not receivers. Refer to [Section 25.0.18.2](#) for a description of the S/PDIF format.

#### 25.0.21.2.3.1 Transmit DIT Encoding

The McASP operation in DIT mode is basically identical to the 2 time slot TDM mode, but the data transmitted is output as a biphase mark encoded bit stream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bit stream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register (XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in the DIT mode, the following pins are typically needed:

- AHCLKX - transmit high-frequency master clock
- One or more serial data pins, AXR[n], whose serializers have been configured to transmit

AHCLKX is optional (the internal clock source may be used instead), but if used as a reference, the DSP provides a clock check circuit that continually monitors the AHCLKX input for stability.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23-0 after passing through the first three stages of the transmit format unit.

For left-aligned Q31 data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 010 (rotate right by 8 bits)
- XRORS = 0 (no bit reversal, LSB first)
- XMASK = FFFF FF00h-FFFF 0000h (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present)
- XPAD = 00 (pad extra bits with 0)

For right-aligned data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 000 (rotate right by 0 bits)
- XRORS = 0 (no bit reversal, LSB first)
- XMASK = 00FF FFFFh to 0000 FFFFh (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present)
- XPAD = 00 (pad extra bits with 0)

### 25.0.21.2.3.2 Transmit DIT Clock and Frame Sync Generation

The DIT transmitter only works in the following configuration:

- In transmit frame control register (AFSXCTL):
  - Internally-generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In transmit clock control register (ACLKXCTL), ASYNC = 1
- In transmit bitstream format register (XFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

This is a summary of the register configurations required for DIT mode. The DIT mode specific bit fields are in bold face:

- PFUNC: The data pins must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIO if desired.
- PDIR: The data pins must be configured as outputs. If AHCLKX is used as an input reference, it should be configured as input. If internal clock source AUXCLK is used as the reference clock, it may be output on the AHCLKX pin by configuring AHCLKX as an output.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable for DIT operation. Leave at default.
- GBLCTL: Follow the initialization sequence in [Section 25.0.21.1.2](#) to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: Not applicable. Loopback is not supported for DIT mode. Leave at default.
- DITCTL: **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- RMASK: Not applicable. Leave at default.
- RFMT: Not applicable. Leave at default.
- AFSRCTL: Not applicable. Leave at default.
- ACLKRCTL: Not applicable. Leave at default.
- AHCLKRCTL: Not applicable. Leave at default.
- RTDM: Not applicable. Leave at default.
- RINTCTL: Not applicable. Leave at default.
- RCLKCHK: Not applicable. Leave at default.
- **XMASK**: Mask desired bits according to the discussion in this section, depending upon left-aligned or right-aligned internal data.
- **XFMT**: **XDATDLY** = 0. **XRVS** = 0. **XPAD** = 0. **XPBIT** = default (not applicable). **XSSZ** = Fh (32-bit slot). XBUSEL = configured as desired. **XROT** bit is configured according to the discussion in this section, either 0 or 8-bit rotate.
- **AFSXCTL**: Configure the bits according to the discussion in this section.
- **ACLKXCTL**: **ASYNC** = 1. Program CLKXDIV bits to obtain the bit clock rate desired. Configure CLKXP and CLKXM bits as desired, because CLKX is not actually used in the DIT protocol.
- **AHCLKXCTL**: Program all fields according to high-frequency clock desired.
- **XTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- XINTCTL: Program all fields according to interrupts desired.
- XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Set **SRMOD** = 1 (transmitter) for the DIT pins. DISMOD field is don't care for DIT mode.
- **DITCSRA[n]**, **DITCSRB[n]**: Program the channel status bits as desired.
- **DITUDRA[n]**, **DITUDRB[n]**: Program the user data bits as desired.

### 25.0.21.2.3.3 DIT Channel Status and User Data Register Files

The channel status registers (DITCSRAn and DITCSRBN) and user data registers (DITUDRAn and DITUDRBN) are not double buffered. Typically the programmer uses one of the synchronizing interrupts, such as last slot, to create an event at a safe time so the register may be updated. In addition, the CPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a requirement that the software avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it will be indeterminate whether the old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 25.0.18.2.2](#). The channel status information (C) and user data (U) are defined in these DIT control registers:

- DITCSRA0 to DITCSRA5: The 192 bits in these six registers contain the channel status information for the LEFT channel within each frame.
- DITCSRB0 to DITCSRB5: The 192 bits in these six registers contain the channel status information for the RIGHT channel within each frame.
- DITUDRA0 to DITUDRA5: The 192 bits in these six registers contain the user data information for the LEFT channel within each frame.
- DITUDRB0 to DITUDRB5: The 192 bits in these six registers contain the user data information for the RIGHT channel within each frame.

The S/PDIF block format is shown in [Figure 25-11](#). There are 192 frames within a block (frame 0 to frame 191). Within each frame there are two subframes (subframe 1 and 2 for left and right channels, respectively). The channel status and user data information sent on each subframe is summarized in [Table 25-3](#).

### 25.0.21.3 Data Transmission and Reception

The DSP services the McASP by writing data to the XBUF register(s) for transmit operations, and by reading data from the RBUF register(s) for receive operations. The McASP sets status flag and notifies the DSP whenever data is ready to be serviced. [Section 25.0.21.3.1](#) discusses data ready status in detail.

The XBUF and RBUF registers can be accessed through one of the two peripheral ports of the device:

- The DMA port: This port is dedicated for data transfers on the device.
- The peripheral configuration port: This port is used for both data transfers and peripheral configuration control on the device.

[Section 25.0.21.3.2](#) and [Section 25.0.21.3.3](#) discuss how to perform transfers through the DMA bus and the peripheral configuration bus.

Either the CPU or the DMA can be used to service the McASP through any of these two peripheral ports. The CPU and DMA usages are discussed in [Section 25.0.21.3.4](#) and [Section 25.0.21.3.5](#).

**Table 25-3. Channel Status and User Data for Each DIT Block**

| Frame                                                    | Subframe | Preamble | Channel Status defined in: | User Data defined in: |
|----------------------------------------------------------|----------|----------|----------------------------|-----------------------|
| <b>Defined by DITCSRA0, DITCSRB0, DITUDRA0, DITUDRB0</b> |          |          |                            |                       |

### 25.0.21.3.1 Data Ready Status and Event/Interrupt Generation

#### 25.0.21.3.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the XSTAT register reflects the status of the XBUF register. The XDATA flag is set when data is transferred from the XRBUFF[n] buffers to the XRSR[n] shift registers, indicating that the XBUF is empty and ready to accept new data from the DSP. This flag is cleared when the XDATA bit is written with a 1, or when all the serializers configured as transmitters are written by the DSP.

Whenever XDATA is set, an DMA event AXEVT is automatically generated to notify the DMA of the XBUF empty status. An interrupt AXINT is also generated if XDATA interrupt is enabled in the XINTCTL register (See [Section 25.0.21.5.1](#) for details).

For DMA requests, the McASP does not require XSTAT to be read between DMA events. This means that even if XSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active transmit serializers are ready to be written to with new data.

[Figure 25-25](#) shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to 5 McASP system clocks (AXEVT Latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the DSP can begin servicing the McASP by writing Word C into the XBUF (DSP Service Time). The DSP must write Word C into the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum DSP Service Time ([Figure 25-25](#)) can be calculated as:

DSP Service Time = Time Slot - AXEVT Latency - Setup Time

A This is not the same as AUXCLK. The DSP uses SYSCLK2 as the McASP system clock source.

### Example 25-5. DSP Service Time Calculation for Transmit DMA Event (AXEVT)

The following is an example to show how to calculate DSP Service Time. Assume the following setup:

- Device: DSP at 300 MHz
- McASP transmits in I2S format at 192 kHz frame rate. Assume slot size is 32 bit

With the above setup, we obtain the following parameters corresponding to [Figure 25-25](#):

- Calculation of McASP system clock cycle:
  - DSP uses SYSCLK2 as the McASP system clock. It runs at 150 MHz (half of device frequency)
  - Therefore, McASP system clock cycle =  $1/150 \text{ MHz} = 6.7 \text{ ns}$
- Calculation of ACLKX clock cycle:
  - This example has two 32-bit slots per frame, for a total of 64 bits per frame
  - ACLKX clock cycle is  $(1/192 \text{ kHz})/64 = 81.4 \text{ ns}$
- Time Slot between AXEVT events:
  - For I2S format, McASP generates two AXEVT events per 192 kHz frame
  - Therefore, Time Slot between AXEVT events is  $(1/192 \text{ kHz})/2 = 2604 \text{ ns}$
- AXEVT Latency
  - = 5 McASP system clocks
  - =  $6.7 \text{ ns} \times 5 = 33.5 \text{ ns}$
- Setup Time
  - = 3 McASP system clocks + 4 ACLKX cycles
  - =  $(6.7 \text{ ns} \times 3) + (81.4 \text{ ns} \times 4)$
  - = 345.7 ns
- DSP Service Time
  - = Time Slot - AXEVT Latency - Setup Time
  - =  $2604 \text{ ns} - 33.5 \text{ ns} - 345.7 \text{ ns}$
  - = 2225 ns

### 25.0.21.3.1.2 Receive Data Ready

Similarly, the receive data ready flag RDATA bit in the RSTAT reflects the status of the RBUF register. The RDATA flag is set when data is transferred from the XRSR[n] shift registers to the XRBUF[n] buffers, indicating that the RBUF contains received data and is ready to have the DSP read the data. This flag is cleared when the RDATA bit is written with a 1, or when all the serializers configured as receivers are read.

Whenever RDATA is set, an DMA event AREVT is automatically generated to notify the DMA of the RBUF ready status. An interrupt ARINT is also generated if RDATA interrupt is enabled in the RINTCTL register (See [Section 25.0.21.5.2](#) for details).

For DMA requests, the McASP does not require RSTAT to be read between DMA events. This means that even if RSTAT already has the RDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active receive serializers are ready to receive new data.

[Figure 25-26](#) shows the timing details of when AREVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to 5 McASP system clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the DSP can begin servicing the McASP by reading Word A from the RBUF (DSP Service Time). The DSP must read Word A from the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum DSP Service Time ([Figure 25-26](#)) can be calculated as:

DSP Service Time = Time Slot - AREVT Latency - Setup Time

The DSP Service Time calculation for receive is similar to the calculation for transmit. See [Example 25-5](#) for DSP Service Time calculation using transmit as an example.

A This is not the same as AUXCLK. The DSP uses SYSCLK2 as the McASP system clock source.

### 25.0.21.3.2 Transfers through the DMA Port

#### CAUTION

To perform internal transfers through the DMA port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

Typically, you will access the McASP XRBUF registers through the DMA port. To access through the DMA port, simply have the CPU or DMA access the XRBUF through its DMA port location. See your device-specific data manual for the exact memory address. Through the DMA port, the DMA/CPU can service all the serializers through a single address. The McASP automatically cycles through the appropriate serializers.

For transmit operations through the DMA port, the DMA/CPU should write to the same XBUF DMA port address to service all of the active transmit serializers. In addition, the DMA/CPU should write to the XBUF for all active transmit serializers in incremental (although not necessarily consecutive) order. For example, if serializers 0, 4, 5, and 7 are set up as active transmitters, the DMA/CPU should write to the XBUF DMA port address four times with data for serializers 0, 4, 5, and 7 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Similarly, for receive operations through the DMA port, the DMA/CPU should read from the same RBUF DMA port address to service all of the active receive serializers. In addition, reads from the active receive serializers through the DMA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 1, 2, 3, and 6 are set up as active receivers, the DMA/CPU should read from the RBUF DMA port address four times to obtain data for serializers 1, 2, 3, and 6 in this exact order, upon each receive data ready event.

When transmitting, the DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition ([Section 25.0.21.6.2](#)). Similarly, when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do so results in a buffer overrun condition ([Section 25.0.21.6.3](#)).

To perform internal transfers through the DMA port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers.

### 25.0.21.3.3 Transfers Through the Peripheral Configuration Bus

#### CAUTION

The DSP does not support the emulation suspend signal. Therefore, if a data window is open in the Code Composer Studio™ integrated development environment to observe the XRBUF locations, the emulation read from the XRBUF locations causes an undesirable side effect of clearing the RDATA bit in RSTAT. Furthermore, if you write to the XRBUF through the Code Composer Studio™ integrated development environment, the emulation write to the XRBUF locations causes the XDATA bit in XSTAT to be cleared.

To perform internal transfers through the peripheral configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

In this method, the DMA/CPU accesses the XRBUF through the peripheral configuration bus address. The exact XRBUF address for any particular serializer is determined by adding the offset for that particular serializer to the base address for the particular McASP (found in the device-specific data manual). XRBUF for the serializers configured as transmitters is given the name XBUF $n$ . For example, the XRBUF associated with transmit serializer 2 is named XBUF2. Similarly, XRBUF for the serializers configured as receivers is given the name RBUF $n$ .

Accessing the XRBUFF through the DMA port is different because the CPU/DMA only needs to access one single address. When accessing through the peripheral configuration bus, the CPU/DMA must provide the exact XBUF<sub>n</sub> or RBUF<sub>n</sub> address for each access.

When transmitting, DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition (Section 25.0.21.6.2). Similarly when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do so results in a buffer overrun condition (Section 25.0.21.6.3).

#### 25.0.21.3.4 Using the CPU for McASP Servicing

The CPU can be used to service the McASP through interrupt (upon AXINT/ARINT interrupts) or through polling the XDATA bit in the XSTAT register. As discussed in Section 25.0.21.3.2 and Section 25.0.21.3.3, the CPU can access either through the DMA port or through the peripheral configuration port.

To use the CPU to service the McASP through interrupts, the XSTAT/RSTAT bit must be enabled in the respective XINTCTL/RINTCTL registers, to generate interrupts AXINT/ARINT to the CPU upon data ready.

#### 25.0.21.3.5 Using the DMA for McASP Servicing

The most typical scenario is to use the DMA to service the McASP through the DMA port, although the DMA can also service the McASP through the peripheral configuration port. Use AXEVT/AREVT that is triggered upon each XDATA/RDATA transition from 0 to 1.

Figure 25-27 shows an example audio system with six audio channels (LF, RF, LS, RS, C, and LFE) transmitted from three AXR[n] pins on the McASP and shows when events AXEVT and AREVT are triggered.

In Figure 25-27, a DMA event AXEVT/AREVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Similarly, AREVT is triggered for each of the receive audio channel time slot. This allows for the use of a single DMA to transmit all audio channels, and a single DMA to receive all audio channels.

Note the difference between DMA event generation and the CPU interrupt generation. DMA events are generated automatically upon data ready; whereas CPU interrupt generation needs to be enabled in the XINTCTL/RINTCTL register.

## McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See [Figure 25-28](#) for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the WFICTL and RFIFCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP (see [Section 25.0.21.1.2](#) for details).

**Figure 25-28. McASP Audio FIFO (AFIFO) Block Diagram**

## AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes *WNUMDMA* 32-bit words to the McASP if and when there are at least *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes *WNUMDMA* words to the McASP. (See description for WFICTL.WNUMDMA in [Section 25.1.45](#).)

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded.

Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

## Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once *WNUMEVT* words have been written to the FIFO, it checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled.

Note that if transmit DMA event pacing is desired, *WFIFOCTL.WNUMEVT* should be set to a non-zero integer multiple of the value in *WFIFOCTL.WNUMDMA*. If transmit DMA event pacing is not desired, then the value in *WFIFOCTL.WNUMEVT* should be set equal to the value in *WFIFOCTL.WNUMDMA*.

## AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McASP, if and when the RFIFO has space for *RNUMDMA* words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads *RNUMDMA* words from the McASP. (See description for *RFIFOCTL.RNUMDMA* in [Section 25.1.47](#).)

If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than *RNUMEVT* words, those words will be read correctly, emptying the FIFO.

## Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty.

Note that if receive DMA event pacing is desired, *RFIFOCTL.RNUMEVT* should be set to a non-zero integer multiple of the value in *RFIFOCTL.RNUMDMA*. If receive DMA event pacing is not desired, then the value in *RFIFOCTL.RNUMEVT* should be set equal to the value in *RFIFOCTL.RNUMDMA*.

## Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

## 25.0.21.4 Formatter

### 25.0.21.4.1 Transmit Bit Stream Data Alignment

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size  $\leq$  Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order: order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the transmit bitstream format register (XFMT):

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

XSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

Table 25-4 and Figure 25-29 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size (SLOT in Table 25-4) and word size (WORD in Table 25-4) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit (see Figure 25-20), and the data is aligned in the same representation as it is written to the transmitter by the DSP (typically Q31 or integer).

**Table 25-4. Transmit Bitstream Data Alignment**

| Figure 25-29       | Bit Stream Order | Bit Stream Alignment | Internal Numeric Representation | XFMT Bit                  |       |
|--------------------|------------------|----------------------|---------------------------------|---------------------------|-------|
|                    |                  |                      |                                 | XROT <sup>(1)</sup>       | XRVRS |
| (a) <sup>(2)</sup> | MSB first        | Left aligned         | Q31 fraction                    | 0                         | 1     |
| (b)                | MSB first        | Right aligned        | Q31 fraction                    | SLOT - WORD               | 1     |
| (c)                | LSB first        | Left aligned         | Q31 fraction                    | 32 - WORD                 | 0     |
| (d)                | LSB first        | Right aligned        | Q31 fraction                    | 32 - SLOT                 | 0     |
| (e) <sup>(2)</sup> | MSB first        | Left aligned         | Integer                         | WORD                      | 1     |
| (f)                | MSB first        | Right aligned        | Integer                         | SLOT                      | 1     |
| (g)                | LSB first        | Left aligned         | Integer                         | 0                         | 0     |
| (h)                | LSB first        | Right aligned        | Integer                         | (32 - (SLOT - WORD)) % 32 | 0     |

<sup>(1)</sup> WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

<sup>(2)</sup> To transmit in I2S format, use MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

**Figure 25-29. Data Flow Through Transmit Format Unit**

### 25.0.21.4.2 Receive Bit Stream Data Alignment

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register (RFMT):

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

RSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 25-5 and Figure 25-30 show the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 25-19), and the data is aligned in the same representation as it is read from the receiver by the DSP (typically Q31 or integer).

**Table 25-5. Receive Bitstream Data Alignment**

| Figure 25-30       | Bit Stream Order | Bit Stream Alignment | Internal Numeric Representation | RFMT Bit                  |       |
|--------------------|------------------|----------------------|---------------------------------|---------------------------|-------|
|                    |                  |                      |                                 | RROT <sup>(1)</sup>       | RRVRS |
| (a) <sup>(2)</sup> | MSB first        | Left aligned         | Q31 fraction                    | SLOT                      | 1     |
| (b)                | MSB first        | Right aligned        | Q31 fraction                    | WORD                      | 1     |
| (c)                | LSB first        | Left aligned         | Q31 fraction                    | (32 - (SLOT - WORD)) % 32 | 0     |
| (d)                | LSB first        | Right aligned        | Q31 fraction                    | 0                         | 0     |
| (e) <sup>(2)</sup> | MSB first        | Left aligned         | Integer                         | SLOT - WORD               | 1     |
| (f)                | MSB first        | Right aligned        | Integer                         | 0                         | 1     |
| (g)                | LSB first        | Left aligned         | Integer                         | 32 - SLOT                 | 0     |
| (h)                | LSB first        | Right aligned        | Integer                         | 32 - WORD                 | 0     |

<sup>(1)</sup> WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

<sup>(2)</sup> To transmit in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

**Figure 25-30. Data Flow Through Receive Format Unit**

## 25.0.21.5 Interrupts

### 25.0.21.5.1 Transmit Data Ready Interrupt

The transmit data ready interrupt (XDATA) is generated if XDATA is 1 in the XSTAT register and XDATA is also enabled in XINTCTL. [Section 25.0.21.3.1](#) provides details on when XDATA is set in the XSTAT register.

A transmit start of frame interrupt (XSTAFRM) is triggered by the recognition of transmit frame sync. A transmit last slot interrupt (XLAST) is a qualified version of the data ready interrupt (XDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended was next-to-last TDM slot, current slot is last slot).

### 25.0.21.5.2 Receive Data Ready Interrupt

The receive data ready interrupt (RDATA) is generated if RDATA is 1 in the RSTAT register and RDATA is also enabled in RINTCTL. [Section 25.0.21.3.2](#) provides details on when RDATA is set in the RSTAT register.

A receiver start of frame interrupt (RSTAFRM) is triggered by the recognition of a receiver frame sync. A receiver last slot interrupt (RLAST) is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

### 25.0.21.5.3 Error Interrupts

Upon detection, the following error conditions generate interrupt flags:

- In the receive status register (RSTAT):
  - Receiver overrun (ROVRN)
  - Unexpected receive frame sync (RSYNCERR)
  - Receive clock failure (RCKFAIL)
  - Receive DMA error (RDMAERR)
- In the transmit status register (XSTAT):
  - Transmit underrun (XUNDRN)
  - Unexpected transmit frame sync (XSYNCERR)
  - Transmit clock failure (XCKFAIL)
  - Transmit DMA error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (RINTCTL) and transmit interrupt control register (XINTCTL). If the enable bit is set in RINTCTL or XINTCTL, an interrupt is requested when the interrupt flag is set in RSTAT or XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

### 25.0.21.5.4 Audio Mute (AMUTE) Function

The McASP includes an automatic audio mute function ([Figure 25-31](#)) that asserts in hardware the AMUTE device pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (AMUTE). The AMUTE device pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the AMUTEIN input. Typically, the AMUTEIN input is shared with a device pin.

The AMUTEIN input allows the on-chip logic to consider a mute input from other devices in the system, so that all errors may be considered. The AMUTEIN input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in AMUTE, and it must be enabled explicitly.

In addition to the external AMUTEIN input, the AMUTE device pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in AMUTE.

When one or more of the errors is detected and enabled, the AMUTE device pin is driven to an active state that is selected by MUTEN in AMUTE. The active polarity of the AMUTE device pin is programmable by MUTEN (and the inactive polarity is the opposite of the active polarity). The AMUTE device pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the AMUTEIN is inactive.

**Figure 25-31. Audio Mute (AMUTE) Block Diagram**

#### 25.0.21.5.5 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in RSTAT or XSTAT is set and the interrupt is enabled in RINTCTL or XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit/receive interrupt ports, but that request has not yet been serviced.
- **Serviced:** The CPU writes to RSTAT or XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the transmitter with the interrupt flag set in XSTAT and the interrupt enabled in XINTCTL generates a request on the McASP transmit interrupt port AXINT.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit interrupt port.

The transmit interrupt is serviced with the CPU writing to XSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit interrupt port.

The receiver operates in a similar way, but using RSTAT, RINTCTL, and the McASP receive interrupt port ARINT.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

#### 25.0.21.6 Error Handling and Management

To support the design of a robust audio system, the McASP includes error-checking capability for the serial protocol, data underrun, and data overrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX/AHCLKR clock cycles. The timer value can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

Upon the detection of any one or more errors (software selectable), or the assertion of the AMUTEIN input pin, the AMUTE output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt may be generated if desired, based on any one or more of the error sources.

##### 25.0.21.6.1 Unexpected Frame Sync Error

An unexpected frame sync occurs when:

- In burst mode, when the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- In TDM mode, a further constraint is that the frame sync must occur exactly during the correct bit clock (not a cycle earlier or later) and only before slot 0. An unexpected frame sync occurs if this condition is not met.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. Early: An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
  - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.

2. Late: A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
  - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in both burst mode and TDM mode; however, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

#### **25.0.21.6.2 Buffer Underrun Error - Transmitter**

A buffer underrun can only occur for serializers programmed to be transmitters. A buffer underrun occurs when the serializer is instructed by the transmit state machine to transfer data from XRBUFF[n] to XRSR[n], but XRBUFF[n] has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the DSP explicitly writes a 1 to the XUNDRN bit to clear the XUNDRN bit.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at  $128 \times f_s$ ). By shifting out a pair of zeros, a clock may be recovered on the receiver. To recover, reset the McASP and start again with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

#### **25.0.21.6.3 Buffer Overrun Error - Receiver**

A buffer overrun can only occur for serializers programmed to be receivers. A buffer overrun occurs when the serializer is instructed to transfer data from XRSR[n] to XRBUFF[n], but XRBUFF[n] has not yet been read by either the DMA or the DSP. When this occurs, the receiver state machine sets the ROVRN flag. However, the individual serializer writes over the data in the XRBUFF[n] register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the DSP catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the DSP explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

#### **25.0.21.6.4 DMA Error - Transmitter**

A transmit DMA error, as indicated by the XDMAERR flag in the XSTAT register, occurs when the DMA (or CPU) writes more words to the DMA port of the McASP than it should. For each DMA event, the DMA should write exactly as many words as there are serializers enabled as transmitters.

XDMAERR indicates that the DMA (or CPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in XSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP transmitter and the DMA to resynchronize them.

### **25.0.21.6.5 DMA Error - Receiver**

A receive DMA error, as indicated by the RDMAERR flag in the RSTAT register, occurs when the DMA (or CPU) reads more words from the DMA port of the McASP than it should. For each DMA event, the DMA should read exactly as many words as there are serializers enabled as receivers.

RDMAERR indicates that the DMA (or CPU) read too many words from the McASP for a given receive DMA event. Reading too few words results in a receiver overrun error setting ROVRN in RSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP receiver and the DMA to resynchronize them.

### **25.0.21.6.6 Clock Failure Detection**

#### **25.0.21.6.6.1 Clock-Failure Check Startup**

It is expected, initially, that the clock-failure circuits will generate an error until at least one measurement has been taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not immediately be enabled, but be enabled only after a specific startup procedure. The startup procedure is:

1. For the transmit clock failure check:
  - (a) Configure transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (XCLKCHK).
  - (b) Clear transmit clock failure flag (XCKFAIL) in the transmit status register (XSTAT).
  - (c) Wait until first measurement is taken (> 32 AHCLKX clock periods).
  - (d) Verify no clock failure is detected.
  - (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
  - (f) After the transmit clock is measured and falls within the acceptable range, the following may be enabled:
    - (i) transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (XINTCTL)
    - (ii) transmit clock failure detect autoswitch enable bit (XCKFAILSW) in the transmit clock check control register (XCLKCHK)
    - (iii) mute option (XCKFAIL) in the mute control register (AMUTE)
2. For the receive clock failure check:
  - (a) Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (RCLKCHK).
  - (b) Clear receive clock failure flag (RCKFAIL) in the receive status register (RSTAT).
  - (c) Wait until first measurement is taken (> 32 AHCLKR clock periods).
  - (d) Verify no clock failure is detected.
  - (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
  - (f) After the receive clock is measured and falls within the acceptable range, the following may be enabled:
    - (i) receive clock failure interrupt enable bit (RCKFAIL) in the receiver interrupt control register (RINTCTL)
    - (ii) mute option (RCKFAIL) in the mute control register (AMUTE)

### 25.0.21.6.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (Figure 25-32) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (XCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in XSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than XMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (XMAX). This is in case the external clock completely stops, so that the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. Note that the XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected, or that the audio source has changed and a new sample rate is being used.

In order for the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKX is internally generated or externally sourced.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in XSTAT is set. This causes an interrupt, if the transmit clock failure interrupt enable bit (XCKFAIL) in XINTCTL is set.

**Figure 25-32. Transmit Clock Failure Detection Circuit Block Diagram**

A This is not the same as AUXCLK. The DSP uses SYSCLK2 as the McASP system clock.

### 25.0.21.6.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (Figure 25-33) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an interrupt (RCKFAIL in RSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKR is internally generated or externally sourced.

**Figure 25-33. Receive Clock Failure Detection Circuit Block Diagram**

A This is not the same as AUXCLK. The DSP uses SYSCLK2 as the McASP system clock source.

## 25.0.21.7 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows testing of the McASP code in TDM mode with a single DSP device. In loopback mode, output of the transmit serializers is connected internally to the input of the receive serializers. Therefore, you can check the receive data against the transmit data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 180h) or burst mode (XMOD = 0).

Figure 25-34 shows the basic logical connection of the serializers in loopback mode. Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register (DLBCTL) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, you should configure odd serializers to be transmitters and even serializers to be receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, you should configure even serializers to be transmitters and odd serializers to be receivers.

Data can be externally visible at the I/O pin of the transmit serializer if the pin is configured as a McASP output pin by setting the corresponding PFUNC bit to 0 and PDIR bit to 1.

In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bit of the DLBCTL register to 01b and the ASYNC bit of the ACLKXCTL register to 0.

**Figure 25-34. Serializers in Loopback Mode**

### 25.0.21.7.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format:

- The DLBEN bit in DLBCTL must be set to 1 to enable loopback mode.
- The MODE bits in DLBCTL must be set to 01b for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The ORD bit in DLBCTL must be programmed appropriately to select odd or even serializers to be transmitters or receivers. The corresponding serializers must be configured accordingly.
- The ASYNC bit in ACLKXCTL must be cleared to 0 to ensure synchronous transmit and receive operations.
- RMOD field in AFSRCTL and XMOD field in AFSXCTL must be set to 2h to 20h to indicate TDM mode. Loopback mode does not apply to DIT or burst mode.

## 25.0.22 Reset Considerations

The McASP has two reset sources: software reset and hardware reset.

### 25.0.22.1 Software Reset Considerations

The transmitter and receiver portions of the McASP may be put in reset through the global control register (GBLCTL). Note that a valid serial clock must be supplied to the desired portion of the McASP (transmit and/or receive) in order to assert the software reset bits in GBLCTL. See [Section 25.0.21.1.2](#) for details on how to ensure reset has occurred.

The entire McASP module may also be reset through the Power and Sleep Controller (PSC). Note that from the McASP perspective, this reset appears as a hardware reset to the entire module.

### 25.0.22.2 Hardware Reset Considerations

When the McASP is reset due to device reset, the entire serial port (including the transmitter and receiver state machines, and other registers) is reset.

## 25.0.23 EDMA Event Support

The McASP-related EDMA events are shown in [Table 25-6](#).

**Table 25-6. EDMA Events - McASP**

| Channel | Event Name | Event Description     |
|---------|------------|-----------------------|
| 0       | AREVT0     | McASP0 Receive Event  |
| 1       | AXEVT0     | McASP0 Transmit Event |

## 25.0.24 Power Management

The McASP can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For information on power management procedures using the PSC, see the *Power and Sleep Controller (PSC)* chapter.

## 25.1 Registers

Control registers for the McASP are summarized in [Table 25-7](#). The control registers are accessed through the peripheral configuration port. The receive buffer registers (RBUF) and transmit buffer registers (XBUF) can also be accessed through the DMA port, as listed in [Table 25-8](#). See your device-specific data manual for the memory address of these registers.

Control registers for the McASP Audio FIFO (AFIFO) are summarized in [Table 25-9](#). Note that the AFIFO Write FIFO (WFIFO) and Read FIFO (RFIFO) have independent control and status registers. The AFIFO control registers are accessed through the peripheral configuration port. See your device-specific data manual for the memory address of these registers.

**Table 25-7. McASP Registers Accessed by CPU/EDMA Through Peripheral Configuration Port**

| Offset | Acronym   | Register Description                                                                                                                               | Section                         |
|--------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| 0h     | REV       | Revision identification register                                                                                                                   | <a href="#">Section 25.1.2</a>  |
| 10h    | PFUNC     | Pin function register                                                                                                                              | <a href="#">Section 25.1.3</a>  |
| 14h    | PDIR      | Pin direction register                                                                                                                             | <a href="#">Section 25.1.4</a>  |
| 18h    | PDOUT     | Pin data output register                                                                                                                           | <a href="#">Section 25.1.5</a>  |
| 1Ch    | PDIN      | Read returns: Pin data input register                                                                                                              | <a href="#">Section 25.1.6</a>  |
| 1Ch    | PDSET     | Writes affect: Pin data set register (alternate write address: PDOUT)                                                                              | <a href="#">Section 25.1.7</a>  |
| 20h    | PDCLR     | Pin data clear register (alternate write address: PDOUT)                                                                                           | <a href="#">Section 25.1.8</a>  |
| 44h    | GBLCTL    | Global control register                                                                                                                            | <a href="#">Section 25.1.9</a>  |
| 48h    | AMUTE     | Audio mute control register                                                                                                                        | <a href="#">Section 25.1.10</a> |
| 4Ch    | DLBCTL    | Digital loopback control register                                                                                                                  | <a href="#">Section 25.1.11</a> |
| 50h    | DITCTL    | DIT mode control register                                                                                                                          | <a href="#">Section 25.1.12</a> |
| 60h    | RGBLCTL   | Receiver global control register: Alias of GBLCTL, only receive bits are affected - allows receiver to be reset independently from transmitter     | <a href="#">Section 25.1.13</a> |
| 64h    | RMASK     | Receive format unit bit mask register                                                                                                              | <a href="#">Section 25.1.14</a> |
| 68h    | RFMT      | Receive bit stream format register                                                                                                                 | <a href="#">Section 25.1.15</a> |
| 6Ch    | AFSRCTL   | Receive frame sync control register                                                                                                                | <a href="#">Section 25.1.16</a> |
| 70h    | ACLKRCTL  | Receive clock control register                                                                                                                     | <a href="#">Section 25.1.17</a> |
| 74h    | AHCLKRCTL | Receive high-frequency clock control register                                                                                                      | <a href="#">Section 25.1.18</a> |
| 78h    | RTDM      | Receive TDM time slot 0-31 register                                                                                                                | <a href="#">Section 25.1.19</a> |
| 7Ch    | RINTCTL   | Receiver interrupt control register                                                                                                                | <a href="#">Section 25.1.20</a> |

<sup>(1)</sup> Writes to XRBUFF[n] by way of XBUFn by the CPU/EDMA can only occur through the peripheral configuration port when XBUSEL = 1 in XFMT.

<sup>(2)</sup> Reads from XRBUFF[n] by way of RBUFn by the CPU/EDMA can only occur through the peripheral configuration port when RBUSEL = 1 in RFMT.

**Table 25-8. McASP Registers Accessed by CPU/EDMA Through DMA Port**

| Offset <sup>(1)</sup> | Access         | Acronym | Register Description                                                                                                                                                                                                                                                                                                   |
|-----------------------|----------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000h                 | Read Accesses  | RBUF    | Receive buffer DMA port address. Cycles through receive serializers, skipping over transmit serializers and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. Reads from XRBUFF[n] by way of RBUF by the CPU/EDMA can only occur through the DMA port when RBUSEL = 0 in RFMT. |
| 2000h                 | Write Accesses | XBUF    | Transmit buffer DMA port address. Cycles through transmit serializers, skipping over receive and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. Writes to XRBUFF[n] by way of XBUF by the CPU/EDMA can only occur through the DMA port when XBUSEL = 0 in XFMT.             |

<sup>(1)</sup> RBUF and XBUF are at the same address location. Reads access RBUF and writes access XBUF.

**Table 25-9. McASP AFIFO Registers Accessed Through Peripheral Configuration Port<sup>(1)</sup>**

| Offset | Acronym  | Register Description                   | Section                         |
|--------|----------|----------------------------------------|---------------------------------|
| 1000h  | AFIFOREV | AFIFO revision identification register | <a href="#">Section 25.1.44</a> |
| 1010h  | WFIFOCTL | Write FIFO control register            | <a href="#">Section 25.1.45</a> |
| 1014h  | WFIFOSTS | Write FIFO status register             | <a href="#">Section 25.1.46</a> |
| 1018h  | RFIFOCTL | Read FIFO control register             | <a href="#">Section 25.1.47</a> |
| 101Ch  | RFIFOSTS | Read FIFO status register              | <a href="#">Section 25.1.48</a> |

<sup>(1)</sup> The AFIFO cannot be used with the peripheral configuration port. Only the DMA port has access to the AFIFO.

### 25.1.1 Register Bit Restrictions

Some bit fields (see [Bits With Restrictions on When They May be Changed](#)) have restrictions on when they may be changed. These restrictions take the form of certain registers that must be asserted in GBLCTL. Once these registers have been asserted, the user may then, and only then, change the desired bit field.

**Bits With Restrictions on When They May be Changed**

| To Change Register: | To Change Bit Field: | ... these registers must be asserted in GBLCTL |       |        |        |       |          |       |        |        |       |
|---------------------|----------------------|------------------------------------------------|-------|--------|--------|-------|----------|-------|--------|--------|-------|

## 25.1.2 Revision Identification Register (REV)

The revision identification register (REV) contains revision data for the peripheral. The REV is shown in [Figure 25-35](#) and described in [Table 25-10](#).

**Figure 25-35. Revision Identification Register (REV)**

|              |     |   |
|--------------|-----|---|
| 31           | REV | 0 |
| R-4430 0A02h |     |   |

LEGEND: R = Read only; -n = value after reset

**Table 25-10. Revision Identification Register (REV) Field Descriptions**

| Bit  | Field | Value      | Description                        |
|------|-------|------------|------------------------------------|
| 31-0 | REV   | 4430 0A02h | Identifies revision of peripheral. |

### 25.1.3 Pin Function Register (PFUNC)

The pin function register (PFUNC) specifies the function of AXR[n], ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either a McASP pin or a general-purpose input/output (GPIO) pin. The PFUNC is shown in [Figure 25-36](#) and described in [Table 25-11](#).

#### CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation. This includes bits that are not implemented on a particular DSP.

**Figure 25-36. Pin Function Register (PFUNC)**

|                         |        |       |       |        |       |       |                         |

### 25.1.4 Pin Direction Register (PDIR)

The pin direction register (PDIR) specifies the direction of AXR[n], ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either an input or an output pin. The PDIR is shown in [Figure 25-37](#) and described in [Table 25-12](#).

Regardless of the pin function register (PFUNC) setting, each PDIR bit must be set to 1 for the specified pin to be enabled as an output and each PDIR bit must be cleared to 0 for the specified pin to be an input.

For example, if the McASP is configured to use an internally-generated bit clock and the clock is to be driven out to the system, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output).

When AXR[n] is configured to transmit, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output). Similarly, when AXR[n] is configured to receive, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be cleared to 0 (an input).

#### CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation. This includes bits that are not implemented on a particular DSP.

### 25.1.5 Pin Data Output Register (PDOUT)

The pin data output register (PDOUT) holds a value for data out at all times, and may be read back at all times. The value held by PDOUT is not affected by writing to PDIR and PFUNC. However, the data value in PDOUT is driven out onto the McASP pin only if the corresponding bit in PFUNC is set to 1 (GPIO function) and the corresponding bit in PDIR is set to 1 (output). When reading data, returns the corresponding bit value in PDOUT[n], does not return input from I/O pin; when writing data, writes to the corresponding PDOUT[n] bit. The PDOUT is shown in [Figure 25-38](#) and described in [Table 25-13](#).

PDOUT has these aliases or alternate addresses:

- PDSET - when written to at this address, writing a 1 to a bit in PDSET sets the corresponding bit in PDOUT to 1; writing a 0 has no effect and keeps the bits in PDOUT unchanged.
- PDCLR - when written to at this address, writing a 1 to a bit in PDCLR clears the corresponding bit in PDOUT to 0; writing a 0 has no effect and keeps the bits in PDOUT unchanged.

There is only one set of data out bits, PDOUT[31-0]. The other registers, PDSET and PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

#### CAUTION

##### Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation. This includes bits that are not implemented on a particular DSP.

| 24-16 | Reserved  | 0      | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility. |
| 15-0  | AXR[15-0] | 0<br>1 | Determines drive on AXR[n] output pin when the corresponding PFUNC[n] and PDIR[n] bits are set to 1.<br>Pin drives low.<br>Pin drives high.                                                                  |

### 25.1.6 Pin Data Input Register (PDIN)

The pin data input register (PDIN) holds the I/O pin state of each of the McASP pins. PDIN allows the actual value of the pin to be read, regardless of the state of PFUNC and PDIR. The value after reset for registers 1 through 15 and 24 through 31 depends on how the pins are being driven. The PDIN is shown in [Figure 25-39](#) and described in [Table 25-14](#).

#### CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation. This includes bits that are not implemented on a particular DSP.

### 25.1.7 Pin Data Set Register (PDSET)

The pin data set register (PDSET) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDSET bit sets the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic high on the pin. PDSET is useful for a multitasking system because it allows you to set to a logic high only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDSET is shown in [Figure 25-40](#) and described in [Table 25-15](#).

#### CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation. This includes bits that are not implemented on a particular DSP.

### 25.1.8 Pin Data Clear Register (PDCLR)

The pin data clear register (PDCLR) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDCLR bit clears the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic low on the pin. PDCLR is useful for a multitasking system because it allows you to clear to a logic low only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDCLR is shown in [Figure 25-41](#) and described in [Table 25-16](#).

#### CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation. This includes bits that are not implemented on a particular DSP.

### 25.1.9 Global Control Register (GBLCTL)

The global control register (GBLCTL) provides initialization of the transmit and receive sections. The GBLCTL is shown in [Figure 25-42](#) and described in [Table 25-17](#).

The bit fields in GBLCTL are synchronized and latched by the corresponding clocks (ACLKX for bits 12-8 and ACLKR for bits 4-0). Before GBLCTL is programmed, you must ensure that serial clocks are running. If the corresponding external serial clocks, ACLKX and ACLKR, are not yet running, you should select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL, and ACLKRCTL before GBLCTL is programmed. Also, after programming any bits in GBLCTL you should not proceed until you have read back from GBLCTL and verified that the bits are latched in GBLCTL.

**Figure 25-42. Global Control Register (GBLCTL)**

|                         |                         |  |       |        |        |          |  |         |  |  |    |

### 25.1.10 Audio Mute Control Register (AMUTE)

The audio mute control register (AMUTE) controls the McASP audio mute (AMUTE) output pin. The value after reset for register 4 depends on how the pins are being driven. The AMUTE is shown in [Figure 25-43](#) and described in [Table 25-18](#).

**Figure 25-43. Audio Mute Control Register (AMUTE)**

### 25.1.11 Digital Loopback Control Register (DLBCTL)

The digital loopback control register (DLBCTL) controls the internal loopback settings of the McASP in TDM mode. The DLBCTL is shown in [Figure 25-44](#) and described in [Table 25-19](#).

**Figure 25-44. Digital Loopback Control Register (DLBCTL)**

| 1    | Reserved | 0      | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                              |
| 0    | DITEN    | 0<br>1 | DIT mode enable bit. DITEN should only be changed while the XSMRST bit in GBLCTL is in reset (and for startup, XSRCLR also in reset). However, it is not necessary to reset the XCLKRST or XHCLKRST bits in GBLCTL to change DITEN.<br>DIT mode is disabled. Transmitter operates in TDM or burst mode.<br>DIT mode is enabled. Transmitter operates in DIT encoded mode. |

### 25.1.13 Receiver Global Control Register (RGLCTL)

Alias of the global control register (GBLCTL). Writing to the receiver global control register (RGLCTL) affects only the receive bits of GBLCTL (bits 4-0). Reads from RGLCTL return the value of GBLCTL. RGLCTL allows the receiver to be reset independently from the transmitter. The RGLCTL is shown in Figure 25-46 and described in Table 25-21. See Section 25.1.9 for a detailed description of GBLCTL.

**Figure 25-46. Receiver Global Control Register (RGLCTL)**

### 25.1.14 Receive Format Unit Bit Mask Register (RMASK)

The receive format unit bit mask register (RMASK) determines which bits of the received data are masked off and padded with a known value before being read by the CPU or DMA. The RMASK is shown in [Figure 25-47](#) and described in [Table 25-22](#).

**Figure 25-47. Receive Format Unit Bit Mask Register (RMASK)**

|         |         |         |         |         |         |         |         |

### 25.1.17 Receive Clock Control Register (ACLKCTL)

The receive clock control register (ACLKCTL) configures the receive bit clock (ACLKR) and the receive clock generator. The ACLKCTL is shown in [Figure 25-50](#) and described in [Table 25-25](#).

**Figure 25-50. Receive Clock Control Register (ACLKCTL)**

### 25.1.18 Receive High-Frequency Clock Control Register (AHCLKRCTL)

The receive high-frequency clock control register (AHCLKRCTL) configures the receive high-frequency master clock (AHCLKR) and the receive clock generator. The AHCLKRCTL is shown in [Figure 25-51](#) and described in [Table 25-26](#).

**Figure 25-51. Receive High-Frequency Clock Control Register (AHCLKRCTL)**

### 25.1.19 Receive TDM Time Slot Register (RTDM)

The receive TDM time slot register (RTDM) specifies which TDM time slot the receiver is active. The RTDM is shown in [Figure 25-52](#) and described in [Table 25-27](#).

**Figure 25-52. Receive TDM Time Slot Register (RTDM)**

| Bit  | Field       | Value | Description                                                                                                                                                  |
|------|-------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RTDMS[31-0] | 0     | Receiver mode during TDM time slot <i>n</i> .<br>Receive TDM time slot <i>n</i> is inactive. The receive serializer does not shift in data during this slot. |
|      |             | 1     | Receive TDM time slot <i>n</i> is active. The receive serializer shifts in data during this slot.                                                            |

### 25.1.20 Receiver Interrupt Control Register (RINTCTL)

The receiver interrupt control register (RINTCTL) controls generation of the McASP receive interrupt (RINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates RINT. The RINTCTL is shown in Figure 25-53 and described in Table 25-28. See Section 25.1.21 for a description of the interrupt conditions.

**Figure 25-53. Receiver Interrupt Control Register (RINTCTL)**

|                         |                         |       |       |         |         |          |       |

### 25.1.21 Receiver Status Register (RSTAT)

The receiver status register (RSTAT) provides the receiver status and receive TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The RSTAT is shown in [Figure 25-54](#) and described in [Table 25-29](#).

**Figure 25-54. Receiver Status Register (RSTAT)**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved | 0      | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                                                                     |
| 8    | RERR     | 0<br>1 | RERR bit always returns a logic-OR of: ROVRN   RSYNCERR   RCKFAIL   RDMAERR<br>Allows a single bit to be checked to determine if a receiver error interrupt has occurred.<br>No errors have occurred.<br>An error has occurred.                                                                                                                                                                                  |
| 7    | RDMAERR  | 0<br>1 | Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the DMA port in a given time slot than were programmed as receivers. Causes a receive interrupt (RINT), if this bit is set and RDMAERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>Receive DMA error did not occur.<br>Receive DMA error did occur.   |
| 6    | RSTAFRM  | 0<br>1 | Receive start of frame flag. Causes a receive interrupt (RINT), if this bit is set and RSTAFRM in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>No new receive frame sync (AFSR) is detected.<br>A new receive frame sync (AFSR) is detected.                                                                                                        |
| 5    | RDATA    | 0<br>1 | Receive data ready flag. Causes a receive interrupt (RINT), if this bit is set and RDATA in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>No new data in RBUF.<br>Data is transferred from XRSR to RBUF and ready to be serviced by the CPU or DMA. When RDATA is set, it always causes a DMA event (AREVT).                                         |
| 4    | RLAST    | 0<br>1 | Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. Causes a receive interrupt (RINT), if this bit is set and RLAST in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>Current slot is not the last slot in a frame.<br>Current slot is the last slot in a frame. RDATA is also set.               |
| 3    | RTDMSLOT | 0<br>1 | Returns the LSB of RSLOT. Allows a single read of RSTAT to determine whether the current TDM time slot is even or odd.<br>Current TDM time slot is odd.<br>Current TDM time slot is even.                                                                                                                                                                                                                        |
| 2    | RCKFAIL  | 0<br>1 | Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error (see <a href="#">Section 25.0.21.6.6</a> ). Causes a receive interrupt (RINT), if this bit is set and RCKFAIL in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>Receive clock failure did not occur.<br>Receive clock failure did occur. |

**Table 25-29. Receiver Status Register (RSTAT) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | RSYNCERR | 0<br>1 | Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. Causes a receive interrupt (RINT), if this bit is set and RSYNCERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>Unexpected receive frame sync did not occur.<br>Unexpected receive frame sync did occur.                                    |
| 0   | ROVRN    | 0<br>1 | Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. Causes a receive interrupt (RINT), if this bit is set and ROVRN in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.<br>Receiver overrun did not occur.<br>Receiver overrun did occur. |

### 25.1.22 Current Receive TDM Time Slot Registers (RSL0T)

The current receive TDM time slot register (RSL0T) indicates the current time slot for the receive data frame. The RSL0T is shown in [Figure 25-55](#) and described in [Table 25-30](#).

**Figure 25-55. Current Receive TDM Time Slot Registers (RSL0T)**

LEGEND: R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-30. Current Receive TDM Time Slot Registers (RSL0T) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                        |
|------|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved | 0      | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                       |
| 8-0  | RSL0TCNT | 0-17Fh | Current receive time slot count. Legal values: 0 to 383 (17Fh). TDM function is not supported for > 32 time slots. However, TDM time slot counter may count to 383 when used to receive a DIR block (transferred over TDM format). |

### 25.1.23 Receive Clock Check Control Register (RCLKCHK)

The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit. The RCLKCHK is shown in [Figure 25-56](#) and described in [Table 25-31](#).

**Figure 25-56. Receive Clock Check Control Register (RCLKCHK)**

|       |    |                         |       |

| R-0   |    | R/W-0                   |       |
| 15    | 8  | 7                       | 0     |
| RMIN  |    | Reserved <sup>(A)</sup> | RPS   |
| R/W-0 |    | R-0                     | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-31. Receive Clock Check Control Register (RCLKCHK) Field Descriptions**

| Bit   | Field    | Value                                                              | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | RCNT     | 0-FFh                                                              | Receive clock count value (from previous measurement). The clock circuit continually counts the number of DSP system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.                                                                                                                   |
| 23-16 | RMAX     | 0-FFh                                                              | Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.      |
| 15-8  | RMIN     | 0-FFh                                                              | Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.                              |
| 7-4   | Reserved | 0                                                                  | Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.                                                                                                                                                                       |

### 25.1.24 Receiver DMA Event Control Register (REVTCTL)

The receiver DMA event control register (REVTCTL) is shown in [Figure 25-57](#) and described in [Table 25-32](#).

#### CAUTION

DSP specific registers

Accessing REVTCTL not implemented on a specific DSP may cause improper device operation.

**Figure 25-57. Receiver DMA Event Control Register (REVTCTL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A If writing to this field, always write the default value for future device compatibility.

**Table 25-32. Receiver DMA Event Control Register (REVTCTL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                  |

### 25.1.25 Transmitter Global Control Register (XGBLCTL)

Alias of the global control register (GBLCTL). Writing to the transmitter global control register (XGBLCTL) affects only the transmit bits of GBLCTL (bits 12-8). Reads from XGBLCTL return the value of GBLCTL. XGBLCTL allows the transmitter to be reset independently from the receiver. The XGBLCTL is shown in Figure 25-58 and described in Table 25-33. See Section 25.1.9 for a detailed description of GBLCTL.

**Figure 25-58. Transmitter Global Control Register (XGBLCTL)**

|     |        | 6h    | Rotate right by 24 bit positions.                                                                                                                                  |
|     |        | 7h    | Rotate right by 28 bit positions.                                                                                                                                  |

## 25.1.28 Transmit Frame Sync Control Register (AFSXCTL)

The transmit frame sync control register (AFSXCTL) configures the transmit frame sync (AFSX). The AFSXCTL is shown in [Figure 25-61](#) and described in [Table 25-36](#).

**Figure 25-61. Transmit Frame Sync Control Register (AFSXCTL)**

### 25.1.29 Transmit Clock Control Register (ACLKXCTL)

The transmit clock control register (ACLKXCTL) configures the transmit bit clock (ACLKX) and the transmit clock generator. The ACLKXCTL is shown in [Figure 25-62](#) and described in [Table 25-37](#).

**Figure 25-62. Transmit Clock Control Register (ACLKXCTL)**

### 25.1.31 Transmit TDM Time Slot Register (XTDM)

The transmit TDM time slot register (XTDM) specifies in which TDM time slot the transmitter is active. TDM time slot counter range is extended to 384 slots (to support SPDIF blocks of 384 subframes). XTDM operates modulo 32, that is, XTDM specifies the TDM activity for time slots 0, 32, 64, 96, 128, etc. The XTDM is shown in [Figure 25-64](#) and described in [Table 25-39](#).

**Figure 25-64. Transmit TDM Time Slot Register (XTDM)**

|      |             | 1     | Transmit TDM time slot <i>n</i> is active. The transmit serializer shifts out data during this slot according to the serializer control register (SRCTL).          |

## 25.1.32 Transmitter Interrupt Control Register (XINTCTL)

The transmitter interrupt control register (XINTCTL) controls generation of the McASP transmit interrupt (XINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates XINT. The XINTCTL is shown in Figure 25-65 and described in Table 25-40. See Section 25.1.33 for a description of the interrupt conditions.

**Figure 25-65. Transmitter Interrupt Control Register (XINTCTL)**

A transmitter underrun interrupt generates a McASP transmit interrupt (XINT).                                 |

### 25.1.33 Transmitter Status Register (XSTAT)

The transmitter status register (XSTAT) provides the transmitter status and transmit TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The XSTAT is shown in [Figure 25-66](#) and described in [Table 25-41](#).

**Figure 25-66. Transmitter Status Register (XSTAT)**

|                         |  |         |  |       |  |       |  |          |   |
