

High-Voltage Ring Generator

Features

- ▶ 105Vrms ring signal
- ▶ Output overcurrent protection
- ▶ 5.0V CMOS logic control
- ▶ Logic enable/disable to save power
- ▶ Adjustable deadband in single-control mode
- ▶ Power-on reset
- ▶ Fault output for problem detection

Applications

- ▶ Line access cards
- ▶ Set-top/Street box

General Description

The Supertex HV430 is a high voltage PWM ring generator integrated circuit. The high voltage outputs, V_{PGATE} and V_{NGATE} , are used to drive the gates of external high voltage N-channel and P-channel MOSFETs in a push-pull configuration. Overcurrent protection is implemented for both the P-channel and N-channel MOSFETs. External sense resistors set the over-current trip point.

The RESET input functions as a power-on reset when connected to an external capacitor. The $\overline{FAULT}$ output indicates an overcurrent condition and is cleared after 4 consecutive cycles with no overcurrent condition. A logic low on RESET or ENABLE clears the $\overline{FAULT}$ output. It is active-low and open-drain to allow wire OR'ing of multiple drivers.

P_{GATE} and N_{GATE} are controlled independently by logic inputs P_{IN} and N_{IN} when the MODE pin is at logic high. A logic high on P_{IN} will turn on the external P-channel MOSFET. Similarly, a logic high on N_{IN} will turn on the external N-channel MOSFET. Lockout circuitry prevents the N and P switches from turning on simultaneously. A pulse width limiter restricts pulse widths to no less than 100 - 200ns.

For applications where a single control input is desired, the MODE pin should be connected to SGND. The PWM control signal is then input to the N_{IN} pin. A user-adjustable deadband in the control logic ensures break-before-make on the outputs, thus avoiding cross conduction on the high voltage output during switching. A logic high on N_{IN} will turn the external P-Channel MOSFET on and the N-Channel off, and vice versa. The IC can be powered down by applying a logic low on the ENABLE pin, placing both external MOSFETs in the off state.

Functional Block Diagram

Ordering Information

Part Number	Package Option	Packing
HV430WG-G	20-Lead SOW	1000/Reel

-G denotes a lead (Pb)-free / RoHS compliant package

Absolute Maximum Ratings

Parameter	Value
$V_{PP1} - V_{NN1}$, power supply voltage	+340V
V_{PP1} , positive high voltage supply	+220V
V_{PP2} , positive gate voltage supply	+220V
V_{NN1} , negative high voltage supply	-220V
V_{NN2} , negative gate voltage supply	-220V
V_{DD} , logic supply	+7.5V
Operating temperature range	-40°C to +85°C
Storage temperature range	-65°C to +150°C
Power dissipation	600mW

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

FAULT Timing

Pin Description

Pin #	Name	Description
1	VDD	Logic supply voltage.
2	$\overline{\text{FAULT}}$	Logic output. Fault is at logic low when either current limit sense pin, VPSEN or VNSEN, is activated. Remains active until overcurrent condition clears or ENABLE = 0 or RESET = 0.
3	MODE	Logic mode input. 0 = single-control; 1 = dual-control. When MODE is high, NIN and PIN independently control N_{OUT} and P_{OUT} respectively. When MODE is low, NIN controls both outputs in a complementary manner. (See Truth Table)
4	PIN	Logic control input. When mode is high, logic input high turns on the external high voltage P-channel MOSFET. Internally pulled low.
5	NIN	Logic control input. When mode is high, logic input high turns on the external high voltage N-channel MOSFET. Internally pulled low.
6	ENABLE	Logic enable input. Logic high enables IC. Internally pulled low.
7	$\overline{\text{RESET}}$	Power-on reset. A capacitor connected between this pin and ground determines the delay time between application of VDD and when the device outputs are enabled. Low leakage tantalum recommended.
8	DEADBAND	A resistor between this pin and ground sets the 'break-before-make' time between output transitions. Applicable only in single-control mode. For minimum deadtime, a 5.6k Ω resistor to ground should be used. For dual-input mode, tie to VDD.
9	SGND	Low voltage logic ground.
10	PGND	High voltage logic ground.
11	VNN2	Negative gate voltage supply. Generated by an internal linear regulator. A 25V, 100nF capacitor should be connected between VNN2 and VNN1.
12	VNN1	Negative high voltage supply.
13	VNSEN	Pulse by pulse over current sensing for N-Channel MOSFET.
14	VNGATE	Gate drive for external N-channel MOSFET.
15	N/C	No connect.
16		
17	VPGATE	Gate drive for external P-channel MOSFET.
18	VPSEN	Pulse by pulse over current sensing for P-Channel MOSFET.
19	VPP1	Positive high voltage supply.
20	VPP2	Positive gate voltage supply. Generated by an internal linear regulator. A 25V, 100nF capacitor should be connected between VPP2 and VPP1.
